Specify the scaling to apply to the output as None, Biased, Unbiased, or Unity at zero-lag. Set this property to None to generate the autocorrelation function without scaling. This option is appropriate if you are computing the autocorrelation of a nonrandom (deterministic) input.

The Biased option scales the autocorrelation by $1/N$, where N is the length of the input data. Scaling by $1/N$ yields a biased, finite-sample approximation to the theoretical autocorrelation of a WSS random process. In spite of the bias, scaling by $1/N$ has the desirable property that the sample autocorrelation matrix is nonnegative definite, a property possessed by the theoretical autocorrelation matrices of all wide-sense stationary random processes. The Fourier transform of the biased autocorrelation estimate is the *periodogram*, a widely used estimate of the power spectral density of a WSS process.

The Unbiased option scales the estimate of the autocorrelation by 1/N-1. Scaling by $N - 1$ produces an unbiased estimate of the theoretical autocorrelation. However, using the unbiased option, you can obtain an estimate of the autocorrelation function that fails to have the nonnegative definite property.

Use the Unity at zero-lag option to normalize the autocorrelation estimate as identically one at lag zero. See

"Definitions" on page 5-116 for more detail on scaling. The default is None.

Method

Domain for computing autocorrelations

Specify the domain for computing autocorrelations as Time Domain or Frequency Domain. You must set this property to Time Domain for fixed-point signals. The default is Time Domain.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set FullPrecisionOverride to true, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set FullPrecisionOverride to false, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as Ceiling, Convergent, Floor, Nearest, Round, Simplest, or Zero. This property applies only when you set the Method property to Time Domain. The default is Floor. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. This property applies only when you set the `Method` property to `Time Domain`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, or `Custom`. This property applies only when you set the `Method` property to `Time Domain`. The default is `Full precision`

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `Method` property to `Time Domain` and the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as product`, `Same as input`, or `Custom`. This property applies only when the `Method` property is `Time Domain`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `Method` property to `Time Domain` and

the `AccumulatorDataType` property to `Custom`. The default `isnumerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as accumulator`, `Same as product`, `Same as input`, or `Custom`. This property applies only when the `Method` property is `Time Domain`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `Method` property to `Time Domain` and the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods		
	clone	Create autocorrelator object with same property values
	getNumInputs	Number of expected inputs to step method
	getNumOutputs	Number of outputs of step method
	isLocked	Locked status for input attributes and nontunable properties
	release	Allow property value and input characteristics changes
	step	Autocorrelation sequence

Definitions   The autocorrelation of a deterministic discrete-time sequence, *x(n)* is:

$$r_x(h) = \sum_{n=0}^{N-h-1} x^*(n)x(n+h) \quad h = 0,1,...,N-1$$

where h is the lag and $*$ denotes the complex conjugate. If the input is a length N realization of a WSS stationary random process, $r_x(h)$ is an estimate of the theoretical autocorrelation:

$$\rho_x(h) = E\{x^*(n)x(n+h)\}$$

where $E\{\}$ is the expectation operator. The `Unity at zero-lag` normalization divides each sequence value by the autocorrelation or autocorrelation estimate at zero lag.

$$\frac{\rho_x(h)}{\rho_x(0)} = \frac{E\{x^*(n)x(n+h)\}}{E\{|x(0)|^2\}}$$

The most commonly used estimate of the theoretical autocorrelation of a WSS random process is the biased estimate:

$$\hat{\rho}_x(h) = \frac{1}{N} \sum_{k=0}^{N-h-1} x^*(n)x(n+h)$$

Examples

Compute autocorrelation for all positive lags:

```
hac1 = dsp.Autocorrelator;
% x is a column vector
x = [1:100]';
y = step(hac1, x);
```

Compute the autocorrelation of a sine wave in white Gaussian noise with approximate 95% upper and lower confidence limits:

```
S = rng('default');
% Sine wave with period N=4
x = 1.4*cos(pi/2*(1:100))'+randn(100,1);
```

```
MaxLag = 20;
H = dsp.Autocorrelator('MaximumLagSource',...
'Property','MaximumLag',MaxLag,'Scaling','Unity at zero-lag');
SigAutocorr = step(H,x);
stem(SigAutocorr,'b','markerfacecolor',[0 0 1]);
line(1:MaxLag+1,1.96/sqrt(100)*ones(MaxLag+1,1),...
     'linestyle','-.','linewidth',2);
line(1:MaxLag+1,-1.96/sqrt(100)*ones(MaxLag+1,1),...
     'linestyle','-.','linewidth',2);
axis([1 20 -1 1]);
title('Sine Wave + Noise Autocorrelation'); xlabel('Lag');
```

As this figure shows, the autocorrelation estimate demonstrates the four sample periodic sine wave with excursions outside the 95% white Gaussian noise confidence limits every two samples.

dsp.Autocorrelator

Algorithms   This object implements the algorithm, inputs, and outputs described on the Autocorrelation block reference page. The object properties correspond to the block parameters.

See Also   dsp.Crosscorrelator

Purpose   Create autocorrelator object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates an autocorrelator object, C, with the same
                   property values as H. The clone method creates a new unlocked object.

dsp.Autocorrelator.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description `N = getNumInputs(H)` returns the number of expected inputs, N, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                     method

                     The getNumOutputs method returns a positive integer that is the
                     number of outputs from the step method. This value will change if you
                     alter any properties that turn outputs on or off.

dsp.Autocorrelator.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the autocorrelator.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.Autocorrelator.step

Purpose	Autocorrelation sequence
Syntax	`Y = step(H,X)`
Description	`Y = step(H,X)` computes the autocorrelation sequence `Y` for the columns of the input `X`.

> **Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose   IIR filter using biquadratic structures

Description   The BiquadFilter object implements an IIR filter structure using biquadratic or second–order sections (SOS).

To implement an IIR filter structure using biquadratic or SOS:

1 Define and set up your biquadratic IIR filter. See "Construction" on page 5-127.

2 Call step to implement the IIR filter according to the properties of dsp.BiquadFilter. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.BiquadFilter returns a default biquadratic IIR filter, H, which independently filters each channel of the input over successive calls to the step method using the SOS section[1 0.3 0.4 1 0.1 0.2] with a direct-form II transposed structure.

H = dsp.BiquadFilter('*PropertyName*',*PropertyValue*, ...) returns a biquadratic filter object, H, with each property set to the specified value.

Properties   **Structure**

Filter structure

Specify the filter structure as one of | Direct form I | Direct form I transposed | Direct form II | Direct form II transposed |. The default is Direct form II transposed.

SOSMatrixSource

SOS matrix source

Specify the source of the SOS matrix as one of | Property | Input port|. The default is Property.

SOSMatrix

SOS matrix

Specify the second-order section (SOS) matrix as an N-by-6 matrix, where N is the number of sections in the filter. The default is [1 0.3 0.4 1 0.1 0.2]. Each row of the SOS matrix contains the numerator and denominator coefficients of the corresponding section of the filter. The system function, *H(z)*, of a biquad filter is:

$$H(z) = \frac{\displaystyle\sum_{k=0}^{2} b_k z^{-k}}{1 - \displaystyle\sum_{l=1}^{2} a_l z^{-l}}$$

The coefficients are ordered in the rows of the SOS matrix as (b_0, b_1 b_2 1, $-a_1$, $-a_2$). You can use coefficients of real or complex values. This property applies only when you set the SOSMatrixSource property to Property. The leading denominator coefficient of the biquad filter, a_0, equals 1 for each filter section, regardless of the specified value. This property is tunable when the OptimizeUnityScaleValues property is false.

ScaleValues

Scale values for each biquad section

Specify the scale values to apply before and after each section of a biquad filter. ScaleValues must be either a scalar or a vector of length N+1, where N is the number of sections. If you set this property to a scalar, the scalar value is used as the gain value only before the first filter section. The remaining gain values are set to 1. If you set this property to a vector of N+1 values, each value is used for a separate section of the filter.

This property applies only when you set the SOSMatrixSource property to Property. The default is 1. This property is tunable when the OptimizeUnityScaleValues property is false.

InitialConditions

Initial conditions for direct form II structures

Specify the initial conditions of the filter states when the
Structure property is one of | Direct form II | Direct form
II transposed |. The number of states or delay elements (zeros
and poles) in a direct-form II biquad filter equals twice the
number of filter sections. You can specify the initial conditions
as a scalar, vector, or matrix.

When you specify a scalar value, the biquad filter initializes all
delay elements in the filter to that value. When you specify a
vector of length equal to the number of delay elements in the
filter, each vector element specifies a unique initial condition for
the corresponding delay element.

The biquad filter applies the same vector of initial conditions to
each channel of the input signal. When you specify a vector of
length equal to the product of the number of input channels and
the number of delay elements in the filter, each element specifies
a unique initial condition for the corresponding delay element in
the corresponding channel. When you specify a matrix with the
same number of rows as the number of delay elements in the filter,
and one column for each channel of the input signal, each element
specifies a unique initial condition for the corresponding delay
element in the corresponding channel. The default is the scalar 0.

NumeratorInitialConditions

Initial conditions on zeros side

Specify the initial conditions of the filter states on the side of the
filter structure with the zeros. This property applies only when
you set the Structure property to one of | Direct form I |
Direct form I transposed |. The number of states or delay
elements in the numerator of a direct-form I biquad filter equals
twice the number of filter sections. You can specify the initial
conditions as a scalar, vector, or matrix. When you specify a
scalar, the biquad filter initializes all delay elements on the zeros
side in the filter to that value. When you specify a vector of length
equal to the number of delay elements on the zeros side in the

filter, each vector element specifies a unique initial condition for the corresponding delay element on the zeros side.

The biquad filter applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements on the zeros side in the filter, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements on the zeros side in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel. The default is the scalar `0`.

DenominatorInitialConditions

Initial conditions on poles side

Specify the initial conditions of the filter states on the side of the filter structure with the poles. This property only applies when you set the `Structure` property to one of | `Direct form I` | `Direct form I transposed` |. The number of denominator states, or delay elements, in a direct-form I (noncanonic) biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the biquad filter initializes all delay elements on the poles side of the filter to that value. When you specify a vector of length equal to the number of delay elements on the poles side in the filter, each vector element specifies a unique initial condition for the corresponding delay element on the poles side.

The object applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements on the poles side in the filter, each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel.

When you specify a matrix with the same number of rows as the number of delay elements on the poles side in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel. The default is the scalar `0`.

OptimizeUnityScaleValues

Optimize unity scale values

When this Boolean property is set to `true`, the biquad filter removes all unity scale gain computations. This reduces the number of computations and increases the fixed-point accuracy. This property applies only when you set the `SOSMatrixSource` property to `Property`. The default is `true`.

ScaleValuesInputPort

How to specify scale values

Select how to specify scale values. This property applies only when the `SOSMatrixSource` property is `Input port`. By default, this property is `true`, and the scale values are specified via the input port. When this property is `false`, all scale values are 1.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. When this property is `true`, the biquad filter treats each column as an independent channel. Set this property to `false` to enable sample-based processing. When this property is `false`, the biquad filter treats each element of the input as an individual channel. The default is `true`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

MultiplicandDataType

Multiplicand word and fraction lengths

Specify the multiplicand fixed-point data type as one of | Same as output | Custom |. This property applies only when you set the Structure property to Direct form I transposed. The default is Same as output.

CustomMultiplicandDataType

Custom multiplicand word and fraction lengths

Specify the multiplicand fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when you set the MultiplicandDataType property to Custom. The default is numerictype([],32,30).

SectionInputDataType

Section input word and fraction lengths

Specify the section input fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

CustomSectionInputDataType

Custom section input word and fraction lengths

Specify the section input fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when you set the SectionInputDataType property to Custom. The default is numerictype([],16,15).

SectionOutputDataType

Section output word and fraction lengths

Specify the section output fixed-point data type as one of | Same as section input | Custom |. The default is Same as section input.

CustomSectionOutputDataType

Custom section output word and fraction lengths

Specify the section output fixed-point type as a signed, scaled numerictype object with a Signedness of Auto. This property applies only when you set the SectionOutputDataType property to Custom. The default is numerictype([],16,15).

NumeratorCoefficientsDataType

Numerator coefficients word and fraction lengths

Specify the numerator coefficients fixed-point data type as one of | Same word length as input | Custom |. This property applies only when you set the SOSMatrixSource property to Property. Setting this property also sets the DenominatorCoefficientsDataType and ScaleValuesDataType properties to the same value. The default is Same word length as input.

CustomNumeratorCoefficientsDataType

Custom numerator coefficients word and fraction lengths

Specify the numerator coefficients fixed-point type as a numerictype object with a Signedness of Auto. This property applies only when you set the SOSMatrixSource property to Property and the NumeratorCoefficientsDataType property to Custom. The word length of the CustomNumeratorCoefficientsDataType, CustomDenominatorCoefficientsDataType, and CustomScaleValuesDataType properties must be the same. The default is numerictype([],16,15).

DenominatorCoefficientsDataType

Denominator coefficients word and fraction lengths

Specify the denominator coefficients fixed-point data type as one of | Same word length as input | Custom |. This property applies only when you set the SOSMatrixSource property to Property. Setting this property also sets the NumeratorCoefficientsDataType and ScaleValuesDataType properties to the same value. The default is Same word length as input.

CustomDenominatorCoefficientsDataType

Custom denominator coefficients word and fraction lengths

Specify the denominator coefficients fixed-point type as a numerictype object with a Signedness of Auto. This property applies only when you set the SOSMatrixSource property to Property and the DenominatorCoefficientsDataType property to Custom. The CustomNumeratorCoefficientsDataType, CustomDenominatorCoefficientsDataType, and CustomScaleValuesDataType properties must have the same word lengths. The default is numerictype([],16,15).

ScaleValuesDataType

Scale values word and fraction lengths

Specify the scale values fixed-point data type as one of | Same word length as input | Custom |. This property applies only when you set the SOSMatrixSource property to Property. Setting this property also sets the NumeratorCoefficientsDataType and DenominatorCoefficientsDataType properties to the same value. The default is Same word length as input.

CustomScaleValuesDataType

Custom scale values word and fraction lengths

Specify the scale values fixed-point type as a numerictype object with a Signedness of Auto. This property applies

only when you set the SOSMatrixSource property to Property and the ScaleValuesDataType property to Custom. The CustomNumeratorCoefficientsDataType, CustomDenominatorCoefficientsDataType, and CustomScaleValuesDataType properties must have the same word lengths. The default is numerictype([],16,15).

NumeratorProductDataType

Numerator product word and fraction lengths

Specify the product fixed-point data type as one of | Same as input | Custom |. Setting this property also sets the DenominatorProductDataType property to the same value. The default is Same as input.

CustomNumeratorProductDataType

Custom numerator product word and fraction lengths

Specify the product fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when you set the NumeratorProductDataType property to Custom. The CustomNumeratorProductDataType and CustomDenominatorProductDataType properties must have the same word lengths. The default is numerictype([],32,30).

DenominatorProductDataType

Denominator product word and fraction lengths

Specify the product fixed-point data type as one of | Same as input | Custom |. Setting this property also sets the NumeratorProductDataType property to the same value. The default is Same as input.

CustomDenominatorProductDataType

Custom denominator product word and fraction lengths

Specify the product fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when you set the DenominatorProductDataType

to `Custom`. The `CustomNumeratorProductDataType` and `CustomDenominatorProductDataType` properties must have the same word lengths. The default is `numerictype([],32,30)`.

NumeratorAccumulatorDataType

Numerator accumulator word and fraction lengths

Specify the numerator accumulator fixed-point data type as one of | `Same as input` | `Same as product` | `Custom` |. Setting this property also sets the `DenominatorAccumulatorDataType` property to the same value. The default is `Same as product`.

CustomNumeratorAccumulatorDataType

Custom numerator accumulator word and fraction lengths

Specify the numerator accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `NumeratorAccumulatorDataType` property to `Custom`. The `CustomNumeratorAccumulatorDataType` and `CustomDenominatorAccumulatorDataType` properties must have the same word lengths. The default is `numerictype([],32,30)`.

DenominatorAccumulatorDataType

Denominator accumulator word and fraction lengths

Specify the denominator accumulator fixed-point data type as one of | `Same as input` | `Same as product` | `Custom`|. Setting this property also sets the `NumeratorAccumulatorDataType` property to the same value. The default is `Same as product`.

CustomDenominatorAccumulatorDataType

Custom denominator accumulator word and fraction lengths

Specify the denominator accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `DenominatorAccumulatorDataType` property to `Custom`. The `CustomNumeratorAccumulatorDataType` and `CustomDenominatorAccumulatorDataType` properties

must have the same word lengths. The default is
`numerictype([],32,30)`.

StateDataType

State word and fraction lengths

Specify the state fixed-point data type as one of | `Same as input` | `Same as accumulator` | `Custom`|. This property applies when you set the `Structure` property to `Direct form II` or `Direct form II transposed`. The default is `Same as accumulator`.

CustomStateDataType

Custom state word and fraction lengths

Specify the state fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `StateDataType` property to `Custom`. The default is `numerictype([],16,15)`.

NumeratorStateDataType

Numerator state word and fraction lengths

Specify the numerator state fixed-point data type as one of | `Same as input` | `Same as accumulator` | `Custom` |. Setting this property also sets the `DenominatorStateDataType` property to the same value. This property applies only when you set the `Structure` property to `Direct form I transposed`. The default is `Same as accumulator`.

CustomNumeratorStateDataType

Custom numerator state word and fraction lengths

Specify the numerator state fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `StateDataType` property to `Custom`. The `CustomNumeratorProductDataType` and `CustomDenominatorProductDataType` properties must have the same word lengths. The default is `numerictype([],16,15)`.

DenominatorStateDataType

Denominator state word and fraction lengths

Specify the denominator state fixed-point data type as one of | Same as input | Same as accumulator | Custom |. Setting this property also sets the NumeratorStateDataType property to the same value. This property applies only when you set the Structure property to Direct form I transposed. The default is Same as accumulator.

CustomDenominatorStateDataType

Custom denominator state word and fraction lengths

Specify the denominator state fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when you set the StateDataType property to Custom. The CustomNumeratorStateDataType and CustomDenominatorStateDataType properties must have the same word lengths. The default is numerictype([],16,15).

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | Same as input | Same as accumulator | Custom |. The default is Same as accumulator.

CustomOutputDataType

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when you set the OutputDataType property to Custom. The default is numerictype([],16,15).

Methods

clone	Create biquad filter object with same property values
freqz	Frequency response
fvtool	Open filter visualization tool
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
impz	Impulse response
isLocked	Locked status for input attributes and nontunable properties
phasez	Unwrapped phase response
release	Allow property value and input characteristics changes
reset	Reset states of biquad filter object
step	Filter input with biquad filter object

More "Analysis Methods for Filter System Objects" on page 4-2.

Examples

Use a fourth order, lowpass biquadratic filter object with a normalized cutoff frequency of 0.4 to filter high frequencies from an input signal. Display the result as a PSD using the Welch method:

```
t = (0:1000)'/8e3;
xin = sin(2*pi*1e3*t)+sin(2*pi*3e3*t); % Input is 1 &
                                       % 3kHz sinusoids
hFromWS = dsp.SignalSource(xin, 100);
hLog = dsp.SignalSink;

[z,p,k] = ellip(4,1,60,.4);    % Set up the filter
[s,g] = zp2sos(z,p,k);
```

```
hBqF=dsp.BiquadFilter('Structure','Direct form I', ...
   'SOSMatrix',s,'ScaleValues',g);

while ~isDone(hFromWS)
     input = step(hFromWS);
     filteredOutput = step(hBqF,input);
     step(hLog,filteredOutput);
end

filteredResult = hLog.Buffer;
swelch = spectrum.welch;
psd(swelch,filteredResult,'Fs',8e3);
```

Design and apply a lowpass Butterworth filter using a biquad filter object. Create another object for Welch spectral analysis.

```
Fs = 10000; % Sampling frequency 10 kHz
t = 0:(1/Fs):1;
x = cos(2*pi*250*t)+0.5*sin(2*pi*1000*t)+0.25*cos(2*pi*2000*t);

% Design SOS Butterworth filter with fdesign.lowpass
Hd = fdesign.lowpass('Fp,Fst,Ap,Ast',500,550,0.5,60,10000);
D = design(Hd,'butter');
H = dsp.BiquadFilter('SOSMatrix',D.sosMatrix,...
'ScaleValues',D.ScaleValues);
y = step(H,x');

SpecWelch = spectrum.welch('Hamming',256,70);
InputPsd = psd(SpecWelch,x,'Fs',1e4);
OutputPsd = psd(SpecWelch,y,'Fs',1e4);

plot(InputPsd.Frequencies,10*log10(InputPsd.Data),'b');
hold on;
plot(OutputPsd.Frequencies,10*log10(OutputPsd.Data),'k',...
  'linewidth',2);
xlabel('Hz'); ylabel('dB');
legend('Input Data','Output Data','Location','best');
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Biquad Filter block reference page. The object properties correspond to the block parameters, except:

- **Coefficient source** – the biquad filter object does not accept `dfilt` objects as an `SOSMatrixSource`.

- **Action when the a0 values of the SOS matrix are not one** – the biquad filter object assumes the zero-th-order denominator coefficient equals 1 regardless of the specified value. The biquad filter object does not support the `Error` or `Warn` options found in the corresponding block.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also   dsp.DigitalFilter

dsp.BiquadFilter.clone

Purpose   Create biquad filter object with same property values

Syntax   `C = clone(H)`

Description   `C = clone(H)` creates a biquad filter object, `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

Purpose   Frequency response

Syntax
```
[h,w] = freqz(H)
[h,w] = freqz(H,n)
[h,w] = freqz(H,Name,Value)
freqz(H)
```

Description   `[h,w] = freqz(H)` returns the complex, 8192–element frequency response vector h, and the corresponding frequencies w in radians/sample.

`[h,w] = freqz(H,n)` returns the complex, n-element frequency response vector h, and the corresponding frequencies w in radians/sample, using n samples.

`[h,w] = freqz(H,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object H.

dsp.BiquadFilter.fvtool

Purpose	Open filter visualization tool
Syntax	`fvtool(H)` `fvtool(H,'Arithmetic',ARITH,...)`
Description	`fvtool(H)` performs an analysis and computes the magnitude response of the filter System object `H`. `fvtool(H,'Arithmetic',ARITH,...)` analyzes the filter System object `H`, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                    the step method.

                    The getNumInputs method returns a positive integer that is the number
                    of expected inputs (not counting the object itself) to the step method.
                    This value will change if you alter any properties that turn inputs on or
                    off. You must call the step method with the number of input arguments
                    equal to the result of getNumInputs(*H*).

dsp.BiquadFilter.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the step
method

The getNumOutputs method returns a positive integer that is the
number of outputs from the step method. This value will change if you
alter any properties that turn outputs on or off.

Purpose   Impulse response

Syntax   ```
[h,t] = impz(H)
[h,t] = impz(H,Name,Value)
impz(H)
```

Description `[h,t] = impz(H)` returns the impulse response h, and the
corresponding time points t at which the impulse response of H is
computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response h, and the
corresponding time points t , with additional options specified by one or
more Name, Value pair arguments.

`impz(H)` uses FVTool to plot the impulse response of the filter System
object H.

Note You can use `impz` for both real and complex filters. When you
omit the output arguments, `impz` plots only the real part of the impulse
response.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the biquad filter object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Unwrapped phase response

Syntax
```
[phi,w] = phasez(H)
[phi,w] = phasez(H,n)
[phi,w] = phasez(H,Name,Value)
phasez(H)
```

Description   `[phi,w] = phasez(H)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the n-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using n samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System object `H`.

dsp.BiquadFilter.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset states of biquad filter object

Syntax   `reset(H)`

Description   `reset(H)` resets the filter states of the biquad filter object,`H`, to the specified initial conditions. After the `step` method applies the biquad filter object to nonzero input data, the states may change. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Example of resetting filter states:

```
n =0:20;
x = cos(pi/4*n)+sin(pi/2*n);
H = dsp.BiquadFilter;
y = step(H,x');
% Apply step method without invoking reset
y1 = step(H,x');
isequal(y,y1) % Returns a 0
% Reset filter states to zero
reset(H)
% Now invoke step method
y2 = step(H,x');
isequal(y,y2) % Returns a 1
```

Purpose   Filter input with biquad filter object

Syntax
```
Y = step(H,X)
Y = step(H,X,NUM,DEN)
Y = step(H,X,NUM,DEN,G)
```

Description   `Y = step(H,X)` filters the real or complex input signal `X` , and outputs the filtered values, `Y`. The biquad filter object filters each channel of the input signal over successive calls to the `step` method.

`Y = step(H,X,NUM,DEN)` filters the input using `NUM` as the numerator coefficients, and `DEN` as the denominator coefficients of the biquad filter. `NUM` must be a 3-by-N numeric matrix and `DEN` must be a 2-by-N numeric matrix, where N is the number of biquad filter sections. The object assumes that the first denominator coefficient of each section is 1. This configuration applies when the `SOSMatrixSource` property is `Input port` and the `ScaleValuesInputPort` property is `false`.

`Y = step(H,X,NUM,DEN,G)` specifies the scale values, `G`, of the biquad filter. `G` must be a 1-by-(N +1) numeric vector, where N is the number of biquad filter sections. This configuration applies when the `SOSMatrixSource` property is `Input Port` and the `ScaleValuesInputPort` property is true.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose   Output, error, and weights using Block LMS adaptive algorithm

Description   The `BlockLMSFilter` object computes output, error, and weights using the Block LMS adaptive algorithm.

To compute the output, error, and weights:

1 Define and set up your adaptive FIR filter. See "Construction" on page 5-153.

2 Call `step` to compute the output, error, and weights according to the properties of `dsp.BlockLMSFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction   `H=dsp.BlockLMSFilter` returns an adaptive FIR filter, `H`, that filters the input signal and computes filter weights based on the Block Least Mean Squares (LMS) algorithm.

`H=dsp.BlockLMSFilter('`*PropertyName*`',`*PropertyValue*`,...)` returns an adaptive FIR filter, `H`, with each specified property set to the specified value.

`H=dsp.BlockLMSFilter(length,blocksize,'`*PropertyName*`',...` *PropertyValue*`,...)` returns an adaptive FIR filter, `H`, with the `Length` property set to `length`, the `BlockSize` property set to `blocksize`, and other specified properties set to the specified values.

Properties   **Length**

Length of FIR filter weights vector

Specify the length of the FIR filter weights vector as a positive integer scalar. The default is `32`.

BlockSize

Number of samples acquired before weight adaptation

Specify the number of samples of the input signal to acquire before the object updates the filter weights. The input frame length must be an integer multiple of the block size. The default is `32`.

StepSizeSource

Source of adaptation step size

Choose to specify the adaptation step size factor as `Property` or `Input port`. The default is `Property`.

StepSize

Adaptation step size

Specify the adaptation step size factor as a scalar, nonnegative numeric value. The default is `0.1`. This property applies only when you set the `StepSizeSource` property to `'Property'`. This property is tunable.

LeakageFactor

Leakage factor used in Leaky LMS algorithm

Specify the leakage factor used in Leaky LMS algorithm as a scalar numeric value between `0` and `1`, both inclusive. When the value is less than `1`, the System object implements a leaky LMS algorithm. The default is `1`, providing no leakage in the adapting algorithm. This property is tunable.

InitialWeights

Initial values of filter weights

Specify the initial values of the filter weights as a scalar or a vector of length equal to the `Length` property value. The default is `0`.

AdaptInputPort

Additional input to enable adaptation of filter weights.

Specify when the object should adapt the filter weights. By default, the value of this property is `false`, and the filter continuously updates the filter weights. When this property is set to `true`, an adaptation control input is provided to the `step` method. If the value of this input is nonzero, the filter continuously updates the filter weights. If the input is zero, the filter weights remain at their current value.

WeightsResetInputPort

Additional input to enable weights reset

Specify whether the FIR filter can reset the filter weights. By default, the value of this property is `false`, and the object does not reset the weights. When this property is set to `true`, a reset control input is provided to the `step` method, and the `WeightsResetCondition` property applies. The object resets the filter weights based on the values of the `WeightsResetCondition` property and the reset input to the `step` method.

WeightsResetCondition

Condition that triggers the resetting of filter weights

Specify the event to reset the filter weights as one of `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`. The object resets the filter weights based on the values of this property and the reset input to the `step` method. This property applies only when you set the `WeightsResetInputPort` property to `true`. The default is `Non-zero`.

WeightsOutputPort

Output filter weights

Set this property to `true` to output the adapted filter weights. The default is `true`.

Methods

clone	Create adaptive block LMS filter object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties

dsp.BlockLMSFilter

release	Allow property value and input characteristics changes
reset	Reset internal states of adaptive FIR filter object
step	Filter inputs using Block LMS algorithm

Examples   Remove noise using the Block LMS adaptive algorithm:

```
hblms = dsp.BlockLMSFilter(10, 5);
hblms.StepSize = 0.01;
hblms.WeightsOutputPort = false;
hfilt = dsp.DigitalFilter;
hfilt.TransferFunction = 'FIR (all zeros)';
hfilt.Numerator = fir1(10, [.5, .75]);
x = randn(1000,1); % Noise
d = step(hfilt, x) + sin(0:.05:49.95)'; % Noise + Signal
[y, err] = step(hblms, x, d);
subplot(2,1,1), plot(d), title('Noise + Signal');
subplot(2,1,2), plot(err), title('Signal');
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Block LMS Filter block reference page. The object properties correspond to the block parameters.

See Also   dsp.LMSFilter | dsp.DigitalFilter

Purpose   Create adaptive block LMS filter object with same property values

Syntax

Description   C = clone(H) creates a BlockLMSFilter object C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

Purpose   Number of expected inputs to step method

Syntax   `N = getNumInputs(H)`

Description   `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(`*H*`)`.

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the step
method.

The getNumOutputs method returns a positive integer that is the
number of outputs from the step method. This value will change if you
alter any properties that turn outputs on or off.

dsp.BlockLMSFilter.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the BlockLMSFilter object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description release(H) releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the release method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.BlockLMSFilter.reset

Purpose   Reset internal states of adaptive FIR filter object

Syntax   reset(H)

Description reset(H) sets the internal states of the BlockLMSFilter object H to their initial values.

Purpose   Filter inputs using Block LMS algorithm

Syntax
```
[Y,ERR,WTS] = step(H,X,D)
[Y,ERR] = step(H,X,D)
[...] = step(H,X,D,MU)
[...] = step(H,X,D,A)
[...] = step(H,X,D,R)
[Y,ERR,WTS] = step(H,X,D,MU,A,R)
```

Description   [Y,ERR,WTS] = step(H,X,D) filters the input X, using D as the desired
signal, and returns the filtered output in Y. The filter error is in ERR,
and the estimated filter weights is in WTS. The filter weights update
once for every block of data that the object processes.

[Y,ERR] = step(H,X,D) returns only the filtered output in Y and the
filter error in ERR, when the WeightsOutputPort property is false.

[...] = step(H,X,D,MU) uses MU as the step size, when you set the
StepSizeSource property to Input port.

[...] = step(H,X,D,A) uses A as the adaptation control, when you
set the AdaptInputPort property to true. When A is nonzero, the
filter continuously updates the filter weights. When A is zero, the filter
weights remain constant.

[...] = step(H,X,D,R) uses R as a reset signal, when you
set the WeightsResetInputPort property to true. Use the
WeightsResetCondition property to set the reset trigger condition. If
a reset event occurs, the filter resets the filter weights to their initial
values.

[Y,ERR,WTS] = step(H,X,D,MU,A,R) filters input X, using D as the
desired signal, MU as the step size, A as the adaptation control, and R as
the reset signal. The objects returns the filtered output in Y, the filter
error in ERR, and the adapted filter weights in WTS. Set the properties
appropriately to provide all possible inputs.

Note The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

Purpose   Buffer input signal

Description   The Buffer object buffers an input signal. The number of samples per
                    channel in the input must equal the difference between the output
                    buffer size and buffer overlap (i.e., Length - OverlapLength). When
                    you set FrameBasedProcessing to true, the number of samples
                    per channel equals the number of rows in the input. If you set
                    FrameBasedProcessing to false, the number of samples per channel
                    equals 1.

                    To buffer an input signal:

                    1 Define and set up your buffer System object. See "Construction" on
                       page 5-165.

                    2 Call step to buffer the input according to the properties of
                       dsp.Buffer. The behavior of step is specific to each object in the
                       toolbox.

Construction   H=dsp.Buffer returns a buffer System object, HBUFF, used to buffer
                    input signals with overlap.

                    H=dsp.Buffer('*PropertyName*',*PropertyValue*,...) returns a buffer
                    object, H, with each specified property set to the specified value.

                    H=dsp.Buffer(LEN,OVRLAP,ICS,'*PropertyName*',...
                    PropertyValue,...) returns a buffer object, H, with Length property
                    set to LEN, OverlapLength property set to OVRLAP, InitialConditions
                    property set to ICS and other specified properties set to the specified
                    values.

Properties   **Length**

                    Number of samples to buffer

                    Specify the number of consecutive samples from each input
                    channel to buffer. You can set this property to any scalar integer
                    greater than 0 of MATLAB built-in numeric data type. The
                    default is 64.

OverlapLength

Amount of overlap between outputs

Specify the number of samples by which consecutive output frames overlap. You can set this property to any scalar integer greater than or equal to `0` of MATLAB built-in numeric data type. The default is `0`.

InitialConditions

Initial output

Specify the value of the object's initial output for cases of nonzero latency as a scalar, vector, or matrix. The default is `0`.

FrameBasedProcessing

Enable frame-based processing

If this property is set to `true`, each column of the input is treated as a separate channel for buffering. If the value of this property is `false`, each element of the input is treated as a separate channel. The default is `true`.

Methods		
	clone	Create instance of an object with the same property values
	getNumInputs	Number of expected inputs to step method
	getNumOutputs	Number of outputs of step method
	isLocked	Locked status for input attributes and nontunable properties
	release	Allow property value and input characteristics changes

reset	Reset the internal states of a System object
step	Buffer input signal based on past values

Examples   Create a buffer of 256 samples with 128 sample overlap:

```
hreader=dsp.SignalSource(randn(1024,1),128);
hbuff=dsp.Buffer(256,128);

for i=1:8
    y=step(hbuff,step(hreader));
    % y is of length 256 with 128 samples
    %   from previous input
 end
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Buffer block reference page. The object properties correspond to the block properties, except as noted.

This object processes inputs as frames or as samples by setting the FrameBasedProcessing property. The corresponding block has a temporary **Treat Mx1 and unoriented sample-based signals as** parameter with One channel option for frame behavior and M channels option for sample behavior. See the Buffer block reference page and "Set the FrameBasedProcessing Property of a System object" for more information.

See Also   dsp.DelayLine | dsp.Delay

dsp.Buffer.clone

Purpose   Create instance of an object with the same property values

Syntax   C=clone(H)

Description   C=clone(H) creates a `Buffer` System object `C`, with the same property values as `H`.

The `clone` method creates a new unlocked object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                   the step method.

                   The getNumInputs method returns a positive integer that is the number
                   of expected inputs (not counting the object itself) to the step method.
                   This value will change if you alter any properties that turn inputs on or
                   off. You must call the step method with the number of input arguments
                   equal to the result of getNumInputs(*H*).

dsp.Buffer.getNumOutputs

Purpose   Number of outputs of step method

Syntax   `N = getNumOutputs(H)`

Description `N = getNumOutputs(H)` returns the number of outputs, N, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the Buffer System object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.Buffer.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset the internal states of a System object

Syntax   `reset(H)`

Description `reset(H)` resets the internal states of buffer to their initial values.

For many System objects, this method is a no-op. Objects that have internal states will describe in their help what the reset method does for that object.

The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

dsp.Buffer.step

Purpose   Buffer input signal based on past values

Syntax   Y = step(H,X)

Description   Y = step(H,X) creates output Y based on current input and stored past values of X . Output length equals the Length property.

Note The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

Purpose   Estimate of autoregressive (AR) model parameters using Burg method

Description   The BurgAREstimator object computes the estimate of the
                   autoregressive (AR) model parameters using the Burg method.

                   To compute the estimate of the AR model parameters:

                   1 Define and set up your System object. See "Construction" on page
                   5-175.

                   2 Call step to compute the estimate according to the properties of
                   dsp.BurgAREstimator. The behavior of step is specific to each object
                   in the toolbox.

Construction   H = dsp.BurgAREstimator returns a Burg BurgAREstimator System
                   object, H, that performs parametric AR estimation using the Burg
                   maximum entropy method.

                   H = dsp.BurgAREstimator('*PropertyName*',*PropertyValue*,...)
                   returns a Burg AR estimator object, H, with each specified property set
                   to the specified value.

Properties   **AOutputPort**

                   Enable output of polynomial coefficients

                   Set this property to true to output the polynomial coefficients, A,
                   of the AR model the object computes. The default is true. Either
                   the AOutputPort property, the KOutputPort property, or both
                   must be true.

                   KOutputPort

                   Enable output of reflection coefficients

                   Set this property to true to output the reflection coefficients, K,
                   for the AR model that the object computes. The default is false.
                   Either the AOutputPort property, the KOutputPort property, or
                   both must be true.

                   EstimationOrderSource

Source of estimation order

Specify how to determine estimator order as `Auto` or `Property`. When you set this property to `Auto`, the object assumes the estimation order is one less than the length of the input vector. When you set this property to `Property`, the value in EstimationOrder is used. The default is `Auto`.

EstimationOrder

Order of AR model

Set the AR model estimation order to a real positive integer. This property applies when you set the `EstimationOrderSource` to `Property`. The default is `4`.

Methods

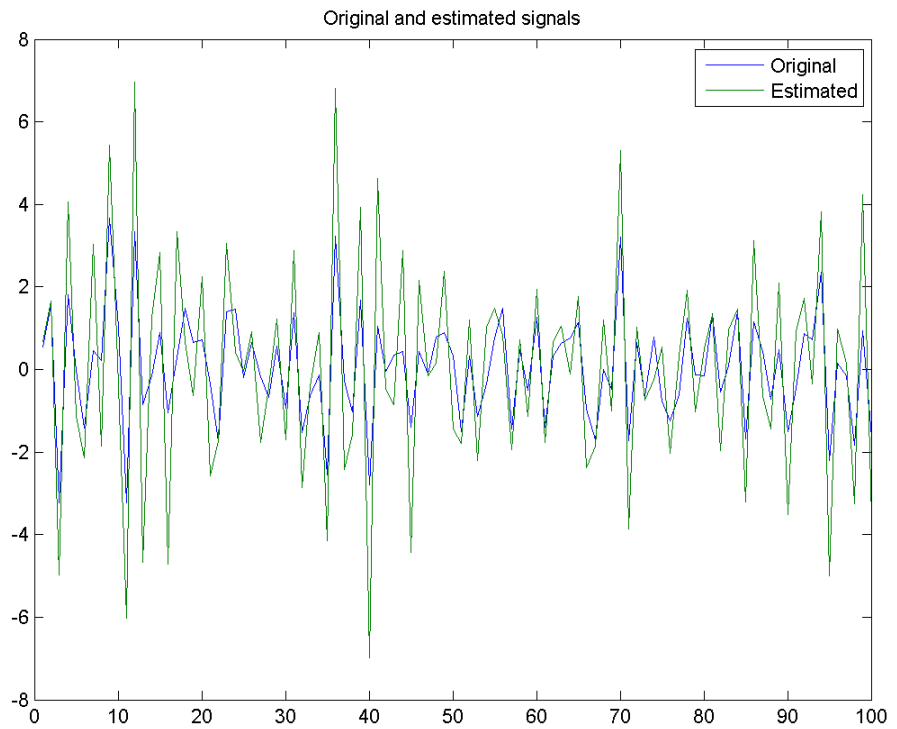
clone	Create Burg AR Estimator object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Normalized estimate of AR model parameter

Examples

Use the Burg AR Estimator System object to estimate the parameters of an AR model:

```
rng default; % Use default random number generator and seed
noise = randn(100,1); % Normalized white Gaussian noise
x = filter(1,[1 1/2 1/3 1/4 1/5],noise);
hburgarest = dsp.BurgAREstimator(...
```

```
'EstimationOrderSource', 'Property', ...
'EstimationOrder', 4);
[a, g] = step(hburgarest, x);
x_est = filter(g, a, x);
plot(1:100,[x x_est]);
title('Original and estimated signals');
legend('Original', 'Estimated');
```



Original and estimated signals

Algorithms   This object implements the algorithm, inputs, and outputs described on the Burg AR Estimator block reference page. The object properties correspond to the block parameters, except:

> **Output(s)** block parameter corresponds to the `AOutputPort` and the `KOutputPort` object properties.

See Also   `dsp.LevinsonSolver`

Purpose   Create Burg AR Estimator object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a BurgAREstimator System object C, with the same property values as H. The clone method creates a new unlocked object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                 method

                 The getNumOutputs method returns a positive integer that is the
                 number of outputs from the step method. This value will change if you
                 alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the BurgAREstimator System object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose　　Allow property value and input characteristics changes

Syntax　　`release(H)`

Description　　`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note　You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Normalized estimate of AR model parameter

Syntax
```
[A,G] = step(H,X)
[K,G] = step(H,X)
[A,K,G] = step(H,X)
```

Description   `[A,G] = step(H,X)` computes the normalized estimate of the AR model parameters to fit the input, X, in the least square sense. The input X must be a column vector. Output A is a column vector that contains the normalized estimate of the AR model polynomial coefficients in descending powers of z. The scalar G is the AR model gain.

`[K,G] = step(H,X)` returns K, a column vector containing the AR model reflection coefficients when you set the KOutputPort property to true and the AOutputPort property to false.

`[A,K,G] = step(H,X)` returns the AR model polynomial coefficients A, reflection coefficients K, and the scalar gain G when the AOutputPort and KOutputPort properties are both true.

Note The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

Purpose   Parametric spectral estimate using Burg method

Description   The BurgSpectrumEstimator object computes a parametric spectral
                   estimate of the input using the Burg method. The object fits an
                   autoregressive (AR) model to the signal by minimizing the forward and
                   backward prediction errors (via least-squares). The AR parameters are
                   constrained to satisfy the Levinson-Durbin recursion.

                   To compute the parametric spectral estimate of the input:

                   1 Define and set up your System object. See "Construction" on page
                   5-185.

                   2 Call step to compute the estimate according to the properties of
                   dsp.BurgSpectrumEstimator. The behavior of step is specific to
                   each object in the toolbox.

Construction   H = dsp.BurgSpectrumEstimator returns an object, H, that estimates
                   the power spectral density (PSD) of the input frame using the Burg
                   method.

                   H =
                   dsp.BurgSpectrumEstimator('*PropertyName*',*PropertyValue*,...)
                   returns a spectrum estimator, H, with each specified property set to
                   the specified value.

Properties   **EstimationOrderSource**

                   Source of estimation order

                   Specify the source of the estimation order as Auto or Property. If
                   you set this property to Auto, the object assumes the estimation
                   order is one less than the length of the input vector. The default
                   value is Property.

                   EstimationOrder

                   Order of AR model

Specify the order of AR model as a real positive integer. This property applies only when you set the `EstimationOrderSource` property to `Property`. The default value is `6`.

FFTLengthSource

Source of FFT length

Specify the source of the FFT length as `Auto` or `Property`. When you set this property to `Auto`, the objects assumes the FFT length is one more than the estimation order. When you set this property to `Property`, the `FFTLength` property value must be an integer power of two.

FFTLength

FFT length as power-of-two integer value

Specify the FFT length as a power-of-two numeric scalar. This property applies when you set the `FFTLengthSource` property to `Property`. The default value is `256`.

SampleRate

Sample rate of input time series

Specify the sampling rate of the original input time series as a positive numeric scalar in hertz. The default value is `1`.

Methods		
	clone	Create estimator object with same property values
	getNumInputs	Number of expected inputs to step method
	getNumOutputs	Number of outputs of step method
	isLocked	Locked status for input attributes and nontunable properties

release	Allow property value and input characteristics changes
step	Estimate of power spectral density

Examples Estimate PSD using the Burg method:

```
x = randn(100,1);
h = dsp.BurgSpectrumEstimator('EstimationOrder', 4);
y = filter(1,[1 1/2 1/3 1/4 1/5],x); % Fourth order AR filter
p = step(h,y); % Uses default FFT length of 256

plot([0:255]/256, p);
title('Burg Method Spectral Density Estimate');
xlabel('Normalized frequency'); ylabel('Power/frequency');
```

Algorithms This object implements the algorithm, inputs, and outputs described on the Burg Method block reference page. The object properties correspond to the block properties.

See Also dsp.BurgAREstimator | dsp.LevinsonSolver

Purpose   Create estimator object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a BurgSpectrumEstimator object C, with the same property values as H. The clone method creates a new unlocked object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                     the step method.

                     The getNumInputs method returns a positive integer that is the number
                     of expected inputs (not counting the object itself) to the step method.
                     This value will change if you alter any properties that turn inputs on or
                     off. You must call the step method with the number of input arguments
                     equal to the result of getNumInputs(*H*).

dsp.BurgSpectrumEstimator.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the BurgSpectrumEstimator object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.BurgSpectrumEstimator.release

Purpose	Allow property value and input characteristics changes
Syntax	`release(H)`
Description	`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Estimate of power spectral density

Syntax   Y = step(H,X)

Description   Y = step(H,X) outputs Y, a spectral estimate of input X, using the
                   Burg method.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

---

dsp.CepstralToLPC

Purpose   Convert cepstral coefficients to linear prediction coefficients

Description   The `CepstralToLPC` object converts cepstral coefficients to linear prediction coefficients (LPC).

To convert cepstral coefficients to LPC:

1 Define and set up your System object. See "Construction" on page 5-194.

2 Call `step` to convert the coefficients according to the properties of `dsp.CepstralToLPC`. The behavior of `step` is specific to each object in the toolbox.

Construction   H=dsp.CepstralToLPC returns a System object, H, that converts the cepstral coefficients(CCs) to linear prediction coefficients (LPCs).

H=dsp.CepstralToLPC('*PropertyName*',*PropertyValue*,...) returns a `Cepstral to LPC` object, H, with each specified property set to the specified value.

Properties   **PredictionErrorOutputPort**

Enable prediction error power output

Set this property to `true` to output the prediction error power. The prediction error power is the power of the error output of an FIR analysis filter represented by the LPCs for a given input signal. The default is `false`.

Methods

clone	Create cepstral to LPC object with same property values
getNumInputs	Number of expected inputs to the method
getNumOutputs	Number of outputs of the method

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	LPC coefficients from column of cepstral coefficients

Examples   Convert cepstral coefficients to linear prediction coefficients (LPC):

```
cc=[0 0.9920 0.4919 0.3252 0.2418 , ...
0.1917 0.1583 0.1344 0.1165 0.0956]';
hcc2lpc=dsp.CepstralToLPC;
a=step(hcc2lpc,cc);
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the LPC to/from Cepstral Coefficients block reference page. The object properties correspond to the block parameters.

See Also   dsp.LPCToCepstral | dsp.LSFToLPC | dsp.RCToLPC

dsp.CepstralToLPC.clone

Purpose   Create cepstral to LPC object with same property values

Syntax   C=clone(H)

Description   C=clone(H) creates a CepstralToLPC System object C, with the same property values as H.

The clone method creates a new unlocked object.

Purpose   Number of expected inputs to the `step` method

Syntax   N = getNumInputs(H)

Description   `N = getNumInputs(H)` returns the number of expected inputs, N, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.CepstralToLPC.getNumOutputs

Purpose   Number of outputs of the `step` method

Syntax   N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the CepstralToLPC System
object.

The isLocked method returns a logical value that indicates whether
input attributes and nontunable properties for the object are locked. The
object performs an internal initialization the first time the step method
is executed. This initialization locks nontunable properties and input
specifications, such as dimensions, complexity, and data type of the
input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   LPC coefficients from column of cepstral coefficients

Syntax   A=step(H,CC)
                 [A,P]=step(H,CC)

Description A=step(H,CC) computes the linear prediction coefficients (LPC)
                 coefficients, A , from the columns of cepstral coefficients, CC.

                 [A,P]=step(H,CC) converts the columns of the cepstral coefficients
                 CC to the LPCs and returns the prediction error power P when the
                 PredictionErrorOutputPort property is true.

                 Note The object performs an initialization the first time the step
                 method is executed. This initialization locks nontunable properties and
                 input specifications, such as dimensions, complexity, and data type
                 of the input data. If you change a nontunable property or an input
                 specification, the System object issues an error. To change nontunable
                 properties or inputs, you must first call the release method to unlock
                 the object.

dsp.Chirp

Purpose	Generate swept-frequency cosine (chirp) signal

Description

The Chirp object generates a swept-frequency cosine (chirp) signal.

To generate the chirp signal:

1 Define and set up your chirp signal. See "Construction" on page 5-202.

2 Call step to generate the signal according to the properties of dsp.Chirp. The behavior of step is specific to each object in the toolbox.

Construction

H = dsp.Chirp returns a chirp signal, H, with unity amplitude.

H = dsp.Chirp('*PropertyName*',*PropertyValue*,...) returns a chirp signal, H, with each specified property set to the specified value.

Properties

Type

Frequency sweep type

Specify the frequency sweep type as Swept cosine, Linear, Logarithmic, or Quadratic. This property specifies how the output instantaneous frequency sweep varies over time. The default value is Linear.

SweepDirection

Sweep direction

Specify the sweep direction as either Unidirectional or Bidirectional. The default value is Unidirectional.

InitialFrequency

Initial frequency (hertz)

When you set the Type property to Linear, Quadratic, or Logarithmic, this property specifies the initial instantaneous frequency in hertz of the output chirp signal. When you set the Type property to Logarithmic, the value of this property is one

less than the actual initial frequency of the sweep. Also, when the sweep is logarithmic, the initial frequency must be less than the target frequency, specified by the `TargetFrequency` property. This property is tunable. The default value is `1000`.

TargetFrequency

Target frequency (hertz)

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the instantaneous frequency of the output signal in hertz at the target time. When you set the `Type` property to `Swept Cosine`, the target frequency is the instantaneous frequency of the output at half the target time. Also, when the sweep is logarithmic, the target frequency must be greater than the initial frequency, specified by the `InitialFrequency` property. This property is tunable. The default value is `4000`.

TargetTime

Target time

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the target time in seconds at which the target frequency is reached. When you set the `Type` property to `Swept cosine`, this property specifies the time at which the sweep reaches $2f_{tgt} - f_{init}$ Hz, where f_{tgt} is the `TargetFrequency` and f_{init} is the `InitialFrequency`. The target time should not be greater than the sweep time, specified by the `SweepTime` property. This property is tunable. The default value is `1`.

SweepTime

Sweep time

When you set the `SweepDirection` property to `Unidirectional`, the sweep time in seconds is the period of the output frequency sweep. When you set the `SweepDirection` property to `Bidirectional`, the sweep time is half the period of the output

frequency sweep. The sweep time should be no less than the target time, specified by the `TargetTime`. This property must be a positive numeric scalar and is tunable. The default value is `1`.

InitialPhase

Initial phase

Specify initial phase of the output in radians at time $t = 0$. This property is tunable. The default value is `0`.

SampleRate

Sample rate

Specify the sampling rate of the output in hertz as a positive numeric scalar. The default value is `8000`.

SamplesPerFrame

Samples per output frame

Specify the number of samples to buffer into each output as a positive integer. The default value is `1`.

OutputDataType

Output data type

Specify the output data type as `double` or `single`. The default value is `double`.

Methods		
	clone	Create chirp object with same property values
	getNumInputs	Number of expected inputs to step method
	getNumOutputs	Number of outputs of step method
	isLocked	Locked status for input attributes and nontunable properties

release	Allow property value and input characteristics changes
reset	Reset internal states of chirp object
step	Generate chirp signal

Examples   Generate a bidirectional swept chirp signal:

```
hchirp = dsp.Chirp(...
'SweepDirection', 'Bidirectional', ...
'TargetFrequency', 25, ...
'InitialFrequency', 0,...
'TargetTime', 1, ...
'SweepTime', 1, ...
'SamplesPerFrame', 400, ...
'SampleRate', 400);
plot(step(hchirp));
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Chirp block reference page. The object properties correspond to the block parameters.

See Also   dsp.SineWave

dsp.Chirp.clone

Purpose Create chirp object with same property values

Syntax C = clone(H)

Description C = clone(H) creates a Chirp object C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                   the step method.

                   The getNumInputs method returns a positive integer that is the number
                   of expected inputs (not counting the object itself) to the step method.
                   This value will change if you alter any properties that turn inputs on or
                   off. You must call the step method with the number of input arguments
                   equal to the result of getNumInputs(*H*).

dsp.Chirp.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the Chirp object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset internal states of chirp object

Syntax   `reset(H)`

Description   `reset(H)` sets the internal states of the `Chirp` object `H` to their initial values. After you reset `H`, the frequency sweep restarts from the beginning.

Purpose   Generate chirp signal

Syntax   Y = step(H)

Description   Y = step(H) returns a swept-frequency cosine output, Y.

Note The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

Purpose   Decimate input using Cascaded Integrator-Comb filter

Description   The CICDecimator object decimates inputs using a Cascaded
Integrator-Comb filter. Inputs and outputs to the object have signed
fixed-point data types. You must have a Fixed-Point Toolbox license to
use the CICDecimator System object.

To decimate inputs using a CIC filter:

1 Define and set up your System object. See "Construction" on page
5-213.

2 Call step to decimate the input according to the properties of
dsp.CICDecimator. The behavior of step is specific to each object
in the toolbox.

Construction   H = dsp.CICDecimator returns a CICDecimator System object, H, that
you can use to decimate the input with a cascaded integrator-comb
(CIC) decimation filter.

H = dsp.CICDecimator(*'PropertyName'*,*PropertyValue*,...)
returns a CICDecimator object, H, with each specified property set to
the value you specify.

H = dsp.CICDecimator(*R*,*M*,*N*,*'PropertyName'*, *PropertyValue*,
...) returns a CICDecimator object, H, with the DecimationFactor
property set to *R*, the DifferentialDelay property set to *M*, the
NumSections property set to *N*, and any other specified properties set
to the values you specify.

Properties   **DecimationFactor**

Decimation factor of filter

Specify a positive integer amount by which the object decimates
the input. The default is 2.

DifferentialDelay

Differential delay of filter comb sections

Specify a positive integer delay value for the object to use in each comb section of the filter. The default is 1.

NumSections

Number of integrator and comb sections

Specify the number of integrator and comb sections in the CIC filter as a positive integer value. The default is 2.

FixedPointDataType

Fixed-point property setting

Specify the fixed-point data type as one of | Full precision | Minimum section word lengths | Specify word lengths | Specify word and fraction lengths |. The default is Full precision. When you set this property to:

- Full precision — the CICDecimator object automatically determines the word and fraction lengths of the filter sections and output.

- Minimum section word length — the object automatically determines the word and fraction lengths of the filter sections and the fraction length of the output. You must specify the OutputWordLength.

- Specify word lengths — the object automatically determines the fraction lengths of the filter sections and the output. You must specify values for the OutputWordLength and the SectionWordLengths properties.

- Specify word and fraction lengths, — the object does not automatically determine word and fraction lengths for the filter sections or the output. You must specify them using the OutputFractionLength, OutputWordLength, SectionFractionLengths, and SectionWordLengths properties.

SectionWordLengths

Word length of each filter section

Specify the fixed-point word length for each section of the CIC filter as a scalar or a vector of length 2*NumSections. This property applies only when you set the FixedPointDataType property to either Specify word lengths or Specify word and fraction lengths. The default is [16 16 16 16].

SectionFractionLengths

Fraction length of each filter section

Specify the fixed-point fraction length for each section of the CIC filter as a scalar or a vector of length 2*NumSections. This property applies only when you set the FixedPointDataType property to Specify word and fraction lengths. The default is 0.

OutputWordLength

Word length of filter output

Specify the fixed-point word length for the filter output. This property applies only when you set the FixedPointDataType property to Minimum section word lengths, Specify word lengths, orSpecify word and fraction lengths. The default is 32.

OutputFractionLength

Fraction length of filter output

Specify the fixed-point fraction length for the output of the CIC filter. This property applies only when you set the FixedPointDataType property to Specify word and fraction lengths. The default is 0.

Methods

clone	Create CIC Decimator object with same property values
freqz	Frequency response

fvtool	Open filter visualization tool
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
impz	Impulse response
isLocked	Locked status for input attributes and nontunable properties
phasez	Unwrapped phase response
release	Allow property value and input characteristics changes
reset	Reset filter states of CIC decimator object
step	Decimate input using Cascaded Integrator-Comb filter

More "Analysis Methods for Filter System Objects" on page 4-2.

Examples   Decimate signal by a factor of 4 (i.e., downsample the signal from 44.1 kHz to 11.025 kHz):

```
hcicdec = dsp.CICDecimator(4);
%    DecimationFactor = 4
%    default NumSections = 2 and DifferentialDelay = 1
hcicdec.FixedPointDataType = 'Minimum section word lengths';
hcicdec.OutputWordLength = 16;

% Create fixed-point sinusoidal input signal
Fs = 44.1e3;              % Original sampling frequency
n = (0:1023)';            % 1024 samples, 0.0232 sec signal
x = fi(sin(2*pi*1e3/Fs*n),true,16,15);

% Create SignalSource System object
```

```
hsr = dsp.SignalSource(x, 64);

% Decimate output with 16 samples per frame
y = zeros(16,16);
for ii=1:16
     y(ii,:) = step(hcicdec, step( hsr ));
end

% Plot first frame of original and decimated signals.
% Output latency is 2 samples.
gainCIC = ...
   (hcicdec.DecimationFactor*hcicdec.DifferentialDelay)^hcicdec.NumSec
stem(n(1:56)/Fs, double(x(4:59))); hold on;
stem(n(1:14)/(Fs/hcicdec.DecimationFactor),double(y(1,3:end))/gainCIC
xlabel('Time (sec)');ylabel('Signal Amplitude');
legend('Original signal', 'Decimated signal', 'location', 'north');
hold off;
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the CIC Decimation block reference page. The object properties correspond to the block properties, except:

- The **Rate options** block parameter is not supported by the dsp.CICDecimator object.

See Also   dsp.CICInterpolator | dsp.FIRDecimator

dsp.CICDecimator.clone

Purpose Create CIC Decimator object with same property values

Syntax C = clone(H)

Description C = clone(H) creates a CICDecimator System object C, with the same property values as H. The clone method creates a new unlocked object with un-initialized states.

Purpose   Frequency response

Syntax
```
[h,w] = freqz(H)
[h,w] = freqz(H,n)
[h,w] = freqz(H,Name,Value)
freqz(H)
```

Description   [h,w] = freqz(H) returns the complex, 8192–element frequency response vector h, and the corresponding frequencies w in radians/sample.

[h,w] = freqz(H,n) returns the complex, n-element frequency response vector h, and the corresponding frequencies w in radians/sample, using n samples.

[h,w] = freqz(H,Name,Value) returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

freqz(H) uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object H.

dsp.CICDecimator.fvtool

Purpose	Open filter visualization tool
Syntax	`fvtool(H)` `fvtool(H,'Arithmetic',ARITH,...)`
Description	`fvtool(H)` performs an analysis and computes the magnitude response of the filter System object `H`.
	`fvtool(H,'Arithmetic',ARITH,...)` analyzes the filter System object `H`, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                 the step method.

                 The getNumInputs method returns a positive integer that is the number
                 of expected inputs (not counting the object itself) to the step method.
                 This value will change if you alter any properties that turn inputs on or
                 off. You must call the step method with the number of input arguments
                 equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                   method.

                   The getNumOutputs method returns a positive integer that is the
                   number of outputs from the step method. This value will change if you
                   alter any properties that turn outputs on or off.

Purpose	Impulse response

Syntax

```
[h,t] = impz(H)
[h,t] = impz(H,Name,Value)
impz(H)
```

Description   `[h,t] = impz(H)` returns the impulse response h, and the corresponding time points t at which the impulse response of H is computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response h, and the corresponding time points t , with additional options specified by one or more Name, Value pair arguments.

`impz(H)` uses FVTool to plot the impulse response of the filter System object H.

Note You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

Purpose   Locked status for input attributes and nontunable properties

Syntax   `isLocked(H)`

Description `isLocked(H)` returns the locked state of the `CICDecimator` System object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose   Unwrapped phase response

Syntax   `[phi,w] = phasez(H)`
`[phi,w] = phasez(H,n)`
`[phi,w] = phasez(H,Name,Value)`
`phasez(H)`

Description   `[phi,w] = phasez(H)` returns the 8192–element phase response vector
`phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the n-element phase response vector
`phi`, and the corresponding frequencies `w` in radians/sample, using
`n` samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the
corresponding frequencies, with additional options specified by one or
more Name, Value pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System
object `H`.

dsp.CICDecimator.release

Purpose　　Allow property value and input characteristics changes

Syntax　　`release(H)`

Description　　`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset filter states of CIC decimator object

Syntax   reset(H)

Description   reset(H) resets the filter states of the CICDecimator System object H to zero.

Purpose   Decimate input using Cascaded Integrator-Comb filter

Syntax   Y = step(H,X)

Description Y = step(H,X) decimates the fixed-point input X to produce a
                 fixed-point output Y using the CICDecimator System object H.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

Purpose   Interpolate signal using Cascaded Integrator-Comb filter

Description   The CICInterpolator object interpolates inputs using a Cascaded
                    Integrator-Comb (CIC) filter. Inputs and outputs to the object have
                    signed fixed-point data types. You must have a Fixed-Point Toolbox
                    license to use the CICInterpolator System object.

                    To interpolate inputs using a CIC filter:

                    1 Define and set up your System object. See "Construction" on page
                       5-229.

                    2 Call step to interpolate the input according to the properties of
                       dsp.CICInterpolator. The behavior of step is specific to each object
                       in the toolbox.

Construction   H = dsp.CICInterpolator returns a System object, H, that you can
                    use to interpolate the input with a cascaded integrator-comb (CIC)
                    interpolation filter.

                    H = dsp.CICInterpolator('*PropertyName*',*PropertyValue*,...)
                    returns a CIC interpolation object, H, with each specified property set to
                    the value you specify.

                    H =
                    dsp.CICInterpolator(*R*,*M*,*N*,'*PropertyName*',*PropertyValue*,...)
                    returns a CICInterpolator object, H, with the InterpolationFactor
                    property set to *R*, the DifferentialDelay property set to *M*, the
                    NumSections property set to *N*, and other specified properties set to the
                    values you specify.

Properties   **InterpolationFactor**

                    Interpolation factor of filter

                    Specify a positive integer amount by which the object interpolates
                    the input signal. The default is 2.

                    DifferentialDelay

Differential delay of filter comb sections

Specify a positive integer delay value for the object to use in each comb section of the filter. The default is 1.

NumSections

Number of integrator and comb sections

Specify the number of integrator and comb sections in the CIC filter as a positive integer value. The default is 2.

FixedPointDataType

Fixed-point property setting

Specify the fixed-point data type as one of | Full precision | Minimum section word lengths | Specify word lengths | Specify word and fraction lengths |. The default is Full precision. When you set this property to:

- Full precision — the CICInterpolator object automatically determines the word and fraction lengths of the filter sections and output.

- Minimum section word length — the object automatically determines the word and fraction lengths of the filter sections and the fraction length of the output. You must specify the OutputWordLength.

- Specify word lengths — the object automatically determines the fraction lengths of the filter sections and the output. You must specify values for the OutputWordLength and the SectionWordLengths properties.

- Specify word and fraction lengths — the object does not automatically determine word and fraction lengths for the filter sections or the output. You must specify them using the OutputFractionLength, OutputWordLength, SectionFractionLengths, and SectionWordLengths properties.

SectionWordLengths

Word length of each filter section

Specify the fixed-point word length for each section of the CIC filter as a scalar or a vector of length 2*NumSections. This property applies only when you set the FixedPointDataType property to Specify word lengths or Specify word and fraction lengths. The default is [16 16 16 16].

SectionFractionLengths

Fraction length of each filter section

Specify the fixed-point fraction length for each section of the CIC filter as a scalar or a vector of length 2*NumSections. This property applies only when you set the FixedPointDataType property to Specify word and fraction lengths. The default is 0.

OutputWordLength

Word length of filter output

Specify the fixed-point word length for the filter output. This property applies only when you set the FixedPointDataType property to Minimum section word lengths, Specify word lengths, orSpecify word and fraction lengths. The default is 32.

OutputFractionLength

Fraction length of filter output

Specify the fixed-point fraction length for the output of the CIC filter. This property applies only when you set the FixedPointDataType property to Specify word and fraction lengths. The default is 0.

dsp.CICInterpolator

Methods

clone	Create CIC Interpolator object with same property values
freqz	Frequency response
fvtool	Open filter visualization tool
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
impz	Impulse response
isLocked	Locked status for input attributes and nontunable properties
phasez	Unwrapped phase response
release	Allow property value and input characteristics changes
reset	Reset internal states of CIC Interpolator object
step	Interpolate signal using Cascaded Integrator-Comb filter

More "Analysis Methods for Filter System Objects" on page 4-2.

Examples   Interpolate signal by a factor of 2 (upsample the signal from 22.05 kHz to 44.1 kHz):

```
hcicint = dsp.CICInterpolator(2);
%    default NumSections = 2, DifferentialDelay = 1

% Create fixed-point sinusoidal input signal
Fs = 22.05e3;      % Original sampling frequency
n = (0:511)';      % 512 samples, 0.0113 sec signal
x = fi(sin(2*pi*1e3/Fs*n),true,16,15);
```

```
% Create SignalSource System object
hsr = dsp.SignalSource(x, 32);

% Interpolate output with 64 samples per frame
y = zeros(16,64);
for ii=1:16
    y(ii,:) = step(hcicint,step( hsr ));
end

% Plot first frame of original and interpolated signals.
% Output latency is 2 samples.
gainCIC = ...
   (hcicint.InterpolationFactor*hcicint.DifferentialDelay)...
   ^hcicint.NumSections/hcicint.InterpolationFactor;
stem(n(1:31)/Fs, double(x(1:31)),'r','filled'); hold on;
stem(n(1:61)/(Fs*hcicint.InterpolationFactor), ...
   double(y(1,4:end))/gainCIC,'b');
xlabel('Time (sec)');ylabel('Signal Amplitude');
legend('Original signal', 'Interpolated signal',...
   'location', 'north');
hold off;
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the CIC Interpolation block reference page. The object properties correspond to the block properties, except:

- The **Framing** block parameter is not supported by the dsp.CICInterpolation object. The object always maintains the input frame rate.

- The **Rate options** block parameter is not supported by the dsp.CICInterpolation object.

- The **Input processing** block parameter is not supported by the dsp.CICInterpolation object.

dsp.CICInterpolator

- The object does not have a property that allows you to specify the source of the coefficients. The object cannot import coefficients from an `mfilt` object.

See Also   dsp.CICDecimator | dsp.FIRInterpolator

Purpose　　　　Create CIC Interpolator object with same property values

Syntax　　　　　C = clone(H)

Description　　　C = clone(H) creates a CICInterpolator System object C, with the same property values as H. The clone method creates a new unlocked object with un-initialized states.

dsp.CICInterpolator.freqz

Purpose   Frequency response

Syntax   ```
                 [h,w] = freqz(H)
                 [h,w] = freqz(H,n)
                 [h,w] = freqz(H,Name,Value)
                 freqz(H)
                 ```

**Description**  `[h,w] = freqz(H)` returns the complex, 8192–element frequency
                 response vector `h`, and the corresponding frequencies `w` in
                 radians/sample.

                 `[h,w] = freqz(H,n)` returns the complex, n-element frequency
                 response vector `h`, and the corresponding frequencies `w` in
                 radians/sample, using `n` samples.

                 `[h,w] = freqz(H,Name,Value)` returns the frequency response and
                 the corresponding frequencies, with additional options specified by one
                 or more Name, Value pair arguments.

                 `freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of
                 the frequency response of the filter System object `H`.

**Purpose**    Open filter visualization tool

**Syntax**    fvtool(H)
              fvtool(H,'Arithmetic',ARITH,...)

**Description**    fvtool(H) performs an analysis and computes the magnitude response
                  of the filter System object H.

                  fvtool(H,'Arithmetic',ARITH,...) analyzes the filter System object
                  H, based on the arithmetic specified in the ARITH input. ARITH can
                  be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a
                  double precision filter when the arithmetic input is not specified and
                  the filter System object is in an unlocked state. The 'Arithmetic' input
                  is only relevant for the analysis of filter System objects.

**Purpose**    Number of expected inputs to step method

**Syntax**    N = getNumInputs(H)

**Description**    N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

**Purpose**          Number of outputs of step method

**Syntax**           N = getNumOutputs(H)

**Description**      N = getNumOutputs(H) returns the number of outputs, N, of the step
                    method.

                    The getNumOutputs method returns a positive integer that is the
                    number of outputs from the step method. This value will change if you
                    alter any properties that turn outputs on or off.

| **Purpose** | Impulse response |
|---|---|

**Syntax**

```
[h,t] = impz(H)
[h,t] = impz(H,Name,Value)
impz(H)
```

Description　　`[h,t] = impz(H)` returns the impulse response h, and the corresponding time points t at which the impulse response of H is computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response h, and the corresponding time points t , with additional options specified by one or more Name, Value pair arguments.

`impz(H)` uses FVTool to plot the impulse response of the filter System object H.

Note You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the CICInterpolator System object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.CICInterpolator.phasez

Purpose   Unwrapped phase response

Syntax
```
[phi,w] = phasez(H)
[phi,w] = phasez(H,n)
[phi,w] = phasez(H,Name,Value)
phasez(H)
```

Description   `[phi,w] = phasez(H)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the n-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System object `H`.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.CICInterpolator.reset

Purpose   Reset internal states of CIC Interpolator object

Syntax   reset(H)

Description   reset(H) resets the internal states of the `CICInterpolator` System
object H to zero.

Purpose   Interpolate signal using Cascaded Integrator-Comb filter

Syntax   Y = step(H,X)

Description   Y = step(H,X) interpolates the fixed-point input X to produce a
fixed-point output Y using the CICInterpolator System object H.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

---

dsp.Convolver

Purpose	Convolution of two inputs
Description	The Convolver computes the convolution of two inputs.

To compute the convolution of two inputs:

1 Define and set up your convolver. See "Construction" on page 5-246.

2 Call step to compute the convolution according to the properties of dsp.Convolver. The behavior of step is specific to each object in the toolbox.

Construction H = dsp.Convolver returns a convolver object, H, that convolves two inputs. For N-D arrays, the convolver computes the convolution column-wise. For arrays, the inputs must have an equal number of columns. If one input is a vector and the other is an N-D array, the convolver computes the convolution of the vector with each column of the N-D array. Convolving inputs of length N and M results in a sequence of length $N+M-1$. Convolving matrices of size M-by-N and P-by-N results in a matrix of size $(M+P-1)$-by-N.

H = dsp.Convolver('*PropertyName*',*PropertyValue*, ...) returns a convolver object, H, with each property set to the specified value.

Properties **Method**

Domain for computing convolutions

Specify the domain in which the convolver performs the convolutions as Time Domain, Frequency Domain, or Fastest. Computing convolutions in the time domain minimizes memory use. Computing convolutions in the frequency domain may require fewer computations depending on the input length. If the value of this property is Fastest, the object computes convolutions in the domain which minimizes the number of computations. The default is Time Domain.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as first input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` property is `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`, `Same as product`, `Same as first input`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as accumulator`, `Same as product`, `Same as first input`, or `Custom`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` property is `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create convolver object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Convolution of inputs

Examples

Convolution of two rectangular sequences:

```
hconv = dsp.Convolver;
x = ones(10,1);
y = step(hconv, x, x);
% Result is a triangular sequence
plot(y);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Convolution block reference page. The object properties correspond to the block parameters.

See Also

dsp.Autocorrelator | dsp.Crosscorrelator

dsp.Convolver.clone

Purpose   Create convolver object with same property values

Syntax   C = clone(H)

Description C = clone(H) creates a convolver object, C, with the same property
                 values as H. The clone method creates a new unlocked object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                   the step method.

                   The getNumInputs method returns a positive integer that is the number
                   of expected inputs (not counting the object itself) to the step method.
                   This value will change if you alter any properties that turn inputs on or
                   off. You must call the step method with the number of input arguments
                   equal to the result of getNumInputs(*H*).

dsp.Convolver.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the convolver object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.Convolver.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Convolution of inputs

Syntax   Y = step(H,A,B)

Description   Y = step(H,A,B) convolves the inputs A and B.

Note The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

---

dsp.Counter

Purpose	Count up or down through specified range of numbers

Description

The Counter object counts up or down through a specified range of numbers.

To count up or down through a specified range of numbers:

1 Define and set up your counter. See "Construction" on page 5-256.

2 Call step to count up or down according to the properties of dsp.Counter. The behavior of step is specific to each object in the toolbox.

Construction

H = dsp.Counter returns a counter System object, H, that counts up when the input is nonzero.

H = dsp.Counter('*PropertyName*',*PropertyValue*,...) returns a counter System object, H, with each specified property set to the specified value.

Properties

Direction

Count up or down

Specify the counter direction as Up or Down. The default is Up. This property is tunable.

CountEventInputPort

Add input to specify a count event

Set this property to true to enable a count event input for the internal counter. The internal counter increments or decrements whenever the count event input satisfies the condition you specify in the CountEventCondition property. When you set this property to false, the internal counter is free running, that is, the counter increments or decrements on every call to the step method. The default is true.

CountEventCondition

Condition that increments, decrements, or resets internal counter

Specify the event at the count event input that increments or decrements the counter as `Rising edge`, `Falling edge`, `Either edge` or `Non-zero`.

If you set the `ResetInputPort` and `CountEventInputPort` properties to `true`, the counter is reset when the event you specify for the `CountEventCondition` occurs. This property applies only when you set the `CountEventInputPort` property to `true`.

CounterSizeSource

Source of counter size data type

Specify the source of the counter size data type as `Property` or `Input port`. The default is `Property`.

CounterSize

Range of integer values to count through

Specify the range of integer values to count through before recycling to zero as `8 bits`, `16 bits`, `32 bits` or `Maximum`. The default is `Maximum`.

MaximumCount

Counter's maximum value

Specify the counter's maximum value as a numeric scalar value. This property applies only when you set the `CounterSizeSource` property to `Property` and the `CounterSize` property to `Maximum`. The default is `255`. This property is tunable.

InitialCount

Counter initial value

Specify the initial value for the counter. The default is `0`. This property is tunable.

CountOutputPort

Output count

Set this property to `true` to enable output of the internal count. The default is `true`. You cannot set both `CountOutputPort` and `HitOutputPort` to `false` at the same time.

HitOutputPort

Output hit events

Set this property to `true` to enable output of the hit events. You cannot set both `CountOutputPort` and `HitOutputPort` to `false` at the same time. The default is `true`.

HitValues

Values whose occurrence in count produce a true hit output

Specify an integer scalar or a vector of integers, whose occurrences in the count you want flagged as a hit. This property applies only when you set the `HitOutputPort` property to `true`.

ResetInputPort

Add input to enable internal counter reset

When you set this property to `true`, specify a reset input to the `step` method. When the reset input receives the event you specify for the `CountEventCondition` property, the counter resets. If you set the `CountEventInputPort` property to `false`, the counter resets whenever the reset input is not zero.

SamplesPerFrame

Number of samples in each output frame

Specify the number of samples in each output frame. This property applies only when you set the `CountEventInputPort` property to `false`, indicating a free-running counter. The default is `1`.

CountOutputDataType

Data type of count output

Specify the data type of the count output, CNT, as `double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32` or `uint32`. This property applies when you set the `CountOutputPort` property to `true`. The default is `double`.

Methods

clone	Create counter object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of Counter object
step	Increment or decrement the internal counter

Examples   Use Counter System object for counting from 0 to 5:

```
hcounter = dsp.Counter('MaximumCount', 5, ...
'CountOutputPort', true, ...
'HitOutputPort', false, ...
'ResetInputPort', false);
 sgnl = [0 1 0 1 0 1 0 1 0 1 0 1 ];
   for ii = 1:length(sgnl)
 %count at every rising edge of the input signal.
 cnt(ii) = step(hcounter, sgnl(ii));
   end
   cnt
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Counter block reference page. The object properties correspond to the block parameters.

- The `CountEventCondition` object property does not have a free-running option. Set the `CountEventInputPort` property to `false` to obtain the free-running option.

- The `CounterSizeSource` and `CounterSize` object properties correspond to the **Counter size** block parameter.

- The `CountOutputPort` and `HitOutputPort` correspond to the **Output** block parameter.

- There is no object property that corresponds to the **Hit data type** block parameter. The output type is logical in MATLAB. (This logical is different from the popup logical in the block. For the object, logical corresponds to Boolean in the block.)

Purpose   Create counter object with same property values

Syntax   C = clone(H)

Description C = clone(H) creates a Counter object C, with the same property
                values as H. The clone method creates a new unlocked object with
                uninitialized states.

dsp.Counter.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to the step method

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, from the
                   step method.

                   The getNumOutputs method returns a positive integer that is the
                   number of outputs from the step method. This value will change if you
                   alter any properties that turn outputs on or off.

dsp.Counter.isLocked

Purpose　　　　Locked status for input attributes and nontunable properties

Syntax　　　　`isLocked(H)`

Description　　　`isLocked(H)` returns the locked state of the `Counter` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description   release(H) releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note   You can use the release method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.Counter.reset

Purpose   Reset internal states of Counter object

Syntax   reset(H)

Description   reset(H) resets the internal states of the counter object H to their
initial values.

Purpose   Increment or decrement the internal counter

Syntax
```
[CNT,HIT] = step(H,EVENT,RESET)
CNT = step(H,EVENT,RESET)
HIT = step(H,EVENT,RESET)
[...] = step(H)
[...] = step(H,EVENT)
```

Description   `[CNT,HIT] = step(H,EVENT,RESET)` increments, decrements, or resets the internal counter as specified by the values of the `EVENT` and `RESET` inputs. The output argument `CNT` denotes the present value of the counter. A trigger event at the `EVENT` input causes the counter to increment or decrement. A trigger event at the `RESET` input resets the counter to its initial state.

`CNT = step(H,EVENT,RESET)` returns the current value of the count when you set the `CountOutputPort` property to `true`, and the `HitOutputPort` property to `false`.

`HIT = step(H,EVENT,RESET)` returns a Boolean value indicating whether the count has reached any of the values specified by the `HitValues` property. This condition applies when you set the `HitOutputPort` property to `true` and the `CountOutputPort` property to `false`.

`[...]  = step(H)` increments or decrements the free-running internal counter when you set the `CountEventInputPort` property to `false` and the `ResetInputPort` property to `false`.

`[...]  = step(H,EVENT)` increments or decrements the internal counter when the `EVENT` input matches the event you specify for the `CountEventCondition` property and you set the `ResetInputPort` property to `false`.

> **Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose   Cross-correlation of two inputs

Description   The `Crosscorrelator` returns the cross-correlation sequence for two discrete-time deterministic inputs. This object can also return the cross-correlation sequence estimate for two discrete-time, jointly wide-sense stationary (WSS), random processes.

To obtain the cross-correlation for two discrete-time deterministic inputs:

1 Define and set up your cross-correlator. See "Construction" on page 5-269.

2 Call `step` to compute the cross-correlation according to the properties of `dsp.Crosscorrelator`. The behavior of `step` is specific to each object in the toolbox.

Construction `H = dsp.Crosscorrelator` returns a cross-correlator object, H, that computes the cross-correlation of two inputs. For N-D arrays, the cross-correlator computes the correlation column-wise. The inputs must have an equal number of columns. If one input is a vector and the other is an N-D array, the cross-correlator computes the cross-correlation of the vector with each column of the N-D array. Cross correlating inputs of length N and M results in a cross-correlation sequence of length $N+M–1$. Cross correlating matrices of size M-by-N and P-by-N results in a matrix of cross-correlation sequences of size $M+P–1$-by-N.

`H = dsp.Crosscorrelator('`*PropertyName*`',`*PropertyValue*`, ...)` returns a cross-correlator, H, with each property set to the specified value.

Properties   **Method**

Domain for computing correlations

Specify the domain for computing correlation as `Time Domain`, `Frequency Domain`, or `Fastest`. Computing correlations in the time domain minimizes memory use. Computing correlations

in the frequency domain may require fewer computations than computing in the time domain depending on the input length. If the value of this property is `Fastest`, the cross-correlator operates in the domain which minimizes the number of computations. The default is `Time Domain`.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of Full Precision, Same as first input, or Custom. The default is Full Precision.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when the ProductDataType property is Custom. The default is numerictype([],32,30).

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as Full Precision, Same as product, Same as first input, or Custom. The default is Full Precision.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when the AccumulatorDataType property is Custom. The default is numerictype([],32,30).

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of Same as accumulator, Same as product, Same as first input, or Custom. The default is Same as accumulator.

CustomOutputDataType

Output word and fraction lengths

dsp.Crosscorrelator

Specify the output fixed-point type as a scaled `numerictype`
object with a `Signedness` of `Auto`. This property applies only
when the `OutputDataType` property is `Custom`. The default is
`numerictype([],16,15)`.

Methods

clone	Create cross-correlator object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Cross-correlation sequence

Definitions

The cross-correlation of two length N deterministic inputs, or
realizations of jointly WSS random processes, x and y, is:

$$r_{xy}(h) = \begin{cases} \sum_{n=0}^{N-h-1} x(n+h)y^*(n) & 0 \le h \le N-1 \\ r_{yx}^*(h) & -(N-1) \le h \le 0 \end{cases}$$

where h is the lag and * denotes the complex conjugate. If the inputs
are realizations of jointly WSS stationary random processes, $r_{xy}(h)$ is an
unnormalized estimate of the theoretical cross-correlation:

$$\rho_{xy}(h) = E\{x(n+h)y^*(n)\}$$

where E{ } is the expectation operator.

Examples   Compute correlation between two signals:

```
hcorr = dsp.Crosscorrelator;
t=[0:0.001:1];
x1=sin(2*pi*2*t)+0.05*sin(2*pi*50*t);
x2=sin(2*pi*2*t);
y=step(hcorr,x1,x2); %computes cross-correlation of x1 and x2
figure,plot(t,x1,'b',t, x2, 'g');
legend('Input signal 1',' Input signal 2')
figure, plot(y); title('Correlated output')
```

Use cross-correlation to detect delay in jointly stationary white
Gaussian noise inputs:

```
S = rng('default');
% white Gaussian noise input
x = randn(100,1);
% Create copy delayed by 10 samples
% x1[n]=x[n-10]
Hdelay = dsp.Delay(10);
x1= step(Hdelay,x);
Hxcorr = dsp.Crosscorrelator;
y = step(Hxcorr,x1,x);
lags = 0:99; %Positive lags
stem(lags,y(100:end),'markerfacecolor',[0 0 1]);
axis([0 99 -125 125]);
xlabel('Lags');
title('Cross-Correlation of Input Noise and Delayed Version');
```

dsp.Crosscorrelator

Cross-Correlation of Input Noise and Delayed Version

The theoretical cross-correlation sequence is identically zero except at lag 10. Note this is not true in the sample cross-correlation sequence, but the estimate demonstrates a peak at the correct lag.

Algorithms   This object implements the algorithm, inputs, and outputs described on the Correlation block reference page. The object properties correspond to the block parameters.

See Also   dsp.Autocorrelator | dsp.Convolver

Purpose   Create cross-correlator object with same property values

Syntax   C = clone(H)

Description C = clone(H) creates a cross-correlator object, C, with the same
                property values as H. The clone method creates a new unlocked object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                   the step method.

                   The getNumInputs method returns a positive integer that is the number
                   of expected inputs (not counting the object itself) to the step method.
                   This value will change if you alter any properties that turn inputs on or
                   off. You must call the step method with the number of input arguments
                   equal to the result of getNumInputs(*H*).

dsp.Crosscorrelator.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                  method.

                  The getNumOutputs method returns a positive integer that is the
                  number of outputs from the step method. This value will change if you
                  alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the cross–correlator.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

> **Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Cross-correlation sequence

Syntax   Y = step(H,A,B)

Description   Y = step(H,A,B) computes the cross–correlation of A and B and returns
                   the result in Y.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

---

dsp.CumulativeProduct

Purpose   Cumulative product of channel, column, or row elements

Description   The `CumulativeProduct` object computes the cumulative product of channel, column, or row elements.

To compute the cumulative product of channel, column, or row elements:

1 Define and set up your cumulative product object. See "Construction" on page 5-282.

2 Call `step` to compute the cumulative product according to the properties of `dsp.CumulativeProduct`. The behavior of `step` is specific to each object in the toolbox.

Construction   `H = dsp.CumulativeProduct` returns a cumulative product object, `H`, that computes the cumulative product of input matrix or input vector elements along the default Dimension.

`H = dsp.CumulativeProduct('PropertyName',PropertyValue,...)` returns a cumulative product object, `H`, with each specified property set to the specified value.

Properties   **Dimension**

Computation dimension for cumulative product

Specify the computation dimension as one of | `Channels (running product)` | `Rows` | `Columns` |. The default is `Channels (running product)`.

ResetInputPort

Enable resetting cumulative product via input port

Set this property to `true` to enable resetting the cumulative product. When you set this property to `true`, specify a reset signal to the `step` method to reset the cumulative product. You can access this property when the `Dimension` property is set to `Channels (running product)`. The default is `false`.

ResetCondition

Reset condition for cumulative product

Specify the event on the reset input port that causes resetting the cumulative product to one of | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero` |. This property applies when you set the `ResetInputPort` property to `true` and the `Dimension` property to `Channels (running product)`. The default is `Rising edge`.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. You can access this property when the `Dimension` property is set to `Channels (running product)`. The default is `false`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest,` | `Round` | `Simplest` | `Zero` |. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

IntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point data type as one of | `Same as input` | `Custom` |. The default is `Same as input`.

CustomIntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `IntermediateProductDataType` property to `Custom`. The default is `numerictype([], 16, 15)`.

ProductDataType

Product output word and fraction lengths

Specify the product output fixed-point data type as one of | `Same as input` | `Custom` |. The default is `Same as input`.

CustomProductDataType

Custom product output word and fraction lengths

Specify the product output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([], 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | `Same as product output` | `Same as input` | `Custom` |. The default is `Same as input`.

CustomAccumulatorDataType

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | Same as
product output | Same as input | Custom |. The default is
Same as input.

CustomOutputDataType

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled numerictype
object with a Signedness of Auto. This property applies when
you set the OutputDataType property to Custom. The default is
numerictype([], 16, 15).

Methods

clone	Create cumulative product object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset running cumulative product
step	Cumulative product of input along specified dimension for input

Examples   Compute the cumulative product of a matrix:

```
hcprod = dsp.CumulativeProduct;
x = magic(2);
y = step(hcprod,x);
y = step(hcprod,x)
```

dsp.CumulativeProduct

Algorithms   This object implements the algorithm, inputs, and outputs described on the Cumulative Product block reference page. The object properties correspond to the block parameters, except:

> The **Reset port** block parameter corresponds to both the `ResetCondition` and `ResetInputPort` object properties.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also   dsp.CumulativeSum

Purpose   Create cumulative product object with same property values

Syntax   C = clone(H)

Description C = clone(H) creates a CumulativeProduct System object C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

dsp.CumulativeProduct.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                  method.

                  The getNumOutputs method returns a positive integer that is the
                  number of outputs from the step method. This value will change if you
                  alter any properties that turn outputs on or off.

dsp.CumulativeProduct.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the CumulativeProduct object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset running cumulative product

Syntax   reset(H)

Description reset(H) resets the running cumulative product for object H to zero.

Purpose   Cumulative product of input along specified dimension for input

Syntax   Y = step(H,X)
                 Y = step(H,X,R)

Description   Y = step(H,X) computes the cumulative product along the specified
                 dimension for the input X.

                 Y = step(H,X,R) resets the cumulative product object's state based on
                 the ResetCondition property value and the value of the reset signal, R
                 when the ResetInputPort property is true.

                 Note The object performs an initialization the first time the step
                 method is executed. This initialization locks nontunable properties and
                 input specifications, such as dimensions, complexity, and data type
                 of the input data. If you change a nontunable property or an input
                 specification, the System object issues an error. To change nontunable
                 properties or inputs, you must first call the release method to unlock
                 the object.

dsp.CumulativeSum

Purpose　　Cumulative sum of channel, column, or row elements

Description　　The CumulativeSum object computes the cumulative sum of channel, column, or row elements.

To compute the cumulative sum of channel, column, or row elements:

1 Define and set up your cumulative sum object. See "Construction" on page 5-294.

2 Call step to compute the cumulative sum according to the properties of dsp.CumulativeSum. The behavior of step is specific to each object in the toolbox.

Construction　　H = dsp.CumulativeSum returns a cumulative sum System object, H, which computes the running cumulative sum for each channel in the input.

H = dsp.CumulativeSum('*PropertyName*',*PropertyValue*,...) returns a cumulative sum object, H, with each specified property set to the specified value.

Properties　　**Dimension**

Computation dimension for cumulative sum

Specify the computation dimension as one of | Channels (running sum) | Rows | Columns |. The default is Channels (running sum).

ResetInputPort

Enable resetting cumulative sum via input port.

Set this property to true to enable resetting the cumulative sum. When you set this property to true, you also specify a reset input to the step method to reset the cumulative sum. The default is false.

ResetCondition

Reset condition for cumulative sum

Specify the event on the reset input port that resets the cumulative sum as one of | Rising edge | Falling edge | Either edge | Non-zero |. This property applies when you set the ResetInputPort property to true. The default is Rising edge.

FrameBasedProcessing

Enable frame-based processing

Set this property to true to enable frame-based processing. Set this property to false to enable sample-based processing. You can access this property when the Dimension property is Channels (running sum). The default is false.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor, Nearest, Round, Simplest | Zero |. The default is Floor.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

CustomAccumulatorDataType

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of one of | `Same as accumulator` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

CustomOutputDataType

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([], 16, 15)`.

Methods

clone	Create cumulative sum object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of cumulative sum object to zero
step	Cumulative sum along specified dimension for input

Examples   Use a cumulative sum object to compute the cumulative sum of a matrix:

```
hcsum = dsp.CumulativeSum;
x = magic(2);
y = step(hcsum,x);
y = step(hcsum,x)
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Cumulative Sum block reference page. The object properties correspond to the block properties, except:

> The **Reset port** block parameter corresponds to both the ResetCondition and the ResetInputPort object properties

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the FrameBasedProcessing property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also   dsp.CumulativeProduct

dsp.CumulativeSum.clone

Purpose   Create cumulative sum object with same property values

Syntax   C = clone(H)

Description C = clone(H) creates a CumulativeSum object C, with same property values as H. The clone method creates a new unlocked object with uninitialized states.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

dsp.CumulativeSum.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the step
method.

The getNumOutputs method returns a positive integer that is the
number of outputs from the step method. This value will change if you
alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the CumulativeSum object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.CumulativeSum.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset internal states of cumulative sum object to zero

Syntax   reset(H)

Description reset(H) sets the states for the running cumulative sum object, H, to zero when the Dimension property is set to Channels (running sum).

dsp.CumulativeSum.step

Purpose	Cumulative sum along specified dimension for input
Syntax	`Y = step(H,X)` `Y = step(H,X,R)`
Description	`Y = step(H,X)` computes the cumulative sum along the specified dimension for the input `X`. `Y = step(H,X,R)` resets the System object's state based on the `ResetCondition` property value and the value of the reset signal, `R`. You can only reset the state if the `ResetInputPort` property is `true`.

> **Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose   Discrete cosine transform (DCT)

Description   The DCT object computes the discrete cosine transform (DCT) of input.

To compute the DCT of input:

1 Define and set up your DCT object. See "Construction" on page 5-305.

2 Call step to compute the DCT according to the properties of dsp.DCT. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.DCT returns a discrete cosine transform (DCT) object, H, used to compute the DCT of a real or complex input signal.

H = dsp.DCT('*PropertyName*',*PropertyValue*, ...) returns a DCT object, H, with each property set to the specified value.

Properties   **SineComputation**

Method to compute sines and cosines

Specify how the DCT object computes the trigonometric values as Trigonometric function or Table lookup. This property must be set to Table lookup for fixed-point inputs. The default is Table lookup.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of Ceiling, Convergent, Floor , Nearest, Round, Simplest, or Zero. This property applies when you set the SineComputation property to Table lookup.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. This property applies when you set the `SineComputation` property to `Table lookup`.

SineTableDataType

Sine table word-length designation

Specify the sine table fixed-point data type as one of `Same word length as input` or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

CustomSineTableDataType

Sine table word length

Specify the sine table fixed-point type as an unscaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `SineTableDataType` property to `Custom`. The default is `numerictype([],16)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as input`, `Same as product`, or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `Full precision`, `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`. The default is `Full precision`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create discrete cosine transform object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Discrete cosine transform (DCT) of input

Examples

Use DCT to analyze the energy content in a sequence:

```
x = (1:128).' + 50*cos((1:128).'*2*pi/40);
hdct = dsp.DCT;
X = step(hdct, x);
% Set the DCT coefficients which represent less
% than 0.1% of the total energy to 0 and
% reconstruct the sequence using IDCT.
[XX, ind] = sort(abs(X),1,'descend');
ii = 1;
while (norm([XX(1:ii);zeros(128-ii,1)]) <= 0.999*norm(XX))
ii = ii+1;
end
disp(['Number of DCT coefficients that represent 99.9%',...
'of the total energy in the sequence: ',num2str(ii)]);
XXt = zeros(128,1);
XXt(ind(1:ii)) = X(ind(1:ii));
hidct = dsp.IDCT;
xt = step(hidct, XXt);
plot(1:128,[x xt]);
legend('Original signal','Reconstructed signal',...
 'location','best');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the DCT block reference page. The object properties correspond to the block parameters.

See Also

dsp.IDCT | dsp.FFT | dsp.IFFT

Purpose Create discrete cosine transform object with same property values

Syntax C = clone(H)

Description C = clone(H) creates an instance of the current discrete cosine transform object, C, with the same property values as H. The clone method creates a new unlocked object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description `N = getNumInputs(H)` returns the number of expected inputs, N, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                   method.

                   The getNumOutputs method returns a positive integer that is the
                   number of outputs from the step method. This value will change if you
                   alter any properties that turn outputs on or off.

dsp.DCT.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the DCT object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Discrete cosine transform (DCT) of input

Syntax   Y = step(H,X)

Description   Y = step(H,X) computes the DCT of the input X.

> **Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

Purpose   Delay input by specified number of samples or frames

Description   The Delay object delays an input by a specified number of samples or frames.

To delay an input by a specified number of samples or frames:

1 Define and set up your delay object. See "Construction" on page 5-315.

2 Call step to delay the input according to the properties of dsp.Delay. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.Delay returns a delay object, H, to delay the input by one sample.

H = dsp.Delay('*PropertyName*', *PropertyValue*, ...) returns a delay object, H, with each property set to the specified value.

H = dsp.Delay(LEN,'*PropertyName*',*PropertyValue*, ...) returns a delay object, H, with the Length property set to LEN and other specified properties set to the specified values.

Properties   **Units**

Delay units as samples or frames

Specify the delay units as one of | Samples | Frames |. This property applies when you set the FrameBasedProcessing property to true. The default is Samples.

Length

Amount of delay

Specify amount of delay to apply to the input signal. You can set this property to a scalar, a vector, or an array containing nonnegative integers depending on the value of the FrameBasedProcessing property.

If the `FrameBasedProcessing` property is `false`, the value can be a scalar by which to delay all input channels equally, or an N-D array of the same dimensions as the input whose values specify the number of sample intervals to delay each channel of the input.

If the `FrameBasedProcessing` property is `true`, the value can be an integer by which to equally delay all channels or a vector whose length equals the number of input columns (channels).

The default is 1.

InitialConditionsPerChannel

Enable different initial conditions per channel

Set this property to `true` to specify different initial conditions per channel. The default value is `false`.

InitialConditionsPerSample

Enable different initial conditions per sample

Set this property to `true` to specify different initial conditions per sample. The default value is `false`.

InitialConditions

Initial output of delay object

Specify the initial output(s) of the delay object. You can set this property to a scalar, vector, matrix, or a cell array depending on the values of the `FrameBasedProcessing`, `InitialConditionsPerChannel`, `InitialConditionsPerSample`, and `Units` properties. The default is `0`.

If the `FrameBasedProcessing` property is `false`, and the input is an N-D array, the dimensions of this property value have the following requirements:

- If the `InitialConditionsPerChannel` and `InitialConditionsPerSample` properties are both `false`, the property value must be a scalar. If the `InitialConditionsPerChannel` property is `true` and the

InitialConditionsPerSample property is `false`, the
value must have the same dimensions as the input. If the
InitialConditionsPerChannel property is `false` and the
InitialConditionsPerSample property is `true`, the value
must be a vector of length equal to the `Length` property value.

- If the `InitialConditionsPerChannel` and
  `InitialConditionsPerSample` properties are both
  `true`, the property value must be a cell array of the same size
  as the input signal. Each cell of the cell array contains the
  delay values for one channel, and must be a vector of length
  equal to the `Length` property value.

If the `FrameBasedProcessing` property is `true`, and the input is
an M-by-N matrix, the dimensions of this property value must
be as follows:

- If the `InitialConditionsPerChannel` and
  `InitialConditionsPerSample` properties are both
  `false`, the property value must be a scalar.

- If the `InitialConditionsPerChannel` property is `true` and the
  `InitialConditionsPerSample` property is `false`, the value
  must be a vector of length N.

- If the `InitialConditionsPerChannel` property is `false`, the
  `InitialConditionsPerSample` property is `true`, and the `Units`
  property is `Frames`, the value must be a vector of length equal
  to the product of M and the `Length` property value.

- If the `InitialConditionsPerChannel` property is `false`, the
  `InitialConditionsPerSample` property is `true`, and the `Units`
  property is `Samples`, the value must be a vector of length equal
  to the `Length` property value.

- If the `InitialConditionsPerChannel` and
  `InitialConditionsPerChannel` properties are both
  `true`, the property value must be a cell array of size N. Each
  cell of the cell array contains the delay values for one channel.

- If the `Units` property is `Frames`, each cell must be a vector of length equal to the product of *M* and the `Length` property value.

- If the `Units` property is `Samples`, each cell must be a vector of length equal to the `Length` property value.

ResetInputPort

Enable resetting delay states

Specify when the delay object should reset the delay states. By default, the value of this property is `false`, and the object does not reset the delay states. When this property is set to `true`, a reset control input is provided to the `step` method, and the `ResetCondition` property applies. The object resets the delay states based on the values of the `ResetCondition` property and the reset input to the `step` method.

ResetCondition

Reset trigger setting for delay

Specify the event to reset the delay as one of | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero` |. The delay object resets the delay based on the values of this property and the reset input to the `step` method. This property applies when you set the `ResetInputPort` property to `true`. The default is `Non-zero`.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

Methods	clone	Create delay object with same property values
	getNumInputs	Number of expected inputs to step method
	getNumOutputs	Number of outputs of step method
	isLocked	Locked status for input attributes and nontunable properties
	release	Allow property value and input characteristics changes
	reset	Reset delay states
	step	Apply delay to input

Examples   Delay input by five samples:

```
hdelay1 = dsp.Delay(5);
% Output is [0 0 0 0 0 1 2 3 4 5]'
y = step(hdelay1, (1:10)');
```

Delay input by one frame:

```
hdelay2 = dsp.Delay;
hdelay2.Units = 'Frames';
hdelay2.Length = 1;

% Output is zeros(10,1)
y1 = step(hdelay2, (1:10)');

% Output is (1:10)'
y2 = step(hdelay2, (11:20)');
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Delay block reference page. The object properties correspond to the block parameters.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also   dsp.VariableIntegerDelay | dsp.VariableFractionalDelay.

Purpose   Create delay object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a delay object, C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

dsp.Delay.getNumInputs

Purpose　　　Number of expected inputs to step method

Syntax　　　`N = getNumInputs(H)`

Description　`N = getNumInputs(H)` returns the number of expected inputs, N, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                   method.

                   The getNumOutputs method returns a positive integer that is the
                   number of outputs from the step method. This value will change if you
                   alter any properties that turn outputs on or off.

dsp.Delay.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the delay object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.Delay.reset

Purpose   Reset delay states

Syntax   reset(H)

Description reset(H) resets the states of the delay object H to the values specified
in the `InitialConditions` property.

After you invoke the `step` method for a nonzero input, the delay object
states may change and invoking the `step` method again without
invoking the `reset` method may produce different outputs for identical
inputs.

For example:

```
H = dsp.Delay(5);
% Delay input by 5 samples
y = step(H, (1:10)');
% Output is [0 0 0 0 0 1 2 3 4 5]'
% Invoke step without reset
y1 = step(H,(1:10)');
% Output is [6 7 8 9 10 1 2 3 4 5]'
% Reset states
reset(H);
y2 = step(H,(1:10)');
% Output is [0 0 0 0 0 1 2 3 4 5]'
```

Purpose   Apply delay to input

Syntax   Y = step(H,X)
Y = step(H,X,R)

Description   Y = step(H,X) adds delay to input X to return output Y.

Y = step(H,X,R) adds delay to X , and selectively resets the delay
object's state based on the value of reset input R and the value of the
ResetCondition property. You can use this option only when you set
the ResetInputPort property to true.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

---

dsp.DelayLine

Purpose	Rebuffer sequence of inputs with one-sample shift

Description   The `DelayLine` object rebuffers a sequence of inputs with one-sample shift.

To rebuffer a sequence of inputs with one-sample shift:

1 Define and set up your delay line object. See "Construction" on page 5-328.

2 Call `step` to rebuffer the sequence of inputs according to the properties of `dsp.DelayLine`. The behavior of `step` is specific to each object in the toolbox.

Construction   `H = dsp.DelayLine` returns a delay line System object, `H`, that buffers the input samples into a sequence of overlapping or underlapping matrix outputs.

`H = dsp.DelayLine('`*PropertyName*`',`*PropertyValue*`,...)` returns a delay line System object, `H`, with each specified property set to the specified value.

`H = dsp.DelayLine(DELAYSIZE,INITIAL,'`*PropertyName*`',`*PropertyValue*`,...)` returns a delay line System object, `H`, with the `Length` property set to `DELAYSIZE`, `InitialConditions` property set to `INITIAL` and other specified properties set to the specified values.

Properties   **Length**

Number of rows in output matrix

Specify the number of rows in the output matrix as a scalar positive integer. The default is `64`.

InitialConditions

Initial delay line output

Set the value of the object's initial output as one of | scalar | vector | matrix |.

For vector outputs, the following selections apply for the `InitialConditions` property:

- A vector of the same size
- A scalar value that you want repeated across all elements of the initial output

For matrix outputs, the following selections apply for the `InitialConditions` property:

- A matrix of the same size
- A vector (equal to the length of the number of matrix rows) that repeats across all columns of the initial output
- A scalar that repeats across all elements of the initial output

The default is `0`.

DirectFeedthrough

Enable passing input data to output without extra frame delay

When you set this property to `true`, there is no input data delay by an extra frame before it is available at the output buffer. Instead, the input data is available immediately at the output. When you set this property to `false`, there is one frame delay on the output. The default is `false`.

EnableOutputInputPort

Enable selective output linearization

The object internally uses a circular buffer, even though the output is linear. To obtain a valid output, the object must linearize the circular buffer. When this property is `true`, the object uses an additional Boolean input to determine if a valid output calculation is needed. If Boolean the input value is `1`, the object's output is linearized and thus valid. If Boolean the input value is `0`, the output is not linearized and is invalid. This allows the object to be

more efficient when each step does not require the tapped delay line output. When you set this property to `false`, the output is always linearized and valid. The default is `false`.

HoldPreviousValue

Hold previous valid value for invalid output

If you set this property to `true`, the most recent, valid value is held on the output. If you set this property to `false`, the signal on the output is invalid data. This property applies only when you set the `EnableOutputInputPort` property to `true`. The default is `false`.

Methods

clone	Create delay line object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of delay line object
step	Delayed version of input

Examples

Use a delay line object with a delay line size of 4 samples:

```
hdelayline = dsp.DelayLine( ...
   'Length', 4, ...
   'DirectFeedthrough', true, ...
   'InitialConditions', -2, ...
   'EnableOutputInputPort', true, ...
   'HoldPreviousValue', true);
```

```
en = logical([1 1 0 1 0]);
y = zeros(4,5);
for ii = 1:5
    y(:,ii) = step(hdelayline, ii, en(ii));
end
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Delay Line block reference page. The object properties correspond to the block properties, except as noted.

This object processes inputs as separate channels (frames). The corresponding block has a temporary **Treat Mx1 and unoriented sample-based signals as** parameter with a One channel option for frame-based behavior and an M channels option for sample-based behavior. See the Delay Line block reference page and "Set the FrameBasedProcessing Property of a System object" for more information.

See Also   dsp.Delay

dsp.DelayLine.clone

Purpose   Create delay line object with same property values

Syntax   C = clone(H)

Description C = clone(H) creates a DelayLine object C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                   the step method.

                   The getNumInputs method returns a positive integer that is the number
                   of expected inputs (not counting the object itself) to the step method.
                   This value will change if you alter any properties that turn inputs on or
                   off. You must call the step method with the number of input arguments
                   equal to the result of getNumInputs(*H*).

dsp.DelayLine.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, from the
                  step method

                  The getNumOutputs method returns a positive integer that is the
                  number of outputs from the step method. This value will change if you
                  alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the DelayLine object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.DelayLine.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

> **Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset internal states of delay line object

Syntax   `reset(H)`

Description   `reset(H)` sets the internal delay buffers of the `DelayLine` object `H` to
                  their initial conditions.

Purpose   Delayed version of input

Syntax   Y = step(H,X)
                 Y = step(H,X,EN)

Description   Y = step(H,X) returns the delayed version of input X. Y is an output
                 matrix with the same number of rows as the delay line size. Each
                 column of X is treated as a separate channel.

                 The System object rebuffers a sequence of Mi-by-N matrix inputs into a
                 sequence of Mo-by-N matrix outputs, where Mo is the output frame size
                 specified by the Length property. Depending on whether Mo is greater
                 than, less than, or equal to the input frame size, Mi, the output frames
                 can be underlapped or overlapped. Each of the N input channels is
                 rebuffered independently:

                 • When $Mo > Mi$, the output frame overlap is the difference between
                   the output and input frame size, Mo–Mi.

                 • When $Mo < Mi$, the output is underlapped; the object discards the
                   first Mi–Mo samples of each input frame so that only the last Mo
                   samples are buffered into the corresponding output frame.

                 • When $Mo = Mi$, the output data is identical to the input data, but is
                   delayed by the latency of the object.

                 Y = step(H,X,EN) selectively outputs the delayed version of input
                 X depending on the Boolean input EN. This occurs only when you set
                 the EnableOutputInputPort property to true. If EN is false, use the
                 HoldPreviousValue property to specify if the object should hold the
                 previous output value(s).

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose   Digitally downconvert input signal

Description   The `DigitalDownConverter` object digitally downconverts the input signal.

To digitally downconvert the input signal:

1 Define and set up your digital down converter. See "Construction" on page 5-340.

2 Call `step` to downconvert the input according to the properties of `dsp.DigitalDownConverter`. The behavior of `step` is specific to each object in the toolbox.

Construction   `h = dsp.DigitalDownConverter` returns a digital down-converter (DDC) System object, `h`. The object frequency downconverts the input signal by multiplying it with a complex exponential with center frequency equal to the value in the `CenterFrequency` property. The object downsamples the frequency down-converted signal using a cascade of three decimation filters. When you set the `FilterSpecification` property to `Design parameters`, the DDC object designs the decimation filters according to the filter parameters that you set in the filter-related object properties. In this case the filter cascade consists of a CIC decimator, a CIC compensator and a third FIR decimation stage. The following block diagram shows the architecture of the digital down converter.

The scaling section normalizes the CIC gain and the oscillator power. It may also contain a correction factor to achieve the desired ripple specification. When you set the **Oscillator** property to InputPort, the normalization factor does not include the oscillator power factor. Depending on the setting of the **DecimationFactor** property, you may be able to bypass the third filter stage. When the arithmetic is double or single precision, the CIC interpolator is implemented as a simple FIR interpolator with a boxcar response. A true CIC interpolator can only operate with fixed-point signals. The CIC filter is emulated with an FIR filter so that you can run simulations with floating-point data.

The following block diagram represents the DDC arithmetic with single or double-precision, floating-point inputs.

The following block diagram represents the DDC arithmetic with signed fixed-point inputs.

- `WL` is the word length of the input, and `FL` is the fraction length of the input.

- The input of each filter is cast to the data type specified in the **FiltersInputDataType** and **CustomFiltersInputDataType** properties.

- The oscillator output is cast to a word length equal to the input word length plus one. The fraction length is equal to the input word length minus one.

- The scaling at the output of the CIC decimator consists of coarse- and fine-gain adjustments. The coarse gain is achieved using the `reinterpretcast` function on the CIC decimator output. The fine gain is achieved using full-precision multiplication.

The following figure depicts the coarse- and fine-gain operations.

If the normalization gain is G, (where 0<G≤1), then:

- `WLcic` is the word length of the CIC decimator output and `FLcic` is the fraction length of the CIC decimator output

- `F1 = abs(nextpow2(G))`, indicating the part of G achieved using bit shifts (coarse gain)

- `F2` = fraction length specified by the **FiltersInputDataType** and **CustomFiltersInputDataType** properties

- `fg = fi((2^F1)*G, true, 16)` , indicating that the remaining gain cannot be achieved with a bit shift (fine gain)

`h = dsp.DigitalDownConverter(Name,Value)` returns a DDC object, h, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1,Value1,...,NameN,ValueN`).

Properties

SampleRate

Sample rate of input signal

Set this property to a positive scalar value, greater than or equal to twice the value of the `CenterFrequency` property. The default is 30 Megahertz.

DecimationFactor

Decimation factor

Set this property to a positive, integer scalar, or to a 1-by-2 or 1-by-3 vector of positive integers.

When you set this property to a scalar the object automatically chooses the decimation factors for each of the three filtering stages. The scalar value you specify cannot be a prime number.

When you set this property to a 1-by-2 vector, the object bypasses the third filter stage and sets the decimation factor of the first and second filtering stages to the values in the first and second vector elements respectively. When you set the `FilterSpecification` property to `Design parameters`, both elements of the `DecimationFactor` vector must be greater than one. When you set the `FilterSpecification` property to `Coefficients`, the first element of the `DecimationFactor` vector must be greater than 1.

When you set this property to a 1-by-3 vector, the i th element of the vector specifies the decimation factor for the i th filtering stage. When you set the `FilterSpecification` property to `Design parameters`, the first and second elements of the `DecimationFactor` vector must be greater than one and the third element must be 1 or 2. When you set the `FilterSpecification` property to `Coefficients`, the first element of the `DecimationFactor` vector must be greater than 1. When you set the `FilterSpecification` property to `Coefficients`, you must set the `DecimationFactor` property to a 1-by-3 or 1-by-2 vector. The default is 100.

FilterSpecification

Filter specification

Set the filter specification as one of `Design parameters` | `Coefficients`. The default is `Design parameters`. The DDC object performs decimation using a cascade of three decimation filters. The first filter stage is always a CIC decimator. When you set the `FilterSpecification` property to `Design parameters`, the object designs the cascade of decimation filters internally, according to a set of parameters that you specify using the filter-related object properties. In this case, the second and third stages of the cascade consist of a CIC compensator, and a halfband or lowpass FIR decimator respectively. When you set the `FilterSpecification` property to `Coefficients`, you specify an arbitrary set of filter coefficients for the second and third filter stages using the `SecondFilterCoefficients`, and `ThirdFilterCoefficients` properties respectively. You specify the number of CIC sections using the `NumCICSections` property. In all cases, the third filter stage can be bypassed by setting the `DecimationFactor` property appropriately.

When the input data type is double or single the object implements an *N*-section CIC decimation filter as an FIR filter with a response that corresponds to a cascade of *N* boxcar filters. A true CIC filter with actual comb and integrator sections is implemented when the input data is of a fixed point type.

MinimumOrderDesign

Minimum order filter design

When you set this property to true the object designs filters with the minimum order that meets the passband ripple, stopband attenuation, passband frequency, and stopband frequency specifications that you set using the `PassbandRipple`, `StopbandAttenuation`, `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties. When you set this property to false, the object designs filters with orders that you specify in the `NumCICSections`, `SecondFilterOrder`, and `ThirdFilterOrder` properties. The filter designs meet the passband and stopband frequency specifications that you set using the Bandwidth, `StopbandFrequencySource`, and `StopbandFrequency` properties. This property applies when you set the `FilterSpecification` property to `Design parameters`. The default is true.

NumCICSections

Number of sections of CIC decimator

Set this property to a positive, integer scalar. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `MinimumOrderDesign` property to false, or when you set the `FilterSpecification` property to `Coefficients`. The default is 3.

SecondFilterCoefficients

Coefficients of second filter stage

Set this property to a double precision row vector of real coefficients that correspond to an FIR filter. Usually, the response of this filter should be that of a CIC compensator since a CIC decimation filter precedes the second filter stage. This property applies when you set the `FilterSpecification` property to `Coefficients`. The default is 1.

ThirdFilterCoefficients

Coefficients of third filter stage

Set this property to a double precision row vector of real coefficients that correspond to an FIR filter. When you set the `DecimationFactor` property to a 1-by-2 vector, the object ignores the value of the `ThirdFilterCoefficients` property because the third filter stage is bypassed. This property applies when you set the `FilterSpecification` property to `Coefficients`. The default is `1`.

SecondFilterOrder

Order of CIC compensation filter stage

Set this property to a positive, integer scalar. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `MinimumOrderDesign` property to false. The default is `12`.

ThirdFilterOrder

Order of third filter stage

Set this property to a positive, integer, even scalar. When you set the `DecimationFactor` property to a 1-by-2 vector, the object ignores the `ThirdFilterOrder` property because the third filter stage is bypassed. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `MinimumOrderDesign` property to false. The default is `10`.

Bandwidth

Two sided bandwidth of input signal in Hertz

Set this property to a positive, integer scalar. The object sets the passband frequency of the cascade of filters to one-half of the value that you specify in the `Bandwidth` property. This property applies when you set the `FilterSpecification` property to `Design parameters`. The default is 200 kilohertz.

StopbandFrequencySource

Source of stopband frequency

Specify the source of the stopband frequency as one of `Auto` | `Property`. The default is `Auto`. When you set this property to `Auto`, the object places the cutoff frequency of the cascade filter response at approximately F_c = `SampleRate`/M/2 Hertz, where M is the total decimation factor that you specify in the `DecimationFactor` property. The object computes the stopband frequency as $F_{stop} = F_c + TW/2$. TW is the transition bandwidth of the cascade response computed as $2*(F_c$-$F_p)$, and the passband frequency, F_p, equals `Bandwidth`/2. This property applies when you set the `FilterSpecification` property to `Design parameters`.

StopbandFrequency

Stopband frequency in Hertz

Set this property to a double precision positive scalar. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `StopbandFrequencySource` property to `Property`. The default is 150 kilohertz.

PassbandRipple

Passband ripple of cascade response in decibels.

Set this property to a double precision, positive scalar. When you set the `MinimumOrderDesign` property to true, the object designs the filters so that the cascade response meets the passband ripple that you specify in the `PassbandRipple` property. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `MinimumOrderDesign` property to true. The default is `0.1` decibels.

StopbandAttenuation

Stopband attenuation of cascade response in decibels

Set this property to a double precision, positive scalar. When you set the `MinimumOrderDesign` property to true, the object designs the filters so that the cascade response meets the stopband attenuation that you specify in the

StopbandAttenuation property. This property applies when you set the FilterSpecification property to Design parameters and the MinimumOrderDesign property to true. The default is 60 decibels.

Oscillator

Type of oscillator

Specify the oscillator as one of Sine wave | NCO | Input port. The default is Sine wave. When you set this property to Sine wave, the object frequency down converts the input signal using a complex exponential obtained from samples of a sinusoidal trigonometric function. When you set this property to NCO the object performs frequency down conversion with a complex exponential obtained using a numerically controlled oscillator (NCO). When you set this property to Input port, the object performs frequency down conversion using the complex signal that you set as an input to the step method.

CenterFrequency

Center frequency of input signal in Hertz

Specify this property as a double precision positive scalar that is less than or equal to half the value of the SampleRate property. The object down converts the input signal from the passband center frequency you specify in the CenterFrequency property, to 0 Hertz. This property applies when you set the Oscillator property to Sine wave or NCO. The default is 14 Megahertz.

NumAccumulatorBits

Number of NCO accumulator bits

Specify this property as an integer scalar in the range [1 128]. This property applies when you set the Oscillator property to NCO. The default is 16.

NumQuantizedAccumulatorBits

Number of NCO quantized accumulator bits

Specify this property as an integer scalar in the range [1 128]. The value you specify in this property must be less than the value you specify in the NumAccumulatorBits property. This property applies when you set the Oscillator property to NCO. The default is 12.

Dither

Dither control for NCO

When you set this property to true, a number of dither bits specified in the NumDitherBits property will be used to apply dither to the NCO signal. This property applies when you set the Oscillator property to NCO. The default is true.

NumDitherBits

Number of NCO dither bits

Specify this property as an integer scalar smaller than the number of accumulator bits that you specify in the NumAccumulatorBits property. This property applies when you set the Oscillator property to NCO and the Dither property to true. The default is 4.

Fixed-Point Properties

SecondFilterCoefficientsDataType

Data type of second filter coefficients

Specify the second filter coefficients data type as Same as input | Custom. The default is Same as input. This property applies when you set the FilterSpecification property to Coefficients.

CustomSecondFilterCoefficientsDataType

Fixed-point data type of second filter coefficients

Specify the second filter coefficients fixed-point type as a scaled numerictype object with a Signedness of Auto. This property

applies when you set the SecondFilterCoefficientsDataType property to Custom. The default is numerictype([],16,15).

ThirdFilterCoefficientsDataType

Data type of third filter coefficients

Specify the third filter coefficients data type as Same as input |Custom. The default is Same as input. This property applies when you set the FilterSpecification property to Coefficients.

CustomThirdFilterCoefficientsDataType

Fixed-point data type of third filter coefficients

Specify the third filter coefficients fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the ThirdFilterCoefficientsDataType property to Custom. The default is numerictype([],16,15).

FiltersInputDataType

Data type of input of each filter stage

Specify the data type at the input of the first, second, and third (if it has not been bypassed) filter stages as one of Same as input | Custom. The default is Same as input. The object casts the data at the input of each filter stage according to the value you set in this property.

CustomFiltersInputDataType

Fixed-point data type of input of each filter stage

Specify the filters input fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the FiltersInputDataType property to Custom. The default is numerictype([],16,15).

OutputDataType

Data type of output

dsp.DigitalDownConverter

Specify the data type of output as `Same as input` | `Custom`. The default is `Same as input`.

CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a scaled numerictype object with a Signedness of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods		
clone	Create digital down converter object with same property values
fvtool	Visualize response of filter cascade
getDecimationFactors	Get decimation factors of each filter stage
getFilterOrders	Get orders of decimation filters
getFilters	Get handles to decimation filter objects
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
groupDelay	Group delay of filter cascade
isLocked	Locked status for input attributes and non-tunable properties
release	Allow property value and input characteristics changes
step	Digitally down convert input signal
visualizeFilterStages	Display response of filter stages

Copy Semantics   Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB Programming Fundamentals documentation.

Examples   Create a digital up converter object that up samples a 1 KHz sinusoidal signal by a factor of 20 and up converts it to 50 KHz. Create a digital down converter object that down converts the signal to 0 Hz and down samples it by a factor of 20.

```
% Create a sine wave generator to obtain the 1 KHz
% sinusoidal signal with a sample rate of 6 KHz.
Fs = 6e3; % Sample rate
hSig = dsp.SineWave('Frequency',1000,'SampleRate',...
Fs,'SamplesPerFrame',1024);
x = step(hSig); % generate signal

% Create a DUC object. Use minimum order filter designs and set
% passband ripple to 0.2 dB and the stopband attenuation to 55 dB.
% Set the double sided signal bandwidth to 2 KHz.
hDUC = dsp.DigitalUpConverter(...
 'InterpolationFactor', 20,...
 'SampleRate', Fs,...
 'Bandwidth', 2e3,...
 'StopbandAttenuation', 55,...
 'PassbandRipple',0.2,...
 'CenterFrequency',50e3);

% Create a DDC object. Use minimum order filter designs and set the
% passband ripple to 0.2 dB and the stopband attenuation to 55 dB.
hDDC = dsp.DigitalDownConverter(...
  'DecimationFactor',20,...
  'SampleRate', Fs*20,...
  'Bandwidth', 3e3,...
  'StopbandAttenuation', 55,...
  'PassbandRipple',0.2,...
  'CenterFrequency',50e3);

% Create a spectrum estimator to visualize the signal spectrum before
```

```
% up converting, after up converting, and after down converting.
hSEst = spectrum.welch; hSEst.SegmentLength = length(x)/10;
hOpts=psdopts(hSEst);
set(hOpts, 'Fs', Fs, 'SpectrumType','twosided','CenterDC',true);
figure; psd(hSEst,x,hOpts)
title('Spectrum of baseband signal x')

% Up convert the signal and visualize the spectrum
xUp = step(hDUC,x); % up convert
hOpts.Fs = Fs*20; hSEst.SegmentLength = length(xUp)/10;
figure; psd(hSEst,xUp,hOpts)
title('Spectrum of up converted signal xUp')

% Down convert the signal and visualize the spectrum
xDown = step(hDDC,xUp); % down convert
hOpts.Fs = Fs; hSEst.SegmentLength = length(xDown)/10;
figure; psd(hSEst,xDown,hOpts)
title('Spectrum of down converted signal xDown')

% Visualize the response of the decimation filters
visualizeFilterStages(hDDC)
```

For additional examples using this System object, see the following
demos:

- Digital Up and Down Conversion for Family Radio Service
- Design and Analysis of a Digital Down Converter

See Also   dsp.DigitalUpConverter

Purpose   Create digital down converter object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a DigitalDownConverter System object, C, with
                   the same property values as H.

                   The clone method creates a new unlocked object with uninitialized
                   states.

Purpose   Visualize response of filter cascade

Syntax
```
fvtool(H)
fvtool(H,..,'Arithmetic',ARITH,...)
fvtool(H,..., PROP1, VALUE1,PROP2,VALUE2,...)
```

Description   fvtool(H) plots the magnitude response of the cascade of filters. By default, the object plots the cascade response up to the second CIC null frequency (or to the first when only one CIC null exists). When you set the `FilterSpecification` property to `Design parameters` the method plots a mask based on the filter specifications.

fvtool(H,..,'Arithmetic',ARITH,...) specifies the arithmetic of the filter cascade. You set input ARITH to `double`, `single`, or `fixed-point`. When object H is in an unlocked state you must specify the arithmetic. When object H is in a locked state the arithmetic input is ignored.

fvtool(H,..., PROP1, VALUE1,PROP2,VALUE2,...) launches FVTool and sets the specified FVTool properties to the specified values.

Purpose   Get decimation factors of each filter stage

Syntax   M = getDecimationFactors(H)

Description M = getDecimationFactors(H)) returns a vector, M, with the
                 decimation factors of each filter stage. If the third filter stage is
                 bypassed, then M is a 1-by-2 vector containing the decimation factors
                 of the first and second filter stages in the first and second elements
                 respectively. If the third filter stage is not bypassed then M is a 1-by-3
                 vector containing the decimation factors of the first, second and third
                 filter stages.

dsp.DigitalDownConverter.getFilters

Purpose   Get handles to decimation filter objects

Syntax   S = getFilters(H)
                 getFilters(H,'Arithmetic',ARITH)

Description   S = getFilters(H) returns a structure, S, with copies of the filter
                 System objects and the CIC normalization factor that form the
                 decimation filter cascade. The ThirdFilterStage structure field is
                 empty if the third filter stage has been bypassed. The CIC normalization
                 factor equals the inverse of the CIC filter gain. In some cases, this gain
                 includes a correction factor to ensure that the cascade response meets
                 the ripple specifications.

                 getFilters(H,'Arithmetic',ARITH) specifies the arithmetic of the
                 filter stages. You can set ARITH to double, single, or fixed-point.
                 When object H is in an unlocked state, you must specify the arithmetic
                 input. When object H is in a locked state, the arithmetic input is ignored.

                 When H is in an unlocked state, and you specify the arithmetic as
                 fixed-point, the getFilters method returns filter System objects.
                 The custom coefficient data type properties of these System objects
                 are set to the values that the dsp.DigitalDownConverter System
                 object uses to process data when you call the step method. All other
                 fixed-point properties are set to their default values.

                 When H is in a locked state, and the input to the step method is of a
                 fixed-point data type, the getFilters method returns filter System
                 objects. All fixed-point properties of these System objects are set to
                 the exact values that the dsp.DigitalDownConverter System object
                 uses to process the data.

Purpose　　Get orders of decimation filters

Syntax　　`S = getFilterOrders(H)`

Description　　`S = getFilterOrders(H)` returns a structure, `S`, that contains the orders of the interpolation filter stages. The `ThirdFilterOrder` structure field will be empty if the third filter stage has been bypassed.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to the step method

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                       method

                       The getNumOutputs method returns a positive integer that is the
                       number of outputs from the step method. This value will change if you
                       alter any properties that turn outputs on or off.

dsp.DigitalDownConverter.groupDelay

Purpose   Group delay of filter cascade

Syntax   D = groupDelay(H,N)
                 [D,F] = groupDelay(H,N)

Description D = groupDelay(H,N) returns a vector of group delays, D, evaluated
                 at N frequency points equally spaced around the upper half of the unit
                 circle. If you don't specify N, it defaults to 8192.

                 [D,F] = groupDelay(H,N) returns a vector of frequencies, F, at which
                 the group delay has been computed.

Purpose   Locked status for input attributes and non-tunable properties

Syntax   Y = isLocked(H)

Description   Y = isLocked(H) returns the locked state, Y, of the
                   DigitalUpConverter object.

                   The isLocked method returns a logical value that indicates whether
                   input attributes and nontunable properties for the object are locked. The
                   object performs an internal initialization the first time the step method
                   is executed. This initialization locks nontunable properties and input
                   specifications, such as dimensions, complexity, and data type of the
                   input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

Purpose   Digitally down convert input signal

Syntax   Y = step(H,X)
                Y = step(H,X,Z)

Description   Y = step(H,X) takes a real or complex input column vector X and outputs a frequency down converted and down sampled signal Y. The length of input X must be a multiple of the decimation factor. X can be of data type double, single, signed integer, or signed fixed point (fi objects). The length of Y is equal to the length of X divided by the DecimationFactor. When the data type of X is double or single precision, the data type of Y is the same as that of X. When the data type of X is of a fixed point type, the data type of Y is defined by the OutputDataType property.

Y = step(H,X,Z) uses the complex input, Z, as the oscillator signal used to frequency down convert input X, when you set the Oscillator property to Input port. The length of Z must be equal to the length of X. Z can be of data type double, single, signed integer, or signed fixed point (fi objects).

dsp.DigitalDownConverter.visualizeFilterStages

Purpose   Display response of filter stages

Syntax
```
visualizeFilterStages(H)
visualizeFilterStages(H,'Arithmetic',ARITH)
hfvt = visualizeFilterStages(H)
```

Description   `visualizeFilterStages(H)` plots the magnitude response of the filter stages and of the cascade response. When you set the `FilterSpecification` property to `Design parameters` the method plots a mask based on the filter specifications. By default, the object plots the response of the filters up to the second CIC null frequency (or to the first when only one CIC null exists).

`visualizeFilterStages(H,'Arithmetic',ARITH)` specifies the arithmetic of the filter stages. You set input `ARITH` to `double`, `single`, or `fixed-point`. When object `H` is in an unlocked state you must specify the arithmetic. When object `H` is in a locked state the arithmetic input is ignored.

`hfvt = visualizeFilterStages(H)` returns the handle to the FVTool object.

Purpose Static or time-varying digital filter

Description The DigitalFilter object filters each channel of the input using static or time-varying digital filter implementations.

To filter each channel of the input using digital filter implementation:

1 Define and set up your IIR digital filter. See "Construction" on page 5-367.

2 Call step to filter each channel according to the properties of dsp.DigitalFilter. The behavior of step is specific to each object in the toolbox.

Construction H = dsp.DigitalFilter returns a default IIR digital filter object, H, which independently filters each channel of the input over successive calls to the step method, using a specified digital filter implementation. The default numerator coefficients are [1 2] and denominator coefficients are [1 0.1].

H = dsp.DigitalFilter('*PropertyName*',*PropertyValue*, ...) returns a digital filter object, H, with each property set to the specified value.

Properties **TransferFunction**

Type of filter transfer function

Specify the type of digital filter transfer function as one of | IIR (poles & zeros) | IIR (all poles) | FIR (all zeros) |. The default is IIR (poles & zeros).

Structure

Filter structure

Specify the filter structure.

When you set the TransferFunction property to FIR (all zeros), you can specify the filter structure as one of |

Direct form | Direct form symmetric | Direct form antisymmetric | Direct form transposed | Lattice MA |. The default is Direct form.

When you set the TransferFunction property to IIR (all poles), you can specify the filter structure as Direct form, Direct form transposed, or Lattice AR. The default is Direct form.

When you set the TransferFunction to IIR (poles & zeros), you can specify the filter structure as Direct form I, Direct form I transposed, Direct form II, Direct form II transposed, Biquad direct form I (SOS), Biquad direct form I transposed (SOS), Biquad direct form II (SOS), or Biquad direct form II transposed (SOS). The biquad filter structure does not apply when you set the CoefficientsSource property to Input port. The default is Direct form II transposed.

CoefficientsSource

Source of filter coefficients

Specify the source of the filter coefficients as one of | Property | Input port |. The default is Property. When you specify Input port, the digital filter object updates the time-varying filter once every frame, when the FrameBasedProcessing property is true. When the FrameBasedProcessing property is false, it updates once every sample.

Numerator

Numerator coefficients

Specify the filter numerator coefficients as a real or complex numeric vector. This property applies when you set the TransferFunction property to FIR (all zeros), the CoefficientsSource property to Property, and the Structure property is not set to Lattice MA. This property also applies when you set the TransferFunction property to IIR (poles & zeros), the CoefficientsSource to Property, and the

TransferFunction property to `Direct form`, `Direct form symmetric`, `Direct form antisymmetric`, or `Direct form transposed`. The default is `[1 2]`. This property is tunable.

Denominator

Denominator coefficients

Specify the filter denominator coefficients as a real or complex numeric vector. This property applies when you set the `TransferFunction` property to `IIR (all poles)`, the `CoefficientsSource` property to `Property` and the `Structure` property is not set to `Lattice AR`. This property also applies when you set the `TransferFunction` property to `IIR (poles & zeros)`, the `CoefficientsSource` to `Property`, and the `TransferFunction` property to `Direct form`, `Direct form symmetric`, `Direct form antisymmetric`, or `Direct form transposed`. When the `TransferFunction` property is `IIR (poles & zeros)`, the numerator and denominator must have the same complexity. The default is `[1 0.1]`. This property is tunable.

ReflectionCoefficients

Reflection coefficients of lattice filter structure

Specify the reflection coefficients of a lattice filter as a real or complex numeric vector. This property applies when you set the `TransferFunction` property to `FIR (all zeros)`, the `Structure` property to `Lattice MA`, and the `CoefficientsSource` property to `Property`. This property also applies when you set the `TransferFunction` property to `IIR (all poles)`, the `Structure` property to `Lattice AR`, and the `CoefficientsSource` property to `Property`. The default is `[0.2 0.4]`. This property is tunable.

SOSMatrix

SOS matrix of biquad filter structure

Specify the second-order section (SOS) matrix of a biquad filter as an M-by-6 matrix, where M is the number of sections in the

filter. Each row of the SOS matrix contains the numerator and denominator coefficients of the corresponding filter section. The first three elements of each row are the numerator coefficients and the last three elements are the denominator coefficients. You can use real or complex coefficients. This property applies when you set the `TransferFunction` property to `IIR (poles and zeros)`, the `CoefficientsSource` property to `Property`, and the `Structure` property to `Biquad direct form I (SOS)`, `Biquad direct form I transposed (SOS)`, `Biquad direct form II (SOS)`, or `Biquad direct form II transposed (SOS)`. The default is [1 0.3 0.4 1 0.1 0.2]. This property is tunable.

ScaleValues

Scale values of biquad filter structure

Specify the scale values to apply before and after each section of a biquad filter. `ScaleValues` must be a scalar or a vector of length M+1, where M is the number of sections. If you specify a scalar value, that value is used as the gain value before the first section of the second-order filter and the rest of the gain values are set to 1. If you specify a vector of M+1 values, each value is used for a separate section of the filter. This property applies when you set the `TransferFunction` property to `IIR (poles & zeros)`, the `CoefficientsSource` property to `Property`, and the `Structure` property to `Biquad direct form I (SOS)`, `Biquad direct form I transposed (SOS)`, `Biquad direct form II (SOS)`, or `Biquad direct form II transposed (SOS)`. The default is 1. This property is tunable.

IgnoreFirstDenominatorCoefficient

Assume first denominator coefficient is 1

Setting this Boolean property to `true` reduces the number of computations to produce the digital filter output by omitting the first denominator term, $a0$, (poles side) in the filter structure. The object output is invalid when you set this property to `true` when the first denominator coefficient is not always 1 for your time-varying filter. The object ignores this property for

fixed-point inputs, because this object does not support nonunity *a0* coefficients for fixed-point inputs.

This property applies when you set the `CoefficientsSource` property to `Input port`, the `TransferFunction` property to `IIR (all poles)`, and the `Structure` property is not set to `Lattice AR`. This property also applies when you set the `CoefficientsSource` property to `Input port`, the `TransferFunction` property to `IIR (poles & zeros)`, and the `Structure` property to `Direct form`, `Direct form symmetric`, `Direct form antisymmetric`, or `Direct form transposed`. The default is `true`.

InitialConditions

Initial conditions for all poles or all zeros filter

Specify the initial conditions of the filter states. When the `TransferFunction` property is `FIR (all zeros)` or `IIR (all poles)`, the number of states or delay elements equals the number of reflection coefficients for the lattice structure, or the number of filter coefficients–1 for the other direct form structures. When the `TransferFunction` property is `IIR (poles & zeros)`, the number of states for direct form II and direct form II transposed structures equals the `max(N,M)`–1, where `N` and `M` are the number of poles and zeros, respectively.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, the digital filter object initializes all delay elements in the filter to that value. If you specify a vector whose length equals the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

If you specify a vector whose length equals the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

If you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. This property applies when you do not set the `Structure` property to `Direct Form I`, `Direct Form I transposed`, `Biquad direct form I (SOS)`, or `Biquad direct form I transposed (SOS)`. The default is 0.

NumeratorInitialConditions

Initial conditions on zeros side

Specify the initial conditions of the filter states on the side of the filter structure with the zeros. This property applies when you set the `TransferFunction` property to `IIR (poles & zeros)` and the `Structure` property is `Direct form I`, `Direct form I transposed`, `Biquad direct form I (SOS)`, or `Biquad direct form I transposed (SOS)`. The default is `0`. See the `InitialConditions` property for information on setting initial conditions.

DenominatorInitialConditions

Initial conditions on poles side

Specify the initial conditions of the filter states on the side of the direct form I (noncanonic) filter structure with the poles. This property applies when you set the `TransferFunction` property to `IIR (poles & zeros)` and the `Structure` property to `Direct form I`, `Direct form I transposed`, `Biquad direct form I (SOS)`, or `Biquad direct form I transposed (SOS)`. The default is 0. See the `InitialConditions` property for information on setting initial conditions.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

TapSumDataType

Tap sum word and fraction lengths

Specify the tap sum fixed-point data type as one of | `Same as input` | `Custom` |. This property applies when you set the `TransferFunction` property to `FIR (all zeros)` and the `Structure` property to either `Direct form symmetric` or `Direct form antisymmetric`. The default is `Same as input`.

CustomTapSumDataType

Custom tap sum word and fraction lengths

Specify the tap sum fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `TapSumDataType` property to `Custom`. The default is `numerictype([],32,30)`.

MultiplicandDataType

Multiplicand word and fraction lengths

Specify the multiplicand fixed-point data type as one of | `Same as output` | `Custom` |. This property applies when you set the `Structure` property to either `Direct form I transposed` or `Biquad direct form I transposed (SOS)`. The default is `Same as output`.

CustomMultiplicandDataType

Custom multiplicand word and fraction lengths

Specify the multiplicand fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `MultiplicandDataType` property to `Custom`. The default to `numerictype([],32,30)`.

SectionInputDataType

Section input word and fraction lengths

Specify the section input fixed-point data type as one of | `Same as input` | `Custom` |. Setting this property also sets the `SectionOutputDataType` property to the same value. This property applies when you set the `TransferFunction` property to `IIR (poles & zeros)` and the `Structure` property to one of the biquad filter structures. The default is `Same as input`.

CustomSectionInputDataType

Custom section input word and fraction lengths

Specify the section input fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SectionInputDataType` property to `Custom`. The `CustomSectionInputDataType` and `CustomSectionOutputDataType` property values must have equal word lengths. The default is `numerictype([],16,15)`.

SectionOutputDataType

Section output word and fraction lengths

Specify the section output fixed-point data type as one of | `Same as input` | `Custom` |. Setting this property also sets

the `SectionInputDataType` property to the same value. This property applies when you set the `TransferFunction` property to `IIR (poles & zeros)` and the `Structure` property to one of the biquad filter structures. The default is `Same as input`.

CustomSectionOutputDataType

Custom section output word and fraction lengths

Specify the section output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SectionOutputDataType` property to `Custom`. The `CustomSectionInputDataType` and `CustomSectionOutputDataType` property values must have equal word lengths. The default is `numerictype([],16,15)`.

NumeratorCoefficientsDataType

Numerator coefficients word and fraction lengths

Specify the numerator coefficients fixed-point data type as one of | `Same word length as input` | `Custom` |. Setting this property also sets the `DenominatorCoefficientsDataType` and the `ScaleValuesDataType` properties, if applicable, to the same value. This property applies when you set the `CoefficientsSource` property to `Property` and the `TransferFunction` property is not set to `IIR (all poles)`. The default is `Same word length as input`.

CustomNumeratorCoefficientsDataType

Custom numerator coefficients word and fraction lengths

Specify the numerator coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `NumeratorCoefficientsDataType` property to `Custom`. The `CustomNumeratorCoefficientsDataType`, `CustomDenominatorCoefficientsDataType` and `ScaleValuesDataType` properties, if applicable, must have equal word lengths. The default is `numerictype([],16,15)`.

DenominatorCoefficientsDataType

Denominator coefficients word and fraction lengths

Specify the denominator coefficients fixed-point data type as one of | Same word length as input | Custom |. Setting this property also sets the NumeratorCoefficientsDataType and ScaleValuesDataType properties, if applicable, to the same value. This property applies when you set the CoefficientsSource property to Property and the TransferFunction property is not set to FIR (all zeros). The default is Same word length as input.

CustomDenominatorCoefficientsDataType

Custom denominator coefficients word and fraction lengths

Specify the denominator coefficients fixed-point type as a numerictype object with a Signedness of Auto. This property applies when you set the DenominatorCoefficientsDataType property to Custom. The CustomNumeratorCoefficientsDataType, CustomDenominatorCoefficientsDataType and CustomScaleValuesDataType properties, if they apply, must have equal word lengths. The default is numerictype([],16,15).

ScaleValuesDataType

Scale values word and fraction lengths

Specify the scale values fixed-point data type as one of | Same word length as input | Custom |. Setting this property also sets the NumeratorCoefficientsDataType and the DenominatorCoefficientsDataType properties, if they apply, to the same value. This property applies when you set the CoefficientsSource property to Property, the TransferFunction property to IIR (poles & zeros), and the Structure property to one of the biquad filter structures. The default is Same word length as input.

CustomScaleValuesDataType

Custom scale values word and fraction lengths

Specify the scale values fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `CoefficientsSource` property to `Property` and the `ScaleValuesDataType` property to `Custom`. The `CustomNumeratorCoefficientsDataType`, `CustomDenominatorCoefficientsDataType`, and the `CustomScaleValuesDataType` properties, if applicable, must have equal word lengths. The default is `numerictype([],16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of | `Same as input` | `Custom` |. The default is `Same as input`.

CustomProductDataType

Custom product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type to one of | `Same as input` | `Same as product` | `Custom` |. The default is `Same as product`.

CustomAccumulatorDataType

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

StateDataType

State word and fraction lengths

Specify the state fixed-point data type as one of | Same as input | Same as accumulator | Custom |. This property does not apply to any of the direct form or direct form I filter structures. The default is Same as accumulator.

CustomStateDataType

Custom state word and fraction lengths

Specify the state fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the StateDataType property to Custom. The default is numerictype([],16,15).

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | Same as input | Same as accumulator | Custom |. The default is Same as accumulator.

CustomOutputDataType

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the OutputDataType property to Custom. The default is numerictype([],16,15).

Methods

clone	Create static or time-varying digital filter with same property values
getNumInputs	Number of expected inputs to step method

getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of digital filter
step	Filter input with digital filter object

Examples

Use an FIR filter to apply a low pass filter to a waveform with two sinusoidal components:

```
t = [0:63]./32e3;
xin = (sin(2*pi*4e3*t)+sin(2*pi*12e3*t)) / 2;

hSR = dsp.SignalSource(xin', 4);
hLog = dsp.SignalSink;
hFilt = dsp.DigitalFilter;
hFilt.TransferFunction = 'FIR (all zeros)';
hFilt.Numerator = fir1(10,0.5);

while ~isDone(hSR)
    input = step(hSR);
    filteredOutput = step(hFilt,input);
    step(hLog,filteredOutput);
end

filteredResult = hLog.Buffer;
sper = spectrum.periodogram;
psd(sper,filteredResult,'Fs',32e3)
```

dsp.DigitalFilter

Algorithms   This object implements the algorithm, inputs, and outputs described on the Digital Filter block reference page. The object properties correspond to the block parameters.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also   dsp.BiquadFilter

Purpose   Create static or time-varying digital filter with same property values

Syntax   C = clone(H)

Description C = clone(H) creates a digital filter object, C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

dsp.DigitalFilter.getNumInputs

Purpose	Number of expected inputs to step method
Syntax	N = getNumInputs(H)
Description	N = getNumInputs(H) returns the number of expected inputs, N, to the step method.
	The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the digital filter.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.DigitalFilter.reset

Purpose   Reset internal states of digital filter

Syntax   reset(H)

Description reset(H) resets the filter states of the digital filter object,H, to their
initial values of 0. The initial filter state values correspond to the initial
conditions for the difference equation defining the filter. After the step
method applies the digital filter object to nonzero input data, the states
may be nonzero. Invoking the step method again without first invoking
thereset method may produce different outputs for an identical input.

For example:

```
H = dsp.DigitalFilter;
H.TransferFunction = 'FIR (all zeros)';
H.Numerator = fir1(20,0.25);
n = 0:100;
x = cos(0.2*pi*n)+sin(0.8*pi*n);
y = step(H,x);
% Filter states are nonzero
% Invoke step method again without resetting states
y1 = step(H,x);
isequal(y,y1) % returns 0
% Now reset filter states to 0
reset(H)
% Invoke step method
y2 = step(H,x);
isequal(y,y2) % returns a 1
```

Purpose　　Filter input with digital filter object

Syntax　　　`Y = step(HFILT,X)`
　　　　　　　`Y = step(HFILT,X,COEFF)`
　　　　　　　`Y = step(HFILT,X,NUM,DEN)`

Description　`Y = step(HFILT,X)` filters the real or complex input signal X using the digital filter, H, to produce the output Y . The digital filter object operates on each channel of the input signal independently over successive calls to step method.

`Y = step(HFILT,X,COEFF)` uses the time-varying numerator or denominator coefficients, COEFF , to filter the input signal X and produce the output Y . You can use this option when you set the `TransferFunction` property to either FIR (all zeros) or IIR (all poles) and the `CoefficientsSource` property to Input port.

`Y = step(HFILT,X,NUM,DEN)` uses the time-varying numerator coefficients NUM and the time-varying denominator coefficients DEN to filter the input signal X and produce the output Y . You can use this option when you set the `TransferFunction` property to IIR (poles and zeros) and the `CoefficientsSource` property to Input port.

Note The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

Purpose	Digitally upconvert input signal

Description   The `DigitalUpConverter` object digitally upconverts the input signal.

To digitally up convert the input signal:

1 Define and set up your digital up converter. See "Construction" on page 5-388.

2 Call `step` to upconvert the input according to the properties of `dsp.DigitalUpConverter`. The behavior of `step` is specific to each object in the toolbox.

Construction   `h = dsp.DigitalUpConverter` returns a digital up-converter (DDC) System object, `h`. The object up samples the input signal using a cascade of three interpolation filters. This object frequency upconverts the up sampled signal by multiplying it with a complex exponential with center frequency equal to the value in the `CenterFrequency` property. When you set the `FilterSpecification` property to 'Design parameters', the DUC object designs the interpolation filters according to the filter specifications that you set in the filter-related object properties. In this case the filter cascade consists of a first FIR interpolation stage, a CIC compensator, and a CIC interpolator. The following block diagram shows the architecture of the digital up converter.

The scaling section normalizes the CIC gain and the oscillator power. It may also contain a correction factor to achieve the desired ripple specification. Depending on the setting of the **InterpolationFactor** property, you may be able to bypass the first filter stage. When the arithmetic is double or single precision, the CIC interpolator is implemented as a simple FIR interpolator with a boxcar response. A true CIC interpolator can only operate with fixed-point signals. The CIC filter is emulated with an FIR filter so that you can run simulations with floating-point data.

The following diagram represents the DUC arithmetic with single or double-precision, floating-point inputs.

The following block diagram represents the DUC arithmetic with signed fixed-point inputs.

- `WL` is the word length of the input, and `FL` is the fraction length of the input.

- The output of each filter is cast to the data type specified in the **FiltersOutputDataType** and **CustomFiltersOutputDataType** properties. The casting of the CIC output occurs after the scaling factor is applied.

- The oscillator output is cast to a word length equal to the **FiltersOutputDataType** word length plus one. The fraction length is equal to the **FiltersOutputDataType** word length minus one.

- The scaling at the output of the CIC interpolator consists of coarse- and fine-gain adjustments. The coarse gain is achieved using the `reinterpretcast` function on the CIC interpolator output. The fine gain is achieved using full-precision multiplication.

The following figure depicts the coarse- and fine-gain operations.

If the normalization gain is G, (where $0 < G \leq 1$), then:

- WLcic is the word length of the CIC interpolator output and FLcic is the fraction length of the CIC interpolator output

- F1 = abs(nextpow2(G)), indicating the part of G achieved using bit shifts (coarse gain)

- F2 = fraction length specified by the **FiltersOutputDataType** and **CustomFiltersOutputDataType** properties

- fg = fi((2^F1)*G, true, 16), indicating that the remaining gain cannot be achieved with a bit shift (fine gain)

h = dsp.DigitalUpConverter('*PropertyName*','*PropertyValue*') returns a DUC object, h, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

SampleRate

Sample rate of input signal

Set this property to a positive scalar. The value of this property multiplied by the total interpolation factor must be greater than

or equal to twice the value of the `CenterFrequency` property. The default is 30e6.

InterpolationFactor

Set this property to a positive, integer scalar, or to a 1-by-2 or 1-by-3 vector of positive integers. When you set this property to a scalar the object automatically chooses the interpolation factors for each of the three filtering stages. The scalar value you specify cannot be a prime number. When you set this property to a 1-by-2 vector, the object bypasses the first filter stage and sets the interpolation factor of the second and third filtering stages to the values in the first and second vector elements respectively. When you set the `FilterSpecification` property to `Design parameters`, both elements of the `InterpolationFactor` vector must be greater than one. When you set the `FilterSpecification` property to `Coefficients`, the second element of the `InterpolationFactor` vector must be greater than 1. When you set this property to a 1-by-3 vector, the ith element of the vector specifies the interpolation factor for the ith filtering stage. When you set the `FilterSpecification` property to `Design parameters`, the second and third elements of the `InterpolationFactor` vector must be greater than one and the first element must be 1 or 2. When you set the `FilterSpecification` property to `Coefficients`, the third element of the `InterpolationFactor` vector must be greater than 1. When you set the `InterpolationFactor` property to `Coefficients`, you must set the `InterpolationFactor` property to a 1-by-3 or 1-by-2 vector . The default is 100.

FilterSpecification

Set the filter specification as one of `Design parameters` |`Coefficients`. The default is `Design parameters`. The DUC object performs interpolation using a cascade of three interpolation filters. The third filter stage is always a CIC interpolator. When you set this property to `Design parameters`, the object designs the cascade of interpolation filters internally, according to a set of parameters that you specify using the

filter-related object properties. In this case, the first and second stages of the cascade consist of a halfband or lowpass FIR interpolator, and a CIC compensator respectively. When you set this property to `Coefficients`, you specify an arbitrary set of filter coefficients for the first and second stages using the `FirstFilterCoefficients`, and `SecondFilterCoefficients` properties respectively. You specify the number of CIC sections using the `NumCICSections` property. In all cases, the first filter stage can be bypassed by setting the `InterpolationFactor` property appropriately.

When the input data type is double or single the object implements an N-section CIC interpolation filter as an FIR filter with a response that corresponds to a cascade of *N* boxcar filters. A true CIC filter with actual comb and integrator sections is implemented when the input data is of a fixed point type.

MinimumOrderDesign

Minimum order filter design.

When you set this property to true the object designs filters with the minimum order that meets the passband ripple, stopband attenuation, passband frequency, and stopband frequency specifications that you set using the `PassbandRipple`, `StopbandAttenuation`, `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties. When you set this property to false, the object designs filters with orders that you specify in the `FirstFilterOrder`, `SecondFilterOrder`, and `NumCICSections` properties. The filter designs meet the passband and stopband frequency specifications that you set using the `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties. This property applies when you set the `FilterSpecification` property to `Design parameters`. The default is true.

FirstFilterCoefficients

Coefficients of first filter stage.

Set this property to a double precision row vector of real coefficients that correspond to an FIR filter. When you set the `InterpolationFactor` property to a 1-by-2 vector, the object ignores the value of the `FirstFilterCoefficients` property because the first filter stage is bypassed. This property applies when you set the `FilterSpecification` property to `Coefficients`. The default is 1.

SecondFilterOrder

Order of CIC compensation filter stage

Set this property to a positive, integer scalar. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `MinimumOrderDesign` property to false. The default is 12.

SecondFilterCoefficients

Coefficients of second filter stage.

Set this property to a double precision row vector of real coefficients that correspond to an FIR filter. Usually, the response of this filter should be that of a CIC compensator since a CIC interpolation filter follows the second filter stage. This property applies when you set the `FilterSpecification` property to `Coefficients`. The default is 1.

FirstFilterOrder

Order of first filter stage

Set this property to a positive, integer, even scalar. When you set the `InterpolationFactor` property to a 1-by-2 vector, the object ignores the `FirstFilterOrder` property because the first filter stage is bypassed. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `MinimumOrderDesign` property to false. The default is 10.

NumCICSections

Number of sections of CIC interpolator

Set this property to a positive, integer scalar. This property applies when you set the FilterSpecification property to Design parameters and the MinimumOrderDesign property to false, or when you set the FilterSpecification property to Coefficients. The default is 3.

Bandwidth

Two sided bandwidth of input signal in Hertz .

Set this property to a positive, integer scalar. The object sets the passband frequency of the cascade of filters to one-half of the value that you specify in the Bandwidth property. This property applies when you set the FilterSpecification property to Design parameters. The default is 200e3 Hertz.

StopbandFrequencySource

Source of stopband frequency.

Specify the source of the stopband frequency as one of Auto | Property. The default is Auto. When you set this property to Auto, the object places the cutoff frequency of the cascade filter response at approximately F_c = SampleRate/2 Hertz, and computes the stopband frequency as $F_{stop} = F_c + TW/2$. TW is the transition bandwidth of the cascade response, computed as $2*(F_c\text{-}F_p)$, and the passband frequency, F_p, equals Bandwidth/2. This property applies when you set the FilterSpecification property to Design parameters.

StopbandFrequency

Stopband frequency in Hertz

Set this property to a double precision positive scalar. This property applies when you set the FilterSpecification property to Design parameters and the StopbandFrequencySource property to Property. The default is 150e3 Hertz.

PassbandRipple

Passband ripple of cascade response in dB.

Set this property to a double precision, positive scalar. When you set the `MinimumOrderDesign` property to true, the object designs the filters so that the cascade response meets the passband ripple that you specify in the `PassbandRipple` property. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `MinimumOrderDesign` property to true. The default is `0.1` dB.

StopbandAttenuation

Stopband attenuation of cascade response in dB.

Set this property to a double precision, positive scalar. When you set the `MinimumOrderDesign` property to true, the object designs the filters so that the cascade response meets the stopband attenuation that you specify in the `StopbandAttenuation` property. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `MinimumOrderDesign` property to true. The default is 60 dB.

Oscillator

Type of oscillator.

Specify the oscillator as one of `Sine wave` | `NCO`. The default is `Sine wave`. When you set this property to `Sine wave`, the object frequency up converts the output of the interpolation filter cascade using a complex exponential signal obtained from samples of a sinusoidal trigonometric function. When you set this property to `NCO` the object performs frequency up conversion with a complex exponential obtained using a numerically controlled oscillator (NCO).

CenterFrequency

Center frequency of output signal in Hertz .

Specify this property as a double precision, positive scalar. The value of this property must be less than or equal to half the product of the `SampleRate` property times the total interpolation

factor. The object up converts the input signal so that the output spectrum centers at the frequency you specify in the CenterFrequency property. The default is 14e6 Hertz.

NumAccumulatorBits

Number of NCO accumulator bits

Specify this property as an integer scalar in the range [1 128]. This property applies when you set the Oscillator property to NCO. The default is 16.

See also dsp.NCO.

NumQuantizedAccumulatorBits

Number of NCO quantized accumulator bits.

Specify this property as an integer scalar in the range[1 128]. The value you specify for this property must be less than the value you specify in the NumAccumulatorBits property. This property applies when you set the Oscillator property to NCO. The default is 12.

See also dsp.NCO.

Dither

Dither control for NCO .

When you set this property to true, the object uses the number of dither bits specified in the NumDitherBits property when applying dither to the NCO signal. This property applies when you set the Oscillator property to NCO. The default is true.

See also dsp.NCO.

NumDitherBits

Number of NCO dither bits.

Specify this property as an integer scalar smaller than the number of accumulator bits that you specify in the NumAccumulatorBits

property. This property applies when you set the Oscillator property to NCO and the Dither property to true. The default is 4.

See also dsp.NCO.

Fixed-Point Properties

FirstFilterCoefficientsDataType

Data type of first filter coefficients

Specify first filter coefficients data type as Same as input|Custom. The default is Same as input. This property applies when you set the FilterSpecification property to Coefficients.

CustomFirstFilterCoefficientsDataType

Fixed-point data type of first filter coefficients

Specify the first filter coefficients fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the FirstFilterCoefficientsDataType property to Custom. The default is numerictype([],16,15).

SecondFilterCoefficientsDataType

Data type of second filter coefficients

Specify the second filter coefficients data type as Same as input |Custom. The default is Same as input. This property applies when you set the FilterSpecification property to Coefficients.

CustomSecondFilterCoefficientsDataType

Fixed-point data type of second filter coefficients

Specify the second filter coefficients fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the SecondFilterCoefficientsDataType property to Custom. The default is numerictype([],16,15).

FiltersOutputDataType

Data type of output of each filter stage

Specify the data type at the output of the first (if it has not been bypassed), second, and third filter stages as one of `Same as input` | `Custom`. The default is `Same as input`. The object casts the data at the output of each filter stage according to the value you set in this property. For the CIC stage, the casting is done after the signal has been scaled by the normalization factor.

CustomFiltersOutputDataType

Fixed-point data type of output of each filter stage

Specify the filters output fixed-point type as a scaled numerictype object with a Signedness of `Auto`. This property applies when you set the `FiltersOutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

OutputDataType

Data type of output

Specify the data type of output as `Same as input` | `Custom`. The default is `Same as input`.

CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a scaled numerictype object with a Signedness of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create digital up converter object with same property values
fvtool	Visualize response of filter cascade

getFilterOrders	Get orders of interpolation filters
getFilters	Get handles to interpolation filter objects
getInterpolationFactors	Get interpolation factors of each filter stage
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
groupDelay	Group delay of filter cascade
isLocked	Locked status for input attributes and non-tunable properties
release	Allow property value and input characteristics changes
step	Process inputs using the object algorithm
visualizeFilterStages	Display response of filter stages

Examples   Create a digital up converter object that up samples a 1 KHz sinusoidal signal by a factor of 20 and up converts it to 50 KHz.

```
% Create a sine wave generator to obtain the 1 KHz sinusoidal signal
% with a sample rate of 6 KHz.
Fs = 6e3; % Sample rate
hSig = dsp.SineWave('Frequency',1000,'SampleRate', Fs,'SamplesPerFram
x = step(hSig); % generate signal

% Create a DUC object. Use minimum order filter designs and set the
% passband ripple to 0.2 dB and the stopband attenuation to 55 dB. Se
% the double sided signal bandwidth to 2 KHz.
hDUC = dsp.DigitalUpConverter(...
 'InterpolationFactor', 20,...
 'SampleRate', Fs,...
 'Bandwidth', 2e3,...
```

```
    'StopbandAttenuation', 55,...
    'PassbandRipple',0.2,...
    'CenterFrequency',50e3);

% Create a spectrum estimator to visualize the signal spectrum bet
% and after up converting.
hSEst = spectrum.welch; hSEst.SegmentLength = length(x)/10;
hOpts=psdopts(hSEst);
set(hOpts, 'Fs', Fs, 'SpectrumType','twosided','CenterDC',true);
figure; psd(hSEst,x,hOpts)
title('Spectrum of baseband signal x')

% Up convert the signal and visualize the spectrum
xUp = step(hDUC,x); % up convert
hOpts.Fs = Fs*20; hSEst.SegmentLength = length(xUp)/10;
figure; psd(hSEst,xUp,hOpts)
title('Spectrum of up converted signal xUp')

% Visualize the response of the interpolation filters
visualizeFilterStages(hDUC)
```

For additional examples using this System object, see the following demos:

- Digital Up and Down Conversion for Family Radio Service
- Design and Analysis of a Digital Down Converter

See Also   dsp.DigitalDownConverter

dsp.DigitalUpConverter.clone

Purpose   Create digital up converter object with same property values

Syntax   C = clone(H)

Description C = clone(H) creates a DigitalUpConverter System object, C, with the same property values as H.

The clone method creates a new unlocked object with uninitialized states.

Purpose   Visualize response of filter cascade

Syntax   fvtool(H)
               fvtool(H,..,'Arithmetic',ARITH,...)
               fvtool(H,..., PROP1, VALUE1,PROP2,VALUE2)

Description   fvtool(H) plots the magnitude response of the cascade of filters. By
                 default, the object plots the cascade response up to the second CIC null
                 frequency (or to the first when only one CIC null exists). When you set
                 the FilterSpecification property to Design parameters the method
                 plots a mask based on the filter specifications.

                 fvtool(H,..,'Arithmetic',ARITH,...) specifies the arithmetic
                 of the filter cascade. You set input ARITH to double, single, or
                 fixed-point. When object H is in an unlocked state you must specify
                 the arithmetic. When object H is in a locked state the arithmetic input
                 is ignored.

                 fvtool(H,..., PROP1, VALUE1,PROP2,VALUE2) launches FVTool and
                 sets the specified FVTool properties to the specified values.

dsp.DigitalUpConverter.getFilters

Purpose   Get handles to interpolation filter objects

Syntax   `S = getFilters(H)`
`getFilters(H,'Arithmetic',ARITH)`

Description   `S = getFilters(H)` returns a structure, `S`, with copies of the filter System objects and the CIC normalization factor that form the interpolation filter cascade. The `FirstFilterStage` structure field is empty if the first filter stage has been bypassed. The CIC normalization factor equals the inverse of the CIC filter gain. In some cases, this gain includes a correction factor to ensure that the cascade response meets the ripple specifications.

`getFilters(H,'Arithmetic',ARITH)` specifies the arithmetic of the filter stages. You set `ARITH` to `double`, `single`, or `fixed-point`. When object `H` is in an unlocked state, you must specify the arithmetic input. When object `H` is in a locked state, the arithmetic input is ignored.

When `H` is in an unlocked state, and you specify the arithmetic as `fixed-point`, the `getFilters` method returns filter System objects. The custom coefficient data type properties of these System objects are set to the values that the `dsp.DigitalUpConverter` System object uses to process data when you call the `step` method. All other fixed-point properties are set to their default values.

When `H` is in a locked state, and the input to the step method is of a fixed-point data type, the `getFilters` method returns filter System objects. All fixed-point properties of these System objects are set to the exact values that the `dsp.DigitalUpConverter` System object uses to process the data.

Purpose   Get orders of interpolation filters

Syntax   S = getFilterOrders(H)

Description   S = getFilterOrders(H) returns a structure, S, that contains the
                    orders of the interpolation filter stages. The FirstFilterOrder
                    structure field will be empty if the first filter stage has been bypassed.

dsp.DigitalUpConverter.getInterpolationFactors

Purpose   Get interpolation factors of each filter stage

Syntax   M = getInterpolationFactors(H

Description M = getInterpolationFactors(H) returns a vector, M, with the
                interpolation factors of each filter stage. If the first filter stage is
                bypassed, then M is a 1-by-2 vector containing the interpolation
                factors of the second and third stages in the first and second elements
                respectively. If the first filter stage is not bypassed then M is a 1-by-3
                vector containing the interpolation factors of the first, second and third
                filter stages.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                     the step method

                     The getNumInputs method returns a positive integer that is the number
                     of expected inputs (not counting the object itself) to the step method.
                     This value will change if you alter any properties that turn inputs on or
                     off. You must call the step method with the number of input arguments
                     equal to the result of getNumInputs(*H*).

dsp.DigitalUpConverter.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
method

The getNumOutputs method returns a positive integer that is the
number of outputs from the step method. This value will change if you
alter any properties that turn outputs on or off.

Purpose   Group delay of filter cascade

Syntax   D = groupDelay(H,N)
                   [D,F] = groupDelay(H,N)

Description   D = groupDelay(H,N) returns a vector of group delays, D, evaluated
                   at N frequency points equally spaced around the upper half of the unit
                   circle. If you don't specify N, it defaults to 8192.

                   [D,F] = groupDelay(H,N) returns a vector, F, of frequencies at which
                   the group delay has been computed.

dsp.DigitalUpConverter.isLocked

Purpose   Locked status for input attributes and non-tunable properties

Syntax   Y = isLocked(H)

Description Y = isLocked(H) returns the locked state, Y, of the
                DigitalUpConverter object.

                The isLocked method returns a logical value that indicates whether
                input attributes and nontunable properties for the object are locked. The
                object performs an internal initialization the first time the step method
                is executed. This initialization locks nontunable properties and input
                specifications, such as dimensions, complexity, and data type of the
                input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.DigitalUpConverter.step

Purpose   Process inputs using the object algorithm

Syntax   Y = step(H,X)

Description   Y = step(H,X) takes a real or complex input column vector X and
                outputs an up sampled and frequency up converted signal Y. X can be
                of data type double, single, signed integer, or signed fixed point (fi
                objects). The length of Y is equal to the length of X multiplied by the
                InterpolationFactor. When the data type of X is double or single
                precision, the data type of Y is the same as that of X. When the data
                type of X is of a fixed point type, the data type of Y is defined by the
                OutputDataType property.

Purpose   Display response of filter stages

Syntax   visualizeFilterStages(H)
visualizeFilterStages(H,'Arithmetic',ARITH)
hfvt = visualizeFilterStages(H)

Description visualizeFilterStages(H) plots the magnitude response of the filter
stages and of the cascade response. When the FilterSpecification
property is set to Design parameters the method plots a mask based
on the filter specifications. By default, the object plots the response of
the filters up to the second CIC null frequency (or to the first when
only one CIC null exists).

visualizeFilterStages(H,'Arithmetic',ARITH) specifies the
arithmetic of the filter stages. You set input ARITH to 'double', 'single',
or 'fixed-point'. When object H is in an unlocked state you must specify
the arithmetic. When object H is in a locked state the arithmetic input
is ignored.

hfvt = visualizeFilterStages(H) returns the handle to the FVTool
object.

dsp.DyadicAnalysisFilterBank

Purpose   Dyadic analysis filter bank

Description   The `DyadicAnalysisFilterBank` object uses a series of highpass and lowpass FIR filters to provide approximate octave band frequency decompositions of the input. Each filter output is downsampled by a factor of two. With the appropriate analysis filters and tree structure, the dyadic analysis filter bank is a discrete wavelet transform (DWT) or discrete wavelet packet transform (DWPT).

To obtain approximate octave band frequency decompositions of the input:

1 Define and set up your dyadic analysis filter bank. See "Construction" on page 5-414.

2 Call `step` to get the octave half band frequency decompositions of the input according to the properties of `dsp.DyadicAnalysisFilterBank`. The behavior of `step` is specific to each object in the toolbox.

Construction   `H = dsp.DyadicAnalysisFilterBank` constructs a dyadic analysis filter bank object, `H`, that computes the level-two discrete wavelet transform (DWT) of a column vector input. For a 2-D matrix input, the object transforms the columns using the Daubechies third-order extremal phase wavelet. The length of the input along the first dimension must be a multiple of 4.

`H = dsp.DyadicAnalysisFilterBank('`*PropertyName*`',`*PropertyValue*`, ...)` returns a dyadic analysis filter bank object, `H`, with each property set to the specified value.

Properties   **Filter**

Type of filter used in subband decomposition

Specify the type of filter used to determine the high and lowpass FIR filters in the dyadic analysis filter bank as `Custom`, `Haar`, `Daubechies`, `Symlets`, `Coiflets`, `Biorthogonal`, `Reverse`

Biorthogonal, or Discrete Meyer. All property values except Custom require Wavelet Toolbox software. If the value of this property is Custom, the filter coefficients are specified by the values of the CustomLowpassFilter and CustomHighpassFilter properties. Otherwise, the dyadic analysis filter bank object uses the Wavelet Toolbox function wfilters to construct the filters. The following table lists supported wavelet filters and example syntax to construct the filters:

Filter	Example Setting	Syntax for Analysis Filters
Haar	N/A	[Lo_D,Hi_D]=wfilters('haar');
Daubechies extremal phase	WaveletOrder=3;	[Lo_D,Hi_D]=wfilters('db3');
Symlets (Daubechies least-asymmetric)	WaveletOrder=4;	[Lo_D,Hi_D]=wfilters('sym4');
Coiflets	WaveletOrder=1;	[Lo_D,Hi_D]=wfilters('coif1');
Biorthogonal	FilterOrder='[3/1]';	[Lo_D,Hi_D,Lo_R,Hi_R]=... wfilters('bior3.1');
Reverse biorthogonal	FilterOrder='[3/1]';	[Lo_D,Hi_D,Lo_R,Hi_R]=... wfilters('rbior3.1');
Discrete Meyer	N/A	[Lo_D,Hi_D]=wfilters('dmey');

CustomLowpassFilter

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in powers of z^{-1}. Use a half-band filter that passes the frequency band stopped by the filter specified in the CustomHighpassFilter property. This property applies when you set the Filter property to Custom. The default specifies a Daubechies third-order extremal phase scaling (lowpass) filter.

CustomHighpassFilter

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in powers of z^{-1}. Use a half-band filter that passes the frequency band stopped by the filter specified in the CustomLowpassFilter property. This property applies when you set the Filter property to Custom. The default specifies a Daubechies 3rd-order extremal phase wavelet (highpass) filter.

WaveletOrder

Order for orthogonal wavelets

Specify the order of the wavelet selected in the Filter property. This property applies when you set the Filter property to an orthogonal wavelet: Daubechies (Daubechies extremal phase), Symlets (Daubechies least-asymmetric), or Coiflets. The default is 2.

FilterOrder

Analysis and synthesis filter orders for biorthogonal filters

Specify the order of the analysis and synthesis filter orders for biorthogonal filter banks as 1 / 1, 1 / 3, 1 / 5, 2 / 2, 2 / 4, 2 / 6, 2 / 8, 3 / 1, 3 / 3, 3 / 5, 3 / 7, 3 / 9, 4 / 4, or 5 / 5, 6 / 8. Unlike orthogonal wavelets, biorthogonal wavelets require different filters for the analysis (decomposition) and synthesis (reconstruction) of an input. The first number indicates the order of the synthesis (reconstruction) filter. The second number indicates the order of the analysis (decomposition) filter. This property applies when you set the Filter property to Biorthogonal or Reverse Biorthogonal. The default is 1 / 1.

NumLevels

Number of filter bank levels used in analysis (decomposition)

Specify the number of filter bank analysis levels a positive integer. A level-N asymmetric structure produces $N+1$ output subbands. A level-N symmetric structure produces 2^N output subbands. The

default is 2. The size of the input along the first dimension must be a multiple of 2^N, where N is the number of levels.

TreeStructure

Structure of filter bank

Specify the structure of the filter bank as Asymmetric or Symmetric. The asymmetric structure decomposes only the lowpass filter output from each level. The symmetric structure decomposes the highpass and lowpass filter outputs from each level. If the analysis filters are scaling (lowpass) and wavelet (highpass) filters, the asymmetric structure is the discrete wavelet transform, while the symmetric structure is the discrete wavelet packet transform.

When this property is Symmetric, the output has 2^N subbands each of size $M/2^N$. In this case, M is the length of the input along the first dimension and N is the value of the NumLevels property. When this property is Asymmetric, the output has $N+1$ subbands. The following equation gives the length of the output in the kth subband in the asymmetric case:

$$M_k = \begin{cases} \dfrac{M}{2^k} & 1 \le k \le N \\ \dfrac{M}{2^N} & k = N+1 \end{cases}$$

The default is Asymmetric.

Methods

clone	Create dyadic analysis filter bank object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method

dsp.DyadicAnalysisFilterBank

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset filter states
step	Decompose input with dyadic filter bank

Examples

Denoise square wave input using dyadic analysis and synthesis filter banks:

```
t = 0:.0001:.0511;
x= square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
hdydanl = dsp.DyadicAnalysisFilterBank;

% The filter coefficients correspond to a 'haar' wavelet.
hdydanl.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
hdydanl.CustomHighpassFilter = [-1/sqrt(2) 1/sqrt(2)];
hdydsyn = dsp.DyadicSynthesisFilterBank;
hdydsyn.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
hdydsyn.CustomHighpassFilter = [1/sqrt(2) -1/sqrt(2)];

C = step(hdydanl, xn);

% Subband outputs
C1 = C(1:256); C2 = C(257:384); C3 = C(385:512);

% Set higher frequency coefficients to zero
% to remove the noise.
x_den = step(hdydsyn, [zeros(length(C1),1);...
zeros(length(C2),1);C3]);

subplot(2,1,1), plot(xn); title('Original noisy Signal');
subplot(2,1,2), plot(x_den); title('Denoised Signal');
```

Algorithms   This object implements the algorithm, inputs, and outputs described
on the Dyadic Analysis Filter Bank block reference page. The object
properties correspond to the block parameters, except:

The dyadic analysis filter bank object always concatenates the
subbands into a single column vector for a column vector input,
or into the columns of a matrix for a matrix input. This behavior
corresponds to the block's behavior when you set the **Output**
parameter to Single port.

See Also   dsp.DyadicSynthesisFilterBank | dsp.SubbandAnalysisFilter

Purpose   Create dyadic analysis filter bank object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a dyadic analysis filter bank object, C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

Purpose Number of expected inputs to step method

Syntax N = getNumInputs(H)

Description N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

dsp.DyadicAnalysisFilterBank.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the dyadic analysis filter bank
                   object.

                   The isLocked method returns a logical value that indicates whether
                   input attributes and nontunable properties for the object are locked. The
                   object performs an internal initialization the first time the step method
                   is executed. This initialization locks nontunable properties and input
                   specifications, such as dimensions, complexity, and data type of the
                   input data. After locking, the isLocked method returns a true value.

dsp.DyadicAnalysisFilterBank.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset filter states

Syntax   reset(H)

Description   reset(H) resets the filter states of the dyadic analysis filter bank
                   object, H, to their initial values of zero. After the step method applies
                   the dyadic analysis filter bank to nonzero input data, the filter states
                   may change. Invoking the step method again without first invoking the
                   reset method may produce different outputs for an identical input.

                   Example of resetting filter states:

```
X = [1 1 7 9 2 8 8 6]';
H = dsp.DyadicAnalysisFilterBank('NumLevels',1);
% Filter states are zero
y = step(H,X);
% Invoke step method again without resetting states
y1 = step(H,X);
isequal(y,y1) % Returns 0
reset(H); % Reset filter states to zero
y2 = step(H,X);
isequal(y,y2) % Returns 1
```

dsp.DyadicAnalysisFilterBank.step

Purpose	Decompose input with dyadic filter bank
Syntax	Y = step(H,X)
Description	Y = step(H,X) computes the subband decomposition of the input X and outputs the dyadic subband decomposition in Y as a single concatenated column vector or matrix of coefficients. Each column of X is treated as an independent input, and the number of rows of X must be a multiple of 2^N, where N is the value of the NumLevels property. The elements of Y are ordered with the highest frequency subband first followed by subbands in decreasing frequency

Examples   Subband ordering for level-two asymmetric tree structure:

```
t = 0:.001:1.023;
% Sampling frequency 1 kHz input length 1024
x= square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
% Default asymmetric structure with
% Daubechies order 3 extremal phase wavelet
H = dsp.DyadicAnalysisFilterBank;
Y = step(H,xn);
% Level 2 yields 3 subbands (two detail-one approximation)
% Nyquist frequency is 500 Hz
D1 =Y(1:512); % subband approx. [250, 500] Hz
D2 = Y(513:768); % subband approx. [125, 250] Hz
Approx = Y(769:1024); % subband approx. [0,125] Hz
```

Subband ordering for symmetric tree structure:

```
t = 0:.001:1.023;
% Sampling frequency 1 kHz input length 1024
x= square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1); % symmetric structure with
% Daubechies order 3 extremal phase wavelet
```

```
H = dsp.DyadicAnalysisFilterBank('TreeStructure',...
'Symmetric');
Y = step(H,xn);
D1 = Y(1:256); % subband approx. [375,500] Hz
D2 = Y(257:512); % subband approx. [250,375] Hz
D3 = Y(513:768); % subband approx. [125,250] Hz
Approx = Y(769:1024); % subband approx. [0, 125] Hz
```

dsp.DyadicSynthesisFilterBank

Purpose   Reconstruct signals from subbands

Description   The `DyadicSynthesisFilterBank` object reconstructs signals from subbands with smaller bandwiths and lower sample rates. The filter bank uses a series of highpass and lowpass FIR filters to repeatedly reconstruct the signal.

To reconstruct signals from subbands with smaller bandwidths and lower sample rates:

1 Define and set up your synthesis filter bank. See "Construction" on page 5-428.

2 Call `step` to reconstruct the signal according to the properties of `dsp.DyadicSynthesisFilterBank`. The behavior of `step` is specific to each object in the toolbox.

Construction   `H = dsp.DyadicSynthesisFilterBank` returns a synthesis filter bank, `H`, that reconstructs a signal from its subbands with smaller bandwidths and smaller sample rates.

`H = dsp.DyadicSynthesisFilterBank('`*Propertyname*`',`*PropertyValue*`,...)` returns a synthesis filter bank, `H`, with each specified property set to the specified value.

Properties   **Filter**

Type of filter used in filter bank

Specify the type of filter used to determine the highpass and lowpass FIR filters in the filter bank as one of `Custom`, `Haar`, `Daubechies`, `Symlets`, `Coiflets`, `Biorthogonal`, `Reverse Biorthogonal`, or `Discrete Meyer`. If you set this property to `Custom`, the `CustomLowpassFilter` and `CustomHighpassFilter` properties specify the filter coefficients. Otherwise, the object uses the Wavelet Toolbox `wfilters` function to construct the filters. Depending on the filter, the `WaveletOrder` or `FilterOrder`

property might apply. For a list of the supported wavelets, see the following table.

Filter	Sample Setting for Related Filter Specification Properties	Corresponding Wavelet Toolbox Function Syntax
Haar	None	wfilters('haar')
Daubechies	H.WaveletOrder = 4	wfilters('db4')
Symlets	H.WaveletOrder = 3	wfilters('sym3')
Coiflets	H.WaveletOrder = 1	wfilters('coif1')
Biorthogonal	H.FilterOrder = '[3/1]'	wfilters('bior3.1')
Reverse Biorthogonal	H.FilterOrder = '[3/1]'	wfilters('rbior3.1')
Discrete Meyer	None	wfilters('dmey')

In order to automatically design wavelet-based filters, install the Wavelet Toolbox product. Otherwise, use the `CustomLowpassFilter` and `CustomHighpassFilter` properties to specify lowpass and highpass FIR filters.

CustomLowpassFilter

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of *z*. Use a half-band filter that passes the frequency band stopped by the filter specified in the `CustomHighpassFilter` property. This property applies only when you set the `Filter` property to `Custom`. To perfectly reconstruct a signal decomposed by the `DyadicAnalysisFilterBank`, design the filters in the

synthesis filter bank to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is imperfect. The default values of this property specify a perfect reconstruction filter for the default settings of the analysis filter bank (based on a third-order Daubechies wavelet).

CustomHighpassFilter

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in descending powers of *z*. Use a half-band filter that passes the frequency band stopped by the filter specified in the `CustomLowpassFilter` property. This property applies only when you set the `Filter` property to `Custom`. To perfectly reconstruct a signal decomposed by the `DyadicAnalysisFilterBank`, design the filters in the synthesis filter bank to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is imperfect. The default values of this property specify a perfect reconstruction filter for the default settings of the analysis filter bank (based on a third-order Daubechies wavelet).

WaveletOrder

Wavelet order

Specify the order of the wavelet selected in the `Filter` property. This property applies only when you set the `Filter` property to `Daubechies`, `Symlets` or `Coiflets`. The default is 2.

FilterOrder

Wavelet order for synthesis filter stage

Specify the order of the wavelet for the synthesis filter stage as:

- First order: `'[1/1]'`, `'[1/3]'`, or `'[1/5]'`.
- Second order: `'[2/2]'`, `'[2/4]'`, `'[2/6]'`, or `'[2/8]'`.
- Third order: `'[3/1]'`, `'[3/3]'`, `'[3/5]'`, `'[3/7]'`, or `'[3/9]'`.
- Fourth order: `'[4/4]'`.

- Fifth order: `'[5/5]'`.

- Sixth order: `'[6/8]'`.

This property applies only when you set the `Filter` property to `Biorthogonal` or `Reverse Biorthogonal`. The default is `'[1/1]'`.

NumLevels

Number of filter bank levels

Specify the number of filter bank levels as a scalar integer. An N-level asymmetric structure has $N + 1$ input subbands, and an N-level symmetric structure has 2^N input subbands. The default is 2.

rg

TreeStructure

Structure of filter bank

Specify the structure of the filter bank as `Asymmetric` or `Symmetric`. In the asymmetric structure, the low-frequency subband input to each level is the output of the previous level, while the high-frequency subband input to each level is an input to the filter bank. In the symmetric structure, both the low- and high-frequency subband inputs to each level are outputs from the previous level. The default is `Asymmetric`.

Methods		
	clone	Create synthesis filter bank object with same property values
	getNumInputs	Number of expected inputs to step method
	getNumOutputs	Number of outputs of the step method
	isLocked	Locked status for input attributes and nontunable properties

dsp.DyadicSynthesisFilterBank

release	Allow property value and input characteristics changes
reset	Reset internal states of dyadic synthesis filter bank object
step	Reconstruct signal from high- and low-frequency subbands

Examples   Remove noise from a signal using filter banks:

```
t = 0:.0001:.0511;
x= square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
hdydanl = dsp.DyadicAnalysisFilterBank;

% The filter coefficients correspond to a 'haar' wavelet.
hdydanl.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
hdydanl.CustomHighpassFilter = [-1/sqrt(2) 1/sqrt(2)];
hdydsyn = dsp.DyadicSynthesisFilterBank;
hdydsyn.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
hdydsyn.CustomHighpassFilter = [1/sqrt(2) -1/sqrt(2)];

C = step(hdydanl, xn);

% Subband outputs
C1 = C(1:256); C2 = C(257:384); C3 = C(385:512);

% Set high-frequency coefficients to zero to remove noise.
x_den = step(hdydsyn, ...
  [zeros(length(C1),1); ...
   zeros(length(C2),1); ...
   C3]);

subplot(2,1,1), plot(xn); title('Original Noisy Signal');
subplot(2,1,2), plot(x_den); title('Denoised Signal');
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Dyadic Synthesis Filter Bank block reference page. The object properties correspond to the block parameters, except:

The object only receives data as a vector or matrix of concatenated subbands, as specified using the `step` method.

See Also   dsp.DyadicAnalysisFilterBank | dsp.SubbandSynthesisFilter

dsp.DyadicSynthesisFilterBank.clone

Purpose   Create synthesis filter bank object with same property values

Syntax   `C = clone(H)`

Description   `C = clone(H)` creates a `DyadicSynthesisFilterBank` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

dsp.DyadicSynthesisFilterBank.getNumOutputs

Purpose   Number of outputs of the step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the
DyadicSynthesisFilterBank object.

The isLocked method returns a logical value that indicates whether
input attributes and nontunable properties for the object are locked. The
object performs an internal initialization the first time the step method
is executed. This initialization locks nontunable properties and input
specifications, such as dimensions, complexity, and data type of the
input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset internal states of dyadic synthesis filter bank object

Syntax   reset(H)

Description   reset(H) sets the internal states of the dyadic synthesis filter bank object H to their initial values.

Purpose   Reconstruct signal from high- and low-frequency subbands

Syntax   X = step(H,S)

Description   X = step(H,S) reconstructs the concatenated subband input S to output X. Each column of input S contains the subbands for an independent signal. Upper rows contain the high-frequency subbands, and lower rows contain the low-frequency subbands. The number of rows of S must be a multiple of 2^N, where *N* is the value of the NumLevels property.

Note The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

Purpose   Discrete Fourier transform

Description   The FFT object computes the discrete Fourier transform (DFT) of an input. The object uses one or more of the following fast Fourier transform (FFT) algorithms depending on the complexity of the input and whether the output is in linear or bit-reversed order:

- Double-signal algorithm

- Half-length algorithm

- Radix-2 decimation-in-time (DIT) algorithm

- Radix-2 decimation-in-frequency (DIF) algorithm

- An algorithm chosen by FFTW [1], [2]

To compute the DFT of an input:

1 Define and set up your FFT object. See "Construction" on page 5-441.

2 Call step to compute the DFT of the input according to the properties of dsp.FFT. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.FFT returns a FFT object, H, that computes the DFT of an *N*-D array. For column vectors or multidimensional arrays, the FFT object computes the DFT along the first dimension. If the input is a row vector, the FFT object computes a row of single-sample DFTs and issues a warning.

H = dsp.FFT('*PropertyName*',*PropertyValue*, ...) returns a FFT object, H, with each property set to the specified value.

Properties   **FFTImplementation**

FFT implementation

Specify the implementation used for the FFT as one of `Auto` | `Radix-2` | `FFTW`. When you set this property to `Radix-2`, the FFT length must be a power of two.

BitReversedOutput

Order of output elements relative to input elements

Designate order of output channel elements relative to order of input elements. Set this property to `true` to output the frequency indices in bit-reversed order. The default is `false`, which corresponds to a linear ordering of frequency indices.

Normalize

Divide butterfly outputs by two

Set this property to `true` if the output of the FFT should be divided by the FFT length. This option is useful when you want the output of the FFT to stay in the same amplitude range as its input. This is particularly useful when working with fixed-point data types.

The default value of this property is `false` with no scaling.

FFTLengthSource

Source of FFT length

Specify how to determine the FFT length as `Auto` or `Property`. When you set this property to `Auto`, the FFT length equals the number of rows of the input signal. The default is `Auto`.

FFTLength

FFT length

Specify the FFT length. This property applies when you set the `FFTLengthSource` property to `Property`. The default is `64`.

This property must be a power of two when the input is a fixed-point data type, or when you set the `BitReversedOutput` property to `true`, or when you set the `FFTImplementation` property to `Radix-2`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

SineTableDataType

Sine table word and fraction lengths

Specify the sine table data type as `Same word length as input` or `Custom`. The default is `Same word length as input`.

CustomSineTableDataType

Sine table word and fraction lengths

Specify the sine table fixed-point type as an unscaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineTableDataType` property to `Custom`. The default is `numerictype([],16)`.

ProductDataType

Product word and fraction lengths

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when

you set the ProductDataType property to Custom. The default is numerictype([],32,30).

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator data type as Full precision, Same as input, Same as product, or Custom. The default is Full precision.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the AccumulatorDataType property to Custom. The default is numerictype([],32,30).

OutputDataType

Output word and fraction lengths

Specify the output data type as one of Full precision, Same as input, Custom. The default is Full precision.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the OutputDataType property to Custom. The default is numerictype([],16,15).

Methods

clone	Create FFT object with same property values
getNumInputs	Number of expected inputs to step method

getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Discrete Fourier transform of input

Examples   Find frequency components of a signal in additive noise:

```
Fs = 800; L = 1000;
t = (0:L-1)'/Fs;
x = sin(2*pi*250*t) + 0.75*cos(2*pi*340*t);
y = x + .5*randn(size(x)); % noisy signal

hfft = dsp.FFT('FFTLengthSource', 'Property', ...
 'FFTLength', 1024);

Y = step(hfft, y);

% Plot the single-sided amplitude spectrum
plot(Fs/2*linspace(0,1,512), 2*abs(Y(1:512)/1024));
title('Single-sided amplitude spectrum of noisy signal y(t)');
xlabel('Frequency (Hz)'); ylabel('|Y(f)|');
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the FFT block reference page. The object properties correspond to the block parameters.

See Also   dsp.IFFT | dsp.DCT | dsp.IDCT

Purpose   Create FFT object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates an FFT object with the same property values as H.
                     The clone method creates a new unlocked object.

dsp.FFT.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
the step method.

The getNumInputs method returns a positive integer that is the number
of expected inputs (not counting the object itself) to the step method.
This value will change if you alter any properties that turn inputs on or
off. You must call the step method with the number of input arguments
equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                   method.

                   The getNumOutputs method returns a positive integer that is the
                   number of outputs from the step method. This value will change if you
                   alter any properties that turn outputs on or off.

dsp.FFT.isLocked

Purpose Locked status for input attributes and nontunable properties

Syntax isLocked(H)

Description isLocked(H) returns the locked state of the FFT object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.FFT.step

Purpose Discrete Fourier transform of input

Syntax `Y = step(H,X)`

Description `Y = step(H,X)` computes the FFT, `Y` , of the input `X` along the first dimension of `X`. When the `FFTLengthSource` property is `Auto`, the length of `X` along the first dimension must be a positive integer power of two. This length is also the FFT length . When the `FFTLengthSource` property is `Property`, the `FFTLength` property must be a positive integer power of two.

Purpose   FIR polyphase decimator

Description   The FIRDecimator object resamples vector or matrix inputs along
                  the first dimension. The object reseamples at a rate *M* times
                  slower than the input sampling rate, where *M* is the integer-valued
                  downsampling factor. The decimation combines an FIR anti-aliasing
                  filter with downsampling. The FIR decimator object uses a polyphase
                  implementation of the FIR filter.

                  To resample vector or matrix inputs along the first dimension:

                  1 Define and set up your FIR decimator. See "Construction" on page
                  5-453.

                  2 Call step to resample the vector or matrix inputs according to the
                  properties of dsp.FIRDecimator. The behavior of step is specific to
                  each object in the toolbox.

Construction H = dsp.FIRDecimator returns an FIR decimator, H, which applies an
                  FIR filter with a cutoff frequency of 0.4*pi radians/sample to the input
                  and downsamples the filter output by factor of 2.

                  H = dsp.FIRDecimator ('*PropertyName*',*PropertyValue*, ...)
                  returns an FIR decimator, H, with each property set to the specified
                  value.

                  H = dsp.FIRDecimator(DECIM, NUM,
                  '*PropertyName*',*PropertyValue*, ...) returns an FIR decimator, H,
                  with the integer-valued DecimationFactor property set to DECIM, the
                  Numerator property set to NUM, and other specified properties set to
                  the specified values.

Properties   **DecimationFactor**

                  Decimation factor

                  Specify the downsampling factor as a positive integer. The FIR
                  decimator reduces the sampling rate of the input by this factor.

The size of the input along the first dimension must be a multiple of the decimation factor. The default is 2.

Numerator

FIR filter coefficients

Specify the numerator coefficients of the FIR filter in powers of z^{-1}. The following equation defines the system function for a filter of length L:

$$H(z) = \sum_{l=0}^{L-1} b_l z^{-l}$$

To prevent aliasing as a result of downsampling, the filter transfer function should have a normalized cutoff frequency no greater than 1/DecimationFactor. You can specify the filter coefficients as a vector in the supported data types. The FIR decimator does not support dfilt or mfilt objects as sources of the filter coefficients. The default is fir1(35,0.4).

Structure

Filter structure

Specify the implementation of the FIR filter as either Direct form or Direct form transposed. The default is Direct form.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set FullPrecisionOverride to true, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are

added, as needed, to ensure that no roundoff or overflow occurs. If you set FullPrecisionOverride to false, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of Wrap or Saturate. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Coefficients word and fraction lengths

Specify the coefficients fixed-point data type as Same word length as input or Custom. The default is Same word length as input.

CustomCoefficientsDataType

Coefficients word and fraction lengths

Specify the coefficients fixed-point type as a numerictype object with a Signedness of Auto. This property applies when you set the CoefficientsDataType property to Custom. The default is numerictype([],16,15).

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | `Full precision` | `Same as product` | `Same as input` | `Custom` |. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when

you set the `OutputDataType` property to `Custom`. The default is `numerictype([]1,16,15)`.

	Methods

Definitions

Polyphase Subfilters

A polyphase implementation of an FIR decimator *splits* the lowpass FIR filter impulse response into *M* different subfilters, where *M* is the downsampling, or decimation factor. Let *h(n)* denote the FIR filter impulse response of length *L* and *u(n)* the input signal. Decimating the filter output by a factor of *M* is equivalent to the downsampled convolution:

dsp.FIRDecimator

$$y(n) = \sum_{l=0}^{L-1} h(l)u(nM - l)$$

The key to the efficiency of polyphase filtering is that specific input values are only multiplied by select values of the impulse response in the downsampled convolution. For example, letting *M=2*, the input values *u(0),u(2),u(4), ...* are only combined with the filter coefficients *h(0),h(2),h(4),...*, and the input values *u(1),u(3),u(5), ...* are only combined with the filter coefficients *h(1),h(3),h(5),....* By splitting the filter coefficients into two polyphase subfilters, no unnecessary computations are performed in the convolution. The outputs of the convolutions with the polyphase subfilters are interleaved and summed to yield the filter output. The following MATLAB code demonstrates how to construct the two polyphase subfilters for the default order 35 filter in the `Numerator` property and the default `DecimationFactor` property value of two:

```
M = 2;
Num = fir1(35,0.4);
FiltLength = length(Num);
Num = flipud(Num(:));

if (rem(FiltLength, M) ~= 0)
    nzeros = M - rem(FiltLength, M);
    Num = [zeros(nzeros,1); Num];  % Appending zeros
end

len = length(Num);
nrows = len / M;
PolyphaseFilt = flipud(reshape(Num, M, nrows).');
```

The columns of `PolyphaseFilt` are subfilters containing the two *phases* of the filter in `Num`. For a general downsampling factor of *M*, there are *M* phases and therefore *M* subfilters.

Examples   Decimate a sum of sine waves with angular frequencies of π/4 and 2π/3 radians/sample by a factor of two. To prevent aliasing, the

FIR decimator filters out the 2π/3 radians/sample component before downsampling:

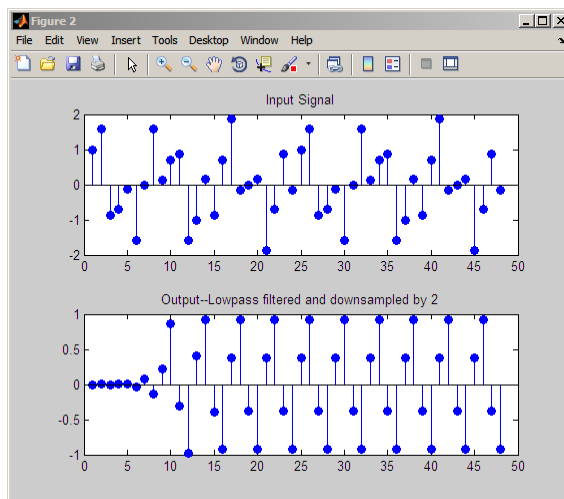
```
x = cos(pi/4*[0:95]')+sin(2*pi/3*[0:95]');
H = dsp.FIRDecimator;
y = step(H,x);

% View group delay of default FIR filter
fvtool(fir1(35,0.4),1,'analysis','grpdelay');
% Group delay of the default linear-phase FIR filter
% is 17.5 samples. Downsampling by a factor of
% two expect an approx. 8.75 sample delay in the output
% y with the initial filter states of zero

subplot(211);
stem(x(1:length(x)/2),'b','markerfacecolor',[0 0 1]);
title('Input Signal');
subplot(212);
stem(y,'b','markerfacecolor',[0 0 1]);
title('Output--Lowpass filtered and downsampled by 2');
```

The figure shows that the delay in the decimated output is consistent with the group delay of the filter when the initial filter states are zero.

Reduce the sampling rate of an audio signal by 1/2 and play it:

```
hmfr = dsp.AudioFileReader('OutputDataType',...
  'single');
hap = dsp.AudioPlayer(22050/2);
hfirdec = dsp.FIRDecimator;


while ~isDone(hmfr)
    frame = step(hmfr);
    y = step(hfirdec, frame);
    step(hap, y);
end

release(hmfr);
pause(0.5);
release(hap);
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the FIR Decimation block reference page. The object properties correspond to the block parameters, except:

- **Coefficient source** – The FIR decimator object does not support `mfilt` objects.

- **Framing** – The FIR decimator object only supports `Maintain input frame rate`

- **Output buffer initial conditions** – The FIR decimator object does not support this parameter.

- **Rate options** – The FIR decimator object does not support this parameter.

- **Input processing** The FIR decimator object does not support this parameter.

See Also   dsp.FIRInterpolator | dsp.FIRRateConverter

dsp.FIRDecimator.clone

Purpose   Create FIR decimator object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates an FIR decimator object, C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

Purpose   Frequency response

Syntax
```
[h,w] = freqz(H)
[h,w] = freqz(H,n)
[h,w] = freqz(H,Name,Value)
freqz(H)
```

Description `[h,w] = freqz(H)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(H,n)` returns the complex, n-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(H,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `H`.

dsp.FIRDecimator.fvtool

Purpose   Open filter visualization tool

Syntax   fvtool(H)
                fvtool(H,'Arithmetic',ARITH,...)

Description fvtool(H) performs an analysis and computes the magnitude response
                of the filter System object H.

                fvtool(H,'Arithmetic',ARITH,...) analyzes the filter System object
                H, based on the arithmetic specified in the ARITH input. ARITH can
                be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a
                double precision filter when the arithmetic input is not specified and
                the filter System object is in an unlocked state. The 'Arithmetic' input
                is only relevant for the analysis of filter System objects.

Purpose   Number of expected inputs to step method

Syntax   `N = getNumInputs(H)`

Description   `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.FIRDecimator.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Impulse response

Syntax   `[h,t] = impz(H)`
                  `[h,t] = impz(H,Name,Value)`
                  `impz(H)`

Description   `[h,t] = impz(H)` returns the impulse response `h`, and the
                  corresponding time points `t` at which the impulse response of `H` is
                  computed.

                  `[h,t] = impz(H,Name,Value)` returns the impulse response `h`, and the
                  corresponding time points `t` , with additional options specified by one or
                  more Name, Value pair arguments.

                  `impz(H)` uses FVTool to plot the impulse response of the filter System
                  object `H`.

                  Note You can use `impz` for both real and complex filters. When you
                  omit the output arguments, `impz` plots only the real part of the impulse
                  response.

                  ---

dsp.FIRDecimator.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the FIR decimator.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Unwrapped phase response

Syntax
```
[phi,w] = phasez(H)
[phi,w] = phasez(H,n)
[phi,w] = phasez(H,Name,Value)
phasez(H)
```

Description   [phi,w] = phasez(H) returns the 8192–element phase response vector phi, and the corresponding frequencies w in radians/sample.

[phi,w] = phasez(H,n) returns the n-element phase response vector phi, and the corresponding frequencies w in radians/sample, using n samples.

[phi,w] = phasez(H,Name,Value) returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

phasez(H) uses FVTool to plot the phase response of the filter System object H.

dsp.FIRDecimator.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset filter states of FIR decimator

Syntax   `reset(H)`

Description `reset(H)` resets the filter states of the FIR decimator object,H, to the
initial values of zero. After the `step` method applies the FIR decimator
to nonzero input data, the filter states may change. Invoking the `step`
method again without first invoking the `reset` method may produce
different outputs for an identical input.

Example of resetting filter states:

```
H = dsp.FIRDecimator;
x = cos(pi/8*[0:1023]')+sin(pi/4*[0:1023]');
y = step(H,x);
% Invoke step method again without reset
y1 = step(H,x);
isequal(y,y1) % Returns 0
% Reset filter states
reset(H);
y2 = step(H,x);
isequal(y,y2) % Returns 1
```

Purpose   Decimate input by integer factor

Syntax   Y = step(H,X)

Description   Y = step(H,X) outputs the filtered and downsampled values, Y, of the
input signal, X. A Ki-by-N input matrix is treated as N independent
channels. The length of each column must be a multiple of the
DecimationFactor property value. The FIR decimator operates on
each channel separately and generates a Ko-by-N output matrix where
$Ko = Ki/M$ with M the decimation factor. The object supports real
and complex floating-point and fixed-point inputs, except for complex
unsigned fixed-point inputs.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

Purpose   Static or time-varying FIR filter

Description   The FIRFilter object filters each channel of the input using static or time-varying FIR filter implementations.

To filter each channel of the input:

1 Define and set up your FIR filter. See "Construction" on page 5-473.

2 Call step to filter each channel of the input according to the properties of dsp.FIRFilter. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.FIRFilter returns a default FIR filter object, H, which independently filters each channel of the input over successive calls to the step method, using a specified FIR filter implementation. The default numerator coefficients are [0.5 0.5].

H = dsp.FIRFilter('*PropertyName*',*PropertyValue*, ...) returns an FIR filter system object, H, with each property set to the specified value.

Properties   **Structure**

Filter structure

Specify the filter structure.

You can specify the filter structure as one of | Direct form | Direct form symmetric | Direct form antisymmetric | Direct form transposed | Lattice MA |. The default is Direct form.

NumeratorSource

Source of filter coefficients

Specify the source of the filter coefficients as one of | Property | Input port |. The default is Property. When you specify Input port, the filter object updates the time-varying filter once

every frame, when the `FrameBasedProcessing` property is `true`. When the `FrameBasedProcessing` property is `false`, it updates once every sample.

This applies when you set the `Structure` to `Direct form` | `Direct form symmetric` | `Direct form antisymmetric` | `Direct form transposed`.

ReflectionCoefficientsSource

Source of filter coefficients

Specify the source of the Lattice filter coefficients as one of | `Property` | `Input port` |. The default is `Property`. When you specify `Input port`, the filter object updates the time-varying filter once every frame, when the `FrameBasedProcessing` property is `true`. When the `FrameBasedProcessing` property is `false`, it updates once every sample.

This applies when you set the `Structure` to `Lattice MA`.

Numerator

Numerator coefficients

Specify the filter coefficients as a real or complex numeric row vector. This property applies when you set the `NumeratorSource` property to `Property`, and the `Structure` property is not set to `Direct form`, `Direct form symmetric`, `Direct form antisymmetric`, or `Direct form transposed`. The default is `[0.5 0.5]`. This property is tunable.

ReflectionCoefficients

Reflection coefficients of lattice filter structure

Specify the reflection coefficients of a lattice filter as a real or complex numeric row vector. This property applies when you set the `Structure` property to `Lattice MA`, and the `ReflectionCoefficientsSource` property to `Property`. The default is `[0.5 0.5]`. This property is tunable.

InitialConditions

Initial conditions for the FIR filter

Specify the initial conditions of the filter states. The number of states or delay elements equals the number of reflection coefficients for the lattice structure, or the number of filter coefficients–1 for the other direct form structures.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, the FIR filter object initializes all delay elements in the filter to that value. If you specify a vector whose length equals the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

If you specify a vector whose length equals the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

If you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. The default is 0.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Coefficients word and fraction lengths

Specify the coefficients fixed-point data type as one of | `Same word length as input` | `Custom` |. This property applies when you set the `NumeratorSource` property to `Property`. The default is `Same word length as input`.

CustomCoefficientsDataType

Custom coefficients word and fraction lengths

Specify the coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `CoefficientsDataType` property to `Custom`. The default is `numerictype(true,16,15)`.

ReflectionCoefficientsDataType

Reflection coefficients word and fraction lengths

Specify the reflection coefficients fixed-point data type as one of | `Same word length as input` | `Custom` |. This property applies when you set the `ReflectionCoefficientsSource` property to `Property`. The default is `Same word length as input`.

CustomReflectionCoefficientsDataType

Custom reflection coefficients word and fraction lengths

Specify the numerator fixed-point type as a signed or unsigned `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ReflectionCoefficientsDataType` property to `Custom`. The default is `numerictype(true,16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`.

CustomProductDataType

Custom product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype(true,32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type to one of | Full precision | Same as input | Same as product | Custom |. The default is Full precision.

CustomAccumulatorDataType

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the AccumulatorDataType property to Custom. The default is numerictype(true,32,30).

StateDataType

State word and fraction lengths

Specify the state fixed-point data type as one of | Same as input | Same as accumulator | Custom |. This property does not apply to any of the direct form or direct form I filter structures. The default is Same as accumulator.

CustomStateDataType

Custom state word and fraction lengths

Specify the state fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the StateDataType property to Custom. The default is numerictype(true,16,15).

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | Same as input | Same as accumulator | Custom |. The default is Same as accumulator.

CustomOutputDataType

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype(true,16,15)`.

Methods

clone	Create static or time-varying FIR filter with same property values
freqz	Frequency response
fvtool	Open filter visualization tool
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
impz	Impulse response
isLocked	Locked status for input attributes and nontunable properties
phasez	Unwrapped phase response
release	Allow property value and input characteristics changes
reset	Reset internal states of FIR filter
step	Filter input with FIR filter object

More "Analysis Methods for Filter System Objects" on page 4-2.

Examples

Use an FIR filter to apply a low pass filter to a waveform with two sinusoidal components:

```
t = [0:63]./32e3;
xin = (sin(2*pi*4e3*t)+sin(2*pi*12e3*t)) / 2;

hSR = dsp.SignalSource(xin', 4);
hLog = dsp.SignalSink;
```

```
hFIR = dsp.FIRFilter;
hFIR.Numerator = fir1(10,0.5);

while ~isDone(hSR)
     input = step(hSR);
     filteredOutput = step(hFIR,input);
     step(hLog,filteredOutput);
end

filteredResult = hLog.Buffer;
sper = spectrum.periodogram;
psd(sper,filteredResult,'Fs',32e3)
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Discrete FIR Filter block reference page. The object properties correspond to the block parameters.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the FrameBasedProcessing property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also   dsp.BiquadFilter

Purpose   Create static or time-varying FIR filter with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a FIR filter object, C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

dsp.FIRFilter.freqz

Purpose   Frequency response

Syntax   ```
                  [h,w] = freqz(H)
                  [h,w] = freqz(H,n)
                  [h,w] = freqz(H,Name,Value)
                  freqz(H)
                  ```

Description   `[h,w] = freqz(H)` returns the complex, 8192–element frequency
                  response vector `h`, and the corresponding frequencies `w` in
                  radians/sample.

                  `[h,w] = freqz(H,n)` returns the complex, n-element frequency
                  response vector `h`, and the corresponding frequencies `w` in
                  radians/sample, using `n` samples.

                  `[h,w] = freqz(H,Name,Value)` returns the frequency response and
                  the corresponding frequencies, with additional options specified by one
                  or more Name, Value pair arguments.

                  `freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of
                  the frequency response of the filter System object `H`.

Purpose   Open filter visualization tool

Syntax   ```
fvtool(H)
fvtool(H,'Arithmetic',ARITH,...)
```

**Description**  `fvtool(H)` performs an analysis and computes the magnitude response of the filter System object `H`.

fvtool(H,'Arithmetic',ARITH,...) analyzes the filter System object H, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

# dsp.FIRFilter.getNumInputs

**Purpose**　　　　Number of expected inputs to step method

**Syntax**　　　　`N = getNumInputs(H)`

**Description**　　`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

**Purpose**      Number of outputs of step method

**Syntax**       N = getNumOutputs(H)

**Description**   N = getNumOutputs(H) returns the number of outputs, N, of the step
                 method.

                 The getNumOutputs method returns a positive integer that is the
                 number of outputs from the step method. This value will change if you
                 alter any properties that turn outputs on or off.

# dsp.FIRFilter.impz

**Purpose**      Impulse response

**Syntax**
```
[h,t] = impz(H)
[h,t] = impz(H,Name,Value)
impz(H)
```

**Description**    `[h,t] = impz(H)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of`H` is computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response `h`, and the corresponding time points`t` , with additional options specified by one or more Name, Value pair arguments.

`impz(H)` uses FVTool to plot the impulse response of the filter System object `H`.

**Note** You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

**Purpose**     Locked status for input attributes and nontunable properties

**Syntax**      isLocked(H)

**Description**  isLocked(H) returns the locked state of the FIR filter.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

# dsp.FIRFilter.phasez

**Purpose**        Unwrapped phase response

**Syntax**
```
[phi,w] = phasez(H)
[phi,w] = phasez(H,n)
[phi,w] = phasez(H,Name,Value)
phasez(H)
```

**Description**     `[phi,w] = phasez(H)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the n-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System object `H`.

**Purpose**      Allow property value and input characteristics changes

**Syntax**       `release(H)`

**Description**  `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note**  You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

# dsp.FIRFilter.reset

**Purpose**    Reset internal states of FIR filter

**Syntax**    `reset(H)`

**Description**    `reset(H)` resets the filter states of the FIR filter object, `H`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the FIR filter object to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

For example:

```
H = dsp.FIRFilter;
H.Numerator = fir1(20,0.25);
n = 0:100;
x = cos(0.2*pi*n)+sin(0.8*pi*n);
y = step(H,x);
% Filter states are nonzero
% Invoke step method again without resetting states
y1 = step(H,x);
isequal(y,y1) % returns 0
% Now reset filter states to 0
reset(H)
% Invoke step method
y2 = step(H,x);
isequal(y,y2) % returns a 1
```

Purpose   Filter input with FIR filter object

Syntax   Y = step(HFIR,X)
              Y = step(HFIR,X,COEFF)

Description   Y = step(HFIR,X) filters the real or complex input signal X using the
                 FIR filter, H, to produce the output Y. When the input data is of a
                 fixed-point type, it must be signed when the structure is set to Direct
                 form symmetric or Direct form antisymmetric. The FIR filter
                 object operates on each channel of the input signal independently over
                 successive calls to step method.

                 Y = step(HFIR,X,COEFF) uses the time-varying coefficients,
                 COEFF, to filter the input signal X and produce the output Y.
                 You can use this option when you set the NumeratorSource or
                 ReflectionCoefficientsSource property to Input port.

                 Note The object performs an initialization the first time the step
                 method is executed. This initialization locks nontunable properties and
                 input specifications, such as dimensions, complexity, and data type
                 of the input data. If you change a nontunable property or an input
                 specification, the System object issues an error. To change nontunable
                 properties or inputs, you must first call the release method to unlock
                 the object.

                 ---

dsp.FIRInterpolator

Purpose   Polyphase FIR interpolator

Description   The FIRInterpolator object upsamples an input by the integer
upsampling factor, *L*, followed by an FIR anti-imaging filter.
The filter coefficients are scaled by the interpolation factor. A
polyphase interpolation structure implements the filter. The resulting
discrete-time signal has a sampling rate *L* times the original sampling
rate.

To upsample an input:

1 Define and set up your FIR interpolator. See "Construction" on page
5-492.

2 Call step to upsample the input according to the properties of
dsp.FIRInterpolator. The behavior of step is specific to each object
in the toolbox.

Construction   H= dsp.FIRInterpolator returns an FIR interpolator, H, which
upsamples an input signal by a factor of 3 and applies an FIR filter
to interpolate the output.

H = dsp.FIRInterpolator('*PropertyName*',*PropertyValue*, ...)
returns an FIR interpolator, H, with each property set to the specified
value.

H = dsp.FIRInterpolator(INTERP,
NUM,'*PropertyName*',*PropertyValue*, ...) returns an FIR
interpolation object, H, with the InterpolationFactor property set to
INTERP, the Numerator property set to NUM, and other properties set to
the specified values.

Properties   **InterpolationFactor**

Interpolation factor

Specify the integer factor, *L*, by which to increase the sampling
rate of the input signal. The polyphase implementation uses *L*
polyphase subfilters to compute convolutions at the lower sample

rate. The FIR interpolator delays and interleaves these lower-rate convolutions to obtain the higher-rate output. The property value defaults to 3.

Numerator

FIR filter coefficients

Specify the numerator coefficients of the FIR anti-imaging filter as the coefficients of a polynomial in z^{-1}. Indexing from zero, the filter coefficients are:

$$H(z) = \sum_{n=0}^{N-1} b(n)z^{-n}$$

To act as an effective anti-imaging filter, the coefficients must correspond to a lowpass filter with a normalized cutoff frequency no greater than the reciprocal of the InterpolationFactor. The filter coefficients are scaled by the value of the InterpolationFactor property before filtering the signal. To form the *L* polyphase subfilters, Numerator is appended with zeros if necessary. The default is the output of fir1(15,0.25).

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set FullPrecisionOverride to true, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set FullPrecisionOverride to false, fixed-point data types are controlled through individual fixed-point property settings.

For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Coefficient word and fraction lengths

Specify the coefficients fixed-point data type as one of | Same word length as input | Custom |. The default is Same word length as input.

CustomCoefficientsDataType

Coefficient word and fraction lengths

Specify the coefficients fixed-point type as a numerictype object with a Signedness of Auto. This property applies only when the CoefficientsDataType property is Custom. The default is numerictype([],16,15).

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of | Full precision | Same as input | Custom |. The default is Full precision.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` property is `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | `Full precision` | `Same as product` | `Same as input` | `Custom` |. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` property is `Custom`. The default is `numerictype([],16,15)`.

dsp.FIRInterpolator

Methods

clone	Create FIR interpolator object with same property values
freqz	Frequency response
fvtool	Open filter visualization tool
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
impz	Impulse response
isLocked	Locked status for input attributes and nontunable properties
phasez	Unwrapped phase response
release	Allow property value and input characteristics changes
reset	Reset FIR interpolator filter states
step	Upsample and interpolate input

More "Analysis Methods for Filter System Objects" on page 4-2.

Examples

Double the sampling rate of an audio signal from 22.05 kHz to 44.1 kHz, and play the audio:

```
hmfr = dsp.AudioFileReader('OutputDataType',...
   'single');
hap = dsp.AudioPlayer(44100);
hfirint = dsp.FIRInterpolator(2, ...
   firpm(30, [0 0.45 0.55 1], [1 1 0 0]));

while ~isDone(hmfr)
    frame = step(hmfr);
    y = step(hfirint, frame);
```

```
    step(hap, y);
end

pause(1);
release(hmfr);
release(hap);
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the FIR Interpolation block reference page. The object properties correspond to the block parameters, except:

- The FIRInterpolator object does not have a property that corresponds to the **Input processing** parameter of the FIR Interpolation block.

- The **Rate options** block parameter is not supported by the FIRInterpolator object.

See Also   dsp.FIRDecimator | dsp.FIRRateConverter

dsp.FIRInterpolator.clone

Purpose   Create FIR interpolator object with same property values

Syntax   C = clone(H)

Description C = clone(H) creates an FIR interpolator, C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

Purpose   Frequency response

Syntax   ```
[h,w] = freqz(H)
[h,w] = freqz(H,n)
[h,w] = freqz(H,Name,Value)
freqz(H)
```

Description   `[h,w] = freqz(H)` returns the complex, 8192–element frequency
                  response vector h, and the corresponding frequencies w in
                  radians/sample.

                  `[h,w] = freqz(H,n)` returns the complex, n-element frequency
                  response vector h, and the corresponding frequencies w in
                  radians/sample, using n samples.

                  `[h,w] = freqz(H,Name,Value)` returns the frequency response and
                  the corresponding frequencies, with additional options specified by one
                  or more Name, Value pair arguments.

                  `freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of
                  the frequency response of the filter System object H.

Purpose	Open filter visualization tool

Syntax

```
fvtool(H)
fvtool(H,'Arithmetic',ARITH,...)
```

Description fvtool(H) performs an analysis and computes the magnitude response of the filter System object H.

fvtool(H,'Arithmetic',ARITH,...) analyzes the filter System object H, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                   the step method.

                   The getNumInputs method returns a positive integer that is the number
                   of expected inputs (not counting the object itself) to the step method.
                   This value will change if you alter any properties that turn inputs on or
                   off. You must call the step method with the number of input arguments
                   equal to the result of getNumInputs(*H*).

dsp.FIRInterpolator.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of output from the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Impulse response

Syntax   [h,t] = impz(H)
                [h,t] = impz(H,Name,Value)
                impz(H)

Description [h,t] = impz(H) returns the impulse response h, and the
                corresponding time points t at which the impulse response ofH is
                computed.

                [h,t] = impz(H,Name,Value) returns the impulse response h, and the
                corresponding time pointst , with additional options specified by one or
                more Name, Value pair arguments.

                impz(H) uses FVTool to plot the impulse response of the filter System
                object H.

                Note You can use impz for both real and complex filters. When you
                omit the output arguments, impz plots only the real part of the impulse
                response.

                ---

dsp.FIRInterpolator.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   `isLocked(H)`

Description   `isLocked(H)` returns the locked state of the FIR interpolator.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose   Unwrapped phase response

Syntax   ```
                   [phi,w] = phasez(H)
                   [phi,w] = phasez(H,n)
                   [phi,w] = phasez(H,Name,Value)
                   phasez(H)
                   ```

**Description**    `[phi,w] = phasez(H)` returns the 8192–element phase response vector
                   `phi`, and the corresponding frequencies `w` in radians/sample.

                   `[phi,w] = phasez(H,n)` returns the n-element phase response vector
                   `phi`, and the corresponding frequencies `w` in radians/sample, using
                   `n` samples.

                   `[phi,w] = phasez(H,Name,Value)` returns the phase response and the
                   corresponding frequencies, with additional options specified by one or
                   more Name, Value pair arguments.

                   `phasez(H)` uses FVTool to plot the phase response of the filter System
                   object `H`.

# dsp.FIRInterpolator.release

**Purpose**        Allow property value and input characteristics changes

**Syntax**         `release(H)`

**Description**    `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

---

**Note**  You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

**Purpose**      Reset FIR interpolator filter states

**Syntax**       reset(H)

**Description**  reset(H) resets the filter states of the FIR filter in the interpolator object, H, to their initial values of 0. The initial filter state values correspond to the initial conditions for the constant coefficient linear difference equation defining the FIR filter. After the step method applies the interpolator to nonzero input data, the states may be nonzero. Invoking the step method again without first invoking the reset method may produce different outputs for an identical input.

Reset filter states to 0 to produce consistent output:

```
H = dsp.FIRInterpolator(2);
x =[1 -1]'; x = repmat(x,8,1);
y = step(H,x); % Filter states are nonzero
% Use reset method to set states to zero
reset(H);
% Apply FIR interpolator to input x
y1 = step(H,x);
isequal(y,y1)
% Returns a 1
```

Purpose   Upsample and interpolate input

Syntax   Y = step(H,X)

Description   Y = step(H,X) outputs the upsampled and interpolated values, Y , of
                 the input signal X . A *K*-by-*N* input matrix is treated as *N* independent
                 channels. The FIR interpolator object interpolates each channel over
                 the first dimension and generates a *M*-by-*N* output matrix, where *M* is
                 the product of *K* and the upsampling factor, *L*.

> **Note** The object performs an initialization the first time the step
> method is executed. This initialization locks nontunable properties and
> input specifications, such as dimensions, complexity, and data type
> of the input data. If you change a nontunable property or an input
> specification, the System object issues an error. To change nontunable
> properties or inputs, you must first call the release method to unlock
> the object.

Purpose   Sample rate converter

Description   The FIRRateConverter performs sampling rate conversion by a rational factor on a vector or matrix input. The FIR rate convertor cascades an interpolator with a decimator. The interpolator upsamples the input by the upsampling factor, *L*, followed by a lowpass FIR filter. The FIR filter acts both as an anti-imaging filter and an anti-aliasing filter prior to decimation. The decimator downsamples the output of upsampling and FIR filtering by the downsampling factor *M*. You must use upsampling and downsampling factors that are relatively prime, or coprime. The resulting discrete-time signal has a sampling rate *L/M* times the original sampling rate.

To perform sampling rate conversion:

1 Define and set up your FIR sample rate converter. See "Construction" on page 5-509.

2 Call step to perform sampling rate conversion according to the properties of dsp.FIRRateConverter. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.FIRRateConverter returns a FIR sample rate converter, H, that resamples an input signal at a rate 3/2 times the original sampling rate.

H = dsp.FIRRateConverter('*PropertyName*',*PropertyValue*, ...) returns an FIR sample rate converter, H, with each property set to the specified value.

H = dsp.FIRRateConverter(L,M,NUM,'*PropertyName*', *PropertyValue*, ...) returns an FIR sample rate converter, H, with the InterpolationFactor property set to L, the DecimationFactor property set to M, the Numerator property set to NUM, and other specified properties set to the specified values.

Properties   **InterpolationFactor**

Interpolation factor

Specify the integer upsampling factor. The default is 3.

DecimationFactor

Decimation factor

Specify the integer downsampling factor. The default is 2.

Numerator

FIR filter coefficients

Specify the FIR filter coefficients in powers of z^{-1}. The length of filter coefficients must exceed the interpolation factor. Use a lowpass with normalized cutoff frequency no greater than `min(1/InterpolationFactor, 1/DecimationFactor)`. All initial filter states are zero. The default is `firpm(70,[0 0.28 0.32 1],[1 1 0 0])`.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Word and fraction lengths of filter coefficients

Specify the filter coefficient fixed-point data type as one of | Same word length as input | Custom |. The default is Same word length as input.

CustomCoefficientsDataType

Word and fraction lengths of filter coefficients

Specify the filter coefficient fixed-point type as a numerictype object with a Signedness of Auto. This property applies only when the CoefficientsDataType property is Custom. The default is numerictype([],16,15).

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of | Full precision | Same as input | Custom |. The default is Full precision.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only

when the `ProductDataType` property is `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | `Full precision` | `Same as product` | `Same as input` | `Custom` |. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` property is `Custom`. The default is `numerictype([],16,15)`.

Methods		
	clone	Create FIR sample rate convertor object with same property values
	getNumInputs	Number of expected inputs to step method

getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset states of FIR sample rate converter
step	Resample input with FIR rate converter

Examples   Resample a 100 Hz sine wave signal by a factor of 3:2:

```
hsin = dsp.SineWave(1, 100,'SampleRate', 5000,'SamplesPerFrame', 50);

% Create a FIR rate converter filter. The default interpolation
% factor is 3 and decimation factor is 2.
hfirrc = dsp.FIRRateConverter;
input = step(hsin);
output = step(hfirrc, input);

% Plot the original and resampled signals.
ndelay = round(length(hfirrc.Numerator)/2/hfirrc.DecimationFactor);
indx = ndelay+1:length(output);
x = (0:length(indx)-1)/hsin.SampleRate*hfirrc.DecimationFactor/hfirrc.
stem((0:38)/hsin.SampleRate, input(1:39)); hold on;
stem(x, hfirrc.InterpolationFactor*output(indx),'r');
legend('Original','Resampled');
```

Resample and play an audio signal from 48 kHz to 32 kHz (Windows only):

```
if ispc %This example runs only on Windows
    hmfr = dsp.AudioFileReader('audio48kHz.wav', ...
```

```
               'OutputDataType', 'single', ...
               'SamplesPerFrame', 300);
             hap = dsp.AudioPlayer(32000);

             % Create an FIRRateConverter System object with interpolation
             % factor = 2, decimation factor = 3. Default FIR filter
             % coefficients define a lowpass filter with normalized
             % cutoff frequency of 1/3.
             hfirrc = dsp.FIRRateConverter(2,3);

             while ~isDone(hmfr)
               audio1 = step(hmfr);
               audio2 = step(hfirrc, audio1);
               step(hap, audio2);
             end

             release(hmfr);
             release(hap);

         else
             disp('This example runs only on Windows platforms.');
         end
```

Algorithms   This object implements the algorithm, inputs, and outputs described on
the FIR Rate Conversion block reference page. The object properties
correspond to the block parameters.

See Also   dsp.FIRInterpolator | dsp.FIRDecimator

Purpose   Create FIR sample rate convertor object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates an FIR sample rate converter object, C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

dsp.FIRRateConverter.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
method.

The getNumOutputs method returns a positive integer that is the
number of outputs from the step method. This value will change if you
alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the FIR sample rate converter.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description   release(H) releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the release method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.FIRRateConverter.reset

Purpose   Reset states of FIR sample rate converter

Syntax   reset(H)

Description reset(H) resets the filter states of the FIR filter in the sample rate converter, H, to their initial values of 0. The initial filter state values correspond to the initial conditions for the constant coefficient linear difference equation defining the FIR filter. After the step method applies the FIR rate converter to nonzero input data, the states may be nonzero. Invoking the step method again without first invoking the reset method may produce different outputs for an identical input.

Reset filter states to 0 to produce consistent output:

```
H = dsp.FIRRateConverter(2,4);
x =[1 -1]'; x = repmat(x,8,1);
y = step(H,x); % Filter states are nonzero
% Use reset method to set states to zero
reset(H);
% Apply sampling rate converter to input x
y1 = step(H,x);
isequal(y,y1)
% Returns a 1
```

Purpose   Resample input with FIR rate converter

Syntax   Y = step(H,X)

Description   Y = step(H,X) resamples the input X and returns the resampled signal
                   Y . An *M*-by-*N* matrix input is treated as *N* independent channels.

dsp.Histogram

Purpose	Histogram of input or sequence of inputs

Description   The Histogram object generates a histogram for an input or a sequence of inputs.

To generate a histogram for an input or a sequence of inputs:

1 Define and set up your histogram object. See "Construction" on page 5-522.

2 Call step to generate the histogram for an input according to the properties of dsp.Histogram. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.Histogram returns a histogram object, H, that computes the frequency distribution of the elements in each input matrix.

H = dsp.Histogram(*'PropertyName'*,*PropertyValue*, ...) returns a histogram object, H, with each specified property set to the specified value.

H = dsp.Histogram(*MIN*,*MAX*,*NUMBINS*,*'PropertyName'*,*PropertyValue*,...) returns a histogram object, H, with the LowerLimit property set to *MIN*, UpperLimit property set to *MAX*, NumBins property set to *NUMBINS* and other specified properties set to the specified values.

Properties   **LowerLimit**

Lower boundary

Specify the lower boundary of the lowest-valued bin as a real-valued scalar. NaN and Inf are not valid values for this property. The default is 0. This property is tunable.

UpperLimit

Upper boundary

Specify the upper boundary of the highest-valued bin as a real-valued scalar. NaN and Inf are not valid values for this property. The default is 10. This property is tunable.

NumBins

Number of bins in histogram

Specify the number of bins in the histogram. The default is 11.

Dimension

Specify how the histogram calculation is performed over the data as one of | All | Column |. The default is Column.

Normalize

Enable output vector normalization

Specify whether the histogram object normalizes the output vector, v, so that $sum(v) = 1$. When you set this property to true, the output vector is normalized. When you set it to false, the object supports fixed-point operations and does not use this property for normalization. The default is false.

RunningHistogram

Enable calculation over successive step method calls

Set this property to true to enable running histogram calculations for the input elements over successive calls to the step method. Set this property to false to compute a histogram for the current input. The default is false.

ResetInputPort

Enable resetting in running histogram mode

Set this property to true to enable resetting the running histogram. When you set the property to true, specify a reset input to the step method that resets the running histogram. This property applies when you set the RunningHistogram property to true. When this property is false, the histogram object does not reset. The default is false.

ResetCondition

Reset condition for running histogram mode

Specify the event that resets the running histogram as one of | Rising edge | Falling edge | Either edge | Non-zero |. This property applies when you set the ResetInputPort property to true. The default is Non-zero

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

CustomProductDataType

Custom product word and fraction lengths

Specify the product fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the ProductDataType property to Custom. The default is numerictype([],32,30).

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | Same as product | Same as input | Custom |. The default is Same as input.

CustomAccumulatorDataType

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the AccumulatorDataType property to Custom. The default is numerictype([],32,30).

Methods

clone	Create histogram object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset histogram bin values to zero
step	Histogram for input data

Examples

Compute a histogram with four bins, for possible input values 1 through 4:

```
hhist = dsp.Histogram(1,4,4);
y = step(hhist, [1 2 2 3 3 3 4 4 4 4]');
% y equals [1; 2; 3; 4] - one one, two twos, etc.
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Histogram block reference page. The object properties correspond to the block parameters, except:

- The **Reset port** block parameter corresponds to both the ResetCondition and the ResetInputPort object properties.

- The **Find histogram over** block parameter corresponds to the Dimension property of the object.

See Also   dsp.Maximum | dsp.Minimum | dsp.Mean

Purpose   Create histogram object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a Histogram System object C, with the same
property values as H. The clone method creates a new unlocked object
with uninitialized states.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description N = getNumInputs(H) returns the number of expected inputs, N, to
the step method.

The getNumInputs method returns a positive integer that is the number
of expected inputs (not counting the object itself) to the step method.
This value will change if you alter any properties that turn inputs on or
off. You must call the step method with the number of input arguments
equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                 method.

                 The getNumOutputs method returns a positive integer that is the
                 number of outputs from the step method. This value will change if you
                 alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   `isLocked(H)`

Description   `isLocked(H)` returns the locked state of the Histogram System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

> **Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

dsp.Histogram.reset

Purpose   Reset histogram bin values to zero

Syntax   reset(H)

Description   reset(H) sets the Histogram object bin values to zero when you set the RunningHistogram property to true.

Purpose   Histogram for input data

Syntax   Y = step(H,X)
Y = step(H,X,R)

Description   Y = step(H,X) returns a histogram Y for the input data X . When the
RunningHistogram property is true, Y corresponds to the histogram of
the input elements over successive calls to the step method.

Y = step(H,X,R) resets the histogram state based on the value of R
and the object's ResetCondition property. You can reset the histogram
state only when the RunningHistogram and the ResetInputPort
properties are true.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

Purpose	Inverse discrete cosine transform (IDCT)
Description	The IDCT object computes the inverse discrete cosine transform (IDCT) of an input.

To compute the IDCT of an input:

1 Define and set up your IDCT object. See "Construction" on page 5-534.

2 Call step to compute the IDCT of an input according to the properties of dsp.IDCT. The behavior of step is specific to each object in the toolbox.

Construction

H = dsp.IDCT returns a inverse discrete cosine transform (IDCT) object, H. This object computes the IDCT of a real or complex input signal using the Table lookup method.

H = dsp.IDCT('*PropertyName*',*PropertyValue*,...) returns an inverse discrete cosine transform (IDCT) object, H, with each property set to the specified value.

Properties

SineComputation

Method to compute sines and cosines

Specify how the IDCT object computes the trigonometric function values as Trigonometric function or Table lookup. You must set this property to Table lookup for fixed-point inputs. The default is Table lookup.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of Ceiling, Convergent, Floor , Nearest, Round, Simplest, or Zero. This property applies when you set the SineComputation property to Table lookup.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of Wrap or Saturate. This property applies when you set the SineComputation property to Table lookup.

SineTableDataType

Sine table word-length designation

Specify the sine table fixed-point data type as one of Same word length as input or Custom. This property applies when you set the SineComputation property to Table lookup.

CustomSineTableDataType

Sine table word length

Specify the sine table fixed-point type as a signed, unscaled numerictype object. This property applies when you set the SineComputation property to Table lookup and the SineTableDataType property to Custom. The default is numerictype(true,16).

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of Full precision, Same as input, Custom. This property applies when you set the SineComputation property to Table lookup.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a signed, scaled numerictype object. This property applies when you set the SineComputation property to Table lookup and the ProductDataType property to Custom. The default is numerictype(true,32,30).

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as input`, `Same as product`, or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a signed, scaled `numerictype` object. This property applies when you set the `SineComputation` property to `Table lookup` and the `AccumulatorDataType` property to `Custom`. The default is `numerictype(true,32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `Full precision`, `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`. The default is `Full precision`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a signed, scaled `numerictype` object. This property applies when you set the `SineComputation` property to `Table lookup` and the `OutputDataType` property to `Custom`. The default is `numerictype(true,16,15)`.

Methods

clone	Create inverse discrete cosine transform object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Inverse discrete cosine transform (IDCT) of input

Examples

Use DCT to analyze the energy content in a sequence:

```
x = (1:128).' + 50*cos((1:128).'*2*pi/40);
hdct = dsp.DCT;

X = step(hdct, x);
% Set the DCT coefficients which represent less
% than 0.1% of the total energy to 0 and
% reconstruct the sequence using IDCT.
[XX, ind] = sort(abs(X),1,'descend');
ii = 1;

while (norm([XX(1:ii);zeros(128-ii,1)]) <= 0.999*norm(XX))
    ii = ii+1;
end

disp(['Number of DCT coefficients that represent 99.9%',...
'of the total energy in the sequence: ',num2str(ii)]);
XXt = zeros(128,1);
XXt(ind(1:ii)) = X(ind(1:ii));
```

```
hidct = dsp.IDCT;
xt = step(hidct, XXt);

plot(1:128,[x xt]);
legend('Original signal','Reconstructed signal',...
'location','best');
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the IDCT block reference page. The object properties correspond to the block parameters.

See Also   dsp.DCT | dsp.FFT | dsp.IFFT.

Purpose   Create inverse discrete cosine transform object with same property
                  values

Syntax   C = clone(H)

Description   C = clone(H) creates a copy of the current IDCT object, C, with the
                  same property values as H. The clone method creates a new unlocked
                  object.

dsp.IDCT.getNumInputs

Purpose　　　　Number of expected inputs to step method

Syntax　　　　`N = getNumInputs(H)`

Description　　`N = getNumInputs(H)` returns the number of expected inputs, N, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose   Number of outputs of step method

Syntax   `N = getNumOutputs(H)`

Description   `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.IDCT.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the IDCT object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Inverse discrete cosine transform (IDCT) of input

Syntax   Y = step(H,X)

Description   Y = step(H,X) computes the inverse discrete cosine transform, Y , of input X.

> **Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

Purpose   Inverse discrete Fourier transform (IDFFT)

Description   The IFFT object computes the inverse discrete Fourier transform
(IDFFT) of the input. The object uses one or more of the following fast
Fourier transform (FFT) algorithms depending on the complexity of the
input and whether the output is in linear or bit-reversed order:

- Double-signal algorithm

- Half-length algorithm

- Radix-2 decimation-in-time (DIT) algorithm

- Radix-2 decimation-in-frequency (DIF) algorithm

- An algorithm chosen by FFTW [1], [2]

To compute the IFFT of the input:

1 Define and set up your IFFT object. See "Construction" on page 5-545.

2 Call step to compute the IFFT of the input according to the
properties of dsp.IFFT. The behavior of step is specific to each object
in the toolbox.

Construction   H = dsp.IFFT returns an IFFT object, H, that computes the IDFT of a
column vector or *N*-D array. For column vectors or N-D arrays, the IFFT
object computes the IDFT along the first dimension of the array. If the
input is a row vector, the IFFT object computes a row of single-sample
IDFTs and issues a warning.

H = dsp.IFFT('*PropertyName*',*PropertyValue*, ...) returns an
IFFT object, H, with each property set to the specified value.

Properties   **FFTImplementation**

FFT implementation

Specify the implementation used for the FFT as one of Auto |
Radix-2 | FFTW. When you set this property to Radix-2, the FFT
length must be a power of two.

BitReversedInput

Enable bit-reversed order interpretation of input elements

Set this property to true if the order of Fourier transformed
input elements to the IFFT object are in bit-reversed order. This
property applies only when the FFTLengthSource property is
Auto. The default is false, which denotes linear ordering.

ConjugateSymmetricInput

Enable conjugate symmetric interpretation of input

Set this property to true if the input is conjugate symmetric to
yield real-valued outputs. The discrete Fourier transform of a real
valued sequence is conjugate symmetric, and setting this property
to true optimizes the IDFT computation method. Setting this
property to false for conjugate symmetric inputs may result
in complex output values with nonzero imaginary parts. This
occurs due to rounding errors. Setting this property to true
for nonconjugate symmetric inputs results in invalid outputs.
This property applies only when the FFTLengthSource property
is Auto. The default is false.

Normalize

Enable dividing output by FFT length

Specify whether to divide the IFFT output by the FFT length.
The default is true and each element of the output is divided
by the FFT length.

FFTLengthSource

Source of FFT length

Specify how to determine the FFT length as Auto or Property.
When you set this property to Auto, the FFT length equals the
number of rows of the input signal. This property applies only

when both the `BitReversedInput` and `ConjugateSymmetricInput` properties are `false`. The default is `Auto`.

FFTLength

FFT length

Specify the FFT length as a numeric scalar. This property applies when you set the `BitReversedInput` and `ConjugateSymmetricInput` properties to `false`, and the `FFTLengthSource` property to `Property`. The default is `64`.

This property must be a power of two when the input is a fixed-point data type, or when you set the `FFTImplementation` property to `Radix-2`.

When you set the `FFT implementation` property to `Radix-2`, or when you set the `BitReversedOutput` property to `true`, this value must be a power of two.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

SineTableDataType

Sine table word and fraction lengths

Specify the sine table data type as `Same word length as input` or `Custom`. The default is `Same word length as input`.

CustomSineTableDataType

Sine table word and fraction lengths

Specify the sine table fixed-point type as an unscaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineTableDataType` property to `Custom`. The default is `numerictype([],16)`.

ProductDataType

Product word and fraction lengths

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator data type as `Full precision`, `Same as input`, `Same as product`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create IFFT object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Inverse discrete Fourier transform of input

Examples

Use DFT and IDFT to analyze the energy content in a sequence:

```
Fs = 40; L = 128;
t = (0:L-1)'/Fs;
x = sin(2*pi*10*t) + 0.75*cos(2*pi*15*t);
y = x + .5*randn(size(x)); % noisy signal
hfft = dsp.FFT;
hifft = dsp.IFFT('ConjugateSymmetricInput', true);
X = step(hfft, x);
[XX, ind] = sort(abs(X),1,'descend');
XXn = sqrt(cumsum(XX.^2))/norm(XX);
```

```
ii = find(XXn > 0.999, 1);
disp('Number of FFT coefficients that represent 99.9% ')
disp(['of the total energy in the sequence: ', num2str(ii)]);
XXt = zeros(128,1);
XXt(ind(1:ii)) = X(ind(1:ii));
xt = step(hifft, XXt);
% Verify the reconstructed signal matches the original
norm(x-xt)
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the IFFT block reference page. The object properties correspond to the block parameters, except:

> **Output sampling mode** parameter is not supported by dsp.IFFT.

See Also   dsp.FFT | dsp.DCT | dsp.IDCT

Purpose   Create IFFT object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates an IFFT object, C, with the same property values
                  as H. The clone method creates a new unlocked object.

dsp.IFFT.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                   method.

                   The getNumOutputs method returns a positive integer that is the
                   number of outputs from the step method. This value will change if you
                   alter any properties that turn outputs on or off.

dsp.IFFT.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the IFFT object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description   release(H) releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the release method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Inverse discrete Fourier transform of input

Syntax   `Y = step(H,X)`

Description   `Y = step(H,X)` computes the inverse discrete Fourier transform
(IDFT) , `Y` , of the input `X` along the first dimension of `X`. When
the `FFTLengthSource` property is `Auto`, the length of `X` along the
first dimension must be a positive integer power of two. When the
`FFTLengthSource` property is `'Property'`, the length of `X` along the
first dimension can be any positive integer and the `FFTLength` property
must be a positive integer power of two.

Note The object performs an initialization the first time the `step`
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the `release` method to unlock
the object.

Purpose   Infinite Impulse Response (IIR) filter

Description   The IIRFilter object filters each channel of the input using IIR filter implementations.

To filter each channel of the input:

1 Define and set up your IIR filter. See "Construction" on page 5-557.

2 Call step to filter each channel of the input according to the properties of dsp.IIRFilter. The behavior of step is specific to each object in the toolbox.

Construction   HIIR = dsp.IIRFilter returns an IIR filter System object, HIIR, which independently filters each channel of the input over successive calls to the step method. This System object uses a specified IIR filter implementation.

HIIR = dsp.IIRFilter('*PropertyName*',*PropertyValue*, ...) returns an IIR filter System object, HIIR, with each property set to the specified value.

Properties   **Structure**

Filter structure

Specify the filter structure.

You can specify the filter structure as one of | Direct form I | Direct form I transposed | Direct form II | Direct form II transposed. The default is Direct form II transposed. This property is nontunable.

Numerator

Filter numerator coefficients

Specify the numerator coefficients as a real or complex numeric row vector. The default is [1 1]. This property is tunable.

Denominator

Filter denominator coefficients

Specify the denominator coefficients as a real or complex numeric row vector. The default value of this property is [1 0.1]. This property is tunable.

InitialConditions

Initial conditions for the IIR filter

Specify the initial conditions of the filter states. This property is applicable when the structure is one of Direct form II | Direct form II transposed. The default value is 0. The number of states equals the max(N,M)-1, where N and M are the number of poles and zeros respectively.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, this System object initializes all delay elements in the filter to that value. You can also specify a vector whose length equals the number of delay elements in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

You can also specify a matrix with the same number of rows as the number of delay elements in the filter and one column for each channel of the input signal. In this case, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. This property is tunable.

NumeratorInitialConditions

Initial conditions on zeros side

Specify the initial conditions of the filter states on the side of the filter structure with the zeros. This property is applicable when the Structure property is one of Direct form I | Direct form I transposed. The default value of this property is 0. The number

of states equals the `max(N,M)-1`, where `N` and `M` are the number of poles and zeros respectively.

You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the IIR filter initializes all delay elements on the zeros side in the filter to that value. You can specify a vector of length equal to the number of delay elements on the zeros side in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element on the zeros side.

You can also specify a matrix with the same number of rows as the number of delay elements on the zeros side in the filter, and one column for each channel of the input signal. In this case, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel. This property is tunable.

DenominatorInitialConditions

Initial conditions on poles side

Specify the initial conditions of the filter states on the side of the filter structure with the poles. This property is applicable when the Structure property is one of `Direct form I` | `Direct form I transposed`. The default value of this property is `0`. The number of states equals the `max(N,M)-1`, where `N` and `M` are the number of poles and zeros respectively.

You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the IIR filter initializes all delay elements on the poles side of the filter to that value. You can specify a vector of length equal to the number of delay elements on the poles side in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element on the poles side.

You can also specify a matrix with the same number of rows as the number of delay elements on the poles side in the filter, and one column for each channel of the input signal. In this case, each

element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel. This property is tunable.

FrameBasedProcessing

Process input as frames or as samples

Set this property to `true` to enable frame-based processing. When this property is `true`, the IIR filter treats each column as an independent channel. Set this property to `false` to enable sample-based processing. When this property is `false`, the IIR filter treats each element of the input as an individual channel. The default is `true`. This property is nontunable.

NumeratorCoefficientsDataType

Numerator coefficients word- and fraction-length designations

Specify the numerator coefficients fixed-point data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`. This property is nontunable.

DenominatorCoefficientsDataType

Denominator coefficients word- and fraction-length designations

Specify the denominator coefficients fixed-point data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`. This property is nontunable.

Fixed-Point Properties

NumeratorProductDataType

Product word- and fraction-length designations on zeros side

Specify the numerator product fixed-point data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`. This property is nontunable.

DenominatorProductDataType

Product word- and fraction-length designations on poles side

Specify the denominator product fixed-point data type as one of | Full precision | Same as input | Custom |. The default is Full precision. This property is nontunable.

NumeratorAccumulatorDataType

Accumulator word- and fraction-length designations on zeros side

Specify the numerator accumulator fixed-point data type to one of | Full precision | Same as input | Same as product | Custom |. The default is Full precision. This property is nontunable.

DenominatorAccumulatorDataType

Accumulator word- and fraction-length designations on poles side

Specify the denominator accumulator fixed-point data type to one of | Full precision | Same as input | Same as product | Custom |. The default is Full precision. This property is nontunable.

OutputDataType

Output word- and fraction-length designations

Specify the output fixed-point data type as one of | Full precision | Same as input | Custom |. The default is Same as input. This property is nontunable.

StateDataType

State word- and fraction-length designations

Specify the state fixed-point data type as one of | Same as input | Custom |. This property does not apply to Direct form I filter structure. The default is Same as input. This property is nontunable.

MultiplicandDataType

Multiplicand word- and fraction-length designations

Specify the multiplicand fixed-point data type as one of | `Same as input` | `Custom` |. This property is applicable only when the `Structure` property is `Direct form I transposed`. The default is `Same as input`. This property is nontunable.

CustomNumeratorCoefficientsDataType

Numerator coefficients word- and fraction-lengths

Specify the numerator coefficients fixed-point type as an autosigned numerictype object. This property is applicable when the `NumeratorCoefficientsDataType` property is `Custom`. The default value of this property is numerictype ([],16,15). This property is nontunable.

CustomDenominatorCoefficientsDataType

Denominator coefficients word- and fraction-lengths

Specify the denominator coefficients fixed-point type as an autosigned numerictype object. This property is applicable when the `DenominatorCoefficientsDataType` property is `Custom`. The default value of this property is numerictype([], 16, 15) . This property is nontunable.

CustomNumeratorProductDataType

Custom product word- and fraction-lengths on zeros side

Specify the numerator product fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `NumeratorProductDataType` property to `Custom`. The default is numerictype ([],32,30). This property is nontunable.

CustomDenominatorProductDataType

Custom product word- and fraction-lengths on poles side

Specify the denominator product fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `DenominatorProductDataType` property to `Custom`. The default is numerictype ([],32,30). This property is nontunable.

CustomNumeratorAccumulatorDataType

Custom accumulator word- and fraction-lengths on zeros side

Specify the numerator accumulator fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `NumeratorAccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`. This property is nontunable.

CustomDenominatorAccumulatorDataType

Custom accumulator word- and fraction-lengths on poles side

Specify the denominator accumulator fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `DenominatorAccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`. This property is nontunable.

CustomStateDataType

Custom state word- and fraction-lengths

Specify the state fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `StateDataType` property to `Custom`. The default is `numerictype([],16,15)`. This property is nontunable.

CustomOutputDataType

Custom output word- and fraction-lengths

Specify the output fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`. This property is nontunable.

CustomMultiplicandDataType

Custom multiplicand word- and fraction-lengths

Specify the multiplicand fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set

the `MultiplicandDataType` property to `Custom`. The default is `numerictype([],16,15)`. This property is nontunable.

Methods

clone	Create IIR filter with same property values
freqz	Frequency response
fvtool	Open filter visualization tool
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
impz	Impulse response
isLocked	Locked status for input attributes and nontunable properties
phasez	Unwrapped phase response
release	Allow property value and input characteristics changes
reset	Reset internal states of IIR filter
step	Filter input with IIR filter object

More "Analysis Methods for Filter System Objects" on page 4-2.

Examples

Use an IIR filter to apply a lowpass filter to a waveform with two sinusoidal frequencies.

```
t = [0:63]./32e3;
xin = (sin(2*pi*4e3*t)+sin(2*pi*12e3*t)) / 2;

hSR = dsp.SignalSource(xin', 4);
hLog = dsp.SignalSink;
hIIR = dsp.IIRFilter;
[b,a] = butter(6,0.5);
```

```
hIIR.Numerator = b;
hIIR.Denominator = a;

while ~isDone(hSR)
    input = step(hSR);
    filteredOutput = step(hIIR,input);
    step(hLog,filteredOutput);
end

filteredResult = hLog.Buffer;
sper = spectrum.periodogram;
psd(sper,filteredResult,'Fs',32e3)
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Discrete Filter block reference page. The object properties correspond to the block parameters.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the FrameBasedProcessing property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also   dsp.BiquadFilter | dsp.FIRFilter | dsp.AllpoleFilter

dsp.IIRFilter.clone

Purpose   Create IIR filter with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a IIR filter object, C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

Purpose   Frequency response

Syntax   ```
[h,w] = freqz(H)
[h,w] = freqz(H,n)
[h,w] = freqz(H,Name,Value)
freqz(H)
```

Description   `[h,w] = freqz(H)` returns the complex, 8192–element frequency response vector h, and the corresponding frequencies w in radians/sample.

`[h,w] = freqz(H,n)` returns the complex, n-element frequency response vector h, and the corresponding frequencies w in radians/sample, using n samples.

`[h,w] = freqz(H,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object H.

dsp.IIRFilter.fvtool

Purpose   Open filter visualization tool

Syntax
```
fvtool(H)
fvtool(H,'Arithmetic',ARITH,...)
```

Description   `fvtool(H)` performs an analysis and computes the magnitude response of the filter System object `H`.

`fvtool(H,'Arithmetic',ARITH,...)` analyzes the filter System object `H`, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description N = getNumInputs(H) returns the number of expected inputs, N, to
the step method.

The getNumInputs method returns a positive integer that is the number
of expected inputs (not counting the object itself) to the step method.
This value will change if you alter any properties that turn inputs on or
off. You must call the step method with the number of input arguments
equal to the result of getNumInputs(*H*).

dsp.IIRFilter.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Impulse response

Syntax   ```
[h,t] = impz(H)
[h,t] = impz(H,Name,Value)
impz(H)
```

**Description**   `[h,t] = impz(H)` returns the impulse response h, and the
corresponding time points t at which the impulse response of H is
computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response h, and the
corresponding time points t , with additional options specified by one or
more Name, Value pair arguments.

`impz(H)` uses FVTool to plot the impulse response of the filter System
object H.

---

**Note**  You can use impz for both real and complex filters. When you
omit the output arguments, impz plots only the real part of the impulse
response.

---

# dsp.IIRFilter.isLocked

**Purpose**          Locked status for input attributes and nontunable properties

**Syntax**           isLocked(H)

**Description**      isLocked(H) returns the locked state of the IIR filter.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

**Purpose**     Unwrapped phase response

**Syntax**      [phi,w] = phasez(H)
                [phi,w] = phasez(H,n)
                [phi,w] = phasez(H,Name,Value)
                phasez(H)

**Description**   [phi,w] = phasez(H) returns the 8192–element phase response vector
                phi, and the corresponding frequencies w in radians/sample.

                [phi,w] = phasez(H,n) returns the n-element phase response vector
                phi, and the corresponding frequencies w in radians/sample, using
                n samples.

                [phi,w] = phasez(H,Name,Value) returns the phase response and the
                corresponding frequencies, with additional options specified by one or
                more Name, Value pair arguments.

                phasez(H) uses FVTool to plot the phase response of the filter System
                object H.

# dsp.IIRFilter.release

**Purpose**          Allow property value and input characteristics changes

**Syntax**           release(H)

**Description**      release(H) releases system resources, such as memory, file handles,
                     and hardware connections, and lets you change any properties or input
                     characteristics.

---

**Note**  You can use the release method on a System object in code
generated from MATLAB, but once you release its resources, you cannot
use that System object again.

---

**Purpose**       Reset internal states of IIR filter

**Syntax**        reset(H)

**Description**   reset(H) resets the filter states of the IIR filter object, H, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the step method applies the IIR filter object to nonzero input data, the states may be nonzero. Invoking the step method again without first invoking the reset method may produce different outputs for an identical input.

For example:

```
H = dsp.IIRFilter;
[b,a] = ellip(20, 0.5, 80, 0.25);
H.Numerator = b;
H.Denominator = a;
n = 0:100;
x = cos(0.2*pi*n)+sin(0.8*pi*n);
y = step(H,x);
% Filter states are nonzero
% Invoke step method again without resetting states
y1 = step(H,x);
isequal(y,y1) % returns 0
% Now reset filter states to 0
reset(H)
% Invoke step method
y2 = step(H,x);
isequal(y,y2) % returns a 1
```

Purpose   Filter input with IIR filter object

Syntax   Y = step(H,X)

Description Y = step(H,X) filters the real or complex input signal X using the IIR
               filter, H, to produce the output Y . When the input data is of a fixed-point
               type, it must be signed. The IIR filter object operates on each channel of
               the input signal independently over successive calls to step method.

               Note The object performs an initialization the first time the step
               method is executed. This initialization locks nontunable properties and
               input specifications, such as dimensions, complexity, and data type
               of the input data. If you change a nontunable property or an input
               specification, the System object issues an error. To change nontunable
               properties or inputs, you must first call the release method to unlock
               the object.

Purpose   Linear or FIR interpolation

Description   The Interpolator object interpolates real-valued inputs using linear
                   or polyphase FIR interpolation.

                   To interpolate real-valued inputs:

                   1 Define and set up your interpolation object. See "Construction" on
                        page 5-577.

                   2 Call step to interpolate the input according to the properties of
                        dsp.Interpolator. The behavior of step is specific to each object
                        in the toolbox.

Construction   H = dsp.Interpolator returns a handle to an interpolation object,
                   H. The interpolation method defaults to Linear and the interpolation
                   points default to a 5×1 vector.

                   H = dsp.Interpolator('*PropertyName*',*PropertyValue*,...)
                   returns an interpolation object, H, with the specified property name
                   and value pairs.

Properties   **InterpolationPointsSource**

                        Source of interpolation points

                        You can select a value of Property or Input port. If you set
                        this property to Input port, you must provide the interpolation
                        points as an input to the step method when you interpolate the
                        input. The default is Property.

                   InterpolationPoints

                        Interpolation points

                        This property only applies when you set the
                        InterpolationPointsSource property to Property.
                        Specify the interpolation points as a column vector or a matrix
                        with the same number of channels as the input.

dsp.Interpolator

The valid range of the values in the interpolation vector is from 1 to the number of samples in each channel of the input. If you specify interpolation points outside the valid range, the object *clips* the point to the nearest point in the valid range. For example, if the input is [2 3.1 -2.1], the valid range of interpolation points is from 1 to 3. If you specify the following vector of interpolation points [-1 1.5 2 2.5 3 3.5], the interpolator object clips -1 to 1 and 3.5 to 3. This clipping results in the interpolation points [1 1.5 2 2.5 3 3]. The default is [1.1;4.8;2.67;1.6;3.2]. This property is tunable.

Method

Interpolation method

Specify the interpolation method as Linear or FIR. When this property is Linear, the interpolator object interpolates data values by assuming that the data varies linearly between adjacent samples. When this property is FIR, the interpolator object uses polyphase interpolation to replace filtering (convolution) at the upsampled rate with a series of convolutions at the lower rate. The interpolator object always performs linear interpolation if there are insufficient low-rate samples to perform FIR interpolation as explained in the description of the FilterHalfLength property. The default is Linear.

FilterHalfLength

Interpolation filter half length

This property applies only when you set the Method property to FIR. For a filter half length of P, the polyphase FIR subfilters have length $2P$. FIR interpolation always requires $2P$ low-rate samples for every interpolation point.

- If the interpolation point does not correspond to a low-rate sample, FIR interpolation requires P low-rate samples below and P low-rate samples above the interpolation point.

- If the interpolation point corresponds to a low-rate sample, the 2*P*-sample requirement includes the low-rate sample.

- If there are less than *2P* neighboring low-rate samples, the interpolator object uses linear interpolation.

For example, for an input [1 4 1 4 1 4 1 4], upsampling by a factor of four results in the equally spaced interpolation points InterP = 1:0.25:8;. The points InterP(9:12) are [3.0 3.25 3.5 3.75]. Assuming a FilterHalfLength property equal to 2, interpolating at these points uses the four low-rate samples from the input with indices (2,3,4,5). If you set the FilterHalfLength property to 4 in this case, the interpolator object uses linear interpolation because there are not enough low-rate samples to perform FIR interpolation.

The longer the FilterHalfLength property, the better the quality of the interpolation. However, the costs are increased computation and requiring more low-rate samples below and above the interpolation point. In general, setting the FilterHalfLength property between 4 and 6 provides reasonably accurate interpolation.

InterpolationPointsPerSample

Interpolation points per input sample

This property only applies when you set the Method property to FIR and indicates the upsampling factor, *L*. An upsampling factor of *L* inserts *L*–1 zeros between low-rate samples. Interpolation results from filtering the upsampled sequence with a lowpass anti-imaging filter. The interpolator object uses a polyphase FIR implementation with InterpolationPointsPerSample subfilters of length 2*P*, where *P* is the FilterHalfLength property. Denoting the low-rate samples in the upsampled input by *nL*, *n=1,2,...*, the interpolator object uses exactly one of the InterpolationPointsPerSample subfilters, or filter arms, to interpolate at the points *nL+i/L*, where *i=0,1,2,...,L-1*.

If you specify interpolation points which do not correspond to a polyphase subfilter, the object rounds the point down to the nearest interpolation point associated with a polyphase subfilter. For example, you set the `InterpolationPointsPerSample` property to `4` and interpolate at the points `[3 3.2 3.4 3.6 3.8]`. The interpolator object uses the first polyphase subfilter for the points `[3.0 3.2]`, the second subfilter for the point `3.4`, the third subfilter for the point `3.6`, and the fourth subfilter for the point `3.8`.

Bandwidth

Normalized input bandwidth

This property applies only when you set the `Method` property to `FIR`. The normalized bandwidth is a real-valued scalar between 0 and 1, where 1 equals the Nyquist frequency, or 1/2 the sampling frequency (*Fs*). You may know that your input does not have frequency content above some cutoff frequency less than the Nyquist frequency. You can use this information to improve the FIR interpolation filters by relaxing the stopband requirements in frequency regions where the signal has no energy. For example, if the input signal does not have frequency content above *Fs/8*, you can specify a value of `0.25` for the `Bandwidth` property. The default value is `0.5`.

Methods		
	clone	Create interpolator object with same property values
	getNumInputs	Number of expected inputs to step method
	getNumOutputs	Number of outputs of step method
	isLocked	Locked status for input attributes and nontunable properties

release	Allow property value and input characteristics changes
step	Linear or FIR interpolation

Definitions   A polyphase implementation of an FIR interpolation filter *splits* the lowpass FIR filter impulse response into a number of different subfilters. Let *L* represent the number of interpolation points per sample, or the upsampling factor, and *P* the half length of the polyphase subfilters. Indexing from zero, if *h(n)* is the impulse response of the FIR filter, the *k*-th subfilter is:

$$h_k(n) = h(k+nL) \quad k = 0,1,\ldots,L-1 \quad n = 0,1,\ldots,2P-1$$

The following table describes the decomposition of an 18-coefficient FIR filter into 3 polyphase subfilters of length 6, the defaults for the FIR interpolator object:

Coefficients	**Polyphase Subfilter**
h(0),h(3),h(6), ..., h(15)	$h_0(n)$
h(1),h(4),h(7), ..., h(16)	$h_1(n)$
h(2),h(5),h(8), ..., h(17)	$h_2(n)$

The following code shows how to find the polyphase subfilters for the default FIR interpolator object:

```
H = dsp.Interpolator('Method','FIR');
L = H.InterpolationPointsPerSample;
P = H.FilterHalfLength;
FiltCoeffs = intfilt(L,P,H.Bandwith);
% Returns filter of length 2*P*L-1
FiltLen=length(FiltCoeffs);
FiltCols = ceil(FiltLen/2/L);
```

```
% We need 2*P*L coefficients
% Prepending a zero does not affect the filter magnitude
FiltCoeffs = [zeros(FiltCols*2*L-FiltLen,1); FiltCoeffs(:)];

% Each column of PolyPhaseCoeffs is a polyphase subfilter
PolyPhaseCoeffs  = reshape(FiltCoeffs,FiltCols,2*L)';
```

Examples   Compare linear interpolation with FIR interpolation:

```
x =[1 4];
x = repmat(x,1,4);
x1 = 1:0.25:8;
hFIR =dsp.Interpolator('Method','FIR','FilterHalfLength',2,...
'InterpolationPoints',x1','InterpolationPointsPerSample',4);
hLin =dsp.Interpolator('InterpolationPoints',x1');
OutFIR = step(hFIR,x');
OutLin = step(hLin,x');
stem(OutFIR,'b-.','linewidth',2); hold on;
stem(OutLin,'r','markerfacecolor',[1 0 0]);
axis([0 30 0 5]); legend('FIR','Linear','Location','Northeast');
```

For the indices 1 to 5 and 25 to 29, the interpolator object uses linear interpolation in both cases. The reason for this is that there are not enough low-rate samples surrounding the interpolation points at those indices to use FIR interpolation with the specified filter length.

Interpolate a sinusoid with linear interpolation:

```
t = 0:.0001:.0511;
x = sin(2*pi*20*t);
x1 = x(1:50:end);
I = 1:0.1:length(x1);
H = dsp.Interpolator('InterpolationPointsSource',...
'Input port');
y = H.step(x1',I');
stem(I',y, 'r');
title('Original and Interpolated Signal');
hold on; stem(x1, 'Linewidth', 2);
legend('Interpolated','Original');
```

dsp.Interpolator

Interpolate a sum of sinusoids with FIR interpolation and `Input Port` as the source of interpolation points:

```
Fs = 1000;
t = 0:(1/Fs):0.1-(1/Fs);
x = cos(2*pi*50*t)+0.5*sin(2*pi*100*t);
x1 = x(1:4:end);
I = 1:(1/4):length(x1);
% Decimate without aliasing
H = dsp.Interpolator('Method','FIR',...
'FilterHalfLength',3,'InterpolationPointsSource','Input Port');
y = H.step(x1',I);
stem(I,y,'r'); hold on;
axis([0 25 -2 2]);
stem(x1,'b','linewidth',2);
legend('Interpolated Signal','Original',...
'Location','Northeast');
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Interpolation block reference page. The object properties correspond to the Simulink block parameters, except:

Out of range interpolation points — The interpolator object only has the `Clip` option. The Simulink block has the additional `Clip and warn` and `Error` options.

See Also   intfilt | dsp.FIRInterpolator | dsp.VariableFractionalDelay

dsp.Interpolator.clone

Purpose   Create interpolator object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates an interpolator object, C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                  the step method.

                  The getNumInputs method returns a positive integer that is the number
                  of expected inputs (not counting the object itself) to the step method.
                  This value will change if you alter any properties that turn inputs on or
                  off. You must call the step method with the number of input arguments
                  equal to the result of getNumInputs(*H*).

dsp.Interpolator.getNumOutputs

Purpose　　　Number of outputs of step method

Syntax　　　`N = getNumOutputs(H)`

Description　`N = getNumOutputs(H)` returns the number of outputs, N, of `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the interpolator.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.Interpolator.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Linear or FIR interpolation

Syntax   Y = step(H,X)
                  Y = step(H,X,IPTS)

Description   Y = step(H,X) outputs the interpolated sequence, Y, of the input vector
                  or matrix X as specified in the InterpolationPoints property.

                  Y = step(H,X,IPTS) outputs the interpolated sequence as specified
                  by the input argument IPTS when the InterpolationPointsSource
                  property is set to 'Input port'. IPTS a column vector or a matrix of
                  interpolation points. If IPTS is a matrix, it must have the same number
                  of channels as the input.

                  Note The object performs an initialization the first time the step
                  method is executed. This initialization locks nontunable properties and
                  input specifications, such as dimensions, complexity, and data type
                  of the input data. If you change a nontunable property or an input
                  specification, the System object issues an error. To change nontunable
                  properties or inputs, you must first call the release method to unlock
                  the object.

dsp.LDLFactor

Purpose   Factor square Hermitian positive definite matrices into components

Description   The `LDLFactor` object factors square Hermitian positive definite
matrices into lower, upper, and diagonal components. The object uses
only the lower triangle of S.

To factor these matrices into lower, upper, and diagonal components:

1 Define and set up your LDL factor object. See "Construction" on
page 5-592.

2 Call `step` to factor the matrices according to the properties of
`dsp.LDLFactor`. The behavior of `step` is specific to each object in
the toolbox.

Construction   H = `dsp.LDLFactor` returns an LDL factor System object, H, that
computes unit lower triangular L and diagonal D such that S = LDL' for
square, symmetric/Hermitian, positive definite input matrix S.

H = `dsp.LDLFactor('`*PropertyName*`',`*PropertyValue*`,...)` returns
an LDL factor System object, H, with each specified property set to the
specified value.

Properties   **Fixed-Point Properties**

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`,
`Same as input`, `Same as product` or `Custom`. The default is `Full
precision`

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype`
object with a `Signedness` of `Auto`. This property applies when you

set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

CustomIntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point type as a signed, scaled `numerictype` object. This property applies when you set the `IntermediateProductDataType` property to `Custom`. The default is `numerictype(true,16,15)`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

IntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of Wrap or Saturate. The default is Wrap.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as Full precision, Same as input or Custom. The default is Full precision.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as: Ceiling, Convergent, Floor, Nearest, Round, Simplest or Zero. The default is Floor.

Methods	clone	Create an LDL Factor object with same property values
	getNumInputs	Number of expected inputs to step method
	getNumOutputs	Number of outputs for step method
	isLocked	Locked status for input attributes and nontunable properties
	release	Allow property value and input characteristics changes
	step	Decompose matrix into components

Examples   Decompose a square Hermitian positive definite matrix using LDL factor:

```
A = gallery('randcorr',5);
hldl = dsp.LDLFactor;
```

```
y = step(hldl, A);
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the LDL Factorization block reference page. The object properties correspond to the block parameters, except:

No object property that corresponds to the **Non-positive definite input** block parameter. The object does not issue any alerts for nonpositive definite inputs. The output is not a valid factorization. A partial factorization is in the upper left corner of the output.

See Also   dsp.LUFactor

dsp.LDLFactor.clone

Purpose   Create an LDL Factor object with same property values

Syntax   C = clone(H)

Description C = clone(H) creates an LDLFactor System object C, with the same property values as H. The clone method creates a new unlocked object.

Purpose   Number of expected inputs to step method

Syntax   `N = getNumInputs(H)`

Description   `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(`*H*`)`.

dsp.LDLFactor.getNumOutputs

Purpose   Number of outputs for step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                     method

                     The getNumOutputs method returns a positive integer that is the
                     number of outputs from the step method. This value will change if you
                     alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the LDLFactor object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.LDLFactor.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Decompose matrix into components

Syntax   Y = step(H,S)

Description Y = step(H,S) decomposes the matrix S into lower, upper, and diagonal components. The output Y is a composite matrix with the L as its lower triangular part and D as the diagonal and L' as its upper triangular part. If S is not positive definite the output Y is not a valid factorization.

Note The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

---

dsp.LevinsonSolver

Purpose   Solve linear system of equations using Levinson-Durbin recursion

Description The `LevinsonSolver` object solves linear systems of equations using Levinson-Durbin recursion.

To solve linear systems of equations using Levinson-Durbin recursion:

1 Define and set up your System object. See "Construction" on page 5-602.

2 Call `step` to solve the system of equations according to the properties of `dsp.LevinsonSolver`. The behavior of `step` is specific to each object in the toolbox.

Construction `H = dsp.LevinsonSolver` returns a System object, H, that solves a Hermitian Toeplitz system of equations using the Levinson-Durbin recursion.

`H = dsp.LevinsonSolver('PropertyName',PropertyValue,...)` returns a Levinson-Durbin object, H, with each specified property set to the specified value.

Properties   **AOutputPort**

Enable polynomial coefficients output

Set this property to `true` to output the polynomial coefficients *A*. Both `AOutputPort` and `KOutputPort` properties cannot be `false` at the same time. For scalar inputs, set the `AOutputPort` property to `true`. The default is `false`.

KOutputPort

Enable reflection coefficients output

Set this property to `true` to output the reflection coefficients *K*. You cannot set both the `AOutputPort` and `KOutputPort` properties to `false` at the same time. For scalar inputs, you must set the `KOutputPort` property to `false`. The default is `true`.

PredictionErrorOutputPort

Enable prediction error output

Set this property to `true` to output the prediction error. The default is `false`.

ZerothLagZeroAction

Action when value of lag zero is zero

Specify the output for an input with the first coefficient as zero. Select `Ignore` or `Use zeros`. The default is `Use zeros`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap`, `Saturate`. The default is `Wrap`.

ACoefficientDataType

A coefficient word and fraction lengths

This constant property has a value of `Custom`.

CustomACoefficientDataType

A coefficient word and fraction lengths

Specify the *A* coefficient fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. The default is `numerictype([],16,15)`.

KCoefficientDataType

K coefficient word and fraction lengths

This constant property has a value of `Custom`.

CustomKCoefficientDataType

K coefficient word and fraction lengths

Specify the *K* coefficient fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. The default is `numerictype([],16,15)`.

PredictionErrorDataType

Prediction error power word and fraction lengths

Specify the prediction error power fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

CustomPredictionErrorDataType

Prediction error power word and fraction lengths

Specify the prediction error power fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `PredictionErrorDataType` property is `Custom`. The default is `numerictype([],16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Same as input` or `Custom`. The default is `Custom`

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` property is `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the Accumulator fixed-point data type as `Same as input`, `Same as product`, or `Custom`. The default is `Custom`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numerictype([],32,30)`.

Methods

clone	Create Levinson solver object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Reflection coefficients corresponding to columns of input

Examples

Use the Levinson solver to compute polynomial coefficients from autocorrelation coefficients:

```
hlevinson = dsp.LevinsonSolver;
hlevinson.AOutputPort = true;
hlevinson.KOutputPort = false;
x = (1:100)';
hac = dsp.Autocorrelator(...
'MaximumLagSource', 'Property', ...
'MaximumLag', 10);
```

```
 a = step(hac, x);
 c = step(hlevinson, a); % Compute polynomial coefficients
```

Algorithms   This object implements the algorithm, inputs, and outputs described
                   on the Levinson-Durbin block reference page. The object properties
                   correspond to the block parameters, except:

    Output(s) block parameter corresponds to the AOutputPort and the
    KOutputPort object properties.

See Also   dsp.Autocorrelator

Purpose   Create Levinson solver object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a LevinsonSolver object System object C, with the same property values as H. The clone method creates a new unlocked object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the step
method

The getNumOutputs method returns a positive integer that is the
number of outputs from the step method. This value will change if you
alter any properties that turn outputs on or off.

dsp.LevinsonSolver.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the LevinsonSolver System object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description   release(H) releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the release method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.LevinsonSolver.step

Purpose   Reflection coefficients corresponding to columns of input

Syntax   K = step(H,X)
                 A = step(H,X)
                 [A, K] = step(H,X)
                 [..., P] = step(H,X)

Description K = step(H,X) returns reflection coefficients K corresponding to the
                 columns of input X. X is typically a column or matrix of autocorrelation
                 coefficients with lag 0 as the first element.

                 A = step(H,X) returns polynomial coefficients A when the AOutputPort
                 property is true and the KOutputPort property is false.

                 [A, K] = step(H,X) returns polynomial coefficients A and reflection
                 coefficients K when both the AOutputPort and KOutputPort properties
                 are true.

                 [..., P] = step(H,X) also returns the error power P when the
                 PredictionErrorOutputPort property is true.

                 Note The object performs an initialization the first time the step
                 method is executed. This initialization locks nontunable properties and
                 input specifications, such as dimensions, complexity, and data type
                 of the input data. If you change a nontunable property or an input
                 specification, the System object issues an error. To change nontunable
                 properties or inputs, you must first call the release method to unlock
                 the object.

Purpose   LMS adaptive filter

Description   The LMSFilter implements an adaptive FIR filter object that returns
the filtered output, the error vector, and filter weights. The LMS filter
uses one of five different LMS algorithms.

To implement the adaptive FIR filter object:

1 Define and set up your adaptive FIR filter object. See "Construction"
on page 5-613.

2 Call step to implement the filter according to the properties of
dsp.LMSFilter. The behavior of step is specific to each object in
the toolbox.

Construction   H = dsp.LMSFilter returns an adaptive FIR filter object, H, that
computes the filtered output, filter error and the filter weights for a
given input and desired signal using the Least Mean Squares (LMS)
algorithm.

H = dsp.LMSFilter('*PropertyName*', *PropertyValue*,...) returns
an LMS filter object, H, with each property set to the specified value.

H = dsp.LMSFilter(LEN,'*PropertyName*',*PropertyValue*,...)
returns an LMS filter object, H, with the Length property set to LEN, and
other specified properties set to the specified values.

Properties   **Method**

Method to calculate filter weights

Specify the method used to calculate filter weights as LMS,
Normalized LMS, Sign-Error LMS, Sign-Data LMS, or Sign-Sign
LMS. The default is LMS.

Length

Length of FIR filter weights vector

Specify the length of the FIR filter weights vector as a positive integer. The default is 32.

StepSizeSource

How to specify adaptation step size

Choose how to specify the adaptation step size factor as `Property` or `Input port`. The default is `Property`.

StepSize

Adaptation step size

Specify the adaptation step size factor as a nonnegative real number. For convergence of the normalized LMS method, set the step size greater than `0` and less than `2`. This property only applies when the `StepSizeSource` property is `Property`. The default is `0.1`. This property is tunable.

LeakageFactor

Leakage factor used in LMS filter

Specify the leakage factor as a real number between `0` and `1` inclusive. A leakage factor of `1` corresponds to no leakage in the adapting method. The default is `1`. This property is tunable.

InitialConditions

Initial conditions of filter weights

Specify the initial values of the FIR filter weights as a scalar or vector of length equal to the `Length` property value. The default is `0`.

AdaptInputPort

Enable weight adaptation

Specify when the LMS filter should adapt the filter weights. By default, the value of this property is `false`, and the object continuously updates the filter weights. When this property is set to `true`, an adaptation control input is provided to the

step method. If the value of this input is nonzero, the object continuously updates the filter weights. If the input is zero, the filter weights remain at their current value.

WeightsResetInputPort

Enable weight reset

Specify when the LMS filter should reset the filter weights. By default, the value of this property is false, and the object does not reset the weights. When this property is set to true, a reset control input is provided to the step method, and the WeightsResetCondition property applies. The object resets the filter weights based on the values of the WeightsResetCondition property and the reset input to the step method.

WeightsResetCondition

Reset trigger setting for filter weights

Specify the event to reset the filter weights as Rising edge, Falling edge, Either edge, or Non-zero. The LMS filter resets the filter weights based on the values of this property and the reset input to the step method. This property only applies when the WeightsResetInputPort property is true. The default is Non-zero.

WeightsOutputPort

Enable returning filter weights

Set this property to true to output the adapted filter weights. The default is true.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as Ceiling, Convergent, Floor, Nearest, Round, Simplest, or Zero. The default is Floor.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

StepSizeDataType

Step size word and fraction lengths

Specify the step size fixed-point data type as `Same word length as first input` or `Custom`. Setting this property also sets the `LeakageFactorDataType` property to the same value. This property only applies when the `StepSizeSource` property is `Property`. The default is `Same word length as first input`.

CustomStepSizeDataType

Step size word and fraction lengths

Specify the step size fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `StepSizeSource` property is `Property` and the `StepSizeDataType` property is `Custom`. Thhis property and the `CustomLeakageFactorDataType` property must have the same word lengths. The default is `numerictype([],16,15)`.

LeakageFactorDataType

Leakage factor word and fraction lengths

Specify the leakage factor fixed-point data type as `Same word length as first input` or `Custom`. Setting this property also sets the `StepSizeDataType` property to the same value. This property only applies when the `StepSizeSource` property is `Property`. The default is `Same word length as first input`.

CustomLeakageFactorDataType

Leakage factor word and fraction lengths

Specify the leakage factor fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property only applies

when the `StepSizeSource` property is `Property` and the `LeakageFactorDataType` property is `Custom`. This property and the `CustomStepSizeDataType` property must have the same word lengths. The default is `numerictype([],16,15)`.

WeightsDataType

Weights word and fraction lengths

Specify the filter weights fixed-point data type as `Same as first input` or `Custom`. The default is `Same as first input`.

CustomWeightsDataType

Weights word and fraction lengths

Specify the filter weights fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `WeightsDataType` property is `Custom`. The default is `numerictype([],16,15)`.

EnergyProductDataType

Energy product word and fraction lengths

Specify the energy product fixed-point data type as `Same as first input` or `Custom`. This property only applies when the `Method` property is `Normalized LMS`. Setting this property also sets the `ConvolutionProductDataType`, `StepSizeErrorProductDataType`, `WeightsUpdateProductDataType`, and `QuotientDataType` properties to the same value. The default is `Same as first input`.

CustomEnergyProductDataType

Energy product word and fraction lengths

Specify the energy product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `Method` property is `Normalized LMS` and the `EnergyProductDataType` property is `Custom`. The `CustomEnergyProductDataType`,

CustomConvolutionProductDataType,
CustomStepSizeErrorProductDataType,
CustomWeightsUpdateProductDataType, and
CustomQuotientDataType properties must have the same word
lengths. The default is numerictype([],32,20).

EnergyAccumulatorDataType

Energy accumulator word and fraction lengths

Specify the energy accumulator fixed-point data type as Same as
first input or Custom. This property only applies when the
Method property is Normalized LMS. Setting this property also
sets the ConvolutionAccumulatorDataType property to the same
value. The default is Same as first input.

CustomEnergyAccumulatorDataType

Energy accumulator word and fraction lengths

Specify the energy accumulator fixed-point type as a
scaled numerictype object with a Signedness of Auto.
This property only applies when the Method property is
Normalized LMS and the EnergyAccumulatorDataType
property is Custom. The CustomEnergyProductDataType,
CustomConvolutionProductDataType,
CustomStepSizeErrorProductDataType,
CustomWeightsUpdateProductDataType, and
CustomQuotientDataType properties must have the same word
lengths. The default is numerictype([],32,20).

ConvolutionProductDataType

Convolution product word and fraction lengths

Specify the convolution product fixed-point data type as Same
as first input or Custom. Setting this property also sets the
EnergyProductDataType, StepSizeErrorProductDataType,
WeightsUpdateProductDataType and QuotientDataType
properties to the same value. The default is Same as first
input.

CustomConvolutionProductDataType

Convolution product word and fraction lengths

Specify the convolution product fixed-point type as a scaled numerictype object with a Signedness of Auto. This property only applies when the ConvolutionProductDataType property is Custom. The CustomEnergyProductDataType, CustomConvolutionProductDataType, CustomStepSizeErrorProductDataType, CustomWeightsUpdateProductDataType, and CustomQuotientDataType properties must have the same word lengths. The default is numerictype([],32,20).

ConvolutionAccumulatorDataType

Convolution accumulator word and fraction lengths

Specify the convolution accumulator fixed-point data type as Same as first input or Custom. Setting this property also sets the EnergyAccumulatorDataType property to the same value. The default is Same as first input.

CustomConvolutionAccumulatorDataType

Convolution accumulator word and fraction lengths

Specify the convolution accumulator fixed-point type as a scaled numerictype object with a Signedness of Auto. This property only applies when the ConvolutionAccumulatorDataType property is Custom. The CustomEnergyAccumulatorDataType and CustomConvolutionAccumulatorDataType properties must have the same word lengths. The default isnumerictype([],32,20).

StepSizeErrorProductDataType

Step size error product word and fraction lengths

Specify the step size error product fixed-point data type as Same as first input or Custom. Setting this property also sets the ConvolutionProductDataType, EnergyProductDataType, WeightsUpdateProductDataType, and QuotientDataType

properties to the same value. The default is `Same as first input`.

CustomStepSizeErrorProductDataType

Step size error product word and fraction lengths

Specify the step size error product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `StepSizeErrorProductDataType` property is `Custom`. The `CustomEnergyProductDataType`, `CustomConvolutionProductDataType`, `CustomStepSizeErrorProductDataType`, `CustomWeightsUpdateProductDataType`, and `CustomQuotientDataType` properties must have the same word lengths. The default is `numerictype([],32,20)`.

WeightsUpdateProductDataType

Weight update product word and fraction lengths

Specify the weight update product fixed-point data type as `Same as first input` or`Custom`. Setting this property also sets the `ConvolutionProductDataType`, `EnergyProductDataType`, `StepSizeErrorProductDataType`, and `QuotientDataType` properties to the same value. The default is `Same as first input`.

CustomWeightsUpdateProductDataType

Weight update product word and fraction lengths

Specify the weight update product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `WeightsUpdateProductDataType` property is `Custom`. The `CustomEnergyProductDataType`, `CustomConvolutionProductDataType`, `CustomStepSizeErrorProductDataType`, `CustomWeightsUpdateProductDataType`, and `CustomQuotientDataType` properties must have the same word lengths. The default is `numerictype([],32,20)`.

QuotientDataType

Quotient word and fraction lengths

Specify the quotient fixed-point data type as `Same as first input`, `Custom`. This property only applies when the `Method` property is `Normalized LMS`. Setting this property also sets the `ConvolutionProductDataType`, `EnergyProductDataType`, `StepSizeErrorProductDataType`, and `WeightsUpdateProductDataType` properties to the same value. The default is `Same as first input`.

CustomQuotientDataType

Quotient word and fraction lengths

Specify the quotient fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `Method` property is `Normalized LMS` and the `QuotientDataType` property is `Custom`. The `CustomEnergyProductDataType`, `CustomConvolutionProductDataType`, `CustomStepSizeErrorProductDataType`, `CustomWeightsUpdateProductDataType`, and `CustomQuotientDataType` properties must have the same word lengths. The default is `numerictype([],32,20)`.

Methods		
	clone	Create LMS filter object with same property values
	getNumInputs	Number of expected inputs to step method
	getNumOutputs	Number of outputs of step method
	isLocked	Locked status for input attributes and nontunable properties
	release	Allow property value and input characteristics changes

dsp.LMSFilter

Examples   Determine system identification of an FIR filter:

```
hlms1 = dsp.LMSFilter(11, 'StepSize', 0.01);
hfilt = dsp.DigitalFilter; % System to be identified
hfilt.TransferFunction = 'FIR (all zeros)';
hfilt.Numerator = fir1(10, .25);
x = randn(1000,1); % input signal

d = step(hfilt, x) + 0.01*randn(1000,1); % desired signal
[y,e,w] = step(hlms1, x, d);

subplot(2,1,1), plot(1:1000, [d,y,e]);
title('System Identification of an FIR filter');
legend('Desired', 'Output', 'Error');
xlabel('time index'); ylabel('signal value');
subplot(2,1,2); stem([hfilt.Numerator.', w]);
legend('Actual','Estimated');
xlabel('coefficient #'); ylabel('coefficient value');
```

Cancel noise in a signal:

```
hlms2 = dsp.LMSFilter('Length', 11, ...
   'Method', 'Normalized LMS',...
   'AdaptInputPort', true, ...
   'StepSizeSource', 'Input port', ...
   'WeightsOutputPort', false);
hfilt2 = dsp.DigitalFilter(...
   'TransferFunction', 'FIR (all zeros)', ...
   'Numerator', fir1(10, [.5, .75]));
x = randn(1000,1); % Noise
d = step(hfilt2, x) + sin(0:.05:49.95)'; % Noise + Signal
```

```
a = 1; % adaptation control
mu = 0.05; % step size
[y, err] = step(hlms2, x, d, mu, a);

subplot(2,1,1), plot(d), title('Noise + Signal');
subplot(2,1,2),plot(err), title('Signal');
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the LMS Filter block reference page. The object properties correspond to the block parameters.

See Also   dsp.BlockLMSFilter | dsp.DigitalFilter

dsp.LMSFilter.clone

Purpose   Create LMS filter object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates an LMS filter object, C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                   the step method.

                   The getNumInputs method returns a positive integer that is the number
                   of expected inputs (not counting the object itself) to the step method.
                   This value will change if you alter any properties that turn inputs on or
                   off. You must call the step method with the number of input arguments
                   equal to the result of getNumInputs(*H*).

dsp.LMSFilter.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                   method.

                   The getNumOutputs method returns a positive integer that is the
                   number of outputs from the step method. This value will change if you
                   alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the LMS filter.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.LMSFilter.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset filter states for LMS filter

Syntax   reset(H)

Description   reset(H) resets the filter states of the LMS FIR filter,H, to their initial values specified in the InitialConditions property. The initial filter state values correspond to the initial conditions for difference equation defining the adaptive filter. After the step method applies the LMS filter to nonzero input data, the states may be different. Invoking the step method again without first invoking thereset method may produce different outputs for an identical input.

Example of resetting filter states:

```
hlms1 = dsp.LMSFilter(11, 'StepSize', 0.01);
hfilt = dsp.DigitalFilter; % System to be identified
hfilt.TransferFunction = 'FIR (all zeros)';
hfilt.Numerator = fir1(10, .25);
x = randn(1000,1); % input signal
d = step(hfilt, x) + 0.01*randn(1000,1); % desired signal
[y,e,w] = step(hlms1, x, d);
% Call step method again without resetting filter states
[y1,e1,w1] = step(hlms1,x,d);
isequal(y,y1) % Returns 0
% Now reset the filter states to zero
reset(hlms1)
% invoke step method
[y2,e2,w2] = step(hlms1,x,d);
isequal(y,y2) % Returns 1
```

dsp.LMSFilter.step

Purpose Apply LMS adaptive filter to input

Syntax
```
[Y,ERR,WTS] = step(H,X,D)
[Y, ERR] = step(H,X,D)
[...] = step(H,X,D,MU)
[...] = step(H,X,D,A)
[...] = step(H,X,D,R)
[Y,ERR,WTS] = step(H,X,D,MU,A,R)
```

Description `[Y,ERR,WTS] = step(H,X,D)` applies the LMS filter object, `H` to the input `X`, using `D` as the desired signal. This approach returns the filtered output in `Y`, the filter error in `ERR`, and the estimated filter weights in `WTS`. The LMS filter estimates the filter weights needed to minimize the mean square error between the output and the desired signal.

`[Y, ERR] = step(H,X,D)` filters the input `X`, using `D` as the desired signal. This approach returns the filtered output in `Y` and the filter error in `ERR` when the `WeightsOutputPort` property is `false`.

`[...]  = step(H,X,D,MU)` uses `MU` as the step size, when the `StepSizeSource` property is `'Input port'`.

`[...]  = step(H,X,D,A)` uses `A` as the adaptation control, when the `AdaptInputPort` property is `true`. When `A` is nonzero, the LMS filter continuously updates the filter weights. When `A` is zero, the filter weights remain constant.

`[...]  = step(H,X,D,R)` uses `R` as a reset signal when the `WeightsResetInputPort` property is `true`. The `WeightsResetCondition` property can be used to set the reset trigger condition. If a reset event occurs, the LMS filter resets the filter weights to their initial values.

`[Y,ERR,WTS] = step(H,X,D,MU,A,R)` filters the input `X` using `D` as the desired signal, `MU` as the step size, `A` as the adaptation control, and `R` as the reset signal. This approach returns the filtered output in `Y`, the filter error in `ERR`, and the adapted filter weights in `WTS`.

Note The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

dsp.LowerTriangularSolver

Purpose   Solve lower-triangular matrix equation

Description   The LowerTriangularSolver object solves $LX = B$ for X when L is a square, lower-triangular matrix with the same number of rows as B.

To solve $LX = B$ for X:

1 Define and set up your linear system solver. See "Construction" on page 5-632.

2 Call step to solve the equation according to the properties of dsp.LowerTriangularSolver. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.LowerTriangularSolver returns a linear system solver, H, used to solve the linear system $LX = B$, where L is a lower (or unit-lower) triangular matrix.

H = dsp.LowerTriangularSolver('*PropertyName*',*PropertyValue*,...) returns a linear system solver, H, with each specified property set to the specified value.

Properties   **OverwriteDiagonal**

Replace diagonal elements of input with ones

When you set this property to true, the linear system solver replaces the elements on the diagonal of the input, *L*, with ones. Set this property to either true or false. The default is false.

RealDiagonalElements

Indicate that diagonal of complex input is real

When you set this property to true, the linear system solver optimizes computation speed if the diagonal elements of complex input, *L*, are real. This property applies only when you set the OverwriteDiagonal property to false. Set this property to either true or false. The default is false.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Data type of product

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as `Full precision`, `Same as first input`, `Same as product`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Data type of output

Specify the output data type as `Same as first input` or `Custom`. The default is `Same as first input`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create lower triangular solver object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Solve matrix equation for specified inputs

Examples

Solve a lower-triangular matrix equation:

```
hlowtriang = dsp.LowerTriangularSolver;
```

```
u = tril(rand(4, 4));
b = rand(4, 1);
% Check that result is the solution to the linear
% equations.
x1 = inv(u)*b
x = step(hlowtriang, u, b)
```

Algorithms   This object implements the algorithm, inputs, and outputs described on
                   the Forward Substitution block reference page. The object properties
                   correspond to the block parameters.

See Also   dsp.UpperTriangularSolver

dsp.LowerTriangularSolver.clone

Purpose   Create lower triangular solver object with same property values

Syntax   C = clone(H)

Description C = clone(H) creates a `LowerTriangularSolver` object C, with the same property values as H. The `clone` method creates a new unlocked object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description N = getNumInputs(H) returns the number of expected inputs, N, to
the step method.

The getNumInputs method returns a positive integer that is the number
of expected inputs (not counting the object itself) to the step method.
This value will change if you alter any properties that turn inputs on or
off. You must call the step method with the number of input arguments
equal to the result of getNumInputs(*H*).

dsp.LowerTriangularSolver.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the LowerTriangularSolver
                    object H.

                    The isLocked method returns a logical value that indicates whether
                    input attributes and nontunable properties for the object are locked. The
                    object performs an internal initialization the first time the step method
                    is executed. This initialization locks nontunable properties and input
                    specifications, such as dimensions, complexity, and data type of the
                    input data. After locking, the isLocked method returns a true value.

dsp.LowerTriangularSolver.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Solve matrix equation for specified inputs

Syntax   X = step(H,L,B)

Description   X = step(H,L,B) computes the solution, *X*, of the matrix equation
                     $LX = B$, where *L* is a square, lower-triangular matrix with the same
                     number of rows as the matrix *B*.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

---

dsp.LPCToAutocorrelation

Purpose	Convert linear prediction coefficients to autocorrelation coefficients
Description	The `LPCToAutocorrelation` System object converts linear prediction coefficients to autocorrelation coefficients.

To convert LPC to autocorrelation coefficients:

1 Define and set up your LPC to autocorrelation object. See "Construction" on page 5-642.

2 Call `step` to convert LPC according to the properties of `dsp.LPCToAutocorrelation`. The behavior of `step` is specific to each object in the toolbox.

Construction	`H = dsp.LPCToAutocorrelation` returns an LPC to autocorrelation System object, `H`, that converts linear prediction coefficients (LPC) to autocorrelation coefficients.

`H = dsp.LPCToAutocorrelation('`*PropertyName*`',`*PropertyValue*`,...)` returns an LPC to autocorrelation conversion object, `H`, with each specified property set to the specified value.

Properties

PredictionErrorInputPort

Enable prediction error power input

Choose how to select the prediction error power. When you set this property to `true`, you must specify the prediction error power as a second input to the `step` method. When you set this property to `false`, the object assumes that the prediction error power is 1. The default is `false`.

NonUnityFirstCoefficientAction

Action to take when first LPC coefficient is not 1

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not 1. Select `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods	clone	Create LPC to autocorrelation object with same property values
	getNumInputs	Number of expected inputs to step method
	getNumOutputs	Number of outputs of step method
	isLocked	Locked status for input attributes and nontunable properties
	release	Allow property value and input characteristics changes
	step	Autocorrelation coefficients from LPC coefficents

Examples
Convert the linear prediction coefficients to autocorrelation coefficients:

```
a = [1.0 -1.4978 1.4282 -1.3930 0.9076 -0.3855 0.0711].';
hlpc2ac = dsp.LPCToAutocorrelation;
ac = step(hlpc2ac, a);
```

Algorithms
This object implements the algorithm, inputs, and outputs described on the LPC/RC to Autocorrelation block reference page. The object properties correspond to the block parameters, except:

The object does not have a property that corresponds to the **Type of Conversion** block parameter. The object's behavior corresponds to the block's behavior when you set the **Type of Conversion** parameter to LPC to autocorrelation.

See Also
dsp.LPCToLSF | dsp.LPCToRC | dsp.LPCToCepstral | dsp.RCToAutocorrelation

dsp.LPCToAutocorrelation.clone

Purpose   Create LPC to autocorrelation object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates an LPCToAutocorrelation System object C,
                   with the same property values as H. The clone method creates a new
                   unlocked object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                   the step method.

                   The getNumInputs method returns a positive integer that is the number
                   of expected inputs (not counting the object itself) to the step method.
                   This value will change if you alter any properties that turn inputs on or
                   off. You must call the step method with the number of input arguments
                   equal to the result of getNumInputs(*H*).

dsp.LPCToAutocorrelation.getNumOutputs

Purpose Number of outputs of step method

Syntax N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the LPCToAutocorrelation
System object H.

The isLocked method returns a logical value that indicates whether
input attributes and nontunable properties for the object are locked. The
object performs an internal initialization the first time the step method
is executed. This initialization locks nontunable properties and input
specifications, such as dimensions, complexity, and data type of the
input data. After locking, the isLocked method returns a true value.

dsp.LPCToAutocorrelation.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

> **Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose　　Autocorrelation coefficients from LPC coefficents

Syntax　　`AC = step(H,A)`
　　　　　　　`AC = step(H,A,P)`

Description　　`AC = step(H,A)` converts the columns of the linear prediction coefficients, `A`, to autocorrelation coefficients, `AC`. The object assumes a prediction error power of 1.

　　　　　　`AC = step(H,A,P)` when you set the `PredictionErrorInputPort` property to `true`, converts the columns of the linear prediction coefficients, `A`, to autocorrelation coefficients, `AC`. This conversion uses `P` as the prediction error power. `P` must be a row vector with same number of columns as `A`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.LPCToCepstral

Purpose　　　Convert linear prediction coefficients to cepstral coefficients

Description　　The `LPCToCepstral` object converts linear prediction coefficients to cepstral coefficients.

To convert LPC to cepstral coefficients:

1 Define and set up your LPC to cepstral converter. See "Construction" on page 5-650.

2 Call `step` to convert LPC according to the properties of `dsp.LPCToCepstral`. The behavior of `step` is specific to each object in the toolbox.

Construction　　`H = dsp.LPCToCepstral` returns an LPC to cepstral converter object, `H`, that converts linear prediction coefficients (LPCs) to cepstral coefficients (CCs).

`H = dsp.LPCToCepstral('`*PropertyName*`',`*PropertyValue*`,...)` returns an LPC to cepstral converter object, `H`, with each specified property set to the specified value.

Properties　　**PredictionErrorInputPort**

Enable prediction error power input

Choose how to set the prediction error power. When you set this property to `true`, you must specify the prediction error as a second input to the `step` method. When you set this property to `false`, the oajbect assumes the prediction error power is 1. The default is `false`.

CepstrumLengthSource

Source of cepstrum length

Select how to specify the length of cepstral coefficients: `Auto` or `Property`. The default is `Auto`. When this property is set to `Auto`, the length of each channel of the cepstral coefficients output is the

same as the length of each channel of the input LPC coefficients. The default is `Property`.

CepstrumLength

Number of output cepstral coefficients

Set the length of the output cepstral coefficients vector as a scalar numeric integer. This property applies when you set the `CepstrumLengthSource` property to `Property`. The default is `10`.

NonUnityFirstCoefficientAction

LPC coeffecent nonunity action

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not `1`. Select `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

clone	Create LPC to cepstral object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Cepstral coefficients from columns of input LPC coefficients

Examples

Convert the linear prediction coefficients (LPC) to cepstral coefficients:

```
hlevinson = dsp.LevinsonSolver;
hlevinson.AOutputPort = true; % Output polynomial coefficients
hac = dsp.Autocorrelator;
```

```
hac.MaximumLagSource = 'Property';
hac.MaximumLag = 9; % Compute autocorrelation lags between [0:9]
hlpc2cc = dsp.LPCToCepstral;
x = [1:100]';
a = step(hac, x);
A = step(hlevinson, a); % Compute LPC coefficients
CC = step(hlpc2cc, A); % Convert LPC to CC.
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the LPC to/from Cepstral Coefficients block reference page. The object properties correspond to the block parameters, except:

The object does not have a property that corresponds to the **Type of Conversion** block parameter. The object's behavior corresponds to the block's behavior when you set the **Type of Conversion** parameter to LPCs to cepstral coefficients.

See Also   dsp.CepstralToLPC | dsp.LPCToLSF | dsp.LPCToRC

Purpose　　　Create LPC to cepstral object with same property values

Syntax　　　　C = clone(H)

Description　　C = clone(H) creates an LPCToCepstral System object C, with the same property values as H. The clone method creates a new unlocked object.

dsp.LPCToCepstral.getNumInputs

Purpose	Number of expected inputs to step method
Syntax	N = getNumInputs(H)
Description	N = getNumInputs(H) returns the number of expected inputs, N, to the step method

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   `N = getNumOutputs(H)`

Description   `N = getNumOutputs(H)` returns the number of outputs, `N`, from the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.LPCToCepstral.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the LPCToCepstral System object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose	Cepstral coefficients from columns of input LPC coefficients
Syntax	CC = step(H,A) CC = step(H,A,P)
Description	CC = step(H,A) computes the cepstral coefficients, CC, from the columns of input linear prediction coefficients, A. The object assumes the prediction error power is 1.

CC = step(H,A,P) when you set the PredictionErrorInputPort property to true, computes the cepstral coefficients, CC, from the columns of input linear prediction coefficients, A. This conversion uses P as the prediction error power.

Note The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

Purpose   Convert linear prediction coefficients to line spectral frequencies

Description   The LPCToLSF object converts linear prediction coefficients to line spectral frequencies.

To convert LPC to LSF:

1 Define and set up your LPC to LSF converter. See "Construction" on page 5-659.

2 Call step to convert LPC according to the properties of dsp.LPCToLSF. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.LPCToLSF returns a System object, H, that converts linear prediction coefficients (LPCs) to line spectral frequencies (LSFs).

H = dsp.LPCToLSF(*'PropertyName'*,*PropertyValue*,...) returns an LPC to LSF System object, H, with each specified property set to the specified value.

Properties   **NumCoarseGridPoints**

Number of coarse subintervals used for finding roots (LSP values)

Specify the number of coarse subintervals, n, used for finding line spectral pairs (LSP) values as a positive scalar integer. LSPs, which are the roots of two particular polynomials related to the input LPC polynomial, always lie in the range (–1, 1). The System object finds these roots using the Chebyshev polynomial root finding method. To compute LSF outputs, the object computes the arc cosine of the LSPs, outputting values ranging from 0 to pi radians. The object divides the interval (–1, 1) into n subintervals and looks for roots in each subinterval. If you set *n* too small in relation to the LPC polynomial order, the object can fail to find some of the roots. The default is 64. This property is tunable.

NumBisects

Value of bisection refinement used for finding roots

Specify the root bisection refinement value, k, used in the Chebyshev polynomial root finding method, where each line spectral pair (LSP) output is within

$$\frac{1}{(n \cdot 2^k)}$$

of the actual LSP value. Here n is the value of the NumCoarseGridPoints property, and the object searches a maximum of $k \cdot (n-1)$ points for finding the roots. You must set the NumBisects property value k, to a positive scalar integer. The default is 4. This property is tunable.

ExceptionOutputPort

Produces output with validity status of LSF output

Set this property to true to return a second output that indicates whether the computed LSF values are valid. The output is a vector with a length equal to the number of channels. A logical value of 1 indicates valid output. A logical value of 0 indicates invalid output. The LSF outputs are invalid when the object fails to find all the LSF values or when the input LPCs are unstable. The default is false.

OverwriteInvalidOutput

Enable overwriting invalid output with previous output

Specify the action that the System object should take for invalid LSF outputs. When you set this property to true, the object overwrites the invalid output with the previous output. When you set this property to false, the object does not take any action on invalid outputs and ignores the outputs.

FirstOutputValuesSource

Source of values for first output when output is invalid

Specify the source of values for the first output when the output is invalid as Auto or Property. This property applies when you

set the OverwriteInvalidOutput property to true. The default is Auto. When you set this property to Auto, the object uses a default value for the first output. The default value corresponds to the LSF representation of an allpass filter.

FirstOutputValues

Value of the first output

Specify a numeric vector of LSF values for overwriting an invalid first output. The length of this vector must be one less than the length of the input LPC vector. For multichannel inputs, you can set this property to a matrix with the same number of channels as the input, or one vector that is applied to every channel. The default is an empty vector. This property applies when you set the OverwriteInvalidOutput property to true and the FirstOutputValuesSource property to Property.

NonUnityFirstCoefficientAction

Action to take when first LPC coefficient is not 1

Specify the action the object takes when the first coefficient of each channel of the LPC input is not 1 as Replace with 1 or Normalize. The default is Replace with 1.

Methods

clone	Create LPC To LSF object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes

reset		Reset values for overwriting invalid outputs to their initial values
step		Convert LPC coefficients to line spectral frequencies

Examples   Convert to linear prediction coefficients to line spectral frequencies:

```
a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]';
hlpc2lsf = dsp.LPCToLSF;
y = step(hlpc2lsf, a); % Convert to LSF coefficients
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the LPC to LSF/LSP Conversion block reference page. The object properties correspond to the block parameters, except:

There is no object property that corresponds to the **Output** block parameter. The object only supports LSF outputs in the range $(0, \prod)$

See Also   dsp.LSFToLPC | dsp.LPCToLSP

Purpose   Create LPC To LSF object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates an LPCToLSF System object C, with the same
property values as H. The clone method creates a new unlocked object.

dsp.LPCToLSF.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                     method

                     The getNumOutputs method returns a positive integer that is the
                     number of outputs from the step method. This value will change if you
                     alter any properties that turn outputs on or off.

dsp.LPCToLSF.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the LPCToLSF System object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.LPCToLSF.reset

Purpose   Reset values for overwriting invalid outputs to their initial values

Syntax   reset(H)

Description   reset(H) resets the values for overwriting the invalid outputs to their initial values.

Purpose   Convert LPC coefficients to line spectral frequencies

Syntax   `LSF = step(H,A)`
`[..., STATUS] = step(H,A)`

Description `LSF = step(H,A)` converts the LPC coefficients, `A`, to line spectral frequencies, `LSF`, in the range (0 pi). The System object operates along the columns of the input `A`.

`[..., STATUS] = step(H,A)` also returns the status flag, `STATUS`, indicating if the current output is valid when the `ExceptionOutputPort` property is `true`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose	Convert linear prediction coefficients to line spectral pairs
Description	The LPCToLSP object converts linear prediction coefficients to line spectral pairs.

To convert LPC to LSP:

1 Define and set up your LPC to LSP converter. See "Construction" on page 5-670.

2 Call step to convert LPC according to the properties of dsp.LPCToLSP. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.LPCToLSP returns a System object, H, that converts linear prediction coefficients (LPCs) to line spectral pairs (LSPs).

H = dsp.LPCToLSP(*'PropertyName'*,*PropertyValue*,...) returns an LPC to LSF System object, H, with each specified property set to the specified value.

Properties   **NumCoarseGridPoints**

Number of coarse subintervals used for finding roots (LSP values)

Specify the number of coarse subintervals, *n*, used for finding line spectral pairs (LSP) values, as a positive scalar integer. LSPs, which are the roots of two particular polynomials related to the input LPC polynomial, always lie in the range (–1, 1). The System object finds these roots using the Chebyshev polynomial root finding method. The object divides the interval (–1, 1) into *n* subintervals and looks for roots in each subinterval. If *n* is set to too small a number in relation to the LPC polynomial order, the object can fail to find some of the roots. The default is 64. This property is tunable.

NumBisects

Value of bisection refinement used for finding roots

Specify the root bisection refinement value, *k*, that the Chebyshev polynomial uses in the root finding method. For each line spectral pair (LSP) the output is within

$$\frac{1}{n \cdot 2^k}$$

of the actual LSP value. Here *n* is the value of the NumCoarseGridPoints property and the object searches a maximum of

$$k \cdot (n\text{-}1)$$

points for finding the roots. The NumBisects property value *k*, must be a positive scalar integer. The default is 4. This property is tunable.

ExceptionOutputPort

Produces output with validity status of LSP output

Set this property to true to return a second output that indicates whether the computed LSP values are valid. The object outputs a vector length equal to the number of channels. A logical value of 1 indicates the output is valid. A logical value of 0 indicates the output is invalid. The LSP outputs are invalid when the object fails to find all the LSP values or when the input LPCs are unstable. The default is false.

OverwriteInvalidOutput

Enable overwriting invalid output with previous output

Specify the action that the object takes for invalid LSP outputs. When you set this property to true, the object overwrites the invalid output with the previous output. When you set this property to false, the object takes no action on invalid outputs and ignores the outputs.

FirstOutputValuesSource

Source of values for first output when output is invalid

Specify the source of values for the first output when the output is invalid as Auto or Property. This property applies only when you set the OverwriteInvalidOutput property to true. The default is Auto. When this property is Auto, the object uses a default value for the first output. The default value corresponds to the LSP representation of an allpass filter.

FirstOutputValues

Value of first output

Specify a numeric vector of LSP values for overwriting an invalid first output. The length of this vector must be one less than the length of the input LPC vector. For multichannel inputs, set this property can to a matrix with the same number of channels as the input or one vector that you apply to every channel. The default is an empty vector. This property applies only when you set the OverwriteInvalidOutput property to true and the FirstOutputValuesSource property to Property.

NonUnityFirstCoefficientAction

First coefficient nonunity action

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not equal to 1. Specify as one of Replace with 1 or Normalize. The default is Replace with 1.

Methods		
	clone	Create LPC To LSP object with same property values
	getNumInputs	Number of expected inputs to step method
	getNumOutputs	Number of outputs of step method
	isLocked	Locked status for input attributes and nontunable properties

release	Allow property value and input characteristics changes
reset	Reset values for overwriting invalid outputs to their initial values
step	Convert linear prediction coefficients to line spectral pairs

Examples　　Convert the LPC coefficients to LSP coefficients:

```
a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]';
hlpc2lsp = dsp.LPCToLSP;
y = step(hlpc2lsp, a); % Convert to LSP coefficients
```

Algorithms　　This object implements the algorithm, inputs, and outputs described on the LPC to LSF/LSP Conversion block reference page. The object properties correspond to the block parameters, except:

No object property corresponds to the **Output** block parameter. The object only supports LSP outputs.

See Also　　dsp.LSPToLPC | dsp.LPCToLSF

dsp.LPCToLSP.clone

Purpose   Create LPC To LSP object with same property values

Syntax   C = clone(H)

Description C = clone(H) creates a LPCToLSP System object C, with the same property values as H. The clone method creates a new unlocked object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                     the step method

                     The getNumInputs method returns a positive integer that is the number
                     of expected inputs (not counting the object itself) to the step method.
                     This value will change if you alter any properties that turn inputs on or
                     off. You must call the step method with the number of input arguments
                     equal to the result of getNumInputs(*H*).

dsp.LPCToLSP.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step method

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the LPCToLSP System object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.LPCToLSP.release

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description   release(H) releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the release method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset values for overwriting invalid outputs to their initial values

Syntax   reset(H)

Description reset(H) resets the values for overwriting the invalid outputs to their initial values.

dsp.LPCToLSP.step

Purpose　　　Convert linear prediction coefficients to line spectral pairs

Syntax　　　　```
LSF = step(H,A)
[..., STATUS] = step(H,A)
```

Description　　LSF = step(H,A) converts the LPC coefficients, A , to line spectral
pairs normalized in the range (–1 1), LSP. The object operates along
the columns of the input A.

[..., STATUS] = step(H,A) also returns the status flag, STATUS,
indicating if the current output is valid when the ExceptionOutputPort
property is true.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

Purpose   Convert linear prediction coefficients to reflection coefficients

Description   The LPCToRC object converts linear prediction coefficients to reflection coefficients.

To convert LPC to reflection coefficients:

1 Define and set up your LPC to RC converter. See "Construction" on page 5-681.

2 Call step to convert LPC according to the properties of dsp.LPCToRC. The behavior of step is specific to each object in the toolbox.

Construction H = dsp.LPCToRC returns an LPC to RC System object, H, that converts linear prediction coefficients (LPC) to reflection coefficients (RC).

H = dsp.LPCToRC('*PropertyName*',*PropertyValue*,...) returns an LPC to RC conversion object, H, with each specified property set to the specified value.

Properties   **PredictionErrorOutputPort**

Enable normalized prediction error power output

Set this property to true to return the normalized error power as a vector with one element per input channel. Each element varies between zero and one. The default is true.

ExceptionOutputPort

Produces output with stability status of filter represented by LPC coefficients

Set this property to true to return the stability status of the filter. A logical value of 1 indicate a stable filter. A logical value of 0 indicate an unstable filter. The default is false.

NonUnityFirstCoefficientAction

Action to take when first LPC coefficient is not 1

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not 1. Select `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods	clone	Create LPC to RC object with same property values
	getNumInputs	Number of expected inputs to step method
	getNumOutputs	Number of outputs of step method
	isLocked	Locked status for input attributes and nontunable properties
	release	Allow property value and input characteristics changes
	step	Convert columns of linear prediction coefficients to reflection coefficients

Examples   Convert the linear prediction coefficients to reflection coefficients:

```
load mtlb

hlevinson = dsp.LevinsonSolver;
hlevinson.AOutputPort = true;
hlevinson.KOutputPort = false;

hac = dsp.Autocorrelator;
hlpc2rc = dsp.LPCToRC;
hac.MaximumLagSource = 'Property';

% Compute autocorrelation for lags between [0:10]
hac.MaximumLag = 10;
a = step(hac, mtlb);
A = step(hlevinson, a); % Compute LPC coefficients
```

```
[K, P] = step(hlpc2rc, A); % Convert to RC
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to/from RC block reference page. The object properties correspond to the block parameters, except:

- There is no object property that corresponds to the **Type of conversion** block parameter. The object always converts LPC to RC.

- The NonUnityFirstCoefficientAction object property corresponds to the **If first input value is not 1** block parameter. There is neither a Normalize and warn nor an Error option for the object.

See Also

dsp.RCToLPC | dsp.LPCToAutocorrelation

dsp.LPCToRC.clone

Purpose   Create LPC to RC object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a LPCToRC System object C, with the same property values as H. The clone method creates a new unlocked object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                   the step method.

                   The getNumInputs method returns a positive integer that is the number
                   of expected inputs (not counting the object itself) to the step method.
                   This value will change if you alter any properties that turn inputs on or
                   off. You must call the step method with the number of input arguments
                   equal to the result of getNumInputs(*H*).

dsp.LPCToRC.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the step method

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the LPCToRC System object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.LPCToRC.release

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description   release(H) releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the release method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Convert columns of linear prediction coefficients to reflection coefficients

Syntax   [K,P] = step(H,A)
                   K = step(H,A)
                   [..., S] = step(H,A)

Description   [K,P] = step(H,A) converts the columns of linear prediction
                   coefficients, A, to reflection coefficients K and outputs the normalized
                   prediction error power, P.

                   K = step(H,A) when you set the PredictionErrorOutputPort
                   property to false, converts the columns of linear prediction coefficients,
                   A, to reflection coefficients K.

                   [..., S] = step(H,A) also outputs the LPC filter stability, S, when
                   you set the ExceptionOutputPort property to true.

                   ───

                   Note The object performs an initialization the first time the step
                   method is executed. This initialization locks nontunable properties and
                   input specifications, such as dimensions, complexity, and data type
                   of the input data. If you change a nontunable property or an input
                   specification, the System object issues an error. To change nontunable
                   properties or inputs, you must first call the release method to unlock
                   the object.

                   ───

dsp.LSFToLPC

Purpose   Convert line spectral frequencies to linear prediction coefficients

Description   The LSFToLPC object converts line spectral frequencies to linear
                   prediction coefficients.

                   To convert LSF to LPC:

                   1 Define and set up your LSF to LPC converter. See "Construction"
                   on page 5-690.

                   2 Call step to convert LSF according to the propeties of dsp.LSFToLPC.
                   The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.LSFToLPC returns an LSF to LPC System object, H, which
                   converts line spectral frequencies (LSFs) to linear prediction coefficients
                   (LPCs).

Methods

clone	Create LSF to LPC object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Convert input line spectral frequencies to linear prediction coefficients

Examples   Convert line spectral frequencies to linear prediction coefficients:

```
a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]'
```

```
hlpc2lsf = dsp.LPCToLSF;
ylsf = step(hlpc2lsf, a);
hlsf2lpc = dsp.LSFToLPC;
ylpc = step(hlsf2lpc, ylsf) % Check values are same as a.
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the LSF/LSP to LPC Conversion block reference page. The object properties correspond to the block parameters, except:

The object does not have a property that corresponds to the **Input** block parameter. The object's behavior corresponds to the block's behavior when you set the **Input** parameter to LSF in range (0 pi).

See Also   dsp.LPCToLSF | dsp.LSPToLPC

dsp.LSFToLPC.clone

Purpose   Create LSF to LPC object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates an LSFToLPC System object C, with the same property values as H. The clone method creates a new unlocked object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
the step method

The getNumInputs method returns a positive integer that is the number
of expected inputs (not counting the object itself) to the step method.
This value will change if you alter any properties that turn inputs on or
off. You must call the step method with the number of input arguments
equal to the result of getNumInputs(*H*).

dsp.LSFToLPC.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the LSFToLPC System object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.LSFToLPC.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Convert input line spectral frequencies to linear prediction coefficients

Syntax   A = step(H,LSF)

Description A = step(H,LSF) converts the input line spectral frequencies, (LSF), in
the range (0,pi), LSF , to linear prediction coefficients, A. The input
can be a vector or a matrix, where each column of the matrix is treated
as a separate channel.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

---

dsp.LSPToLPC

Purpose   Convert line spectral pairs to linear prediction coefficients

Description   The LSPToLPC object converts line spectral pairs to linear prediction coefficients.

To convert LSP to LPC:

1 Define and set up your LSP to LPC converter. See "Construction" on page 5-698.

2 Call step to convert LSP according to the properties of dsp.LSPToLPC. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.LSPToLPC returns an LSP to LPC System object, H, which converts line spectral pairs (LSPs) to linear prediction coefficients (LPCs).

Methods

clone	Create LSP to LPC object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Convert input line spectral pairs to linear prediction coefficients

Examples   Convert line spectral pairs to linear prediction coefficients:

```
ylsp = [0.7080 0.0103 -0.3021 -0.3218 -0.7093]';
hlsp2lpc = dsp.LSPToLPC;
```

```
ylpc = step(hlsp2lpc, ylsp)
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the LSF/LSP to LPC Conversion block reference page. The object properties correspond to the block parameters, except:

No object property corresponds to the **Input** block parameter. The object converts LSP in the range (–1, 1) to LPC.

See Also   dsp.LPCToLSP | dsp.LSFToLPC

dsp.LSPToLPC.clone

Purpose   Create LSP to LPC object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates an LSPToLPC System object C, with the same property values as H. The clone method creates a new unlocked object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description N = getNumInputs(H) returns the number of expected inputs, N, to
the step method.

The getNumInputs method returns a positive integer that is the number
of expected inputs (not counting the object itself) to the step method.
This value will change if you alter any properties that turn inputs on or
off. You must call the step method with the number of input arguments
equal to the result of getNumInputs(*H*).

dsp.LSPToLPC.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the LSPToLPC System object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.LSPToLPC.release

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description release(H) releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the release method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Convert input line spectral pairs to linear prediction coefficients

Syntax   A = step(H,LSP)

Description A = step(H,LSP) converts the input line spectral pairs in the range
(–1,1), LSP, to linear prediction coefficients, A. The input can be a vector
or a matrix, where each column of the matrix is treated as a separate
channel.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

---

dsp.LUFactor

Purpose   Factor square matrix into lower and upper triangular matrices

Description   The LUFactor object factors a square matrix into lower and upper triangular matrices.

To factor a square matrix into lower and upper triangular matrices:

1 Define and set up your System object. See "Construction" on page 5-706.

2 Call step to factor the square matrix according to the properties of dsp.LUFactor. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.LUFactor returns an LUFactor System object, H, which factors a row permutation of a square input matrix A as $A_p = L \cdot U$, where L is the unit-lower triangular matrix, and U is the upper triangular matrix. The row-pivoted matrix A_p contains the rows of *A* permuted as indicated by the permutation index vector *P*. The equivalent MATLAB code is Ap = A(P,:).

H = dsp.LUFactor(*'PropertyName'*,*PropertyValue*,...) returns an LUFactor object, H, with each specified property set to the specified value.

Properties   **ExceptionOutputPort**

Set to true to output singularity of input

Set this property to true to output the singularity of the input as logical data type values of true or false. An output of true indicates that the current input is singular, and an output of false indicates the current input is nonsingular.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as
|Ceiling|Convergent|Floor|Nearest |Round | Simplest |
Zero|. The default is Floor.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as Wrap or Saturate. The default is
Wrap.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as Full precision,
Same as input or Custom. The default is Full precision.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled numerictype
object with a Signedness of Auto. This property applies when
you set the ProductDataType property to Custom. The default is
numerictype([],32,30).

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as Full precision,
Same as input, Same as product or Custom. The default is Full
precision.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numerictype
object with a Signedness of Auto. This property applies when you
set the AccumulatorDataType property to Custom. The default is
numerictype([],32,30).

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create LU Factor object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Decompose matrix into lower and upper triangular matrices

Examples

Decompose a square matrix into the lower and upper components:

```
hlu = dsp.LUFactor;
x = rand(4)
[LU, P] = step(hlu, x);
L = tril(LU,-1)+diag(ones(size(LU,1),1));
U = triu(LU);
y = L*U
```

```
                   % Check back whether this equals the permuted x
                   xp = x(P,:)
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the LU Factorization block reference page. The object properties correspond to the block parameters.

See Also   dsp.LDLFactor

Purpose   Create LU Factor object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates an LUFactor object C, with the same property values as H. The clone method creates a new unlocked object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, of
the step method.

The getNumInputs method returns a positive integer that is the number
of expected inputs (not counting the object itself) to the step method.
This value will change if you alter any properties that turn inputs on or
off. You must call the step method with the number of input arguments
equal to the result of getNumInputs(*H*).

dsp.LUFactor.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the LUFactor object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.LUFactor.release

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description release(H) releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the release method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose	Decompose matrix into lower and upper triangular matrices
Syntax	`[LU,P] = step(H,A)` `[LU,P,S] = step(H,A)`
Description	`[LU,P] = step(H,A)` decomposes the matrix A into lower and upper triangular matrices. The output LU is a composite matrix with lower triangle elements from L and upper triangle elements from U . The permutation vector P is the second output. `[LU,P,S] = step(H,A)` returns an additional output S indicating if the input is singular when the `ExceptionOutputPort` property is set to `true`.

> **Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

.

dsp.MatFileReader

Purpose   Read MAT file

Description   The `MatFileReader` object reads V7.3 MAT files.

To read V7.3 MAT files:

1 Define and set up your System object. See "Construction" on page 5-716.

2 Call `step` to read the MAT file according to the properties of `dsp.MatFileReader`. The behavior of `step` is specific to each object in the toolbox.

Construction   `H = dsp.MatFileReader` returns a System object, H, to read data from a V7.3 MAT file.

`H = dsp.MatFileReader('PropertyName',PropertyValue,...)` returns a MAT file reader System object, H, with each specified property set to the specified value.

`H = dsp.MatFileReader(FILENAME,VARIABLENAME'PropertyName',PropertyValue,...)` returns a MAT file reader System object, H, with the `Filename` property set to *FILENAME*, the `VariableName` property set to *VARIABLENAME*, and other specified properties set to the specified values.

Properties   **Filename**

Name of MAT file from which to read

Specify the name of a MAT file as a string. Specify the full path for the file only if the file is not on the MATLAB path. The default file name is `Untitled.mat`.

VariableName

Name of the variable to read

Name of the variable stored in and read from the MAT file. The default variable name is `x`.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

SamplesPerFrame

Number of samples per output frame

Specify the number of elements to read from the MAT file each time the `step` method is called. This property applies when `FrameBaseProcessing` is `true`. The default number of samples per frame is `1`.

Methods

clone	Create MAT file reader object with same property values
isDone	End-of-file status
isLocked	Locked status (logical) for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of multimedia file reader to read from beginning of file
step	Read data from a variable in the MAT file

Examples

Use `dsp.MatFileReader` and `dsp.MatFileWriter` to stream data.

```
filename = [tempname '.mat'];  % Create variable name

originalData = rand(40,2);
```

```
save(filename,'originalData','-v7.3'); % Write to MAT file

H = dsp.MatFileReader(filename,'VariableName',...
    'originalData','SamplesPerFrame', 4);
while ~isDone(H)          % Stream data into MATLAB
    finalData = step(H);
end
```

See Also   dsp.MatFileWriter

Purpose   Create MAT file reader object with same property values

Syntax   C = clone(H)

Description C = clone(H) creates a MatFileReader System object C, with the same
property values as H.

The clone method creates a new unlocked object with uninitialized
states.

dsp.MatFileReader.isLocked

Purpose   Locked status (logical) for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the MatFileReader object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   End-of-file status

Syntax   STATUS = isDone(H)

Description   STATUS = isDone(H) returns a logical value, STATUS. When the
                    MatFileReader object, H , reaches the end of the MAT file, STATUS is
                    true.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset internal states of multimedia file reader to read from beginning of file

Syntax   reset(H)

Description   reset(H) resets the MatFileReader object to read from the beginning of the file.

dsp.MatFileReader.step

Purpose   Read data from a variable in the MAT file

Syntax   X = step(H)

Description X = step(H) reads data, X, from a variable stored in a MAT-file. The variable is assumed to be *N*-dimensional and a MATLAB built-in datatype. If the FrameBasedProcessing property is true, the data is read into MATLAB by reading along the first dimension. If FrameBasedProcessing is false, the data is read into MATLAB along the last dimension.

Note The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

Purpose   Write MAT file

Description   The MatFileWriter object writes data to a V7.3 MAT file.

To write data to a V7.3 MAT file:

1 Define and set up your System object. See "Construction" on page 5-725.

2 Call step to write data according to the properties of dsp.MatFileWriter. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.MatFileWriter returns a MAT file writer System object, H, that writes data to a V7.3 MAT file.

H = dsp.MatFileWriter(*'PropertyName'*,*PropertyValue*,...) returns a MAT file writer System object, H, with each specified property set to the specified value.

H = dsp.MatFileWriter(*FILENAME*,*'PropertyName'*,*PropertyValue*,...) returns a MAT file writer System object, H, with Filename property set to *FILENAME* and other specified properties set to the specified values.

Properties   **Filename**

Name of MAT file to write

Specify the name of a MAT file as a string. Specify the full path for the file only if the file is not on the MATLAB path. The default file name is Untitled.mat.

VariableName

Name of the variable to write

Name of the variable to which to write. This variable is stored in the MAT file. The default variable name is x.

FrameBasedProcessing

dsp.MatFileWriter

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. In frame-based mode, this System object streams the data to the first dimension. In sample-based mode, a new dimension is appended to the end of the data set. The default is `true`.

Methods

clone	Create MAT file writer object with the same property values
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Write one frame of MAT file data

Examples   Use `dsp.MatFileWriter` and `dsp.MatFileReader` to stream data.

```
% First, create a variable name
      filename = [tempname '.mat'];

% Next, write that variable to a MAT-file.
      hmfw = dsp.MatFileWriter(filename, 'VariableName', 'originalData')
      for i=1:10
          originalData = rand(4,2);
          step(hmfw, originalData);
      end
      release(hmfw); % This will close the MAT file

% Finally, load the variable back into MATLAB.
      data = load(filename, 'originalData');
```

See Also   dsp.MatFileReader

Purpose   Create MAT file writer object with the same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a MatFileWriter System object C, with the same property values as H. The clone method creates a new unlocked object.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the MatFileWriter System
object H.

The isLocked method returns a logical value that indicates whether
input attributes and nontunable properties for the object are locked. The
object performs an internal initialization the first time the step method
is executed. This initialization locks nontunable properties and input
specifications, such as dimensions, complexity, and data type of the
input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description `release(H)` releases system resources, such as memory, file handles, and hardware connections. `release` also closes the file. This method lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Write one frame of MAT file data

Syntax   step(H,X)

Description   step(H,X) writes one frame of data, X , to the variable stored in the
                     MAT file. The variable is assumed to be N-dimensional and a MATLAB
                     built-in data type. If the FrameBasedProcessing property is true, the
                     data is written to the file by concatenating along the first dimension. If
                     FrameBasedProcessing is false, the data is written by appending an
                     additional dimension to the end of the data set.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

Purpose   Find maximum value of input or sequence of inputs

Description   The Maximum object finds the maximum values of an input or sequence of inputs.

To compute the maximum value of an input or sequence of inputs:

1 Define and set up your System object. See "Construction" on page 5-731.

2 Call step to find the maximum according to the properties of dsp.Maximum. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.Maximum returns an object, H, that computes the value and index of the maximum elements in an input or a sequence of inputs along the specified Dimension.

H = dsp.Maximum('*PropertyName*',*PropertyValue*,...) returns a maximum-finding object, H, with each specified property set to the specified value.

Properties   **ValueOutputPort**

Output maximum value

Set this property to true in order to output the maximum of the input. This property applies only when you set the RunningMaximum property to false. The default is true.

RunningMaximum

Calculate over single input or multiple inputs

When you set this property to true, the object computes the maximum value over successive calls to the step method. When you set this property to false, the object computes the maximum value over the current input. The default is false.

IndexOutputPort

Output index of maximum value

Set this property to `true` to output the index of the maximum value of the input. This property applies only when you set the `RunningMaximum` property to `false`. The default is `true`.

ResetInputPort

Additional input to enable resetting of running maximum

Set this property to `true` to enable resetting the running maximum. When you set this property to `true`, you must specify a reset input to the `step` method to reset the running maximum. This property applies only when you set the `RunningMaximum` property to `true`. The default is `false`.

ResetCondition

Condition that triggers resetting of running maximum

Specify the event that resets the running maximum as one of | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero` |. This property applies only when you set the `ResetInputPort` property to `true`. The default is `Non-zero`.

IndexBase

Numbering base for index of maximum value

Specify whether to start the index numbering from `One` or `Zero` when computing the index of the maximum value. This property applies only when you set the `IndexOutputPort` property to `true`. The default is `One`.

Dimension

Dimension to operate along

Specify how the maximum calculation is performed over the data as one of | `All` | `Row` | `Column` | `Custom` |. This property applies when you set the `RunningMaximum` property to `false`. The default is `Column`.

CustomDimension

Numerical dimension to calculate over

Specify the integer dimension of the input signal over which the object finds the maximum. The cannot exceed the number of dimensions in the input signal. This property only applies when you set the `Dimension` property to `Custom`. The default is `1`.

ROIProcessing

Enable region-of-interest processing

Set this property to `true` to enable calculation of the maximum value within a particular region of an image. This property applies when you set the `Dimension` property to `All` and the `RunningMaximum` property to `false`. The default is `false`.

For full ROI processing support, install the Computer Vision System Toolbox product. If you only have the DSP System Toolbox product installed, you can only specify the value of the `ROIForm` property as `Rectangles`.

ROIForm

Type of region of interest

Specify the type of region of interest as one of | `Rectangles` | `Lines` | `Label matrix` | `Binary mask` |. This property applies only when you set the `ROIProcessing` property to `true`. The default is `Rectangles`.

For full ROI processing support, install the Computer Vision System Toolbox product. If you have only the DSP System Toolbox product installed, you can only specify the as `Rectangles`.

ROIPortion

Calculate over entire ROI or just perimeter

Specify whether to calculate the maximum over the `Entire ROI` or the `ROI perimeter`. This property applies only when you set the `ROIForm` property to `Rectangles`. The default is `Entire ROI`.

ROIStatistics

Calculate statistics for each ROI or one for all ROIs

Specify whether to calculate `Individual statistics for each ROI` or a `Single statistic for all ROIs`. This property applies only when you set the `ROIForm` property to `Rectangles`, `Lines`, or `Label matrix`.

ValidityOutputPort

Output flag indicating if any part of ROI is outside input image

When you set the `ROIForm` property to one of | `Lines` | `Rectangles` |, set this property to `true` to return the validity of the specified ROI being completely inside of the image. When you set the `ROIForm` property to `Label Matrix`, set this property to `true` to return the validity of the specified label numbers. The default is `false`.

FrameBasedProcessing

Process input as frames or samples

Set this property to `true` to enable frame-based processing for 2-D inputs. Set this property to `false` to enable sample-based processing. The object always performs sample-based processing for N-D inputs where N is greater than 2. This property applies when you set the `RunningMaximum` to `true`. The default is `true`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`.

OverflowAction

Action to take when integer input is out-of-range

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

ProductDataType

Data type of product

Specify the product fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when you set the AccumulatorDataType property to Custom. The default is numerictype([],32,30).

AccumulatorDataType

Data type of accumulator

Specify the accumulator fixed-point data type as one of | Same as product | Same as input | Custom |. The default is Same as product.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when you set the AccumulatorDataType property to Custom. The default is numerictype([],32,30).

Methods

clone	Create maximum-finding object with same property values
getNumInputs	Number of expected inputs to step method

getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset computation of running maximum
step	Maximum value

Examples

Find a maximum value and its index:

```
hmax1 = dsp.Maximum;
x = randn(100,1);
[y, I] = step(hmax1, x);
```

Compute a running maximum:

```
hmax2 = dsp.Maximum;
hmax2.RunningMaximum = true;
x = randn(100,1);
y = step(hmax2, x);
% y(i) is the maximum of all values in the vector x(1:i)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Maximum block reference page. The object properties correspond to the block parameters, except:

Treat sample-based row input as a column block parameter is not supported by the dsp.Maximum object.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the FrameBasedProcessing property. The block uses the **Input**

processing parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also   dsp.Minimum | dsp.Mean

dsp.Maximum.clone

Purpose   Create maximum-finding object with same property values

Syntax   C = clone(H)

Description C = clone(H) creates a Maximum object C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description N = getNumInputs(H) returns the number of expected inputs, N, to
the step method.

The getNumInputs method returns a positive integer that is the number
of expected inputs (not counting the object itself) to the step method.
This value will change if you alter any properties that turn inputs on or
off. You must call the step method with the number of input arguments
equal to the result of getNumInputs(*H*).

dsp.Maximum.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the step
                 method.

                 The getNumOutputs method returns a positive integer that is the
                 number of outputs from the step method. This value will change if you
                 alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the Maximum object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.Maximum.release

Purpose Allow property value and input characteristics changes

Syntax `release(H)`

Description `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset computation of running maximum

Syntax   reset(H)

Description   reset(H) resets the computation of the running maximum for the
Maximum object H.

dsp.Maximum.step

Purpose   Maximum value

Syntax   [VAL,IND] = step(H,X)
                 VAL = step(H,X)
                 IND = step(H,X)
                 VAL = step(H,X,R)
                 [...] = step(H,I,ROI)
                 [...] = step(H,I,LABEL,LABELNUMBERS)
                 [...,FLAG] = step(H,I,ROI)
                 [...,FLAG] = step(H,I,LABEL,LABELNUMBERS)

Description [VAL,IND] = step(H,X) returns the maximum value, VAL, and the
                 index or position of the maximum value, IND, along the specified
                 Dimension of X.

                 VAL = step(H,X) returns the maximum value, VAL, of the input X.
                 When the RunningMaximum property is true, VAL corresponds to the
                 maximum value over successive calls to the step method.

                 IND = step(H,X) returns the zero- or one-based index IND of
                 the maximum value. To enable this type of processing, set the
                 IndexOutputPort property to true and the ValueOutputPort and
                 RunningMaximum properties to false.

                 VAL = step(H,X,R) resets the state of H based on the value of reset
                 signal, R, and the ResetCondition property. To enable this type
                 of processing, set the RunningMaximum property to true and the
                 ResetInputPort property to true.

                 [...] = step(H,I,ROI) computes the maximum of an input image,
                 I, within the given region of interest, ROI. To enable this type of
                 processing, set the ROIProcessing property to true and the ROIForm
                 property to Lines, Rectangles or Binary mask.

                 [...] = step(H,I,LABEL,LABELNUMBERS) computes the maximum of
                 an input image, I, for a region whose labels are specified in the vector
                 LABELNUMBERS. To enable this type of processing, set the ROIProcessing
                 property to true and the ROIForm property to Label matrix.

`[...,FLAG] = step(H,I,ROI)` returns `FLAG`, indicating whether the given region of interest is within the image bounds. To enable this type of processing, set the `ROIProcessing` and `ValidityOutputPort` properties to `true` and the `ROIForm` property to `Lines`, `Rectangles` or `Binary mask`.

`[...,FLAG] = step(H,I,LABEL,LABELNUMBERS)` returns `FLAG`, indicating whether the input label numbers are valid. To enable this type of processing, set the `ROIProcessing` and `ValidityOutputPort` properties to `true` and the `ROIForm` property to `Label matrix`.

For full ROI processing support, install the Computer Vision System Toolbox product. If you only have the DSP System Toolbox product installed, you can only specify the value of the `ROIForm` property as `Rectangles`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.Mean

Purpose	Find mean value of input or sequence of inputs

Description

The Mean object finds the mean of an input or sequence of inputs.

To compute the mean of an input or sequence of inputs:

1 Define and set up your System object. See "Construction" on page 5-746.

2 Call step to compute the mean according to the properties of dsp.Mean. The behavior of step is specific to each object in the toolbox.

Construction

H = dsp.Mean returns an object, H, that computes the mean of an input or a sequence of inputs.

H = dsp.Mean(*'PropertyName'*,*PropertyValue*,...) returns a mean-finding object, H, with each specified property set to the specified value.

Properties

RunningMean

Calculate over single input or multiple inputs

When you set this property to true, the object calculates the mean over successive calls to the step method. When you set this property to false, the object computes the mean over the current input. The default is false.

ResetInputPort

Additional input to enable resetting of running mean

Set this property to true to enable resetting of the running mean. When you set this property to true, you must specify a reset input to the step method to reset the running mean. This property applies only when you set the RunningMean property to true. The default is false.

ResetCondition

Condition that triggers resetting of running mean

Specify the event that resets the running maximum as one of | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero` |. This property applies only when you set the `ResetInputPort` property to `true`. The default is `Non-zero`.

Dimension

Dimension to operate along

Specify how the mean calculation is performed over the data as one of | `All` | `Row` | `Column` | `Custom` |. This property applies when you set the `RunningMean` property to `false`. The default is `Column`.

CustomDimension

Numerical dimension to calculate over

Specify the integer dimension, indexed from one, of the input signal over which the object calculates the mean. The value cannot exceed the number of dimensions in the input signal. This property only applies when you set the `Dimension` property to `Custom`. The default is `1`.

ROIProcessing

Enable region-of-interest processing

Set this property to `true` to enable calculation of the mean within a particular region of an image. This property applies when you set the `Dimension` property to `All` and the `RunningMean` property to `false`. The default is `false`.

For full ROI processing support, install the Computer Vision System Toolbox product. If you only have the DSP System Toolbox product installed, you can only specify the value of the `ROIForm` property as `Rectangles`.

ROIForm

Type of region of interest

Specify the type of region of interest as one of | `Rectangles` | `Lines` | `Label matrix` |. This property applies only when you set the `ROIProcessing` property to `true`. The default is `Rectangles`.

For full ROI processing support, install the Computer Vision System Toolbox product. If you have only the DSP System Toolbox product installed, you can only specify the as `Rectangles`.

ROIPortion

Calculate over entire ROI or just perimeter

Specify whether to calculate the mean over the `Entire ROI` or the `ROI perimeter`. This property applies only when you set the `ROIForm` property to `Rectangles`. The default is `Entire ROI`.

ROIStatistics

Calculate statistics for each ROI or one for all ROIs

Specify whether to calculate `Individual statistics for each ROI` or a `Single statistic for all ROIs`. This property applies only when you set the `ROIForm` property to `Rectangles`, `Lines`, or `Label matrix`. The default is `Individual statistics for each ROI`.

ValidityOutputPort

Output flag indicating if any part of ROI is outside input image

When you set the `ROIForm` property to one of | `Lines` | `Rectangles` | `Binary mask` |, set this property to `true` to return the validity of the specified ROI being completely inside of the image. When you set the `ROIForm` property to `Label Matrix`, set this property to `true` to return the validity of the specified label numbers. The default is `false`.

FrameBasedProcessing

Process input as frames or samples

Set this property to `true` to enable frame-based processing for 2-D inputs. Set this property to `false` to enable sample-based

processing. The object always performs sample-based processing for N-D inputs where N is greater than 2. This property applies when you set the RunningMean to true. The default is true.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor.

OverflowAction

Action to take when integer input is out-of-range

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

AccumulatorDataType

Data type of accumulator

Specify the accumulator fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when you set the AccumulatorDataType property to Custom. The default is numerictype([],32,30).

OutputDataType

Data type of output

Specify the output fixed-point data type as one of | Same as accumulator | Same as input | Custom |. The default is Same as accumulator.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],32,30)`.

Methods

clone	Create mean object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of mean-finding object
step	Mean value

Examples

Compute the mean of a signal:

```
hmean1 = dsp.Mean;
x = randn(100,1);
y = step(hmean1, x);
```

Compute the running mean of a signal:

```
hmean2 = dsp.Mean;
hmean2.RunningMean = true;
x = randn(100,1);
```

```
 y = step(hmean2, x);
% y(i) is the mean of all values in the vector x(1:i)
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Mean block reference page. The object properties correspond to the block parameters, except:

> **Treat sample-based row input as a column** block parameter is not supported by the dsp.Mean object.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the FrameBasedProcessing property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also   dsp.Maximum | dsp.Minimum

dsp.Mean.clone

Purpose   Create mean object with same property values

Syntax   C = clone(H)

Description C = clone(H) creates a Mean object C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                   the step method.

                   The getNumInputs method returns a positive integer that is the number
                   of expected inputs (not counting the object itself) to the step method.
                   This value will change if you alter any properties that turn inputs on or
                   off. You must call the step method with the number of input arguments
                   equal to the result of getNumInputs(*H*).

Purpose	Number of outputs of step method
Syntax	N = getNumOutputs(H)
Description	N = getNumOutputs(H) returns the number of outputs, N, of the step method.
	The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the Mean object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.Mean.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset internal states of mean-finding object

Syntax   reset(H)

Description   reset(H) sets the internal states of the Mean object H to their initial
                  values.

dsp.Mean.step

Purpose　　Mean value

Syntax　　　Y = step(H,X)
　　　　　　　Y = step(H,X,R)
　　　　　　　Y = step(H,X,ROI)
　　　　　　　Y = step(H,X,LABEL,LABELNUMBERS)
　　　　　　　[Y,FLAG] = step(H,X,ROI)
　　　　　　　[Y,FLAG] = step(H,X,LABEL,LABELNUMBERS)

Description　Y = step(H,X) computes the mean of X. When you set the RunningMean property to true, Y corresponds to the mean successive calls to the step method.

Y = step(H,X,R) resets the computation of the running mean based on the value of the reset signal, R, and the ResetCondition property. To enable this type of processing, set the RunningMean property to true and the ResetInputPort property to true.

Y = step(H,X,ROI) computes the mean of input image X within the given region of interest ROI. To enable this type of processing, set the ROIProcessing property to true and the ROIForm property to Lines, Rectangles or Binary mask.

Y = step(H,X,LABEL,LABELNUMBERS) computes the mean of the input image, X, for the region whose labels are specified in the vector LABELNUMBERS. The regions are defined and labeled in the matrix LABEL. To enable this type of processing, set the ROIProcessing property to true and the ROIForm property to Label matrix.

[Y,FLAG] = step(H,X,ROI) returns FLAG, indicating whether the given region of interest ROI, is within the image bounds. To enable this type of processing, set the ROIProcessing and ValidityOutputPort properties to true and the ROIForm property to Lines, Rectangles or Binary mask.

[Y,FLAG] = step(H,X,LABEL,LABELNUMBERS) returns FLAG which indicates whether the input label numbers are valid. To enable this type of processing, set the ROIProcessing and ValidityOutputPort properties to true and the ROIForm property to Label matrix.

For full ROI processing support, install the Computer Vision System Toolbox product. If you have only the DSP System Toolbox product installed, you can only specify the value of this property as `Rectangles`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.Median

Purpose　　　Median value of input

Description　　The Median object computes the median value of the input. The object can compute the median along each dimension (row or column) of the input or of the entire input.

To compute the median of the input:

1 Define and set up your median System object. See "Construction" on page 5-760.

2 Call step to compute the median according to the properties of dsp.Median. The behavior of step is specific to each object in the toolbox.

Construction　　H = dsp.Median returns a median System object, H, that computes the median along the columns of the input using the Quick sort sorting method.

H = dsp.Median('*PropertyName*',*PropertyValue*,...) returns a median System object, H, with each property set to the value you specify.

Properties　　**SortMethod**

Sort method

Specify the method the object should use to sort the data before computing the median. You can specify Quick sort or Insertion sort. The quick sort algorithm uses a recursive sort method and is faster at sorting more than 32 elements. The insertion sort algorithm uses a nonrecursive method and is faster at sorting less than 32 elements. If you are using the Median object to generate code, you should use the insertion sort algorithm to prevent recursive function calls in your generated code. The default is Quick sort.

Dimension

Dimension to operate along

Specify the dimension along which the object computes the median values. You can specify one of | All | Row | Column | Custom |. The default is Column.

CustomDimension

Numerical dimension to operate along

Specify the dimension of the input signal (as a one-based value), over which the object computes the median. The cannot exceed the number of dimensions in the input signal. This property applies only when you set the Dimension property to Custom. The default is 1.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

ProductDataType

Product word and fraction lengths

Specify the product data type as one of | Same as input | Custom |. The default is Same as input.

CustomProductDataType

Product word and fraction lengths

Specify the product data type as a scaled numerictype object with a Signedness of Auto. This property applies only when

you set the ProductDataType property to Custom. The default is numerictype([],32,30).

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator data type as one of | Same as product | Same as input | Custom |. The default is Same as product.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the fixed-point accumulator data type as a scaled numerictype object with a Signedness of Auto. This property applies only when you set the AccumulatorDataType property to Custom. The default is numerictype([],32,30).

OutputDataType

Output word and fraction lengths

Specify the output data type as one of | Same as accumulator | Same as product | Same as input | Custom |. The default is Same as accumulator.

CustomOutputDataType

Output word and fraction lengths

Specify the data type of the output as a scaled numerictype object with a Signedness of Auto. This property applies only when you set the OutputDataType property to Custom. The default is numerictype([],16,15).

Methods	clone	Create median object with same property values
	getNumInputs	Number of expected inputs to step method

getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Median value

Examples   Compute the median value of the input column:

```
h = dsp.Median;
x = [7 -9 0 -1 2 0 3 5 -9]';
y = step(h, x)
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Median block reference page. The object properties correspond to the block properties, except:

> **Treat sample-based row input as a column** block parameter is not supported by the dsp.Median System object.

See Also   dsp.Mean | dsp.Minimum | dsp.Maximum | dsp.Variance

dsp.Median.clone

Purpose Create median object with same property values

Syntax C = clone(H)

Description C = clone(H) creates a median object C, with the same property values as H. The clone method creates a new unlocked object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
the step method.

The getNumInputs method returns a positive integer that is the number
of expected inputs (not counting the object itself) to the step method.
This value will change if you alter any properties that turn inputs on or
off. You must call the step method with the number of input arguments
equal to the result of getNumInputs(*H*).

dsp.Median.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                     method.

                     The getNumOutputs method returns a positive integer that is the
                     number of outputs from the step method. This value will change if you
                     alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the Median System object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.Median.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Median value

Syntax   Y = step(H,X)

Description   Y = step(H,X) computes the median value of the input X and returns
                   the result in Y.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

Purpose	Find minimum values of input or sequence of inputs
Description	The Minimum object finds the minimum value of an input or sequence of inputs.

To compute the minimum value of an input or sequence of inputs:

1 Define and set up your System object. See "Construction" on page 5-770.

2 Call step to compute the minimum according to the properties of dsp.Minimum. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.Minimum returns an object, H, that computes the value and/or index of the minimum elements in an input or a sequence of inputs over the specified Dimension.

H = dsp.Minimum('*PropertyName*',*PropertyValue*,...) returns a minimum-finding object, H, with each specified property set to the specified value.

Properties   **ValueOutputPort**

Output minimum value

Set this property to true in order to output the minimum value of the input. This property applies only when you set theRunningMinimum property to false. The default is true.

RunningMinimum

Calculate over single input or multiple inputs

When you set this property to true, the object computes the minimum value over successive calls to the step method. When you set this property to false, the object computes the minimum value over the current input. The default is false.

IndexOutputPort

Output index of minimum value

Set this property to `true` to output the index of the minimum value of the input. This property applies only when you set the `RunningMinimum` property to `false`. The default is `true`.

ResetInputPort

Additional input to enable resetting of running minimum

Set this property to `true` to enable resetting of the running minimum. When you set this property to `true`, you must specify a reset input to the `step` method to reset the running minimum. This property applies only when you set the `RunningMinimum` property to `true`. The default is `false`.

ResetCondition

Condition that triggers resetting of running minimum

Specify the event that resets the running minimum as one of | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero` |. This property applies only when you set the `ResetInputPort` property to `true`. The default is `Non-zero`.

IndexBase

Numbering base for index of minimum value

Specify the numbering used when computing the index of the minimum value as starting from either `One` or `Zero`. This property applies only when you set the `IndexOutputPort` property to `true`. The default is `One`.

Dimension

Dimension to operate along

Specify how the minimum calculation is performed over the data as one of | `All` | `Row` | `Column` | `Custom` |. This property applies when you set the `RunningMinimum` property to `false`. The default is `Column`.

CustomDimension

Numerical dimension to calculate over

Specify the integer dimension of the input signal over which the object finds the minimum. The cannot exceed the number of dimensions in the input signal. This property only applies when you set the `Dimension` property to `Custom`. The default is `1`.

ROIProcessing

Enable region-of-interest processing

Set this property to `true` to enable calculation of the minimum value within a particular region of an image. This property applies when you set the `Dimension` property to `All` and the `RunningMinimum` property to `false`. The default is `false`.

For full ROI processing support, install the Computer Vision System Toolbox product. If you only have the DSP System Toolbox product installed, you can only specify the value of the `ROIForm` property as `Rectangles`.

ROIForm

Type of region of interest

Specify the type of region of interest as one of | `Rectangles` | `Lines` | `Label matrix` | `Binary mask` |. This property applies only when you set the `ROIProcessing` property to `true`. The default is `Rectangles`.

For full ROI processing support, install the Computer Vision System Toolbox product. If you have only the DSP System Toolbox product installed, you can only specify the as `Rectangles`.

ROIPortion

Calculate over entire ROI or just perimeter

Specify whether to calculate the minimum over the `Entire ROI` or the `ROI perimeter`. This property applies only when you set the `ROIForm` property to `Rectangles`. The default is `Entire ROI`.

ROIStatistics

Calculate statistics for each ROI or one for all ROIs

Specify whether to calculate `Individual statistics for each ROI` or a `Single statistic for all ROIs`. This property applies only when you set the `ROIForm` property to `Rectangles`, `Lines`, or `Label matrix`.

ValidityOutputPort

Output flag indicating if any part of ROI is outside input image

When you set the `ROIForm` property to `Lines` or `Rectangles`, set this property to `true` to return the validity of the specified ROI being completely inside of the image. When you set the `ROIForm` property to `Label Matrix`, set this property to `true` to return the validity of the specified label numbers. The default is `false`.

FrameBasedProcessing

Process input as frames or samples

Set this property to `true` to enable frame-based processing for 2-D inputs. Set this property to `false` to enable sample-based processing. The object always performs sample-based processing for N-D inputs where N is greater than 2. This property applies when you set the `RunningMinimum` to `true`. The default is `true`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`.

OverflowAction

Action to take when integer input is out-of-range

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

ProductDataType

Data type of product

Specify the product fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when you set the AccumulatorDataType property to Custom. The default is numerictype([],32,30).

AccumulatorDataType

Data type of accumulator

Specify the accumulator fixed-point data type as one of | Same as product | Same as input | Custom |. The default is Same as product.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when you set the AccumulatorDataType property to Custom. The default is numerictype([],32,30).

Methods	clone	Create minimum-finding object with same property values
	getNumInputs	Number of expected inputs to step method
	getNumOutputs	Number of outputs of step method

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of minimum-finding object
step	Operate on inputs to calculate outputs

Examples   Find a minimum value and its index:

```
hmin1 = dsp.Minimum;
x = randn(100,1);
[y, I] = step(hmin1, x);
```

Compute a running minimum:

```
hmin2 = dsp.Minimum;
hmin2.RunningMinimum = true;
x = randn(100,1);
y = step(hmin2, x);
% y(i) is the minimum of all values in the vector x(1:i)
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Minimum block reference page. The object properties correspond to the block parameters, except:

Treat sample-based row input as a column block parameter is not supported by the dsp.Minimum object.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the FrameBasedProcessing property. The block uses the **Input**

dsp.Minimum

processing parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also   dsp.Maximum | dsp.Mean

Purpose   Create minimum-finding object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a Minimum object C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

dsp.Minimum.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
the step method.

The getNumInputs method returns a positive integer that is the number
of expected inputs (not counting the object itself) to the step method.
This value will change if you alter any properties that turn inputs on or
off. You must call the step method with the number of input arguments
equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
method.

The getNumOutputs method returns a positive integer that is the
number of outputs from the step method. This value will change if you
alter any properties that turn outputs on or off.

dsp.Minimum.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the Minimum object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.Minimum.reset

Purpose   Reset internal states of minimum-finding object

Syntax   reset(H)

Description reset(H) sets the internal states of the Minimum object H to their initial values.

Purpose   Operate on inputs to calculate outputs

Syntax   ```
[VAL,IND] = step(H,X)
VAL = step(H,X)
IND = step(H,X)
VAL = step(H,X,R)
[...] = step(H,I,ROI)
[...] = step(H,I,LABEL,LABELNUMBERS)
[...,FLAG] = step(H,I,ROI)
[...,FLAG] = step(H,I,LABEL,LABELNUMBERS)
```

**Description**   [VAL,IND] = step(H,X) returns the minimum value, VAL, and the
index or position of the minimum value, IND, along the specified
Dimension of X.

VAL = step(H,X) returns the minimum value, VAL, of the input X.
When the RunningMinimum property is true, VAL corresponds to the
minimum value over successive calls to the step method.

IND = step(H,X) returns the zero- or one-based index IND of the
minimum value when the IndexOutputPort property is true and the
ValueOutputPort property is false. You must set the RunningMinimum
property to false to use this syntax.

VAL = step(H,X,R) resets the state of H based on the value of reset
signal, R, and the ResetCondition property. To enable this type
of processing, set the RunningMinimum property to true and the
ResetInputPort property to true.

[...] = step(H,I,ROI) computes the minimum of an input image,
I, within the given region of interest, ROI. To enable this type of
processing, set the ROIProcessing property to true and the ROIForm
property to Lines, Rectangles or Binary mask.

[...] = step(H,I,LABEL,LABELNUMBERS) computes the minimum
of an input image, I, for a region whose labels are specified in the
vector LABELNUMBERS. This property applies only when you set the
ROIProcessing property to true and the ROIForm property to Label
matrix.

[...,FLAG] = step(H,I,ROI) returns FLAG, indicating hether the given region of interest is within the image bounds. To enable this type of processing, set the ROIProcessing and ValidityOutputPort properties to true and the ROIForm property to Lines, Rectangles or Binary mask.

[...,FLAG] = step(H,I,LABEL,LABELNUMBERS) returns FLAG, indicating whether the input label numbers are valid. To enable this type of processing, set the ROIProcessing and ValidityOutputPort properties to true and the ROIForm property to Label matrix.

For full ROI processing support, install the Computer Vision System Toolbox product. If you have only the DSP System Toolbox product installed, you can only specify the value of the ROIForm property as Rectangles.

**Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

**Purpose**          Read video frames, audio samples, or both from multimedia file

---

**Note** `MultimediaFileReader` will be removed in a future release. Use `AudioFileReader` instead. See `dsp.AudioFileReader`.

---

**Description**      The `MultimediaFileReader` object reads video frames, audio samples, or both from a multimedia file.

To read video frames, audio samples, or both from a multimedia file:

**1** Define and set up your multimedia file reader. See "Construction" on page 5-785.

**2** Call `step` to read from a multimedia file according to the properties of `signalblks.MultimediaFileReader`. The behavior of `step` is specific to each object in the toolbox.

**Construction**     `H = signalblks.MultimediaFileReader` returns a multimedia file reader System object, `H`, to read video and/or audio from a multimedia file.

`H = signalblks.MultimediaFileReader('`*PropertyName*`',`*PropertyValue*`,...)` returns a multimedia file reader System object, `H`, with each specified property set to the specified value.

`H = signalblks.MultimediaFileReader(FILENAME,'`*PropertyName*`',`*PropertyValue*`,` returns a multimedia file reader System object, `H`, with `Filename` property set to *FILENAME* and other specified properties set to the specified values.

**Properties**       **Filename**

Name of multimedia file from which to read

Specify the name of a multimedia file as a string. Specify the full path for the file only if the file is not on the MATLAB path. On UNIX platforms, the multimedia file reader only supports uncompressed AVI files. The default is `speech_dft.avi`.

**PlayCount**

Number of times to play file

Specify a positive integer or `inf` to represent the number of times to play the file. The default is `inf`.

**AudioOutputPort**

Choose to output audio data

Use this property to control the audio output from the multimedia file reader. This property applies only when a multimedia file contains both audio and video streams. The default is `true`.

**VideoOutputPort**

Choose to output video data

Use this property to control the video output from the multimedia file reader. This property only applies when a multimedia file contains both audio and video streams. The default is `false`.

**SamplesPerAudioFrame**

Number of samples per audio frame

Specify the number of samples per audio frame as a positive scalar integer value. This property applies when the multimedia file contains only audio data. The default is `1024`.

**ImageColorSpace**

Choose whether output is RGB, intensity, or YCbCr

Specify whether you want the multimedia file reader to output `RGB`, `Intensity`, or `YCbCr 4:2:2` video frames. This property applies only when the multimedia file contains video. The default is `RGB`.

**VideoOutputDataType**

Data type of video data output

Set the data type of the video data output from the multimedia file reader. The multimedia file reader supports the following output data types: `double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32` or `Inherit`. This property applies if the multimedia file contains video. The default is `single`.

**AudioOutputDataType**

Data type of audio samples output

Set the data type of the audio data output from the multimedia file reader. The multimedia file reader supports the following output data types: `double`, `single`, `int16`, `uint8`. This property applies only if the multimedia file contains audio. The default is `int16`.

**Methods**

| | |
|---|---|
| clone | Create multimedia file reader object with same property values |
| close | Release resources |
| getNumInputs | Number of expected inputs to step method |
| getNumOutputs | Number of outputs of step method |
| info | Information about specific multimedia file |
| isDone | End-of-file status (logical) |
| isLocked | Locked status for input attributes and nontunable properties |

# signalblks.MultimediaFileReader

| | |
|---|---|
| reset | Reset internal states of multimedia file reader to read from beginning of file |
| step | Output one frame of video frames, audio samples, or both to multimedia signal |

**Examples**

Read an audio file and play the file back using the standard audio output device:

```
hmfr = signalblks.MultimediaFileReader('speech_dft.avi');
hap = dsp.AudioPlayer('SampleRate', 22050);
while ~isDone(hmfr)
audio = step(hmfr);
step(hap, audio);
end
close(hmfr); % close the input file
close(hap); % close the audio output device
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the From Multimedia File block reference page. The object properties correspond to the block parameters, except:

- The object has no corresponding property for the **Inherit sample time from file** block parameter. The object always inherits the sample time from the file.

- The object has no corresponding property for the **Output end-of-file indicator** parameter. The object always outputs EOF as the last output.

- The **Multimedia outputs** block parameter corresponds to both the AudioOutputPort and the VideoOutputPort object properties.

- The object has no corresponding property for the **Image signal** block parameter. The object always outputs an *M*-by-*N*-by-*P* color video signal.

See Also   signalblks.MultimediaFileWriter

signalblks.MultimediaFileReader.clone

Purpose Create multimedia file reader object with same property values

---

Note `MultimediaFileReader` will be removed in a future release. Use `AudioFileReader` instead. See `dsp.AudioFileReader.clone`.

Syntax `C = clone(H)`

Description `C = clone(H)` creates a `MultimediaFileReader` System object `C`, with the same property values as `H`.

The clone method creates a new unlocked object with uninitialized states.

Purpose   Release resources

> **Note** `MultimediaFileReader` will be removed in a future release. Use `AudioFileReader` instead. See `dsp.AudioFileWriter.release` .

Syntax   `close(H)`

Description   `close(H)` releases system resources (such as memory, file handles or hardware connections).

Purpose   Number of expected inputs to step method

> **Note** `MultimediaFileReader` will be removed in a future release. Use
> `AudioFileReader` instead. See `dsp.AudioFileReader.getNumInputs`.

Syntax   `N = getNumInputs(H)`

Description   `N = getNumInputs(H)` returns the number of outputs, N, to the `step`
                     method

                     The `getNumInputs` method returns a positive integer that is the number
                     of expected inputs (not counting the object itself) to the `step` method.
                     This value will change if you alter any properties that turn inputs on or
                     off. You must call the `step` method with the number of input arguments
                     equal to the result of `getNumInputs(H)`.

signalblks.MultimediaFileReader.getNumOutputs

Purpose   Number of outputs of step method

> **Note** MultimediaFileReader will be removed in a future release. Use
> AudioFileReader instead. See dsp.AudioFileReader.getNumOutputs.

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
method

The getNumOutputs method returns a positive integer that is the
number of outputs from the step method. This value will change if you
alter any properties that turn outputs on or off.

signalblks.MultimediaFileReader.info

Purpose   Information about specific multimedia file

> **Note** `MultimediaFileReader` will be removed in a future release. Use
> `AudioFileReader` instead. See `dsp.AudioFileReader.info`.

Syntax   `S = info(H)`

Description `S = info(H)` returns a MATLAB structure, `S`, with information about
the multimedia file specified in the `Filename` property. The number
of fields for `S` varies depending on the audio or video content of the
file. The possible fields and values for the structure `S` are shown in
the following table.

Field	Value
Audio	Logical value indicating if the file has audio content.
Video	Logical value indicating if the file has video content.
AudioSampleRate	Audio sampling rate of the multimedia file in hertz. This field is available when the file has audio content.
AudioNumBits	Number of bits used to encode the audio stream. This field is available when the file has audio content.
AudioNumChannels	Number of audio channels. This field is available when the file has audio content.
FrameRate	Frame rate of the video stream in frames per second. The value may vary from the actual frame rate of the recorded video, and considers any synchronization issues between audio and video streams when the file contains both audio and video content. This variation indicates that video frames may be dropped if the audio stream leads the video stream by more than 1/(actual video frames per second). This field is available when the file has video content.

Field	Value
VideoSize	Video size as a two-element numeric vector of the form [VideoWidthInPixels, VideoHeightInPixels]. This field is available when the file has video content.
VideoFormat	Video signal format. This field is available when the file has video content.

signalblks.MultimediaFileReader.isDone

Purpose   End-of-file status (logical)

Note `MultimediaFileReader` will be removed in a future release. Use
`AudioFileReader` instead. See `dsp.AudioFileReader.isDone`.

Syntax   STATUS = isDone(H)

Description   STATUS = isDone(H) returns a logical value, STATUS , when the
`MultimediaFileReader` object, H , reaches the end of the multimedia
file. If you set the `PlayCount` property to a value greater than 1 , STATUS
is `true` each time the object reaches the end of the file. STATUS is the
same as the EOF output value in the process method syntax.

Purpose   Locked status for input attributes and nontunable properties

> **Note** MultimediaFileReader will be removed in a future release. Use
> AudioFileReader instead. See dsp.AudioFileReader.isLocked.

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the MultimediaFileReader
object.

The isLocked method returns a logical value that indicates whether
input attributes and nontunable properties for the object are locked. The
object performs an internal initialization the first time the step method
is executed. This initialization locks nontunable properties and input
specifications, such as dimensions, complexity, and data type of the
input data. After locking, the isLocked method returns a true value.

signalblks.MultimediaFileReader.reset

Purpose   Reset internal states of multimedia file reader to read from beginning of file

---

Note MultimediaFileReader will be removed in a future release. Use AudioFileReader instead. See dsp.AudioFileReader.reset.

Syntax   reset(H)

Description reset(H) resets the MultimediaFileReader object to read from the beginning of the file.

Purpose   Output one frame of video frames, audio samples, or both to multimedia signal

---

Note `MultimediaFileReader` will be removed in a future release. Use `AudioFileReader` instead. See `dsp.AudioFileReader.step`.

Syntax   AUDIO = step(H)
I = step(H)
[I,AUDIO] = step(H)
[...,EOF] = step(H)
[Y,CB,CR] = step(H)
[Y,CB,CR,AUDIO] = step(H)

Description AUDIO = step(H) outputs one frame of audio samples, AUDIO. This behavior requires the AudioOutputPort property to be true and an input file that contains audio data. After the object plays the file the number of times PlayCount specifies, AUDIO contains silence.

I = step(H) outputs one frame of multidimensional video signal, I. To obtain this behavior, set the VideoOutputPort property to true and use an input file that contains video data.

[I,AUDIO] = step(H) outputs one frame of multidimensional video signal, I , and one frame of audio samples, AUDIO . This behavior requires the AudioOutputPort and VideoOutputPort properties to be true and an input file that contains audio and video data.

[...,EOF] = step(H) gives the end-of-file indicator in EOF. EOF is true each time the output contains the last audio sample and/or video frame in the file.

[Y,CB,CR] = step(H) outputs one frame of YCbCr 4:2:2 video data in the color components Y, CB, and CR. This behavior applies when you set the VideoOutputPort property to true, the ImageColorSpace property to YCbCr 4:2:2, and an input file which contains video data.

[Y,CB,CR,AUDIO] = step(H) outputs one frame of YCbCr 4:2:2 video data in the color components Y, CB, and CR, and one frame of audio samples in AUDIO. This applies when you set the AudioOutputPort and VideoOutputPort properties to true, the ImageColorSpace property to YCbCr 4:2:2, and an input file which contains audio and video data.

Note The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

Purpose   Write video frames, audio samples, or both to multimedia file

> **Note** `MultimediaFileWriter` will be removed in a future release. Use `AudioFileWriter` instead. See `dsp.AudioFileWriter`.

Description   The `MultimediaFileWriter` object writes video frames, audio samples, or both to a multimedia file.

To write video frames, audio samples, or both to a multimedia file:

1 Define and set up your multimedia file writer. See "Construction" on page 5-801.

2 Call `step` to write to a multimedia file according to the properties of `signalblks.MultimediaFileWriter`. The behavior of `step` is specific to each object in the toolbox.

Construction   `H = signalblks.MultimediaFileWriter` returns a multimedia file writer System object, `H`, that writes video frames, audio samples, or both to a multimedia file (such as an `AVI` file).

`H = signalblks.MultimediaFileWriter('`*PropertyName*`',`*PropertyValue*`,...)` returns a multimedia file writer System object, `H`, with each specified property set to the specified value.

`H = signalblks.MultimediaFileWriter(`*FILENAME*`,'`*PropertyName*`',`*PropertyValue*`` returns a multimedia file writer System object, `H`, with `Filename` property set to *FILENAME* and other specified properties set to the specified values.

Properties   **Filename**

Name of multimedia file to which to write

Specify the name of the multimedia file as a string. The default is `output.avi`.

FileFormat

Multimedia file format

Specify which multimedia file format the object writes. On Microsoft platforms, select `AVI`, `WAV`, `WMV`, or `WMA`. These abbreviations correspond to the following file formats:

- WAV: Microsoft WAVE Files

- WMV: Windows Media Video

- WMA: Windows Media Audio

- AVI: Audio-Video Interleave

The default setting for this property is AVI.

On all other platforms, the only selection is AVI.

AudioInputPort

Choose to write audio data

Use this property to specify whether the multimedia file writer object writes audio samples to a multimedia file. When you enable both this property and `VideoInputPort`, ensure that the video and audio input signals have the same frame period. Adjust the frame size (or number of rows) of the audio signal so that the frame period of the video signal is the same as the frame period of the audio signal. Calculate frame size by dividing the audio signal frequency by the frame rate of the video signal. The audio signal frequency is in samples per second (specified by `SampleRate`). The video signal frame rate is in frames per second (specified by `FrameRate`). The default selection for this property is `true`.

The multimedia file object takes a column vector as an input. Every column is a separate channel and each row corresponds to a single audio sample.

VideoInputPort

Choose to write video data

Use this property to specify whether the multimedia file writer object writes video frames to a multimedia file. When you enable both this property and the AudioInputPort property, ensure that the video and audio input signals have the same frame period. Adjust frame size (or number of rows) for the audio signal so the frame period is equal of both the video signal and the audio signal. Calculate frame size by dividing the audio signal frequency by the frame rate of the video signal. The audio signal frequency is in samples per second (specified by SampleRate). The video signal frame rate is in frames per second (specified by FrameRate). The default selection for this property is false

AudioCompressor

Algorithm that compresses audio data

Specify the type of compression algorithm the multimedia file writer uses to compress the audio data. Compression reduces the size of the multimedia file. Select None (uncompressed) to save uncompressed audio data to a multimedia file. The other options available reflect the audio compression algorithms installed on your system. This property is only available when writing WAV or AVI files on Windows platforms.

VideoCompressor

Algorithm that compresses video data

Specify the type of compression algorithm to multimedia file writer uses to compress the video data. This compression reduces the size of the multimedia file. Choose None (uncompressed) to save uncompressed video data to a multimedia file. The other options reflect the available video compression algorithms installed on your system. This property is only available when writing AVI files on Windows platforms.

SampleRate

Sampling rate of audio data stream

Specify the sampling rate of the input audio data as a positive numeric scalar. The default is 44100. This property only applies when you set the AudioInputPort property to true.

FrameRate

Frame rate of video data stream

Specify the frame rate of the video data in frames per second as a positive numeric scalar. The default is 30. This property only applies when you set the VideoInputPort property to true.

AudioDataType

Data type of the uncompressed audio

Specify the type of uncompressed audio data written to the file. This property only applies when writing uncompressed WAV files.

FileColorSpace

Color space to use when creating a file

Specify the color space of AVI files as RGB or YCbCr 4:2:2. This property only applies on Windows platforms when you set the FileFormat property to AVI. The default is RGB.

Methods	clone	Create multimedia file writer object with the same property values
	close	Release resources
	getNumInputs	Number of expected inputs to step method
	getNumOutputs	Number of outputs of step method

isLocked	Locked status for input attributes and nontunable properties
step	Write one frame of audio output samples

Examples   Decimate an audio signal, and write signal to disk as an AVI file:

```
hmfr = signalblks.MultimediaFileReader...
   ('AudioOutputDataType','double');
hfirdec = dsp.FIRDecimator; % decimate by 2
hmfw = signalblks.MultimediaFileWriter...
   ('speech_dft_11025.avi', ...
   'SampleRate', 22050/2);

while ~isDone(hmfr)
    audio = step(hmfr);
    audiod = step(hfirdec, audio);
    step(hmfw, audiod);
end

close(hmfr);
close(hmfw);
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the To Multimedia File block reference page. The object properties correspond to the block parameters, except:

- The **Write** block parameter corresponds to both the AudioOutputPort and the VideoOutputPort object properties.

- The FrameRate and SampleRate properties are not available on the block. The block inherits these signals from the input line connected to the ports.

signalblks.MultimediaFileWriter

See Also   signalblks.MultimediaFileReader

5-806

Purpose   Create multimedia file writer object with the same property values

---

Note MultimediaFileWriter will be removed in a future release. Use AudioFileWriter instead. See dsp.AudioFileWriter.clone.

Syntax   C = clone(H)

Description   C = clone(H) creates a MultimediaFileWriter System object C, with the same property values as H. The clone method creates a new unlocked object.

signalblks.MultimediaFileWriter.close

Purpose   Release resources

> **Note** MultimediaFileWriter will be removed in a future release. Use
> AudioFileWriter instead. See dsp.AudioFileWriter.release.

Syntax   close(H)

Description close(H) releases system resources (such as memory, file handles or
hardware connections).

Purpose   Number of expected inputs to step method

> **Note** MultimediaFileWriter will be removed in a future release. Use
> AudioFileWriter instead. See dsp.AudioFileWriter.getNumInputs.

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, of
                   the step method

                   The getNumInputs method returns a positive integer that is the number
                   of expected inputs (not counting the object itself) to the step method.
                   This value will change if you alter any properties that turn inputs on or
                   off. You must call the step method with the number of input arguments
                   equal to the result of getNumInputs(*H*).

signalblks.MultimediaFileWriter.getNumOutputs

Purpose   Number of outputs of step method

> **Note** `MultimediaFileWriter` will be removed in a future release. Use
> `AudioFileWriter` instead. See `dsp.AudioFileWriter.getNumOutputs`.

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the `step`
method.

The `getNumOutputs` method returns a positive integer that is the
number of outputs from the `step` method. This value will change if you
alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

---

Note MultimediaFileWriter will be removed in a future release. Use AudioFileWriter instead. See dsp.AudioFileWriter.isLocked.

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the MultimediaFileWriter System object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

signalblks.MultimediaFileWriter.step

Purpose   Write one frame of audio output samples

> **Note** `MultimediaFileWriter` will be removed in a future release. Use
> `AudioFileWriter` instead. See `dsp.AudioFileWriter.step`.

Syntax
```
step(H,AUDIO)
step(H,I)
step(H,I,AUDIO)
step(H,Y,Cb,Cr)
step(H,Y,CB,CR)
step(H,Y,CB,CR,AUDIO)
```

Description   `step(H,AUDIO)` writes one frame of audio samples, `AUDIO` , to the output
file when you enable the `AudioInputPort` property. `AUDIO` is either a
vector or an M-by-2 matrix for mono or stereo inputs, respectively.

`step(H,I)` writes one frame of video, `I` , to the output file when you
enable the `VideoInputPort` property. `I` is an M-by-N-by-3 color video
signal.

`step(H,I,AUDIO)` writes one frame of video, `I` , and one frame of
audio samples, `AUDIO` , to the output file when you enable both the
`AudioInputPort` and `VideoInputPort` properties.

`step(H,Y,Cb,Cr)` writes one frame of video with Y, Cb, Cr components
to the file. This applies only when you set the `FileColorSpace` property
to `YCbCr 4:2:2`

`step(H,Y,CB,CR)` writes one frame of `YCbCr 4:2:2` data in the
color components Y, CB, and CR, to the output file when you set the
`VideoInputPort` property to `true`. The width of CB and CR must be
half of the width of Y, and the value of the `FileColorSpace` property
must be set to `YCbCr 4:2:2`.

`step(H,Y,CB,CR,AUDIO)` writes one frame of `YCbCr 4:2:2` data in
the color components Y, CB, and CR, and one frame of audio samples,
AUDIO, to the output file when you set both the `AudioInputPort` and

`VideoInputPort` properties to `true`. The width of `CB` and `CR` must be half of the width of `Y`, and the value of the `FileColorSpace` property must be set to `YCbCr 4:2:2`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.NCO

Purpose	Generate real or complex sinusoidal signals
Description	The numerically controlled oscillator, or NCO, object generates real or complex sinusoidal signals. The amplitude of the generated signal is always 1.

To generate real or complex sinusoidal signals:

1 Define and set up your NCO System object. See "Construction" on page 5-814.

2 Call step to generate the signals according to the properties of dsp.NCO. The behavior of step is specific to each object in the toolbox.

Construction	H = dsp.NCO returns an NCO System object, H, that generates a multichannel real or complex sinusoidal signal, with independent frequency and phase in each output channel.

H = dsp.NCO('*PropertyName*',*PropertyValue*,...) returns an NCO System object, H, with each specified property set to the specified value.

Properties **PhaseIncrementSource**

Source of phase increment

Indicate how to specify the phase increment: Property or Input port. The default is Input port.

PhaseIncrement

Phase increment

Specify the phase increment as an integer scalar. This property applies only when you set the PhaseIncrementSource property to Property. The default is 100.

PhaseOffsetSource

Source of phase offset

Specify the phase offset as `Property` or `Input port`. The default is `Property`.

PhaseOffset

Phase offset

Specify the phase offset as an integer scalar. This property applies only when you set the `PhaseOffsetSource` property to `Property`. The default is `0`.

Dither

Enable adding internal dithering to NCO algorithm

Set this property to `true` to add internal dithering to the NCO algorithm. Dithering is added using the PN Sequence Generator from the Communications System Toolbox product. The default is `true`.

NumDitherBits

Number of dither bits

Specify the number of dither bits as a positive integer. This property applies only when you set the `Dither` property to `true`. The default is `4`.

PhaseQuantization

Enable quantization of accumulated phase

Set this property to `true` to enable quantization of the accumulated phase. The default is `true`.

NumQuantizerAccumulatorBits

Number of quantizer accumulator bits

Specify the number of quantizer accumulator bits as an integer scalar greater than 1 and less than the accumulator word length. This property determines the number of entries in the lookup table of sine values. This property applies only when you set the `PhaseQuantization` property to `true`. The default is `12`.

PhaseQuantizationErrorOutputPort

Enable output of phase quantization error

Set this property to `true` to output the phase quantization error. This property applies only when you set the `PhaseQuantization` property to `true`. The default is `false`.

Waveform

Type of output signal

Specify the type of the output signal: `Sine`, `Cosine`, `Complex exponential` or `Sine and cosine`. The default is `Sine`.

SamplesPerFrame

Number of output samples per frame

Specify the number of samples per frame of the output signal. This property applies only when you set the `PhaseOffsetSource` property to `Property`. The default is 1. When the `PhaseOffsetSource` property is `Input port`, and the `PhaseIncrementSource` property is `Property`, the number of rows or frame size of the phase offset input determines the number of samples per frame of the output signal. When you set both the `PhaseOffsetSource` and `PhaseIncrementSource` properties to `Input port`, the number of rows in the inputs must be 1, and the samples per frame of the output signal is 1.

OutputDataType

Output data type

Specify the output data type as one of `double`, `single` or `Custom`. The default is `Custom`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

This constant property has a value `Floor`.

OverflowAction

Overflow action for fixed-point operations

This constant property has a value `Wrap`.

AccumulatorDataType

Accumulator word and fraction lengths

This constant property has a value `Custom`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as an unscaled `numerictype` object with a `Signedness` of `Auto`. The default is `numerictype([],16)`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,14)`.

Methods

clone	Create NCO object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
info	Characteristic information about generated signal

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset accumulator of NCO object
step	Sinusoidal signal with specified phase increment

Examples   Design an NCO source according to given specifications:

```
F0 = 510; % Output frequency = 510 Hz
df = 0.05; % Frequency resolution = 0.05 Hz
minSFDR = 96; % Spurious free dynamic range >= 96 dB
Ts = 1/8000; % Sample period = 1/8000 sec
dphi = pi/2; % Desired phase offset = pi/2;
```

Calculate number of accumulator bits required for the given frequency resolution

```
Nacc = ceil(log2(1/(df*Ts)));
% Actual frequency resolution achieved
actdf = 1/(Ts*2^Nacc);
% Calculate number of quantized accumulator bits
% required from the SFDR requirement
Nqacc = ceil((minSFDR-12)/6);
% Calculate the phase increment
phIncr = round(F0*Ts*2^Nacc);
% Calculate the phase offset
phOffset = 2^Nacc*dphi/(2*pi);

hnco = dsp.NCO('PhaseIncrementSource', 'Property', ...
'PhaseIncrement', phIncr,...
'PhaseOffset', phOffset,...
'NumDitherBits', 4, ...
'NumQuantizerAccumulatorBits', Nqacc,...
```

```
'SamplesPerFrame', 1/Ts, ...
'CustomAccumulatorDataType', numerictype([],Nacc));

y = step(hnco);
% Plot the mean-square spectrum of the 510 Hz sinewave
% generated by the NCO
sperd = spectrum.periodogram('hann'); ...
sperd.SamplingFlag = 'periodic';
msspectrum(sperd,double(y),'Fs',1/Ts);
```

Algorithms This object implements the algorithm, inputs, and outputs described on the NCO block reference page. The object properties correspond to the block properties, except:

There is no object property that corresponds to the **Sample time** block parameter. The objects assumes a sample time of one second.

See Also dsp.SineWave

dsp.NCO.clone

Purpose   Create NCO object with same property values

Syntax   C = clone(H)

Description C = clone(H) creates an NCO system object C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs to the
                     step method.

                     The getNumInputs method returns a positive integer that is the number
                     of expected inputs (not counting the object itself) to the step method.
                     This value will change if you alter any properties that turn inputs on or
                     off. You must call the step method with the number of input arguments
                     equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   `N = getNumOutputs(H)`

Description   `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Characteristic information about generated signal

Syntax   S = info(H)

Description S = info(H) returns a structure containing characteristic information, S, about the signal being generated by the NCO System object, H. The number of fields of S, and their values vary depending on the property value settings of H. For description of the possible fields and their values, see the following table.

Field	Value
NumPointsLUT	Number of data points for lookup table. The lookup table is implemented as a quarter-wave sine table.
SineLUTSize	Quarter-wave sine lookup table size in bytes.
TheoreticalSFDR	Theoretical spurious free dynamic range (SFDR) in dBc. This field applies when you set the PhaseQuantization property to true.
FrequencyResolution	Frequency resolution of the NCO in Hz. The sample time of the output signal is assumed to be 1 sec.

dsp.NCO.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the NCO System object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description   release(H) releases system resources, such as memory, file handles,
                   and hardware connections, and lets you change any properties or input
                   characteristics.

> **Note** You can use the release method on a System object in code
> generated from MATLAB, but once you release its resources, you cannot
> use that System object again.

Purpose   Reset accumulator of NCO object

Syntax   reset(H)

Description reset(H) resets the accumulator of the NCO System object, H, to zero.

Purpose   Sinusoidal signal with specified phase increment

Syntax   Y = step(H,INC)
               Y = step(H)
               Y = step(H,OFFSET)
               Y = step(H,INC,OFFSET)
               [Y, QERR] = step(H,...)

Description Y = step(H,INC) returns a sinusoidal signal, Y , generated by the NCO
               with the specified phase increment, INC. INC must be a built-in integer
               or a fi object comprising either a scalar or a row vector, where each row
               element corresponds to a separate channel.

               Y = step(H) when the PhaseIncrementSource and
               PhaseOffsetSource properties are both Property, returns a
               sinusoidal signal, Y.

               Y = step(H,OFFSET) returns a sinusoidal signal, Y, with phase offset,
               OFFSET, when the PhaseOffsetSource property is Input port. OFFSET
               must be a built-in integer or a fi object. The number of rows of OFFSET
               determines the number of samples per frame of the output signal. The
               number of columns of the OFFSET determines the number of channels
               of the output signal.

               Y = step(H,INC,OFFSET) returns a sinusoidal signal, Y, with
               phase increment, INC, and phase offset, OFFSET, when the
               PhaseIncrementSource and the PhaseOffsetSource properties are
               both Input port. INC and OFFSET must both be row vectors of the
               same length, where the length determines the number of channels in
               the output signal.

               [Y, QERR] = step(H,...) when the PhaseQuantization and the
               PhaseQuantizationErrorOutputPort properties are both true, returns
               a sinusoidal signal, Y, and output quantization error, QERR.

> **Note** The object performs an initialization the first time the step
> method is executed. This initialization locks nontunable properties and
> input specifications, such as dimensions, complexity, and data type
> of the input data. If you change a nontunable property or an input
> specification, the System object issues an error. To change nontunable
> properties or inputs, you must first call the release method to unlock
> the object.

Purpose   Vector normalization along specified dimension

Description The Normalizer object performs vector normalization along rows, columns, or specified dimension.

To perform vector normalization:

1 Define and set up your normalization object. See "Construction" on page 5-829.

2 Call step to perform vector normalization according to the properties of dsp.Normalizer. The behavior of step is specific to each object in the toolbox.

Construction H = dsp.Normalizer returns a normalization object, H, that normalizes the input over each column by the squared 2-norm of the column plus a bias term of 1e-10 used to protect against divide-by-zero.

H = dsp.Normalizer('*PropertyName*',*PropertyValue*, ...) returns a normalization object, H, with each property set to the specified value.

Properties **Method**

Type of normalization to perform

Specify the type of normalization to perform as 2-norm or Squared 2-norm. The 2-norm mode supports floating-point signals only. The Squared 2-norm supports both fixed-point and floating-point signals. The default is Squared 2-norm.

Bias

Real number added in denominator to avoid division by zero

Specify the real number to add in the denominator to avoid division by zero. The default is 1e-10. This property is tunable.

Dimension

Dimension to operate along

Specify whether to normalize along `Column` , `Row`, or `Custom`. The default is `Column`.

CustomDimension

Numerical dimension to operate along

Specify the one-based value of the dimension over which to normalize. The value of this parameter cannot exceed the number of dimensions in the input signal. This property applies when `Dimension` property is `Custom`. The default is 1.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor` , `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Same as input` or `Custom`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default to `numerictype([],32,32)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Same as product`, `Same as input`, `Custom`. The default is `Same as product`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `Same as accumulator`, `Same as product`, `Same as input`, `Custom`. The default is `Same as product`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],32,32)`.

Methods

clone	Create normalization object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method

dsp.Normalizer

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Normalize input along specified dimension

Examples   Normalize a matrix:

```
hnorm = dsp.Normalizer;
x = magic(3);
y = step(hnorm, x);
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Normalization block reference page. The object properties correspond to the block parameters, except:

- **Treat sample-based row input as column** — The block allows you to input a row vector and normalize the row vector as a column vector. The normalization object always normalizes along the value of the Dimension property.

- The normalization object does not support the **Minimum** and **Maximum** options for data output.

See Also   dsp.ArrayVectorMultiplier

Purpose   Create normalization object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a normalizer object, C, with the same property
                   values. The clone method creates a new unlocked object.

dsp.Normalizer.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   `N = getNumInputs(H)` returns the number of expected inputs to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                    method.

                    The getNumOutputs method returns a positive integer that is the
                    number of outputs from the step method. This value will change if you
                    alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   `isLocked(H)`

Description   `isLocked(H)` returns the locked state of the normalization object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose	Normalize input along specified dimension
Syntax	Y = step(H,X)
Description	Y = step(H,X) returns a normalized outputY . The input X must be floating-point for the 2-norm mode, and either fixed-point and floating-point for the Squared 2-norm mode.

> **Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

Purpose   Determine extrema (maxima or minima) in input signal

Description The PeakFinder object determines the extrema (maxima or minima) in the input signal.

To compute the extrema in the input signal:

1 Define and set up your peak finder. See "Construction" on page 5-839.

2 Call step to compute the extrema according to the properties of dsp.PeakFinder. The behavior of step is specific to each object in the toolbox.

Construction H = dsp.PeakFinder returns a peak finder System object, H, that compares the current signal value to the previous and next values to determine if the current value is an extremum.

H = dsp.PeakFinder('*PropertyName*',*PropertyValue*,...) returns a peak finder System object, H, with each specified property set to the specified value.

Properties   **PeakType**

Looking for maxima, minima, or both

Specify whether the object is looking for maxima, minima, or both. You can set this property to oMaxima, Minima, Maxima and Minima. The default is Maxima and Minima.

PeakIndicesOutputPort

Enable output of extrema indices

Set this property to true to output the extrema indices. The default is false.

PeakValuesOutputPort

Enable output of extrema values

Set this property to true to output the extrema values. The default is false.

MaximumPeakCount

Number of extrema to look for in each input signal

The object stops searching the input signal for extrema after the maximum number of extrema has been found. The value of this property must be an integer greater than or equal to one. The default is 10.

IgnoreSmallPeaks

Enable ignoring peaks below threshold

Set this property to `true` if you want to eliminate the detection of peaks whose amplitudes are within a specified threshold of neighboring values. The default is `false`.

PeakThreshold

Threshold below which peaks are ignored

Specify the noise threshold value. This property defines the current input value as a maximum if:

- The current input value minus the previous input value is greater than the threshold, and

- The current input value minus next input value is greater than the threshold.

This property applies when you set the `IgnoreSmallPeaks` property to `true`. The default is 0.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

The rounding method is a constant property set to `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

Methods

clone	Create peak finder object with same property values
getNumInputs	Number of expected inputs to the step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Number of extrema in input signal

Examples

Determine whether each value of an input signal is local maximum or minimum:

```
hpeaks1 = dsp.PeakFinder;
hpeaks1.PeakIndicesOutputPort = true;
hpeaks1.PeakValuesOutputPort = true;

x1 = [9 6 10 3 4 5 0 12]';
% Find the peaks of each input
% [prev;cur;next]: {[9;6;10],[6;10;3],...}
[cnt1, idx1, val1, pol1] = step(hpeaks1, x1);
```

Determine peak values for a fixed-point input signal:

```
hpeaks2 = dsp.PeakFinder('PeakType', 'Maxima', ...
```

```
                     'PeakValuesOutputPort', true, ...
                     'MaximumPeakCount', 2, ...
                     'IgnoreSmallPeaks', true, ...
                     'PeakThreshold', 0.25, ...
                     'OverflowAction', 'Saturate');
                     x2 = fi([-1;0.5;0],true,16,15);
                     [cnt2, val2] = step(hpeaks2, x2);
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Peak Finder block reference page. The object properties correspond to the block parameters.

See Also   dsp.Maximum | dsp.Minimum

Purpose   Create peak finder object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a PeakFinder System object C, with the same
property values as H. The clone method creates a new unlocked object
with uninitialized states.

dsp.PeakFinder.getNumInputs

Purpose   Number of expected inputs to the step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs to the
                   step method.

                   The getNumInputs method returns a positive integer that is the number
                   of expected inputs (not counting the object itself) to the step method.
                   This value will change if you alter any properties that turn inputs on or
                   off. You must call the step method with the number of input arguments
                   equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   `N = getNumOutputs(H)`

Description   `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.PeakFinder.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the `PeakFinder` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.PeakFinder.step

Purpose	Number of extrema in input signal
Syntax	YCNT = step(H,X) [YCNT,IDX] = step(H,X) [..., VAL] = step(H,X) [..., POL] = step(H,X)
Description	YCNT = step(H,X) returns the number of extrema (minima, maxima, or both) YCNT in input signal X.

[YCNT,IDX] = step(H,X) when the PeakIndicesOutputPort property is true, returns the number of extrema YCNT and peak indices IDX in input signal X.

[..., VAL] = step(H,X) also returns the peak values VAL in input signal X when the PeakValuesOutputPort property is true.

[..., POL] = step(H,X) also returns the extrema polarity POL in input signal X when the PeakType property is Maxima and Minima and the PeakIndicesOutputPort property is true. The polarity is 1 for maxima and 0 for minima.

Note The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

Purpose   Peak-to-peak value

Description   The `PeakToPeak` object computes the peak-to-peak value of an input.

To obtain the peak-to-peak value:

1 Define and set up your peak-to-peak calculation. See "Construction" on page 5-849.

2 Call `step` to compute the peak-to-peak value for an input vector according to the properties of `dsp.PeakToPeak`. The behavior of `step` is specific to each object in the toolbox.

Construction   `H = dsp.PeakToPeak` creates a peak-to-peak System object, `H`, that computes the difference between the maximum and minimum value in an input or a sequence of inputs.

`H = dsp.PeakToPeak('`*PropertyName*`',`*PropertyValue*`,...)` returns an `PeakToPeak` System object, `H`, with each specified property set to the specified value.

Properties   **CustomDimension**

Dimension to operate along. Specify the dimension as a positive integer along which the peak-to-peak difference is computed. The value of this property cannot exceed the number of dimensions in the input signal. This property applies when the `Dimension` property is `'Custom'`.

Default: `1`

Dimension

Dimension to operate along. Specify the dimension along which to calculate the peak-to-peak ratio as one of `'All'`, `'Row'`, `'Column'`, or `'Custom'`. This property applies when the `RunningPeakToPeak` property is `false`. If you set this property to `'Custom'`, specify the dimension using the `CustomDimension` property.

Default: `'Column'`

FrameBasedProcessing

Process input in frames or as samples. Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. This property applies when the `RunningPeakToPeak` property is `true`.

Default: `true`

ResetCondition

Reset condition for running peak-to-peak mode. Specify the event to reset the running peak-to-peak as one of `'Rising edge'`, `'Falling edge'`, `'Either edge'`, or `'Non-zero'`. This property applies when the `ResetInputPort` property is `true`.

ResetInputPort

Enables resetting in running peak-to-peak mode. Set this property to `true` to enable resetting the running peak-to-peak. When the property is set to `true`, a reset input must be specified to the call of `step` to reset the running peak-to-peak difference. This property applies when the `RunningPeakToPeak` property is `true`.

Default: `false`

RunningPeakToPeak

Calculation over successive calls to `step`. Set this property to `true` to enable the calculation of the peak-to-peak difference over successive calls to the `step`.

Default: `false`

Methods

clone	Clones the current instance of the peak-to-peak object
getNumInputs	Number of expected inputs to the method
getNumOutputs	Number of outputs of the method
isLocked	Locked status (logical) for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset the running peak-to-peak object
step	Compute peak-to-peak value

Examples

Peak-to-Peak Value of Vector

Determine the peak-to-peak value for a vector input.

```
in1 = (1:10)';
h1 = dsp.PeakToPeak;
y1 = step(h1, in1);
```

Peak-to-Peak Value of Matrix Input

Determine the peak-to-peak value of a matrix input.

```
in2 = magic(4);
h2 = dsp.PeakToPeak;
h2.Dimension = 'All';
y2 = step(h2, in2)
```

References

dsp.PeakToPeak

See Also   dsp.Maximum **|** dsp.PeakToRMS **|**

Purpose   Clones the current instance of the peak-to-peak object

Syntax   clone(H)

Description   clone(H) clones the current instance of the peak-to-peak object, H.

dsp.PeakToPeak.getNumInputs

Purpose   Number of expected inputs to the `step` method

Syntax   `N = getNumInputs(H)`

Description   `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method for the peak-to-peak object `H`.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose   Number of outputs of the step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                   method for the peak-to-peak object, H.

                   The getNumOutputs method returns a positive integer that is the
                   number of outputs from the step method. This value will change if you
                   alter any properties that turn outputs on or off.

dsp.PeakToPeak.isLocked

Purpose   Locked status (logical) for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the peak-to-peak object H.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.PeakToPeak.reset

Purpose   Reset the running peak-to-peak object

Syntax   reset(H)

Description   reset(H) resets the running peak-to-peak value for the object H.

Purpose   Compute peak-to-peak value

Syntax   Y = step(H,X)
Y = step(H,X,R)

Description   Y = step(H,X) computes the peak-to-peak value, Y, of the floating-point input vector X. When the RunningPeakToPeak property is true, Y corresponds to the peak-to-peak value of the input elements over successive calls to the step method.

Y = step(H,X,R) computes the peak-to-peak value of the input elements over successive calls to the step method. The object optionally resets its state based on the reset input signal, R, and the value of the ResetCondition property. This is possible when you set both the RunningPeakToPeak and the ResetInputPort properties to true.

dsp.PeakToRMS

Purpose	Peak-to-root-mean-square value of vector

Description   The `PeakToRMS` object calculates the peak-to-root-mean-square ratio of a vector.

To compute the peak-to-root-mean-square ratio:

1 Define and set up your peak-to-root-mean-square calculation. See "Construction" on page 5-860.

2 Call `step` to calculate the peak-to-root-mean-square value for an input vector according to the properties of `dsp.PeakToRMS`. The behavior of `step` is specific to each object in the toolbox.

Construction   `H = dsp.PeakToRMS` creates a peak-to-root-mean-square System object, `H`, that returns the ratio of the maximum magnitude (peak) to the root-mean-square (RMS) value in an input or a sequence of inputs.

`H = dsp.PeakToRMS('`*PropertyName*`',`*PropertyValue*`,...)` returns an `PeakToRMS` System object, `H`, with each specified property set to the specified value.

Properties   **CustomDimension**

Numerical dimension to operate along. Specify the dimension as a positive integer along which the peak-to-RMS ratio is computed. The value of this property cannot exceed the number of dimensions in the input signal. This property applies when `Dimension` property is `'Custom'`.

Default: 1

DecibelScaledOutput

Report output in decibels (dB). Set this property to `true` to enable output in dB. Set this property to `false` to report output as a ratio.

Default: `true`

Dimension

Dimension to operate along. Specify the dimension along which to calculate the peak-to-RMS ratio as one of `'All'`, `'Row'`, `'Column'`, or `'Custom'`. This property applies when the `RunningPeakToRMS` property is `false`. If you set this property to `'Custom'`, specify the dimension using the `CustomDimension` property.

Default: `'Column'`

FrameBasedProcessing

Process input in frames or as samples. Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. This property applies when the `RunningPeakToRMS` property is `true`.

Default: `true`

ResetCondition

Reset condition for running peak-to-RMS mode. Specify the event to reset the running peak-to-RMS as one of `'Rising edge'`, `'Falling edge'`, `'Either edge'`, or `'Non-zero'`. This property applies when the `ResetInputPort` property is `true`.

ResetInputPort

Enables resetting in running peak-to-RMS mode. Set this property to `true` to enable resetting. When the property is set to `true`, a reset input must be specified in the call to `step` to reset the running peak-to-RMS ratio. This property applies when the `RunningPeakToRMS` property is `true`.

Default: `false`

RunningPeakToRMS

Calculation over successive calls to step. Set this property to
true to enable the calculation of the peak-to-RMS ratio over
successive calls to the step.

Default: false

Methods	clone	Clones the current instance of the peak-to-root-mean-square object
	getNumInputs	Number of expected inputs to the method
	getNumOutputs	Number of outputs of the method
	isLocked	Locked status (logical) for input attributes and nontunable properties
	release	Allow property value and input characteristics changes
	reset	Reset the running peak-to-root-mean-square object
	step	Compute peak-to-RMS ratio

Definitions   **Peak-magnitude-to-RMS Level**

The peak-magnitude-to-RMS level is

$$\frac{||X||_\infty}{\sqrt{\frac{1}{N}\sum_{n=1}^{N}|X_n|^2}}$$

where the *l*-infinity norm and RMS values are computed along the
specified dimension.

Examples   **Peak-to-RMS Ratio of Vector Input**

Determine the peak-to-RMS ratio of a vector input.

```
in1 = (1:10)';
h1 = dsp.PeakToRMS;
y1 = step(h1,in1);
```

Peak-to-RMS Ratio of Matrix Input

Determine the peak-to-RMS ratio of a matrix input.

```
in2 = magic(4);
h2 = dsp.PeakToRMS;
h2.Dimension = 'All';
y2 = step(h2, in2)
```

References   [1] *IEEE Standard on Transitions, Pulses, and Related Waveforms,*
                   IEEE Standard 181, 2003.

See Also   dsp.Maximum **|** dsp.PeakToPeak **|**

dsp.PeakToRMS.clone

Purpose   Clones the current instance of the peak-to-root-mean-square object

Syntax   `clone(H)`

Description   `clone(H)` clones the current instance of the peak-to-root-mean-square (RMS) object `H`.

Purpose   Number of expected inputs to the step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to the step method for the peak-to-root-mean-square object H.

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

dsp.PeakToRMS.getNumOutputs

Purpose   Number of outputs of the `step` method

Syntax   `N = getNumOutputs(H)`

Description   `N = getNumOutputs(H)` returns the number of outputs, N, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status (logical) for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the peak-to-root-mean-square object H.

dsp.PeakToRMS.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset the running peak-to-root-mean-square object

Syntax   `reset(H)`

Description   `reset(H)` resets the running peak-to-root-mean-square value for the object `H`.

Purpose   Compute peak-to-RMS ratio

Syntax   `Y = step(H,X)`
`Y = step(H,X,R)`

Description   `Y = step(H,X)` computes the peak-to-RMS ratio, `Y`, of the floating-point input vector `X`. When the `RunningPeakToRMS` property is `true`, `Y` corresponds to the peak-to-RMS ratio of the input elements over successive calls to the `step` method.

`Y = step(H,X,R)` computes the peak-to-RMS ratio of the input elements over successive calls to the `step` method. The object optionally resets its state based on the reset input signal, `R`, and the value of the `ResetCondition` property. This is possible when you set both the `RunningPeakToRMS` and the `ResetInputPort` properties to `true`.

Purpose   Unwrap signal phase

Description   The PhaseUnwrapper object unwraps the signal phase input specified in radians.

To unwrap the signal phase input:

1 Define and set up your System object. See "Construction" on page 5-871.

2 Call step to unwrap the signal phase according to the properties of dsp.PhaseUnwrapper. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.PhaseUnwrapper returns a System object, H. This System object adds or subtracts appropriate multiples of 2π to each input element to remove phase discontinuities (unwrap).

H = dsp.PhaseUnwrapper('*PropertyName*',*PropertyValue*,...) returns an unwrapped System object, H, with each specified property set to the specified value.

Properties   **InterFrameUnwrap**

Enable unwrapping of phase discontinuities between successive frames

Set this property to false to unwrap phase discontinuities only within the frame. Set this property to true to also unwrap phase discontinuities between successive frames. This property applies when you set the FrameBasedProcessing to true. The default is true.

Tolerance

Jump size as true phase discontinuity

Specify the jump size that the phase unwrapper recognizes as a true phase discontinuity. The default is set to π (rather than a smaller value) to avoid altering legitimate signal features.

To increase the phase wrapper sensitivity, set the Tolerance property to a value slightly less than π.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

Methods

clone	Create phase unwrapper object with same property values
getNumInputs	Number of expected inputs to the method
getNumOutputs	Number of outputs of the method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of Phase Unwrapper System object
step	Unwrap input phase signal input

Examples

Unwrap input phase data:

```
hunwrap = dsp.PhaseUnwrapper;
p = [0 2/5 4/5 -4/5 -2/5 0 2/5 4/5 -4/5 -2/5 0 2/5 ...
 4/5 -4/5, -2/5]*pi;
y = step(hunwrap, p');
figure,stem(p); hold
stem(y, 'r');
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Unwrap block reference page. The object properties correspond to the Simulink block parameters.

Objects and blocks interpret frames differently. Objects process inputs as frames or as samples by setting the FrameBasedProcessing property. Blocks process inputs as frames or as samples by inheriting the frame information from the input ports. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also   unwrap

Purpose   Create phase unwrapper object with same property values

Syntax   clone(H)

Description   clone(H) clones the current instance of the phase unwrapper object H.

Purpose   Number of expected inputs to the step method

Syntax   N = getNumInputs(H)

Description N = getNumInputs(H) returns the number of expected inputs to the
step method

The getNumInputs method returns a positive integer that is the number
of expected inputs (not counting the object itself) to the step method.
This value will change if you alter any properties that turn inputs on or
off. You must call the step method with the number of input arguments
equal to the result of getNumInputs(*H*).

dsp.PhaseUnwrapper.getNumOutputs

Purpose   Number of outputs of the `step` method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the phase unwrapper object H.

dsp.PhaseUnwrapper.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset internal states of Phase Unwrapper System object

Syntax   reset(H)

Description   reset(H) resets the 2π multiplier k to 0 for the phase unwrapper
                   object H. See "Frame-Based Processing" on page 2-1630 for details.

Purpose   Unwrap input phase signal input

Syntax   `Y = step(H,X)`

Description   `Y = step(H,X)` unwraps the input signal `X` in radians for the root mean square (RMS) object `H`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose   Pulse metrics of bilevel waveforms

Description   The `PulseMetrics` object computes rise times, fall times, pulse widths, and cycle metrics including pulse period, pulse separation, and duty cycle for bilevel waveforms.

To obtain pulse metrics for a bilevel waveform:

1 Define and set up your pulse metrics. See "Construction" on page 5-881.

2 Call `step` to compute the pulse metrics according to the properties of `dsp.PulseMetrics`. The behavior of `step` is specific to each object in the toolbox.

Construction   `H = dsp.PulseMetrics` creates a pulse metrics System object, `H`. The object computes the rise time, fall time, and width of a pulse. `dsp.PulseMetrics` also computes cycle metrics such as pulse separations, periods, and duty cycles. Because a pulse contains two transitions, the object contains a superset of the capability defined in `dsp.TransitionMetrics`.

`H = dsp.PulseMetrics('`*PropertyName*`',`*PropertyValue*`,...)` returns a `PulseMetrics` System object, `H`, with each specified property set to the specified value.

Properties   **CycleOutputPort**

        Enable cycle metrics. If `CycleOutputPort` is `true`, cycle metrics are reported for each pulse period.

        Default: `false`

    MaximumRecordLength

        Maximum samples to preserve between calls to `step`. This property requires a positive integer that specifies the maximum number of samples to save between calls to the step method. When the number of samples to be saved exceeds this length, the

oldest excess samples are discarded. This property applies when the RunningMetrics property is true and is tunable.

Default: 1000

PercentReferenceLevels

Lower-, middle-, and upper-percent reference levels. This property contains a three-element numeric row vector that contains the lower-, middle-, and upper-percent reference levels. These reference levels are used as an offset between the lower and upper states of the waveform when computing the duration of each transition.

Default: [10 50 90]

PercentStateLevelTolerance

Tolerance of the state level (in percent). This property requires a scalar that specifies the maximum deviation from either the low or high state before it is considered to be outside that state. The tolerance is expressed as a percentage of the waveform amplitude.

Default: 2

Polarity

Polarity of pulse to extract. This property specifies the type of pulse to extract by the polarity of the leading transition. Valid values for this property are 'positive' or 'negative'.

Default: 'positive'

PostshootOutputPort

Enable posttransition aberration metrics. If this property is set to true, overshoot and undershoot metrics are reported for a region defined immediately after each transition. The posttransition aberration region is defined as the waveform interval that begins

at the end of each transition and whose duration is the value of
PostshootSeekFactor times the computed transition duration. If
a complete subsequent transition is detected before the interval
is over, the region is truncated at the start of the subsequent
transition. The metrics are computed for each transition that has
a complete posttransition aberration region.

Default: false

PostshootSeekFactor

Corresponds to the duration of time to search for the overshoot and
undershoot metrics immediately following each transition. The
duration is expressed as a factor of the duration of the transition.
This property is enabled only when the PostshootOutputPort
property is set to true and is tunable.

Default: 3

PreshootOutputPort

Enable pretransition aberration metrics. If PreshootOutputPort
is set to true, overshoot and undershoot metrics are reported
for a region defined immediately before each transition. The
pretransition aberration region is defined as the waveform
interval that ends at the start of each transition and whose
duration is PreshootSeekFactor times the computed transition
duration.

Default: 'false'

PreshootSeekFactor

Corresponds to the duration of time to search for the overshoot and
undershoot metrics immediately preceding each transition. The
duration is expressed as a factor of the duration of the transition.
This property is enabled only when the PreshootOutputPort
property is set to true and is tunable.

Default: 3

RunningMetrics

Enable metrics over all calls to `step`. If `RunningMetrics` is set to `false`, metrics are computed for each call to `step` independently. If `RunningMetrics` is set to `true`, metrics are computed across subsequent calls to `step`. If there are not enough samples to compute metrics associated with the last transition, posttransition aberration region, or settling seek duration in the current record, the object will defer reporting all transition, aberration, and settling metrics associated with the last transition until a subsequent call to `step` is made with enough data to compute all enabled metrics for that transition.

Default: `false`

SampleRate

Sampling rate of uniformly-sampled signal. Specify the sample rate in hertz as a positive scalar. This property is used to construct the internal time values that correspond to the input sample values. Time values start with zero. This property applies when the `TimeInputPort` property is set to `false`.

Default: 1

SettlingOutputPort

Enable settling metrics. If the `SettlingOutputPort` property is set to `true`, settling metrics are reported for each transition. The region used to compute the settling metrics starts at the midcrossing and lasts until the `SettlingSeekDuration` has elapsed. If an intervening transition occurs, or the signal has not settled within the `PercentStateLevelTolerance` of the final level, `NaN` is returned for each metric. If there are not enough samples after the last transition to complete the `SettlingSeekDuration`, no metrics are reported for the last

transition. The metrics are reported for the transition the next time `step` is called if the `RunningMetrics` property is set to `true`.

Default: `false`

SettlingSeekDuration

Duration of time over which to search for settling. This property value is a scalar that specifies the amount of time to inspect from the mid-reference level crossing (in seconds). If the transition has not yet settled, or a subsequent complete transition is detected within this duration, the `PulseMetrics` object will report `NaN` for all settling metrics. This property is tunable and applies only when you set the `SettlingOutputPort` property to `true`.

Default: `0.02`

StateLevels

Low- and high-state levels. This property is a 2–element numeric row vector that contains the low- and high-state levels respectively. These state levels correspond to the nominal logic low and high levels of the pulse waveform. This property is tunable.

Default: `[0 2.3]`

StateLevelsSource

Auto or manual state-level computation. If `StateLevelsSource` is set to `'Auto'`, the first record sent to `step` is sent to `dsp.StateLevels` with the default settings to determine the state levels of the incoming waveform. If this property is set to `'Property'`, the object uses the values the user specifies in the `StateLevels` property.

Default: `'Property'`

TimeInputPort

> Add input to specify sample instants. Set `TimeInputPort` to `true` to enable an additional real input column vector to `step` to specify the sample instants that correspond to the sample values. If this property is `false`, the sample instants are built internally. The sample instants start at zero and increment by the reciprocal of the `SampleRate` property for subsequent samples. The sample instants continue to increment if the `RunningMetrics` property is set to `true` and no intervening calls to the `reset` or `release` methods are encountered.
>
> **Default:** `false`

TransitionOutputPort

> Enable transition metrics. If the `TransitionOutputPort` property is set to `true`, transition metrics are reported for the initial and final transitions of each pulse.
>
> **Default:** `false`

Methods		
	clone	Clones the current instance of the pulse metrics object
	getNumInputs	Number of expected inputs to the method
	getNumOutputs	Number of outputs of the method
	isLocked	Locked status (logical) for input attributes and nontunable properties
	plot	Plots signal and metrics computed in last call to

reset	Reset the running pulse metrics object
step	Pulse metrics of bilevel waveforms

Examples

Width, Period, and Duty Cycle

Determine the width, period, and duty cycle of a 5 V pulse sampled at 4 MHz.

Load the data and sampling instants.

```
load('pulseex.mat', 'x', 't');
```

Construct your pulse metrics System object. Set the `TimeInputPort` property to `true` to specify the sampling instants as an input to `step`. Set the `CycleOutputPort` property to `true` to obtain metrics for each pulse. Because the input is a 5V pulse, set the `StateLevels` property to `[O 5]`.

```
hpm1 = dsp.PulseMetrics('TimeInputPort',true, ...
                        'CycleOutputPort', true, ...
                        'StateLevels',[O 5])
```

Call `step` to compute the cycle metrics and plot the result.

```
[pulse, cycle] = step(hpm1,x,t);
plot(hpm1)
text(t(2),-0.5,['Duty Cycle: ',num2str(cycle.DutyCycle)]);
```

Slew Rates for 2.3 V Digital Clock

Find the slew rates of the leading and trailing edges of a 2.3 V digital clock sampled at 4 MHz.

Construct your pulse metrics System object. Set the `TransitionOutputPort` property to `true` to report transition metrics for the initial and final transitions. Set the `StateLevelsSource` property to `'Auto'` to estimate the state levels from the data.

dsp.PulseMetrics

```
hpm2 = dsp.PulseMetrics('SampleRate',4e6, ...
                        'TransitionOutputPort', true, ...
                        'StateLevelsSource','Auto');
```

Compute the pulse and transition metrics and plot the result.

```
[pulse, transition] = step(hpm2,x);
plot(hpm2)
```

References   [1] *IEEE Standard on Transitions, Pulses, and Related Waveforms*, IEEE Standard 181, 2003.

See Also   dsp.StateLevels **|** dsp.TransitionMetrics **|**

Purpose   Clones the current instance of the pulse metrics object

Syntax   clone(H)

Description   clone(H) clones the current instance of the pulse metrics object H.

dsp.PulseMetrics.getNumInputs

Purpose   Number of expected inputs to the `step` method

Syntax   `N = getNumInputs(H)`

Description   `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method for the pulse metrics object `H`.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose   Number of outputs of the step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

dsp.PulseMetrics.isLocked

Purpose   Locked status (logical) for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the pulse metrics object H.

Purpose   Plots signal and metrics computed in last call to `step`

Syntax   `plot(H)`

Description   `plot(H)` plots the signal and metrics resulting from the last call of the step method.

By default `plot` displays

- the low and high state levels and the state-level boundaries defined by the `PercentStateLevelTolerance` property.

- the lower-, middle-, and upper-reference levels.

- the locations of the mid-reference level crossings of the positive (+) and negative (-) transitions of each detected pulse.

When the `TransitionOutputPort` property is set to `true`, the locations of the upper and lower crossings are also plotted. When the `PreshootOutputPort` or `PostShootOutputPort` properties are set to `true,` the corresponding overshoots and undershoots are plotted as inverted or noninverted triangles. When the `SettlingOutputPort` property is set to `true`, the locations where the signal enters and remains within the lower and upper state boundaries over the specified seek duration are plotted.

dsp.PulseMetrics.reset

Purpose   Reset the running pulse metrics object

Syntax   reset(H)

                   Description

                   reset(H) clears information from previous calls to step.

Purpose   Pulse metrics of bilevel waveforms

Syntax   PULSE = step(H,X)
                [PULSE,CYCLE] = step(H,X)
                [PULSE, TRANSITION] = step(H,X)
                [PULSE,PRESHOOT] = step(H,X)
                [PULSE,POSTSHOOT] = step(H,X)
                [PULSE,SETTLING] = step(H,X)
                [...] = step(H,X,T)

Description PULSE = step(H,X) returns a structure array, PULSE, whose fields
                contain real-valued column vectors. The number of rows of each field
                corresponds to the number of complete pulses found in the real-valued
                column vector input, X. Each pulse starts with a transition of the
                polarity specified by the Polarity property and ends with a transition
                of the opposite polarity.

                PULSE fields:

                • PositiveCross — Instants where the positive-going transitions cross
                  the mid-reference level of each pulse

                • NegativeCross — Instants where the negative-going transitions
                  cross the mid-reference level of each pulse

                • Width — Absolute difference between PositiveCross and
                  NegativeCross of each pulse

                • RiseTime — Duration between the linearly-interpolated instants
                  when the positive-going (rising) transition of each pulse crosses the
                  lower- and upper-reference levels

                • FallTime — Duration between the linearly-interpolated instants
                  when the negative-going (falling) transition of each pulse crosses the
                  upper- and lower-reference levels

                [PULSE,CYCLE] = step(H,X) returns a structure array, CYCLE,
                whose fields contain real-valued column vectors when you set the
                CycleOutputPort property to true. The number of rows of each field

corresponds to the number of complete pulse periods found in the real-valued column vector input, X. You need at least three consecutive alternating polarity transitions that start and end with the same polarity as the value of the Polarity property if you want to compute cycle metrics. If the last transition found in the input X does not match the polarity of the Polarity property, the pulse separation, period, frequency, and duty cycle are not reported for the last pulse. If the RunningMetrics property is set to true when this occurs, all pulse, cycle, transition, preshoot, postshoot, and settling metrics associated with the last pulse are deferred until a subsequent call to step detects the next transition.

CYCLE fields:

- Period — Duration between the first transition of the current pulse and the first transition of the next pulse

- Frequency — Reciprocal of the period

- Separation — Durations between the mid-reference level crossings of the second transition of each pulse and the first transition of the next pulse

- Width — Durations between the mid-reference level crossings of the first and second transitions of each pulse. This is equivalent to the width parameter of the PULSE structure.

- DutyCycle — Ratio of the width to the period for each pulse

[PULSE, TRANSITION] = step(H,X) returns a structure array, TRANSITION, when you set the TransitionOutputPort property to true. The fields of TRANSITION contain real-valued matrices with two columns which correspond to the metrics of the first and second transitions. The number of rows corresponds to the number of pulses found in the input waveform.

TRANSITION fields:

- Duration — Amount of time between the interpolated instants where the transition crosses the lower- and upper-reference levels

- `SlewRate` — Ratio of absolute difference between the upper and lower reference levels to the transition duration

- `MiddleCross` — Linearly-interpolated instant in time where the transition first crosses the mid-reference level

- `LowerCross` — Linearly-interpolated instant where the signal crosses the lower-reference level

- `UpperCross` — Linearly-interpolated instant where the signal crosses the upper-reference level

`[PULSE,PRESHOOT] = step(H,X)` returns a structure array, `PRESHOOT`, when you set the `PreshootOutputPort` property to `true`. The fields of `PRESHOOT` contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform. The field names are identical to those of the `POSTSHOOT` structure array.

`[PULSE,POSTSHOOT] = step(H,X)` returns a structure, `POSTSHOOT`, when you set the `PostshootOutputPort` property to `true`. The fields of `POSTSHOOT` contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform.

`PRESHOOT` and `POSTSHOOT` fields:

- `Overshoot` — Overshoot of the region of interest expressed as a percentage of the waveform amplitude

- `Undershoot` — Undershoot of the region of interest expressed as a percentage of the waveform amplitude

- `OvershootLevel` — Level of the overshoot

- `UndershootLevel` — Level of the undershoot

- `OvershootInstant` — Instant that corresponds to the overshoot

- `UndershootInstant` — Instant that corresponds to the undershoot

`[PULSE,SETTLING] = step(H,X)` returns a structure array, `SETTLING`, when you set the `SettlingOutputPort` property to `true`. The fields of `SETTLING` correspond to the settling metrics for each transition. Each

field is a column vector whose elements correspond to the individual settling durations, levels, and instants.

SETTLING fields:

- Duration — Amount of time from when the signal crosses the mid-reference level to the time where the signal enters and remains within the specified PercentStateLevelTolerance of the waveform amplitude over the specified settling seek duration

- Instant — Instant in time where the signal enters and remains within the specified tolerance

- Level — Level of the waveform where it enters and remains within the specified tolerance

The above operations can be used simultaneously, provided the System object properties are set appropriately. One example of providing all possible inputs and returning all possible outputs is :

[PULSE,CYCLE,TRANSITION,PRESHOOT,POSTSHOOT,SETTLING] = step(H,X) which returns the PULSE, CYCLE, TRANSITION, PRESHOOT, POSTSHOOT, and SETTLING structures when the CycleOutputPort, PreshootOutputPort, PostshootPort, and SettlingOutputPort properties are true. You may enable or disable any combination of output ports. However, the output arguments are defined in the order shown here.

[...] = step(H,X,T) performs the above metrics with respect to a sampled signal, whose sample values, X, and sample instants, T, are real-valued column vectors of the same length. The additional input T applies only when you set the TimeInputPort property to true.

Purpose   Convert reflection coefficients to autocorrelation coefficients

Description   The `RCToAutocorrelation` object converts reflection coefficients to autocorrelation coefficients.

To convert reflection coefficients to autocorrelation coefficients:

1 Define and set up your System object. See "Construction" on page 5-899.

2 Call `step` to convert reflection coefficients according to the properties of `dsp.RCToAutocorrelation`. The behavior of `step` is specific to each object in the toolbox.

Construction `H = dsp.RCToAutocorrelation` returns an `RCToAutocorrelation` System object, `H`. This object converts reflection coefficients to autocorrelation coefficients, assuming an error power of 1.

`H = dsp.RCToAutocorrelation('`*PropertyName*`',`*PropertyValue*`,...)` returns an object, `H`, that converts reflection coefficients into autocorrelation coefficients, with each specified property set to the specified value.

Properties   **PredictionErrorInputPort**

Enable prediction error power input

Choose how to select the prediction error power. When you set this property to `true`, you must specify the prediction error power as a second input to the `step` method. When you set this property to `false`, the object assumes a prediction error power of 1. The default is `false`.

dsp.RCToAutocorrelation

Methods

clone	Create RC to autocorrelation object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Convert columns of reflection coefficients to autocorrelation coefficients

Examples

Convert reflection coefficients to autocorrelation coefficients:

```
k = [-0.8091 0.2525 -0.5044 0.4295 -0.2804 0.0711].';
hrc2ac = dsp.RCToAutocorrelation;
ac = step(hrc2ac, k);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC/RC to Autocorrelation block reference page. The object properties correspond to the block parameters, except:

- There is no object property that corresponds to the **Type of conversion** block parameter.

- **PredictionErrorInputPort** is a pop-up menu choice on the block. Setting the PredictionErrorInputPort object property to false corresponds to selecting Assume P = 1 in the pop-up menu. Setting PredictionErrorInputPort to true corresponds to selecting Via input port from the pop-up menu.

See Also   dsp.LPCToLSF | dsp.LPCToRC | dsp.LPCToCepstral |
                  dsp.LPCToAutocorrelation

dsp.RCToAutocorrelation.clone

Purpose   Create RC to autocorrelation object with same property values

Syntax   `C = clone(H)`

Description   `C = clone(H)` creates a `RCToAutocorrelation` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs to the
                   step method.

                   The getNumInputs method returns a positive integer that is the number
                   of expected inputs (not counting the object itself) to the step method.
                   This value will change if you alter any properties that turn inputs on or
                   off. You must call the step method with the number of input arguments
                   equal to the result of getNumInputs(*H*).

dsp.RCToAutocorrelation.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the RCToAutocorrelation
System object.

The isLocked method returns a logical value that indicates whether
input attributes and nontunable properties for the object are locked. The
object performs an internal initialization the first time the step method
is executed. This initialization locks nontunable properties and input
specifications, such as dimensions, complexity, and data type of the
input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Convert columns of reflection coefficients to autocorrelation coefficients

Syntax   AC = step(H,K)
                   AC = step(H,K,P)

Description   AC = step(H,K) converts the columns of the reflection coefficients, K, to autocorrelation coefficients, AC.

AC = step(H,K,P) when you set the PredictionErrorInputPort property to true, converts the columns of the reflection coefficients, K , to autocorrelation coefficients, AC, using P as the prediction error power. P must be a row vector with same number of columns as in K.

Note The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

---

dsp.RCToLPC

Purpose
Convert reflection coefficients to linear prediction coefficients

Description
The RCToLPC object converts reflection coefficients to linear prediction coefficients.

To convert reflection coefficients to LPC:

1 Define and set up your RC to LPC System object. See "Construction" on page 5-908.

2 Call step to convert RC to LPC according to the properties of dsp.RCToLPC. The behavior of step is specific to each object in the toolbox.

Construction
H = dsp.RCToLPC returns an RC to LPC System object, H, that converts reflection coefficients (RC) to linear prediction coefficients (LPC).

H = dsp.RCToLPC('*PropertyName*',*PropertyValue*,...) returns an RC to LPC conversion object, H, with each specified property set to the specified value.

Properties

PredictionErrorOutputPort

Enable normalized prediction error power output

Set this property to true to return the normalized error power as a vector with one element per input channel. Each element varies between 0 and 1. The default is true.

ExceptionOutputPort

Produce output with stability status of filter represented by LPC coefficients

Set this property to true to return the stability of the filter. The output is a vector of a length equal to the number of channels. A logical value of 1 indicates a stable filter. A logical value of 0 indicates an unstable filter. The default is false.

Methods

clone	Creates instance of object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Convert columns of reflection coefficients to linear prediction coefficients

Examples

Convert reflection coefficients to linear prediction coefficients:

```
hlevinson = dsp.LevinsonSolver;
hac = dsp.Autocorrelator;
hac.MaximumLagSource = 'Property';
hac.MaximumLag = 10; % Compute autocorrelation
                     % lags between [0:10]
hrc2lpc = dsp.RCToLPC;

x = (1:100)';
a = step(hac, x);
k = step(hlevinson, a); % Compute reflection coefficients
[A, P] = step(hrc2lpc, k);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to/from RC block reference page. The object properties correspond to the block parameters, except:

There is no object property that corresponds to the **Type of conversion** block parameter. The object always converts LPC to RC.

.

dsp.RCToLPC

See Also   `dsp.LPCToRC` | `dsp.LPCToAutocorrelation`

Purpose   Creates instance of object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates an RCToLPC System object C, with the same
                   property values as H. The clone method creates a new unlocked object.

dsp.RCToLPC.getNumInputs

Purpose　　　Number of expected inputs to step method

Syntax　　　`N = getNumInputs(H)`

Description　`N = getNumInputs(H)` returns the number of expected inputs to the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                   method.

                   The getNumOutputs method returns a positive integer that is the
                   number of outputs from the step method. This value will change if you
                   alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the RCToLPC System object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description   release(H) releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the release method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.RCToLPC.step

Purpose   Convert columns of reflection coefficients to linear prediction coefficients

Syntax
```
[A,P] = step(H,K)
A = step(H,K)
[..., S] = step(H,K)
```

Description   `[A,P] = step(H,K)` converts the columns of the reflection coefficients, `K`, to linear prediction coefficients, `A`, and outputs the normalized prediction error power, `P`.

`A = step(H,K)` when the `PredictionErrorOutputPort` property is `false`, converts the columns of the reflection coefficients, `K`, to linear prediction coefficients, `A`.

`[..., S] = step(H,K)` also outputs the LPC filter stability, `S`, when the `ExceptionOutputPort` property is `true`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose   Root mean square of vector elements

Description   The RMS object computes the root mean square (RMS) value.

To compute the RMS value of your input:

1 Define and set up your RMS calculation. See "Construction" on page 5-917.

2 Call step to compute the RMS value for an input according to the properties of dsp.RMS. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.RMS returns a System object, H, that computes the root mean square (RMS) of an input or a sequence of inputs over the specified Dimension.

H = dsp.RMS(*'PropertyName'*,*PropertyValue*,...) returns an RMS System object, H, with each specified property set to the specified value.

Properties   **RunningRMS**

Enable calculating RMS over time

Set this property to true to enable calculating the RMS over successive calls to the step method.

Default: false

ResetInputPort

Enable resetting in running RMS mode

Set this property to true to enable resetting the running RMS. When the property is set to true, you must specify a reset input to the step method to reset the running RMS. This property applies when you set the RunningRMS property to true.

Default: false

ResetCondition

Reset condition for running RMS mode

Specify the event to reset the running RMS as one of `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`. `Non-zero` resets the running RMS each time a nonzero sample is acquired. See "Rising and Falling Edges" on page 5-919 for definitions of rising and falling edges. This property applies when you set the `ResetInputPort` property to `true`.

Default: `Non-zero`

Dimension

Dimension to compute RMS value along

Specify the dimension along which to calculate the RMS as one of `All`, `Row`, `Column`, or `Custom`. This property applies only when you set the `RunningRMS` property to `false`. Specifying the `Dimension` property as `All` computes the RMS value over the entire input.

Default: `Column`

CustomDimension

Numerical dimension to operate along

Specify the dimension (one-based scalar integer value) of the input signal, along which the RMS is computed. The cannot exceed the number of dimensions in the input signal. This property applies when you set the `Dimension` property to `Custom`.

Default: 1

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing for 2-dimensional inputs. Set this property to `false` to

enable sample-based processing. The object always performs sample-based processing for N-D inputs where N is greater than 2. This property applies when you set the RunningRMS property to true.

Default: true

Methods

clone	Clones the current instance of the root mean square object
getNumInputs	Number of expected inputs to the method
getNumOutputs	Number of outputs of the method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset the running root mean square object
step	Root mean square of input

Definitions

Root-Mean-Square Level

The root-mean-square level of a vector, *X*, is

$$X_{\text{RMS}} = \sqrt{\frac{1}{N} \sum_{n=1}^{N} |X_n|^2}$$

with the summation performed along the specified dimension.

Rising and Falling Edges

A rising edge:

- Rises from a negative value to a positive value or zero.

- Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

Rising edge

Rising edge

Rising edge

Rising edge

Not a rising edge because it continues a rise from a negative value to zero.

A falling edge:

- Falls from a positive value to a negative value or zero.

- Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

Falling edge   Falling edge

Falling edge

Falling edge

Not a falling edge because it continues a fall from a positive value to zero.

Examples   **RMS Value of Vector Input**

Compute the RMS value of a vector consisting of the integers 1 to 10.

Create a row vector of the integers 1 to 10. Construct the RMS System object with the Dimension property set to `'literal'`. Compute the RMS value.

```
x = 1:10;
hrms = dsp.RMS('Dimension','row');
rmsval = step(hrms,x);
```

RMS Value of Matrix Input

Compute the RMS value of a matrix with the Dimension property set to `'All'`.

```
in2 = magic(4);
hrms2d = dsp.RMS;
hrms2d.Dimension = 'All';
y_rms2 = step(hrms2d, in2);
```

The output is equivalent to reshaping the 4-by-4 matrix into a 16-by-1, or 1-by-16 vector and computing the RMS value for the vector.

Algorithms   This object implements the algorithm, inputs, and outputs described on the RMS block reference page. The object properties correspond to the Simulink block parameters, except:

- **Treat sample-based row input as a column** block parameter is not supported by the dsp.RMS object.

- **Reset Port** block parameter corresponds to both the ResetCondition and the ResetInputPort object properties.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the FrameBasedProcessing property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

dsp.RMS

See Also   dsp.Mean | dsp.StandardDeviation | dsp.Variance.

Purpose   Clones the current instance of the root mean square object

Syntax   clone(H)

Description   clone(H) clones the current instance of the root mean square (RMS) object H

dsp.RMS.getNumInputs

Purpose   Number of expected inputs to the `step` method

Syntax   `N = getNumInputs(H)`

Description   `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method for the root mean square (RMS) object `H`.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose   Number of outputs of the step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                   method

                   The getNumOutputs method returns a positive integer that is the
                   number of outputs from the step method. This value will change if you
                   alter any properties that turn outputs on or off.

dsp.RMS.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the root mean square (RMS) object H.

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description   release(H) releases system resources, such as memory, file handles,
                  and hardware connections, and lets you change any properties or input
                  characteristics.

Note You can use the release method on a System object in code
generated from MATLAB, but once you release its resources, you cannot
use that System object again.

---

dsp.RMS.reset

Purpose   Reset the running root mean square object

Syntax   `reset(H)`

Description   `reset(H)` resets the running root mean square (RMS) for the object `H`.

Purpose   Root mean square of input

Syntax   Y = step(H,X)
                Y = step(H,X,R)

Description Y = step(H,X) computes the root mean square (RMS) output, Y , of
                input vector X. When the RunningRMS property is true, Y corresponds to
                the RMS of the input elements over successive calls to the step method.

                Y = step(H,X,R) resets the running RMS state based on the value of R,
                the reset signal, and the ResetCondition property. This computation is
                possible when you set both the RunningRMS and the ResetInputPort
                properties to true.

                Note The object performs an initialization the first time the step
                method is executed. This initialization locks nontunable properties and
                input specifications, such as dimensions, complexity, and data type
                of the input data. If you change a nontunable property or an input
                specification, the System object issues an error. To change nontunable
                properties or inputs, you must first call the release method to unlock
                the object.

                ---

dsp.ScalarQuantizerDecoder

Purpose　　Convert each index value into quantized output value

Description　　The `ScalarQuantizerDecoder` object converts each index value into a quantized output value. The specified codebook defines the set of all possible quantized output values or codewords. Input index values less than 0 are set to 0 and index values greater $N-1$ are set to $N-1$. N is the length of the codebook vector.

To convert an index value into a quantized output value:

1 Define and set up your scalar quantizer decoder. See "Construction" on page 5-930.

2 Call `step` to convert the index value according to the properties of `dsp.ScalarQuantizerDecoder`. The behavior of `step` is specific to each object in the toolbox.

Construction　　`H = dsp.ScalarQuantizerDecoder` returns a scalar quantizer decoder System object, `H`, that transforms zero-based input index values into quantized output values.

`H = dsp.ScalarQuantizerDecoder('PropertyName',PropertyValue,...)` returns a scalar quantizer decoder object, `H`, with each specified property set to the specified value.

Properties　　**CodebookSource**

How to specify codebook values

Specify how to determine the codebook values as `Property` or `Input port`. The default is `Property`.

Codebook

Codebook

Specify the codebook as a vector of quantized output values that correspond to each index value. The default is `1:10`. This property is tunable.

OutputDataType

Data type of codebook and quantized output

Specify the data type of the codebook and quantized output values as `Same as input`, `double`, `single` or `Custom`. The default is `double`.

Fixed-Point Properties

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a signed or unsigned `numerictype` object. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype(true,16)`.

Methods

clone	Create scalar quantizer decoder object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Operate on inputs to calculate outputs

Examples

Given a codebook and index values as inputs, determine the corresponding output quantized values:

```
codebook = single([-2.1655 -1.3238 -0.7365 -0.2249 0.2726, ...
```

```
                        0.7844 1.3610 2.1599]);
                        indices = uint8([1 3 5 7 6 4 2 0]);
                        hsqdec = dsp.ScalarQuantizerDecoder;
                        hsqdec.CodebookSource = 'Input port';
                        qout = step(hsqdec, indices, codebook);
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Scalar Quantizer Decoder block reference page. The object properties correspond to the block parameters, except:

There is no object property that directly corresponds to the **Action for out of range index value** block parameter. The object sets any index values less than 0 to 0 and any index values greater than or equal to N to $N - 1$.

See Also   dsp.ScalarQuantizerEncoder | dsp.VectorQuantizerDecoder

Purpose   Create scalar quantizer decoder object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a `ScalarQuantizerDecoder` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

dsp.ScalarQuantizerDecoder.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                     method.

                     The getNumOutputs method returns a positive integer that is the
                     number of outputs from the step method. This value will change if you
                     alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   `isLocked(H)`

Description   `isLocked(H)` returns the locked state of the `ScalarQuantizerDecoder`
                   System object.

                   The `isLocked` method returns a logical value that indicates whether
                   input attributes and nontunable properties for the object are locked. The
                   object performs an internal initialization the first time the `step` method
                   is executed. This initialization locks nontunable properties and input
                   specifications, such as dimensions, complexity, and data type of the
                   input data. After locking, the `isLocked` method returns a `true` value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.ScalarQuantizerDecoder.step

Purpose   Operate on inputs to calculate outputs

Syntax   Q = step(H, I)
                   Q = step(H,I,C)

Description   Q = step(H, I) returns the quantized output values Q corresponding
                   to the input indices I. The data type of I can be uint8, uint16, uint32,
                   int8, int16, or int32. The OutputDataType property determines the
                   data type for Q.

                   Q = step(H,I,C) uses input C as the codebook values when you set
                   the CodebookSource property to Input port. The data type of C can
                   be double, single, or fixed-point. The output Q has the same data
                   type as the codebook input C.

Purpose   Associate input value with index value of quantization region

Description   The `ScalarQuantizerEncoder` object encodes each input value by associating that value with the index value of the quantization region. Then, the object outputs the index of the associated region.

To encode an input value by associating it with an index value of the quantization region:

1 Define and set up your scalar quantizer encoder. See "Construction" on page 5-939.

2 Call `step` to encode the input value according to the properties of `dsp.ScalarQuantizerEncoder`. The behavior of `step` is specific to each object in the toolbox.

Construction   `H = dsp.ScalarQuantizerEncoder` returns a scalar quantizer encoder System object, `H`. This object maps each input value to a quantization region by comparing the input value to the user-specified boundary points.

```
H =
dsp.ScalarQuantizerEncoder('PropertyName',PropertyValue,...)
```
returns a scalar quantizer encoder object, `H`, with each specified property set to the specified value.

Properties   **BoundaryPointsSource**

        Source of boundary points

        Specify how to determine the boundary points and codebook values as `Property` or `Input port`. The default is `Property`.

Partitioning

        Quantizer is bounded or unbounded

        Specify the quantizer as `Bounded` or `Unbounded`. The default is `Bounded`.

BoundaryPoints

Boundary points of quantizer regions

Specify the boundary points of quantizer regions as a vector. The vector values must be in ascending order. Let [p0 p1 p2 p3 ... pN] denote the boundary points property in the quantizer. If the quantizer is bounded, the object uses this property to specify [p0 p1 p2 p3 ... pN]. If the quantizer is unbounded, the object uses this property to specify [p1 p2 p3 ... p(N-1)] and sets p0 = -Inf and pN = +Inf. This property applies when you set the BoundaryPointsSource property to Property. The default is 1:10. This property is tunable.

SearchMethod

Find quantizer index by linear or binary search

Specify whether to find the appropriate quantizer index using a linear search or a binary search as one of Linear or Binary. The computational cost of the linear search method is of the order P and the computational cost of the binary search method is of the order

$$\log_2(P)$$

where P is the number of boundary points. The default is Linear.

TiebreakerRule

Behavior when input equals boundary point

Specify whether the input value is assigned to the lower indexed region or higher indexed region when the input value equals boundary point by selecting Choose the lower index or Choose the higher index. The default is Choose the lower index.

CodewordOutputPort

Enable output of codeword value

Set this property to true to output the codeword values that correspond to each index value. The default is false.

QuantizationErrorOutputPort

Enable output of quantization error

Set this property to `true` to output the quantization error for each input value. The quantization error is the difference between the input value and the quantized output value. The default is `false`.

Codebook

Codebook

Specify the codebook as a vector of quantized output values that correspond to each region. If the `Partitioning` property is `Bounded` and the boundary points vector has length N, you must set this property to a vector of length N-1. If the `Partitioning` property is `Unbounded` and the boundary points vector has length N, you must set this property to a vector of length N+1. This property applies when you set the `BoundaryPointsSource` property to `Property` and either the `CodewordOutputPort` property or the `QuantizationErrorOutputPort` property is `true`. The default is `1.5:9.5`. This property is tunable.

ClippingStatusOutputPort

Enable output of clipping status

Set this property to `true` to output the clipping status. The output is a 1 when an input value is outside the range defined by the `BoundaryPoints` property. When the value is inside the range, the exception output is a 0. This property applies when you set the `Partitioning` property to `Bounded`. The default is `false`.

OutputIndexDataType

Data type of the index output

Specify the data type of the index output from the object as: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`. The default is `int32`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest` or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

Methods

clone	Create an instance of an object with the same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Operate on inputs to calculate outputs

Examples

Quantize the varying fractional inputs between zero and five to the closest integers, and then plot the results:

```
hsqe = dsp.ScalarQuantizerEncoder;
hsqe.BoundaryPoints = [-.001 .499 1.499 ...
   2.499 3.499 4.499 5.001];
hsqe.CodewordOutputPort = true;
hsqe.Codebook = [0 1 2 3 4 5];
input = (0:0.02:5)';
[index, quantizedValue] = step(hsqe, input);
plot(1:length(input), [input quantizedValue]);
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Scalar Quantizer Encoder block reference page. The object properties correspond to the block parameters.

See Also   dsp.ScalarQuantizerDecoder | dsp.VectorQuantizerEncoder

Purpose   Create an instance of an object with the same property values

Syntax

Description   `C = clone(H)` creates a `ScalarQuantizerEncoder` object `C`, with the
same property values as `H`. The clone method creates a new unlocked
object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                       the step method.

                       The getNumInputs method returns a positive integer that is the number
                       of expected inputs (not counting the object itself) to the step method.
                       This value will change if you alter any properties that turn inputs on or
                       off. You must call the step method with the number of input arguments
                       equal to the result of getNumInputs(*H*).

dsp.ScalarQuantizerEncoder.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step method

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the ScalarQuantizerEncoder object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.ScalarQuantizerEncoder.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Operate on inputs to calculate outputs

Syntax   INDEX= step(HSQE,INPUT)
[...] = step(HSQE,INPUT,BPOINTS)
[...] = step(HSQE,INPUT,BPOINTS,CODEBOOK)
[...,CODEWORD] = step(HSQE, ...)
[..., QERR] = step(HSQE, ...)
[...,CLIPSTATUS] = step(HSQE, ...)

Description   INDEX= step(HSQE,INPUT) returns the INDEX of the quantization
region to which the INPUT belongs. The input data, boundary points,
codebook values, quantized output values, and the quantization error
must have the same data type whenever they are present.

[...] = step(HSQE,INPUT,BPOINTS) when the
BoundaryPointsSource property is Input port, uses input BPOINTS
as the boundary points .

[...] = step(HSQE,INPUT,BPOINTS,CODEBOOK) uses input BPOINTS
as the boundary points and input CODEBOOK as the codebook when
the BoundaryPointsSource property is Input port and either the
CodewordOutputPort property or the QuantizationErrorOutputPort
property is true.

[...,CODEWORD] = step(HSQE, ...) outputs the CODEWORD values
that corresponds to each index value when the CodewordOutputPort
property is true.

[..., QERR] = step(HSQE, ...) outputs the quantization error QERR
for each input value when the QuantizationErrorOutputPort property
is true.

[...,CLIPSTATUS] = step(HSQE, ...) also returns output
CLIPSTATUS as the clipping status output port for each input
value when the Partitioning property is Bounded and the
ClippingStatusOutputPort property is true. If an input value is
outside the range defined by the BoundaryPoints property, CLIPSTATUS
is true. If an input value is inside the range, CLIPSTATUS is false.

> **Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose   Log simulation data in buffer

Description   The SignalSink object logs MATLAB simulation data. This object accepts any numeric data type.

To log MATLAB simulation data :

1 Define and set up your signal sink. See "Construction" on page 5-951.

2 Call step to log the simulation data according to the properties of dsp.SignalSink. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.SignalSink returns a signal sink, H, that logs 2-D input data in the object.

H = dsp.SignalSink('*PropertyName*',*PropertyValue*,...) returns a signal sink, H, with each specified property set to the specified value.

Properties   **FrameBasedProcessing**

Process input as frames or samples

To enable frame-based processing for 2-D inputs, set this property to true. When you set this property to false, the object performs sample-based processing on 2-D inputs. The signal sink object always performs sample-based processing for N-D inputs when N is greater than 2. The default is true.

BufferLength

Maximum number of input frames or samples to log

Specify the maximum number of frames to log when the object is performing frame-based processing, or the maximum number of samples to log when the object is performing sample-based processing. The object always preserves the most recent data in the buffer. When you specify a buffer length that is greater than the input length, the object pads the end of the logged data with

zeros. To capture all input data without extra padding, set the BufferLength property to inf. The default is inf.

Decimation

Decimation factor

Setting this property to any positive integer d causes the signal sink to write data at every dth sample. The default is 1.

FrameHandlingMode

Output dimensionality for frame-based inputs

Set the dimension of the output array for frame-based inputs as 2-D array (concatenate) or 3-D array (separate). Concatenation occurs along the first dimension for 2-D array (concatenate). This property applies only when you set the FrameBasedProcessing property to true. The default is 2-D array (concatenate).

Buffer

Logged Data (read only)

The signal sink writes simulation data into a buffer. Specify the maximum length of the buffer with the BufferLength property.

Methods		
clone	Create signal logger object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes

reset	Reset internal states of signal logger object
step	Store signal in buffer

Examples

Log input data.

```
hlog = dsp.SignalSink;
 for i=1:10
     y = sin(i);
     step(hlog,y);
 end
log = hlog.Buffer; % log = sin([1;2;3;4;5;6;7;8;9;10])
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Signal To Workspace block reference page. The object properties correspond to the block properties, except:

The object always generates fixed-point output for fixed-point input.

Objects and blocks interpret frames differently. Objects process inputs as frames or as samples by setting the FrameBasedProcessing property. Blocks process inputs as frames or as samples by inheriting the frame information from the input ports. See "Set the FrameBasedProcessing Property of a System object" for more information.

dsp.SignalSource

dsp.SignalSink.clone

Purpose   Create signal logger object with same property values

Syntax   `C = clone(H)`

Description   `C = clone(H)` creates a `SignalSink` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                   the step method.

                   The getNumInputs method returns a positive integer that is the number
                   of expected inputs (not counting the object itself) to the step method.
                   This value will change if you alter any properties that turn inputs on or
                   off. You must call the step method with the number of input arguments
                   equal to the result of getNumInputs(*H*).

dsp.SignalSink.getNumOutputs

Purpose   Number of outputs of step method

Syntax   `N = getNumOutputs(H)`

Description   `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the SignalSink object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.SignalSink.reset

Purpose   Reset internal states of signal logger object

Syntax   reset(H)

Description   reset(H) sets the internal states of the SignalSink object H to their initial values.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.SignalSink.step

Purpose   Store signal in buffer

Syntax   step(H,Y)

Description   step(H,Y) buffers the signal Y. The buffer may be accessed at any time
from the Buffer property of H.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

Purpose Import variable from workspace

Description The SignalSource object imports a variable from the MATLAB workspace.

To import a variable from the MATLAB workspace:

1 Define and set up your signal source. See "Construction" on page 5-961.

2 Call step to import the variable according to the properties of dsp.SignalSource. The behavior of step is specific to each object in the toolbox.

Construction H = dsp.SignalSource returns a signal source System object, H, that outputs the variable one sample or frame at a time.

H = dsp.SignalSource('*PropertyName*',*PropertyValue*,...) returns a signal source object, H, with each specified property set to the specified value.

H = dsp.SignalSource(signal,spf,'*PropertyName*',*PropertyValue*,...) returns a signal source object, H, with the Signal property set to signal, the SamplesPerFrame property set to spf, and other specified properties set to the specified values.

Properties **Signal**

Variable or expression containing the signal

Specify the name of the workspace variable from which to import the signal, or a valid expression specifying the signal. The default is [1:10].

SamplesPerFrame

Number of samples per output frame

Specify the number of samples to buffer into each output frame. This property must be 1 when you specify a 3-D array in the Signal property. The default is 1.

SignalEndAction

Action after final signal values are generated

Specify the output after all of the specified signal samples have been generated as one of Set to zero, Hold final value, or Cyclic repetition. The default is Set to zero.

Methods

clone	Create signal reader object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isDone	End-of-file status for signal reader object
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of signal reader object
step	Read one sample or frame of signal

Examples

Create a signal source to output one sample at a time:

```
hsr1 = dsp.SignalSource;
hsr1.Signal = randn(1024, 1);
y1 = zeros(1024,1);
idx = 1;
```

```
while(~isDone(hsr1))
  y1(idx) = step(hsr1);
  idx = idx+1;
end
```

Create a signal source to output vectors:

```
hsr2 = dsp.SignalSource(randn(1024, 1), 128);
y2 = step(hsr2); % y2 is a 128-by-1 frame of samples
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Signal From Workspace block reference page. The object properties correspond to the block parameters, except:

The object does not have properties that correspond to the **Sample time** or **Warn when frame size does not evenly divide input length** block parameters.

See Also   dsp.SignalSink

dsp.SignalSource.clone

Purpose   Create signal reader object with same property values

Syntax   C = clone(H)

Description C = clone(H) creates a SignalSource object C, with the same property values as H. The clone method creates a new unlocked object with un-initialized states.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                   the step method.

                   The getNumInputs method returns a positive integer that is the number
                   of expected inputs (not counting the object itself) to the step method.
                   This value will change if you alter any properties that turn inputs on or
                   off. You must call the step method with the number of input arguments
                   equal to the result of getNumInputs(*H*).

dsp.SignalSource.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                   method.

                   The getNumOutputs method returns a positive integer that is the
                   number of outputs from the step method. This value will change if you
                   alter any properties that turn outputs on or off.

Purpose   End-of-file status for signal reader object

Syntax   isDone(H)

Description   isDone(H) returns a logical value indicating whether or not the
SignalSource object, H, has reached the end of the imported signal.
If the SignalEndAction property is set to Cyclic repetition, this
method will return true every time the reader reaches the end.

Purpose   Locked status for input attributes and nontunable properties

Syntax   `isLocked(H)`

Description   `isLocked(H)` returns the locked state of the `SignalSource` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose   Reset internal states of signal reader object

Syntax   reset(H)

Description reset(H) resets the signal reader object H, to start reading from the
beginning of the imported signal.

dsp.SignalSource.release

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description   release(H) releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the release method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Read one sample or frame of signal

Syntax   Y = step(H)

Description   Y = step(H) outputs one sample or frame of data, Y, from each column
                  of the imported signal. The imported signal is the variable or expression
                  you specify for the Signal property of the SignalSource System object
                  H.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

---

dsp.SineWave

Purpose   Discrete-time sinusoid

Description   The SineWave object generates a discrete-time sinusoid. The sine wave object generates a real–valued sinusoid or a complex exponential. A real-valued, discrete-time sinusoid is defined as:

$$y(n) = A\sin(2\pi f n + \phi)$$

where A is the amplitude, f is the frequency in hertz, and φ is the initial phase, or phase offset, in radians. A complex exponential is defined as:

$$y(n) = A e^{j(2\pi f n + \phi)}$$

For both real and complex sinusoids, the amplitude, frequency, and phase offsets can be scalars or length-N vectors, where N is the desired number of channels in the output. When you specify at least one of these properties as a length-N vector, scalar values specified for the other properties are applied to each of the N channels.

To generate a discrete-time sinusoid:

1 Define and set up your sine wave. See "Construction" on page 5-972.

2 Call step to generate the sinusoid according to the properties of dsp.SineWave. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.SineWave returns a sine wave object, H, that generates a real-valued sinusoid with an amplitude of 1, a frequency of 100 Hz, and a phase offset of 0. By default, the sine wave object only generates one sample.

H = dsp.SineWave('*PropertyName*',*PropertyValue*, ...) returns a sine wave object, H, with each property set to the specified value.

H = dsp.SineWave(AMP,FREQ,PHASE,
'*PropertyName*',*PropertyValue*, ...) returns a sine wave object, H, with the Amplitude property set to AMP, the Frequency property set to

FREQ, the `PhaseOffset` property set to PHASE, and the other specified properties set to the specified values.

Properties

Amplitude

Amplitude of the sine wave

Specify the amplitude as a length-*N* vector containing the amplitudes of the sine waves in each of *N* output channels, or a scalar to apply to all *N* channels. The vector length must equal that specified for the `Frequency` and `PhaseOffset` properties. The default value is 1. This property is tunable when the `Method` property is `Trigonometric function` or `Differential`.

Frequency

Frequency of the sine wave

Specify a length-*N* vector containing frequencies, in hertz, of the sine waves in each of *N* output channels, or a scalar to apply to all *N* channels. The vector length must equal that specified for the `Amplitude` and `PhaseOffset` properties. You can specify positive, zero, or negative frequencies. The default is 100. This property is tunable when the `Method` property is `Trigonometric function`.

PhaseOffset

Phase offset of the sine wave in radians

A length-*N* vector containing the phase offsets, in radians, of the sine waves in each of *N* output channels, or a scalar to apply to all *N* channels. The vector length must equal that specified for the `Amplitude` and `Frequency` properties. The default value is 0. This property is tunable when the `Method` property is `Trigonometric function`.

ComplexOutput

Indicates whether the sine wave is complex or real

Set to `true` to output a complex exponential. The default value is `false`.

dsp.SineWave

Method

Method used to generate sinusoids

The sinusoids are generated by either the `Trigonometric function` , `Table lookup`, or `Differential` methods . The `trigonometric function` method computes the sinusoid by sampling the continuous-time sinusoid. The `table lookup` method precomputes the unique samples of every output sinusoid at the start of the simulation, and recalls the samples from memory as needed. The `differential` method uses an incremental algorithm. This algorithm computes the output samples based on the output values computed at the previous sample time and precomputed update terms. The default value is `Trigonometric function`.

TableOptimization

Optimizes the table of sine values for speed or memory

Optimizes the table of sine values for `Speed` or `Memory`. When optimized for speed, the table contains k elements, and when optimized for memory, the table contains $k/4$ elements, where k is the number of input samples in one full period of the sine wave. This property applies only when the `Method` property is `Table lookup`. The default value is `Speed`.

SampleRate

Sampling rate for the sine wave

Specify the sampling rate of the output, in hertz, as a positive numeric scalar. The default is 1000.

SamplesPerFrame

Number of samples per frame

Specify the number of consecutive samples from each sinusoid to buffer into the output frame. The default is 1.

OutputDataType

Output data type

Specify the output data type as double, single, or Custom. The default value is double.

Fixed-Point Properties

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a numerictype object with a Signedness of Auto. This property applies only when the OutputDataType property is Custom. The default value is numerictype([]1,16).

Methods		
	clone	Create sine wave object with same property values
	getNumInputs	Number of expected inputs to step method
	getNumOutputs	Number of outputs of step method
	isLocked	Locked status for input attributes and nontunable properties
	release	Allow property value and input characteristics changes
	reset	Reset sine wave to the beginning
	step	Discrete-time sine wave

Examples   Generate a sine wave with an amplitude of 2, frequency of 10 Hz, and initial phase of 0:

```
hsin1 = dsp.SineWave(2, 10);
hsin1.SamplesPerFrame = 1000;
y = step(hsin1);
```

```
plot(y);
```

Generate two sine waves offset by a phase of π/2 radians:

```
hsin2 = dsp.SineWave;
hsin2.Frequency = 10;
hsin2.PhaseOffset = [0 pi/2];
hsin2.SamplesPerFrame = 1000;
y = step(hsin2);
plot(y);
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Sine Wave block reference page. The object properties correspond to the block parameters.

See Also   dsp.Chirp | dsp.NCO

Purpose   Create sine wave object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a sine wave object, C, with the same property
                   values as H. The clone method creates a new unlocked object with
                   uninitialized states.

dsp.SineWave.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                  the step method.

                  The getNumInputs method returns a positive integer that is the number
                  of expected inputs (not counting the object itself) to the step method.
                  This value will change if you alter any properties that turn inputs on or
                  off. You must call the step method with the number of input arguments
                  equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the step
method.

The getNumOutputs method returns a positive integer that is the
number of outputs from the step method. This value will change if you
alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the sine wave object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.SineWave.reset

Purpose　　Reset sine wave to the beginning

Syntax　　`reset(H)`

Description　　`reset(H)` resets the sine wave object to the beginning (*n=0*). If you invoke the `step` method without first invoking the `reset` method, the sine wave object generates additional samples of the original sinusoid. As an example:

```
H = dsp.SineWave('Amplitude',1,'Frequency',1/4,'SamplesPerFrame',7);
% 7 samples of a sine wave with frequency of 1/4 Hz
y = step(H);
% Call step method without reset
y1 = step(H);
stem([y; y1])
% y1 is a continuation of y
% Now reset
reset(H);
y2 = step(H);
% y2 starts at n=0 and equals y
isequal(y,y2)
```

Purpose   Discrete-time sine wave

Syntax   `Y = step(H)`

Description   `Y = step(H)` produces the sine wave `Y` using the specifications in the object `H`.

dsp.SpectrumAnalyzer

Purpose   Display frequency spectrum of time-domain signals

Description   The `SpectrumAnalyzer` object displays the frequency spectrum of time-domain signals.

To display the spectra of signals in the Spectrum Analyzer:

1 Define and set up your Spectrum Analyzer. See "Construction" on page 5-986.

2 Call `step` to display the frequency spectrum of the signals in the Spectrum Analyzer figure. The behavior of `step` is specific to each object in the toolbox.

Use the MATLAB `clear` function to close the Spectrum Analyzer figure window and clear its associated data. Use the `hide` method to hide the Spectrum Analyzer window and the `show` method to make it visible.

See the following sections for more information on the Spectrum Analyzer Graphical User Interface:

dsp.SpectrumAnalyzer

Construction   H = dsp.SpectrumAnalyzer creates a Spectrum Analyzer System object, H. This object displays the frequency spectrum of real- and complex-valued floating- and fixed-point signals.

H = dsp.SpectrumAnalyzer('*Name*','*Value*',...) creates a Spectrum Analyzer System object, H, with each specified property *Name* set to the specified value. You can specify *Name–Value* arguments in any order.

Properties   **CenterFrequency**

Frequency over which span is centered

Specify as a real scalar the center frequency, in hertz, of the span over which the Spectrum Analyzer computes and plots the spectrum. This property applies when you set the FrequencySpan property to 'Span and center frequency'. The overall span, defined by the Span and CenterFrequency properties, must fall within the Nyquist frequency interval. When the TwoSidedSpectrum property is set to true, the interval is

$$\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2} \right] + FrequencyOffset \text{ hertz. When}$$

the TwoSidedSpectrum property is set to false, the interval

$$\text{is} \left[0, \frac{SampleRate}{2} \right] + FrequencyOffset \text{ hertz.}$$

This property is Tunable.

Default: 0

FFTLength

FFT length

Specify as a positive, scalar integer the length of the FFT that Spectrum Analyzer uses to compute spectral estimates. This property applies only when you set the FFTLengthSource property to 'Property'.

This property is Tunable.

Default: 128

FFTLengthSource

Source of the FFT length value

Specify the source of the FFT length value as one of 'Auto' or 'Property'.

- When you set this property to 'Auto', the Spectrum Analyzer sets the FFT length to the data segment length required to achieve the specified resolution bandwidth.

- When you set this property to 'Property', specify the number of FFT points using the FFTLength property.

This property is Tunable.

Default: 'Auto'

FrequencyOffset

Frequency offset

Specify as a real, scalar value a frequency offset, in hertz. The *frequency*-axis values, which you also specify, are offset by the value specified in this property. The overall span must fall within the *Nyquist* frequency interval. When the TwoSidedSpectrum property is true, the Nyquist interval is

$$\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$$ hertz. When you set the TwoSidedSpectrum property to false, the Nyquist

interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. You can control the overall span in different ways based on how you set the FrequencySpan property.

Default: 0

FrequencyScale

Frequency scale

Specify the frequency scale as either `'Linear'` or `'Log'`. When you set this property to `'Log'`, the Spectrum Analyzer displays the frequencies on the *x*-axis on a logarithmic scale. To use the `'Log'` setting, you must also set the `TwoSidedSpectrum` property to `false`. When the `TwoSidedSpectrum` property is `true`, you must set this property to `'Linear'`.

This property is Tunable.

Default: `'Linear'`

FrequencySpan

Frequency span mode

Specify the frequency span mode as one of `'Full'`, `'Span and center frequency'`, or `'Start and stop frequencies'`.

- When you set this property to `'Full'`, the Spectrum Analyzer computes and plots the spectrum over the entire *Nyquist* frequency interval. When the `TwoSidedSpectrum` property is `true`, the Nyquist interval is

$$\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset \text{ hertz. If}$$

you set the `TwoSidedSpectrum` property to `false`, the Nyquist

interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.

- When you set this property to `'Span and center frequency'`, the Spectrum Analyzer computes and plots the spectrum over the interval specified by the `Span` and `CenterFrequency` properties.

- When you set this property to `'Start and stop frequencies'`, the Spectrum Analyzer computes and plots the

spectrum over the interval specified by the `StartFrequency` and `StopFrequency` properties.

This property is Tunable.

Default: `'Full'`

Grid

Option to enable or disable grid display

When you set this property to `true`, the grid appears. When you set this property to `false`, the grid does not appear.

This property is Tunable.

Default: `false`

LegendSource

Source of legend

Specify the source of the legend as either `None` or `Auto`. When you set this property to `'None'`, the Spectrum Analyzer does not display a legend. When you set this property to `'Auto'`, the Spectrum Analyzer displays a legend with automatic string labels for each input channel.

This property is Tunable.

Default: `'None'`

MaxHoldTrace

Max-hold trace flag

Set this property to `true` to compute and plot the maximum-hold spectrum of each input channel. The maximum-hold spectrum at each frequency bin is computed by keeping the maximum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its maximum-hold computations.

This property is Tunable.

See also: `MinHoldTrace`, `NormalTrace`.

Default: `false`

MinHoldTrace

Min-hold trace flag

Set this property to `true` to compute and plot the minimum-hold spectrum of each input channel. The minimum-hold spectrum at each frequency bin is computed by keeping the minimum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its minimum-hold computations.

This property is Tunable.

See also: `MaxHoldTrace`, `NormalTrace`.

Default: `false`

Name

Caption to display on Spectrum Analyzer window

Specify the caption to display on the Spectrum Analyzer window as any string.

This property is Tunable.

Default: `'Spectrum Analyzer'`

NormalTrace

Normal trace flag

Set this property to `false` to remove the display of the normal traces. These traces display the free-running spectral estimates. Note that even when the traces are removed from the display, the Spectrum Analyzer continues its spectral computations.

This property is Tunable.

See also: `MaxHoldTrace`, `MinHoldTrace`.

Default: `true`

Position

Spectrum Analyzer window position in pixels

Specify, in pixels, the size and location of the Spectrum Analyzer window as a 4-element double vector of the form, `[left bottom width height]`. You can place the Spectrum Analyzer window in a specific position on your screen by modifying the values for this property.

This property is Tunable.

Default: The default depends on your screen resolution. By default, the Spectrum Analyzer window appears in the center of your screen with a width of `410` pixels and height of `300` pixels.

PowerUnits

Power units

Specify the units in which the Spectrum Analyzer displays power values as either `'dBm'`, `'dBW'`, or `'Watts'`.

This property is Tunable.

Default: `'dBm'`

RBW

Resolution bandwidth

Specify as a real, positive scalar the resolution bandwidth (RBW), in hertz. RBW controls the spectral resolution of Spectrum Analyzer. This property applies only when you set the `RBWSource` property to `'Property'`. You must specify a value to ensure that

there are at least two RBW intervals over the specified frequency span. Thus, the ratio of the overall span to RBW must be greater

than two: $\frac{span}{RBW} > 2$. You can specify the overall span in different ways based on how you set the FrequencySpan property.

This property is Tunable.

See also: RBWSource.

Default: 9.76

RBWSource

Source of resolution bandwidth value

Specify the source of the resolution bandwidth (RBW) as either 'Auto' or 'Property'.

- When you set this property to 'Auto', the Spectrum Analyzer adjusts the spectral estimation resolution. This adjustment ensures that there are 1024 RBW intervals over the defined frequency span.

- When you set this property to 'Property', specify the resolution bandwidth directly when you set the RBW property.

This property is Tunable.

See also: RBW.

Default: 'Auto'

ReferenceLoad

Reference load

Specify as a real, positive scalar the load, in ohms, that the Spectrum Analyzer uses as a reference to compute power values.

This property is Tunable.

Default: 1

SampleRate

Sample rate of input

Specify the sampling rate, in hertz, of the input signals, as a finite numeric scalar.

Default: 10e3

SidelobeAttenuation

Sidelobe attenuation of window

Specify as a real, positive scalar the window sidelobe attenuation, in decibels (dB). This property applies only when you set the Window property to 'Chebyshev' or 'Kaiser'.

This property is Tunable.

Default: 60

Span

Frequency span over which spectrum is computed and plotted

Specify as a real, positive scalar the frequency span, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the FrequencySpan property to 'Span and center frequency'. The overall span, defined by this property and the CenterFrequency property, must fall within the *Nyquist* frequency interval. When the TwoSidedSpectrum property is true, the Nyquist interval is

$$\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset \text{ hertz. When}$$

you set the TwoSidedSpectrum property to false, the Nyquist

interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.

This property is Tunable.

See also: `CenterFrequency`, `TwoSidedSpectrum`.

Default: `10e3`

SpectralAverages

Number of spectral averages

Specify as a positive, scalar integer the number of spectral averages. The Spectrum Analyzer computes the current power spectrum estimate by averaging the last *N* power spectrum estimates. This property defines the number of spectral averages, *N*.

This property is Tunable.

Default: `10`

SpectrumType

Spectrum type

Specify the spectrum type as one of `'Power'` or `'Power density'`.

- When you set this property to `'Power'`, the Spectrum Analyzer shows the power spectrum.

- When you set this property to `'Power density'`, the Spectrum Analyzer shows the power spectral density. The power spectral density is the magnitude squared of the spectrum normalized to a bandwidth of 1 hertz.

This property is Tunable.

Default: `'Power'`

StartFrequency

Start frequency over which spectrum is computed

Specify as a real scalar the start frequency, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the FrequencySpan property to 'Start and stop frequencies'. The overall span, which is defined by StopFrequency and this property, must fall within the *Nyquist* frequency interval. When the TwoSidedSpectrum property is true, the Nyquist interval is

$$\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2} \right] + FrequencyOffset \text{ hertz. If you}$$

set the TwoSidedSpectrum property to false, the Nyquist interval

$$\text{is} \left[0, \frac{SampleRate}{2} \right] + FrequencyOffset \text{ hertz.}$$

This property is Tunable.

See also: StopFrequency, TwoSidedSpectrum.

Default: -5e3

StopFrequency

Stop frequency over which spectrum is computed

Specify as a real scalar the stop frequency, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the FrequencySpan property to 'Start and stop frequencies'. The overall span, defined by this property and the StartFrequency property, must fall within the *Nyquist* frequency interval. When the TwoSidedSpectrum property is set to true, the interval is

$$\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2} \right] + FrequencyOffset \text{ hertz. When}$$

the TwoSidedSpectrum property is set to false, the interval

$$\text{is} \left[0, \frac{SampleRate}{2} \right] + FrequencyOffset \text{ hertz.}$$

This property is Tunable.

See also: `StartFrequency`, `TwoSidedSpectrum`.

Default: 5e3

Title

Display title

Specify the display title as a string.

This property is Tunable.

Default: `''`

TwoSidedSpectrum

Two sided spectrum flag

Set this property to `true` to compute and plot two-sided spectral estimates. Set this property to `false` to compute and plot one-sided spectral estimates. If you set this property to `false`, then the input signal must be real valued. When the input signal is complex valued, you must set this property to `true`.

When this property is `false`, Spectrum Analyzer uses *power folding*. The *y*-axis values are twice the amplitude that they would be if this property were set to `true`, except at 0 and the Nyquist frequency. A one-sided PSD contains the total power of the signal in the frequency interval from DC to half of the Nyquist rate. For more information, see the `pwelch` function reference page.

Default: `true`

Window

Window function

Specify a window function for the spectral estimator as one of the options in the following table. For information on any window

function, follow the link to the corresponding function reference in the Signal Processing Toolbox documentation.

Window Option	Corresponding Function in Signal Processing Toolbox
'Rectangular'	rectwin
'Chebyshev'	chebwin
'Flat Top'	flattopwin
'Hamming'	hamming
'Hann'	hann
'Kaiser'	kaiser

This property is Tunable.

Default: 'Hann'

YLabel

The label for the *y*-axis

Specify as a string the *y*-axis label. Regardless of this property, Spectrum Analyzer always displays power units as one of 'dBm', 'dBW', 'Watts', 'dBm/Hz', 'dBW/Hz', 'Watts/Hz'.

This property is Tunable.

See also: PowerUnits.

Default: ''

YLimits

The limits for the *y*-axis

Specify as a 2-element numeric vector the *y*-axis limits, [ymin, ymax]. The units directly depend upon the PowerUnits property.

This property is Tunable.

dsp.SpectrumAnalyzer

Default: `[-80, 20]`

Methods

clone	Create spectrum scope object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
hide	Hide Spectrum Analyzer window
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of Spectrum Analyzer object
show	Make Spectrum Analyzer window visible
step	Display signal in Spectrum Analyzer figure

Examples

View a two-sided power spectrum of a sine wave with noise on the Spectrum Analyzer.

```
hsin = dsp.SineWave('Frequency',100,'SampleRate',1000);
hsin.SamplesPerFrame = 1000;
hsa = dsp.SpectrumAnalyzer('SampleRate',hsin.SampleRate);
for ii = 1:250
  x = step(hsin) + 0.05*randn(1000,1);
  step(hsa, x);
end
```

Run the `release` method to automatically scale the axes.

```
release(hsa);
```

Run the MATLAB clear function to close the Spectrum Analyzer window.

```
clear('hsa');
```

View a one-sided power spectrum made from the sum of five real sine waves with different amplitudes and frequencies.

```
Fs = 100e6;  % Sampling frequency
fSz = 5000;  % Frame size

hsin1 = dsp.SineWave(1e0,   5e6, 0, 'SamplesPerFrame', fSz, 'SampleRat
hsin2 = dsp.SineWave(1e-1, 15e6, 0, 'SamplesPerFrame', fSz, 'SampleRat
hsin3 = dsp.SineWave(1e-2, 25e6, 0, 'SamplesPerFrame', fSz, 'SampleRat
hsin4 = dsp.SineWave(1e-3, 35e6, 0, 'SamplesPerFrame', fSz, 'SampleRat
hsin5 = dsp.SineWave(1e-4, 45e6, 0, 'SamplesPerFrame', fSz, 'SampleRat

hsb = dsp.SpectrumAnalyzer;
hsb.SampleRate = Fs;
hsb.SpectralAverages = 1;
hsb.TwoSidedSpectrum = false;
hsb.RBWSource = 'Auto';
hsb.PowerUnits = 'dBW';
hsb.Position = [749 227 976 721];
for idx = 1:1e2
    y1 = step(hsin1);
    y2 = step(hsin2);
    y3 = step(hsin3);
    y4 = step(hsin4);
    y5 = step(hsin5);
    step(hsb,y1+y2+y3+y4+y5+0.0001*randn(fSz,1));
end
```

Run the release method to automatically scale the axes.

```
release(hsb);
```

Run the MATLAB clear function to close the Spectrum Analyzer window.

```
clear('hsb');
```

Signal Display

The Spectrum Analyzer indicates the spectrum computation settings that are represented in the current display. Check the **Resolution Bandwidth**, **Number of FFT Points**, **Frequency Span**, and **Center Frequency** indicators on the axes in the scope window for this information. These indicators relate to the **Minimum Frequency-Axis limit** and **Maximum Frequency-Axis limit** values on the *frequency*-axis of the scope window. The values specified by these indicators may be changed by modifying parameters in the **Spectrum Settings** panel. You can also view the object state and the amount of time data that correspond to the current display. Check the **Simulation Status** and **Simulation time** indicators on the status bar in the scope window for this information. The following figure highlights these aspects of the Spectrum Analyzer window.

- **Frequency Span** — The range of values shown on the *frequency*-axis on the Spectrum Analyzer window.

  Details

  Spectrum Analyzer sets the frequency span using the values of parameters on the **Main options** pane of the **Spectrum Settings** panel.

  - Span (Hz) and CF (Hz) visible — The **Frequency Span** value equals the **Span** parameter in the **Main options** pane. You can also get or set this value from the Span property when the FrequencySpan property is set to 'Span and Center Frequency'.

  - FStart (Hz) and FStop (Hz) — The **Frequency Span** value equals the difference of the **FStop** and **FStart** parameters in the

    Main options pane, as given by the formula: $f_{span} = f_{stop} - f_{start}$. You can also get or set these values from the StartFrequency and StopFrequency properties when the FrequencySpan property is set to 'Start and stop frequencies'.

  By default, the **Full Span** check box in the **Main options** pane is enabled, and its equivalent FrequencySpan property is set to 'Full'. In this case, the Spectrum Analyzer computes and plots the spectrum over the entire *Nyquist* frequency interval. When the **Two-sided spectrum** check box in the **Trace options** pane is enabled, and its equivalent TwoSidedSpectrum property is true, the Nyquist interval

  is $\left[-\dfrac{SampleRate}{2}, \dfrac{SampleRate}{2} \right] + FrequencyOffset$ hertz. If you set the TwoSidedSpectrum property to false, the Nyquist interval

  is $\left[0, \dfrac{SampleRate}{2} \right] + FrequencyOffset$ hertz.

- **Resolution Bandwidth** — The smallest positive frequency that can be resolved.

Details

Spectrum Analyzer sets the resolution bandwidth using the value of the **RBW** parameter on the **Main options** pane of the **Spectrum Settings** panel. You can also get or set this value from the RBW property when RBWSource is set to 'Property'. By default, the **RBW** parameter on the **Main options** pane and the related RBWSource property are set to 'Auto'. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified **Frequency Span**.

You can set the resolution bandwidth to whatever value you choose. For this reason, there is a minimum boundary on the number of input samples required to compute a spectral update. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly

related to *RBW* by the following equation: $N = \dfrac{0.2 \times NENBW \times F_s}{RBW}$. *NENBW* is the normalized effective noise bandwidth, a factor of the windowing method used, which is shown in the **Frequency Options** pane. F_s is the sample rate. In some cases, the number of samples provided in the input are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer produces a message on the display, as shown in the following figure.

Spectrum Analyzer removes this message and displays a spectral estimate as soon as enough data has been input.

- **Number of FFT Points** — The Fast Fourier Transform (FFT) length.

Details

Spectrum Analyzer sets the number of FFT points using the value of the **NFFT** parameter on the **Trace options** pane of the **Spectrum Settings** panel. You can also get or set this value from the FFTLength property when the FFTLengthSource property is set to 'Property'. By default, the **NFFT** parameter on the **Trace options** pane and the related FFTLengthSource property are set to 'Auto'. In this case, the Spectrum Analyzer sets the number of FFT points to the data segment length needed to achieve the specified **Resolution Bandwidth**.

- **Center Frequency** — The value shown at the middle point of the *frequency*-axis on the Spectrum Analyzer display.

  Details

  Spectrum Analyzer sets the center frequency using the values of parameters on the **Main options** pane of the **Spectrum Settings** panel.

  - Span (Hz) and CF (Hz) visible — The **Center Frequency** value equals the **CF** parameter in the **Main options** pane. You can also get or set this value from the CenterFrequency property when the FrequencySpan property is set to 'Span and Center Frequency'.

  - FStart (Hz) and FStop (Hz) visible — The **Center Frequency** value equals half the sum of the **FStop** and **FStart** parameters in the **Main options** pane, as given by the

    formula: $f_{center} = \dfrac{f_{start} + f_{stop}}{2}$. You can also get or set these values from the StartFrequency and StopFrequency properties when the FrequencySpan property is set to 'Start and stop frequencies'.

- **Minimum Frequency-Axis limit** — The value shown at the far-left side of the frequency-axis on the Spectrum Analyzer window. Spectrum Analyzer sets the minimum *frequency*-axis limit using the values of the parameters on the **Main options** pane of the **Spectrum Settings** panel.

  Details

  - Span (Hz) and CF (Hz) visible — The **Minimum Frequency-Axis limit** value equals the difference between the center frequency and half the frequency span, as given by the

    following formula: $f_{min} = f_{center} - \dfrac{f_{span}}{2}$. In this case, you can modify the minimum *frequency*-axis limit by changing the **Span** and **CF** parameters in the **Main options** pane. You can also get

or set these values from the Span and CenterFrequency properties when the FrequencySpan property is set to 'Span and Center Frequency'.

- FStart (Hz) and FStop (Hz) visible — The **Minimum Frequency-Axis limit** value equals the **FStart** parameter in the **Main options** pane. You can also get or set this value from the StartFrequency property when the FrequencySpan property is set to 'Start and stop frequencies'.

- **Maximum Frequency-Axis limit** — The value shown at the far-right side of the *frequency*-axis on the Spectrum Analyzer window. Spectrum Analyzer sets the maximum *frequency*-axis limit using the values of the parameters on the **Main options** pane of the **Spectrum Settings** panel.

  Details

  - Span (Hz) and CF (Hz) visible — The **Maximum Frequency-Axis limit** value equals the sum of the center frequency and half the frequency span, as given by the following

    formula: $f_{max} = f_{center} + \dfrac{f_{span}}{2}$. In this case, you can modify the maximum *frequency*-axis limit by changing the **Span** and **CF** parameters in the **Main options** pane. You can also get or set these values from the Span and CenterFrequency properties when the FrequencySpan property is set to 'Span and Center Frequency'.

  - FStart (Hz) and FStop (Hz) visible — The **Maximum Frequency-Axis limit** value equals the **FStop** parameter in the **Main options** pane. You can also get or set this value from the StopFrequency property when the FrequencySpan property is set to 'Start and stop frequencies'.

- **Simulation Status** — Provides the current status of the model simulation.

Details

The status can be one of the following conditions:

- Processing — Occurs after you construct the SpectrumAnalyzer
  object and before you run the release method.

- Stopped — Occurs after you run the release method.

The **Simulation Status** is part of the **Status Bar** in the Spectrum
Analyzer window. You can choose to hide or display the entire **Status
Bar**. From the Spectrum Analyzer menu, select **View > Status Bar**.

- **Simulation time** — The amount of time that has progressed since
  the Spectrum Analyzer System object was first constructed or reset.

Details

Every time you call the step method, the simulation time increases
by the number of rows in the input signal divided by the sample

rate, as given by the following formula: $t_{sim} = t_{sim} + \dfrac{\text{length}(x)}{SampleRate}$.
At the beginning of a simulation, you can modify the **SampleRate**
parameter on the **Main options** pane of the **Spectrum Settings**
panel. You can also set the sample rate using the SampleRate
property.

The **Simulation time** indicator is a component of the **Status Bar** in
the Spectrum Analyzer window. You can choose to hide or display
the entire **Status Bar**. From the Spectrum Analyzer menu, select
View > Status Bar .

For more information, see "Spectrum Settings" on page 5-1009.

Toolbar   The Spectrum Analyzer toolbar contains the following buttons.

Print, Settings, and Properties Buttons

Button	Menu Location	Shortcut Keys	Description
🖶	**File > Print**	**Ctrl+P**	Print the current Spectrum Analyzer window. To enable printing, run the release method.
			To print the current scope window to a figure rather than sending it to your printer, select **File > Print to figure**.
📊	**View > Spectrum Settings**	N/A	Open or close the **Spectrum Settings** panel. You can modify the settings in this panel to control the manner in which the spectrum is calculated.
			See the "Spectrum Settings" on page 5-1009 section for more information.
⚙	**View > Properties**	N/A	Open the **Visuals — Spectrum Options** dialog box.
			See the "Visuals — Spectrum Options" on page 5-1022 section for more information.

Axes Control Buttons

Button	Menu Location	Shortcut Keys	Description
🔍	**Tools > Zoom In**	N/A	When this tool is active, you can zoom in on the scope window. To do so, click in the center of your area of interest, or click and drag your cursor to draw

			a rectangular area of interest inside the scope window.
⼮Q⼮	**Tools > Zoom X**	N/A	When this tool is active, you can zoom in on the *x*-axis. To do so, click inside the scope window, or click and drag your cursor along the *x*-axis over your area of interest.
⼮Q⼮	**Tools > Zoom Y**	N/A	When this tool is active, you can zoom in on the *y*-axis. To do so, click inside the scope window, or click and drag your cursor along the *y*-axis over your area of interest.
⛶	**Tools > Scale Axes Limits**	**Ctrl+A**	Click this button to scale the axes in the active scope window. Alternatively, you can enable automatic axes scaling by selecting one of the following options from the **Tools** menu: • **Automatically Scale Axes Limits** — When you select this option, the scope scales the axes as needed during simulation. • **Scale Axes Limits at Stop** — When you select this option, the scope scales the axes each time the simulation is stopped.

Measurements Buttons

	Tools > Measurements > Peak Finder	N/A	Open or close the **Peak Finder** panel. This panel displays maxima and the frequencies at which they occur, allowing the settings for peak threshold, maximum number of peaks, and peak excursion to be modified.
			See the "Peak Finder Panel" on page 5-1018 section for more information.

Note The zoom buttons do not change the settings related to span for Spectrum Analyzer. These buttons are purely graphical. Spectrum computations are not affected when you zoom.

You can control whether this toolbar appears in the Spectrum Analyzer window. From the Spectrum Analyzer menu, select **View > Toolbar**.

Spectrum Settings

The **Spectrum Settings** panel appears at the right side of the Spectrum Analyzer figure. This panel enables you to modify settings to control the manner in which the spectrum is calculated. You can choose to hide or display the **Spectrum Settings** panel. In the Spectrum Analyzer menu, select **View > Spectrum Settings**. Alternatively, in the Spectrum Analyzer toolbar, select the Spectrum Settings button.

The **Spectrum Settings** panel is separated into three panes, labeled **Main Options**, **Trace Options**, and **Frequency Options**. You can expand each pane to see the available options.

Main Options Pane

The **Main Options** pane enables you to modify the main options.

- **Sample rate (Hz)** — The sample rate, in hertz, of the input signals. This parameter is also known as sampling frequency.

- **Full span** — Enable this check box to have Spectrum Analyzer compute and plot the spectrum over the entire *Nyquist* frequency interval. By default, when the **Two-sided spectrum** check box is also enabled, the Nyquist interval is

$$\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2} \right] + FrequencyOffset$$ hertz. If you clear the **Two-sided spectrum** check box, the Nyquist interval

is $\left[0, \frac{SampleRate}{2} \right] + FrequencyOffset$ hertz. Enabling this check box is equivalent to setting the FrequencySpan property to 'Full'.

- **Span (Hz)** and **CF (Hz)**, or **FStart (Hz)** and **FStop (Hz)** — When **Span (Hz)** is showing in the **Main Options** pane, you define the range of values shown on the *frequency*-axis on the Spectrum Analyzer window using frequency span and center frequency. From the drop-down list, select **FStart (Hz)** to define the range of *frequency*-axis values using start frequency and stop frequency instead.

  - **Span (Hz)** — The frequency span, in hertz. This parameter defines the range of values shown on the *frequency*-axis on the Spectrum Analyzer window. When this parameter is set to a numeric value, then it is equivalent to the Span property when the FrequencySpan property is set to 'Span and Center Frequency'.

    When this parameter is set to

  - **CF (Hz)** — The center frequency, in hertz. This parameter defines the value shown at the middle point of the *frequency*-axis on the Spectrum Analyzer window. This parameter is equivalent to the CenterFrequency property when the FrequencySpan property is set to 'Span and Center Frequency'.

  - **FStart (Hz)** — The start frequency, in hertz. This parameter defines the value shown at the leftmost side of the *frequency*-axis on the Spectrum Analyzer window. This parameter is equivalent to the StartFrequency property when the FrequencySpan property is set to 'Start and stop frequencies'.

  - **FStop (Hz)** — The stop frequency, in hertz. The parameter defines the value shown at the rightmost side of the *frequency*-axis on the Spectrum Analyzer window. This parameter is equivalent to the StopFrequency property when the FrequencySpan property is set to 'Start and stop frequencies'.

- **RBW (Hz)** — The resolution bandwidth, in hertz. This parameter defines the smallest positive frequency that can be resolved. By default, this parameter is set to Auto. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 *RBW* intervals over the specified **Frequency Span**. This case is equivalent to when you set the RBWSource property to 'Auto'.

If you set this parameter to a numeric value, then you must specify a value that ensures there are at least two *RBW* intervals over the specified frequency span. In other words, the ratio of the overall span to *RBW* must be at least two: $\frac{span}{RBW} > 2$. In this case, this parameter is equivalent to the RBW property, when RBWSource is set to 'Property'.

- **Samples/update** — The number of input samples required to compute one spectral update. This parameter is directly related to *RBW* by the following equation: $N = \frac{0.2 \times NENBW \times F_s}{RBW}$. *NENBW* is the normalized effective noise bandwidth, a factor of the windowing method used, which is shown in the **Frequency Options** pane. F_s is the sample rate. If the number of samples provided in the input are not sufficient to achieve the resolution bandwidth that you specify, Spectrum Analyzer produces a message on the display as shown in the following figure.

Trace Options Pane

The **Trace Options** pane enables you to modify the trace options.

- **Type** — The type of spectrum to display. Acceptable options are
  Power and Power density. When you set this parameter to Power,
  the Spectrum Analyzer shows the power spectrum. When you set
  this parameter to Power density, the Spectrum Analyzer shows the
  power spectral density. The power spectral density is the magnitude
  of the spectrum normalized to a bandwidth of 1 hertz. This parameter
  is equivalent to the SpectrumType property.

- **Units** — The units of the spectrum. Acceptable options are dBm, dBW,
  and Watts. This parameter is equivalent to the PowerUnits property.

- **Averages** — Specify as a positive, scalar integer the number
  of spectral averages. Spectrum Analyzer computes the current
  power spectrum estimate by averaging the last N power spectrum

estimates. This property defines the number of spectral averages, *N*. This parameter is equivalent to the `SpectralAverages` property.

- **NFFT** — The number of Fast Fourier Transform (FFT) points. This parameter defines the length of the FFT that Spectrum Analyzer uses to compute spectral estimates. Acceptable options are `Auto` or a positive, scalar integer. By default, when this parameter is set to `Auto`, Spectrum Analyzer sets the number of FFT points to the data segment length needed to achieve the resolution bandwidth you specified. This case is equivalent to when you set the `FFTLengthSource` property to `'Auto'`.

  When this parameter is set to a positive integer, this parameter is equivalent to the `n` parameter that you can set when you run the MATLAB `fft` function. In this case, this parameter is also equivalent to `FFTLength` when you set `FFTLengthSource` to `'Property'`.

- **Ref. load** — The reference load, in ohms, used to scale the spectrum. Specify as a real, positive scalar load, in ohms, that the Spectrum Analyzer uses as a reference to compute power values. This parameter is equivalent to the `ReferenceLoad` property.

- **Normal trace** — Normal trace view. By default, when this check box is enabled, Spectrum Analyzer calculates and plots the power spectrum or power spectrum density computed by the *Welch* estimator. The Welch estimator performs a smoothing operation by averaging a number of spectral estimates. To clear this check box, you must first select either the **Max hold trace** or the **Min hold trace** check box. This parameter is equivalent to the `NormalTrace` property.

- **Max hold trace** — Maximum hold trace view. Select this check box to enable Spectrum Analyzer to plot the maximum spectral values of all the estimates obtained. This parameter is equivalent to the `MaxHoldTrace` property.

- **Min hold trace** — Minimum hold trace view. Select this check box to enable Spectrum Analyzer to plot the minimum spectral values of all the estimates obtained. This parameter is equivalent to the `MinHoldTrace` property.

• **Two-sided spectrum** — Select this check box to enable two-sided spectrum view. In this view, both negative and positive frequencies are shown. If you clear this check box, Spectrum Analyzer shows a one-sided spectrum with only positive frequencies. Spectrum Analyzer requires that this parameter is selected when the input signal is complex-valued. This parameter is equivalent to the `TwoSidedSpectrum` property.

Frequency Options Pane

The **Frequency Options** pane enables you to modify the frequency options.

• **Scale** — Linear or logarithmic scale. When the frequency span contains negative frequency values, Spectrum Analyzer disables the logarithmic option. This parameter is equivalent to the `FrequencyScale` property.

• **Offset** — The constant frequency offset to apply to the entire spectrum. This constant offset parameter is simply added to the values on the *frequency*-axis in the Spectrum Analyzer window. It is not used in any spectral computations. It does not affect any settings related to frequency span or resolution. This parameter is equivalent to the `FrequencyOffset` property.

• **Window** — The windowing method to apply to the spectrum. This parameter is equivalent to the `Window` property.

Windowing is used to control the effect of sidelobes in spectral estimation. For more information about windowing, see "Windows" in the Signal Processing Toolbox documentation.

• **Attenuation (dB)** — The sidelobe attenuation, in decibels (dB). This property applies only when you set the **Window** parameter to `Chebyshev` or `Kaiser`. This parameter is equivalent to the `SidelobeAttenuation` property.

• **NENBW** — Normalized Effective Noise Bandwidth of the window. This parameter is a measure of the noise performance of the window. It is the width of a rectangular filter that accumulates the same

noise power with the same peak power gain. NENBW can be calculated from the windowing function using the following equation:

$$NENBW = \frac{\sum\limits_{n} w^2(nT)}{\left[\sum\limits_{n} w(nT)\right]^2}$$. The rectangular window has the smallest NENBW, with a value of 1. All other windows have a larger NENBW value. For example, the Hann window has an NENBW value of 1.5.

Measurements Panels
The Measurements panels are the other two panels that appear to the right side of the Spectrum Analyzer figure. These panels are labeled **Trace selection** and **Peak finder**.

Measurements Panel Buttons

Each of the Measurements panels contains the following buttons that enable you to modify the appearance of the current panel.

Button	Description
⊼	Move the current panel to the top. When you are displaying more than one panel, this action moves the current panel above all the other panels.
▼	Collapse the current panel. When you first enable a panel, by default, it displays one or more of its panes. Click this button to hide all of its panes to conserve space. After you click this button, it becomes the expand button ▶.
▶	Expand the current panel. This button appears after you click the collapse button to hide the panes in the current panel. Click this button to display the panes in the current panel and show measurements again. After you click this button, it becomes the collapse button ▼ again.

Button	Description
↗	Undock the current panel. This button lets you move the current panel into a separate window that can be relocated anywhere on your screen. After you click this button, it becomes the dock button ↘ in the new window.
↘	Dock the current panel. This button appears only after you click the undock button. Click this button to put the current panel back into the right side of the Scope window. After you click this button, it becomes the undock button ↗ again.
✕	Close the current panel. This button lets you remove the current panel from the right side of the Scope window.

Some panels have their measurements separated by category into a number of panes. Click the pane expand button ▶ to show each pane that is hidden in the current panel. Click the pane collapse button ▼ to hide each pane that is shown in the current panel.

Trace Selection Panel

When you use the Scope to view multiple signals, the Trace Selection panel appears if you have more than one signal displayed and you click on any of the other Measurements panels. Choose the signal name for which you would like to display time domain measurements. See the following figure.

You can choose to hide or display the **Trace Selection** panel. In the Scope menu, select **Tools > Measurements > Trace Selection**.

Peak Finder Panel

The **Peak Finder** panel displays maxima and the times at which they occur, allowing the settings for peak threshold, maximum number of peaks, and peak excursion to be modified. You can choose to hide or display the **Peak Finder** panel. In the Spectrum Analyzer menu, select **Tools > Measurements > Peak Finder**. Alternatively, in the Spectrum Analyzer toolbar, select the Peak Finder [icon] button.

The **Peak finder** panel is separated into two panes, labeled **Settings** and **Peaks**. You can expand each pane to see the available options.

Settings Pane

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the Signal Processing Toolbox `findpeaks` function reference.

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the MINPEAKHEIGHT parameter, which you can set when you run the findpeaks function.

- **Max Num of Peaks** — The maximum number of peaks to show. This setting is equivalent to the NPEAKS parameter, which you can set when you run the findpeaks function.

- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the MINPEAKDISTANCE parameter, which you can set when you run the findpeaks function.

- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples. Peak excursion is illustrated alongside peak threshold in the following figure.

Whereas the peak threshold is a minimum value necessary for a sample value to be a peak, the peak excursion is the minimum difference between a peak sample and the samples to its left and right in the time domain. In the figure, the green vertical line illustrates the lesser of the two height differences between the labeled peak and its neighboring samples. This height difference must be greater than the **Peak Excursion** value for the labeled peak to be classified as a peak. Compare this setting to peak threshold, which is illustrated by the red horizontal line. The amplitude must be above this horizontal line for the labeled peak to be classified as a peak.

The peak excursion setting is equivalent to the THRESHOLD parameter, which you can set when you run the findpeaks function.

- **Label peaks** — When this check box is selected, the Peak Finder displays the calculated peak values directly on the plot. By default, this check box is cleared and no values are displayed on the plot.

- **Sort by order** — When this check box is selected, the Peak Finder puts the largest calculated peak values in frequency-sorted order. The Peak Finder displays the peak values in the **Peaks** pane. The number of peaks listed is still controlled by the **Max Num of Peaks** parameter. By default, this check box is cleared and the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height.

Peaks Pane

The **Peaks** pane displays all of the largest calculated peak values and the frequencies at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list. You set the order in which the peaks are listed using the **Sort by time** check box.

The numerical values displayed in the **Value** column are equivalent to the pks output argument returned when you run the findpeaks function. The numerical values displayed in the **Frequency** column are similar to the locs output argument returned when you run the findpeaks function.

When you use the zoom options in the Spectrum Analyzer GUI, the peak locations automatically adjust to the frequency range shown in the display. In the Spectrum Analyzer toolbar, click the **Zoom In** or **Zoom X** button to make adjustments. If you constrict the *x*-axis range of the display, then the statistics shown reflect this frequency range. For example, if you zoom in on one peak, the **Peak Finder** panel displays information about only that particular peak.

**Visuals —
Spectrum
Options**

The Visuals:Spectrum Options dialog box controls the visual configuration settings of the Spectrum Analyzer displays. From the Spectrum Analyzer menu, select **View > Properties** to open this dialog box. Alternatively, in the Spectrum Analyzer toolbar, click the properties ⚙ button.

Display Pane

The **Display** pane of the Spectrum Analyzer — Visuals:Spectrum Options dialog box appears as follows.

Title

Specify the display title as a string. By default, the display has no title. Tunable.

Show legend

Select this check box to show the legend in the active display. The channel legend displays a name for each channel of each input signal. When the legend appears, you can place it anywhere inside of the scope window. To turn the legend off, clear the **Show legend** check box. Tunable.

You can edit the name of any channel in the legend. To do so, double-click the current name, and enter a new channel name. By default, the scope names each channel according to either its signal name or the name of the block from which it comes. If the signal has multiple channels, the scope uses an index number to identify each channel of that signal. For example, a 2-channel signal would have the following default names in the channel legend: `Channel 1`, `Channel 2`.

To change the appearance of any channel of any input signal in the Spectrum Analyzer window, from the Spectrum Analyzer menu, select **View > Style**.

Show grid

When you select this check box, a grid appears in the active display of the Spectrum Analyzer GUI. To hide the grid, clear this check box. Tunable.

Minimum Y-limit

Specify the minimum value of the *y*-axis. Tunable.

Maximum Y-limit

Specify the maximum value of the *y*-axis. Tunable.

Y-axis label

Specify the text for the scope to display to the left of the *y*-axis. Regardless of this property, Spectrum Analyzer always displays power units after this text as one of `'dBm'`, `'dBW'`, `'Watts'`, `'dBm/Hz'`, `'dBW/Hz'`, or `'Watts/Hz'`.Tunable.

Style Dialog Box

In the **Style** dialog box, you can customize the style of displays. You are able to change the color of the figure, the background and foreground colors of the axes, and properties of the lines. From the Spectrum Analyzer menu, select **View > Style** to open this dialog box.

Properties

The **Style** dialog box allows you to modify the following properties of the Spectrum Analyzer GUI:

Figure color
Specify the color that you want to apply to the background of the Spectrum Analyzer GUI. By default, the figure color is gray.

Axes colors
Specify the color that you want to apply to the background of the axes for the display.

Properties for line
Specify the channel for which you want to modify the visibility, line properties, and marker properties.

Visible
Specify whether the selected signal on the display should be visible. If you clear this check box, the line disappears.

Line

Specify the line style, line width, and line color for the selected signal on the display.

Marker

Specify marks for the selected signal on the display to show at data points. This parameter is similar to the Marker property for the MATLAB Handle Graphics plot objects. You can choose any of the marker symbols from the following table.

Specifier	Marker Type
none	No marker (default)
○	Circle
□	Square
×	Cross
●	Point
+	Plus sign
＊	Asterisk
◇	Diamond
▽	Downward-pointing triangle
△	Upward-pointing triangle
◁	Left-pointing triangle
▷	Right-pointing triangle

Specifier	Marker Type
☆	Five-pointed star (pentagram)
✡	Six-pointed star (hexagram)

**Tools —
Plot
Navigation
Options**

The Tools:Plot Navigation Options dialog box allows you to
automatically zoom in on and zoom out of your data. You can also scale
the axes of the Spectrum Analyzer. In the Spectrum Analyzer menu,
select **Tools > Axes Scaling Options** to open this dialog box.

Parameters

The Tools:Plot Navigation Options dialog box appears as follows.

Axis Scaling

Specify when the Scope should automatically scale the axes. You can
select one of the following options:

- Manual — When you select this option, the Scope does not
  automatically scale the axes. You can manually scale the axes in
  any of the following ways:

- ▪ Select **Tools > Scale axes limits**.

- ▪ Press the **Scale Axes Limits** toolbar button.

- ▪ When the scope GUI is the active window, press **Ctrl+A**.

- Auto — When you select this option, the Scope scales the axes as needed, both during and after simulation. Selecting this option enables the **Do not allow Y-axis limits to shrink** check box. By default, this parameter is selected, and the Scope does not shrink the *y*-axis limits when scaling the axes.

- Once at stop — Selecting this option causes the Scope to scale the axes each time simulation is stopped. The Scope does not scale the axes during simulation.

This parameter is Tunable.

Do not allow Y-axis limits to shrink

When you select this parameter, the *y*-axis limits are only allowed to grow during axes scaling operations. If you clear this check box, the *y*-axis limits may shrink during axes scaling operations.

This parameter appears only when you select Auto for the **Axis Scaling** parameter. When you set the **Axis Scaling** parameter to Manual or Once at stop, the *y*-axis limits are allowed to shrink. Tunable.

Y-axis Data range (%)

Set the percentage of the *y*-axis that the Scope should use to display the data when scaling the axes. Valid values are between 1 and 100. For example, if you set this parameter to 100, the Scope scales the *y*-axis limits such that your data uses the entire *y*-axis range. If you then set this parameter to 30, the Scope increases the *y*-axis range such that your data uses only 30% of the *y*-axis range. Tunable.

Y-axis Align

Specify where the Scope should align your data with respect to the *y*-axis when it scales the axes. You can select Top, Center, or Bottom. Tunable.

Scale X-axis limits

Check this box to allow the Scope to scale the *x*-axis limits when it scales the axes. Tunable.

X-axis Data range (%)

Set the percentage of the x-axis that the Scope should use to display the data when scaling the axes. Valid values are between 1 and 100. For example, if you set this parameter to 100, the Scope scales the x-axis limits such that your data uses the entire x-axis range. If you then set this parameter to 30, the Scope increases the x-axis range such that your data uses only 30% of the x-axis range. Use the x-axis **Align** parameter to specify data placement with respect to the x-axis.

This parameter appears only when you select the **Scale X-axis limits** check box. Tunable.

X-axis Align

Specify how the Scope should align your data with respect to the x-axis: Left, Center, or Right. This parameter appears only when you select the **Scale X-axis limits** check box. Tunable.

See Also   dsp.TimeScope

Purpose   Create spectrum scope object with same property values

Syntax   `C = clone(H)`

Description   `C = clone(H)` creates a `SpectrumAnalyzer` object `C`, with the same
                 property values as `H`. The `clone` method creates a new unlocked object
                 with uninitialized states.

dsp.SpectrumAnalyzer.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description N = getNumInputs(H) returns the number of expected inputs, N, to the
step method. N equals the value of the NumInputPorts property.

The getNumInputs method returns a positive integer that is the number
of expected inputs (not counting the object itself) to the step method.
This value will change if you alter any properties that turn inputs on or
off. You must call the step method with the number of input arguments
equal to the result of getNumInputs(*H*).

Purpose　　　　Number of outputs of step method

Syntax　　　　N = getNumOutputs(H)

Description　　N = getNumOutputs(H) returns the number of outputs, N, of the step method. The Spectrum Analyzer is a sink object, so N equals 0.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

dsp.SpectrumAnalyzer.hide

Purpose	Hide Spectrum Analyzer window
Syntax	`hide(H)`
Description	`hide(H)` hides the Spectrum Analyzer window, associated with System object, `H`.
See Also	dsp.SpectrumAnalyzer	dsp.SpectrumAnalyzer.show

Purpose   Locked status for input attributes and nontunable properties

Syntax   `isLocked(H)`

Description   `isLocked(H)` returns the locked state of the `SpectrumAnalyzer` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.SpectrumAnalyzer.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

You should call the `release` method after calling the `step` method when there is no new data for the simulation. When you call the `release` method, the axes will automatically scale in the Spectrum Analyzer figure window. After calling the `release` method, any non-tunable properties can be set once again.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Algorithms   In operation, the `release` method is similar to the `mdlTerminate` function.

See Also   dsp.SpectrumAnalyzer | dsp.SpectrumAnalyzer.reset

Purpose   Reset internal states of Spectrum Analyzer object

Syntax   reset(H)

Description   reset(H) sets the internal states of the SpectrumAnalyzer object H to
                     their initial values.

                     You should call the reset method after calling the step method
                     when you want to clear the Spectrum Analyzer figure displays, prior
                     to releasing system resources. This action enables you to start a
                     simulation from the beginning. When you call the reset method, the
                     displays will become blank again. In this sense, its functionality is
                     similar to that of the MATLAB clf function. Do not call the reset
                     method after calling the release method.

Algorithms   In operation, the reset method is similar to a consecutive execution
                     of the mdlTerminate function and the mdlInitializeConditions
                     function.

See Also   dsp.SpectrumAnalyzer | dsp.SpectrumAnalyzer.release

dsp.SpectrumAnalyzer.show

Purpose   Make Spectrum Analyzer window visible

Syntax   show(H)

Description show(H) makes the Spectrum Analyzer window, associated with System
object, H, visible.

See Also   dsp.SpectrumAnalyzer | dsp.SpectrumAnalyzer.hide

Purpose   Display signal in Spectrum Analyzer figure

Syntax   step(H,X)
                step(H,X1,X2,...,XN)

Description step(H,X) displays the signal, X, in the Spectrum Analyzer figure.

                step(H,X1,X2,...,XN) displays the signals X1, X2,...,XN in the
                Spectrum Analyzer figure when you set the NumInputPorts property
                to N. In this case, X1, X2,...,XN can have different data types and
                dimensions.

dsp.StandardDeviation

Purpose	Standard deviation of input or sequence of inputs

Description

The StandardDeviation object computes the standard deviation for an input or sequence of inputs.

To compute the standard deviation for an input or sequence of inputs:

1 Define and set up your standard deviation object. See "Construction" on page 5-1038.

2 Call step to compute the standard deviation according to the properties of dsp.StandardDeviation. The behavior of step is specific to each object in the toolbox.

Construction

H = dsp.StandardDeviation returns a standard deviation System object, H, that computes the standard deviation for the columns of input.

H = dsp.StandardDeviation('*PropertyName*',*PropertyValue*,...) returns a standard deviation System object, H, with each specified property set to the specified value.

Properties

RunningStandardDeviation

Enable calculation over successive calls to the step method

Set this property to true to enable the calculation of standard deviation over successive calls to the step method. The default is false.

ResetInputPort

Enable resetting in running standard deviation mode

Set this property to true to enable resetting for the running standard deviation. When the property is set to true, you must specify a reset input to the step method to reset the running standard deviation. This property applies only when you set the RunningStandardDeviation property to true. The default is false.

ResetCondition

Reset condition for running standard deviation mode

Specify event to reset the running standard deviation as one of | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero` |. This property applies only when you set the `ResetInputPort` property to `true`. The default is `Non-zero`.

Dimension

Dimension to operate along

Specify how the standard deviation calculation is performed over the data as one of | `All` | `Row` | `Column` | `Custom` |. This property applies only when you set the `RunningStandardDeviation` property to `false`. The default is `Column`.

CustomDimension

Numerical dimension to operate along

Specify the dimension (one-based value) of the input signal, over which the object computes the standard deviation. The cannot exceed the number of dimensions for the input signal. This property applies when you set the `Dimension` property to `Custom`. The default is `1`.

ROIProcessing

ROIProcessing

Enable region of interest processing

Set this property to `true` to enable calculating the standard deviation within a particular region for each image. This property applies only when you set the `RunningStandardDeviation` property to `false` and the `Dimension` property is `All`. The default is `false`.

Full ROI processing support requires a Computer Vision System Toolbox license. With only the DSP System Toolbox license, `Rectangles` is the only selection that applies for the `ROIForm` property.

ROIForm

Type of region of interest

Specify the type of region of interest as one of | Rectangles | Lines | Label matrix | Binary mask |. This property applies only when you set the ROIProcessing property to true. The default is Rectangles.

Full ROI processing support requires a Computer Vision System Toolbox license. With only the DSP System Toolbox license, Rectangles is the only selection that applies for the ROIForm property.

ROIPortion

Calculate over entire ROI or just perimeter

Specify the region over which to calculate the standard deviation as one of | Entire ROI | ROI perimeter |. This property applies if the ROIForm property is Rectangles. The default is Entire ROI.

ROIStatistics

Statistics for each ROI, or one for all ROIs

Specify what statistics to calculate as one of | Individual statistics for each ROI | Single statistic for all ROIs |. This property applies when you set the ROIForm property to Rectangles, Lines, or Label matrix. The default is Individual statistics for each ROI.

ValidityOutputPort

Enable output of validity check of ROI or label numbers

Indicate whether to return the validity of the specified ROI being completely inside image when the ROIForm property is Lines, Rectangles or Binary mask. Indicate whether to return the validity of the specified label numbers when the ROIForm property is Label Matrix. This property applies when you set the ROIForm property to anything except Binary Mask. The default is false.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. This property applies only when you set the `RunningStandardDeviation` property to `true`. The default is `true`.

Methods

clone	Create standard deviation object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset states for running standard deviation computation
step	Calculate standard deviation of input

Examples

Compute running standard deviation of a signal:

```
hstd2 = dsp.StandardDeviation;
hstd2.RunningStandardDeviation = true;
x = randn(100,1);
y = step(hstd2,x);
% y(i) is the standard deviation of all values
% in the vector x(1:i)
```

dsp.StandardDeviation

Algorithms   This object implements the algorithm, inputs, and outputs described
on the Standard Deviation block reference page. The object properties
correspond to the block parameters, except:

- The **Reset port** block parameter corresponds to the ResetInputPort
  and ResetCondition object properties.

- **Treat sample-based row input as a column** block parameter is
  not supported by the dsp.StandardDeviation object.

Both this object and its corresponding block let you specify whether to
process inputs as individual samples or as frames of data. The object
uses the FrameBasedProcessing property. The block uses the **Input
processing** parameter. See "Set the FrameBasedProcessing Property
of a System object" for more information.

See Also   dsp.Variance | dsp.Maximum | dsp.Minimum | dsp.Mean

Purpose   Create standard deviation object with same property values

Syntax   C = clone(H)

Description C = clone(H) creates a StandardDeviation object C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

dsp.StandardDeviation.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                   method.

                   The getNumOutputs method returns a positive integer that is the
                   number of outputs from the step method. This value will change if you
                   alter any properties that turn outputs on or off.

dsp.StandardDeviation.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the StandardDeviation object
H.

The isLocked method returns a logical value that indicates whether
input attributes and nontunable properties for the object are locked. The
object performs an internal initialization the first time the step method
is executed. This initialization locks nontunable properties and input
specifications, such as dimensions, complexity, and data type of the
input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset states for running standard deviation computation

Syntax   reset(H)

Description   reset(H) sets the internal states of the StandardDeviation object H to their initial values when computing the running standard deviation.

Purpose   Calculate standard deviation of input

Syntax   Y = step(H,X)
                   Y = step(H,X,R)
                   Y = step(H,X,ROI)
                   Y = step(H,X,LABEL,LABELNUMBERS)
                   [Y, FLAG] = step(H,X,ROI)
                   [Y, FLAG] = step(H,X,LABEL,LABELNUMBERS)

Description   Y = step(H,X) computes the standard deviation,Y, of input X. The
                   object computes the standard deviation over successive calls to the step
                   method when the RunningStandardDeviation property is true.

                   Y = step(H,X,R) resets its state based on the value of reset signal R
                   and the ResetCondition property. You can use this option only when
                   the RunningStandardDeviation property is true.

                   Y = step(H,X,ROI) uses additional input ROI as the region of interest
                   when the ROIProcessing property is set to true and the ROIForm
                   property is set to Lines, Rectangles or Binary mask.

                   Y = step(H,X,LABEL,LABELNUMBERS) computes the standard deviation
                   of input image X for region labels contained in vector LABELNUMBERS
                   , with matrix LABEL marking pixels of different regions. This option
                   is available when the ROIProcessing property is set to true and the
                   ROIForm property is set to Label matrix.

                   [Y, FLAG] = step(H,X,ROI) returns FLAG which indicates whether
                   the given region of interest is within the image bounds when the
                   ValidityOutputPort property is true.

                   [Y, FLAG] = step(H,X,LABEL,LABELNUMBERS) returns FLAG which
                   indicates whether the input label numbers are valid when the
                   ValidityOutputPort property is true.

Note The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

Purpose   State-level estimation for bilevel rectangular waveform

Description   The StateLevels object estimates the state levels of a bilevel rectangular waveform.

To estimate the state levels of a bilevel waveform:

1 Define and set up your state-level estimation. See "Construction" on page 5-1051.

2 Call step to estimate the state levels for an input vector according to the properties of dsp.StateLevels. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.StateLevels creates a state-level estimation System object, H, that estimates state levels in a bilevel rectangular waveform using the histogram method with 100 bins.

H = dsp.StateLevels('*PropertyName*',*PropertyValue*,...) returns an StateLevels System object, H, with each specified property set to the specified value.

Properties   **HistogramBounds**

Minimum and maximum levels of the histogram. Specify the range of the histogram as a 2-element real–valued row vector. Signal values outside the range defined by this property are ignored. This property applies when you set the Method property to 'Histogram mode' or 'Histogram mean', and either RunningStateLevels is true, or the HistogramBoundsSource property is set to 'Property'.

Default: [0 5]

HistogramBoundsSource

Source of histogram bounds. Specify how to determine the histogram bounds as one of 'Auto' or 'Property'. When you set this property to 'Auto', the histogram bounds are determined by

the minimum and maximum input values. When you set this property to `'Property'`, the histogram bounds are determined by the value of the `HistogramBounds` property. This property applies when you set the `Method` property to `'Histogram mode'` or `'Histogram mean'`, and the `RunningStateLevels` property is `false`.

Default: `'Auto'`

HistogramNumBins

Number of bins in the histogram. Specify the number of bins in the histogram. This property applies when you set the `Method` property to `'Histogram mode'` or `'Histogram mean'`.

Default: 100

HistogramOutputPort

Enable histogram output. Set this property to `true` to output the histogram used in the computation of the state levels. This property applies when you set the `Method` property to `'Histogram mode'` or `'Histogram mean'`.

Default: false

Method

Algorithm used to compute state levels. Specify the method used to compute state levels as one of `'Histogram mean'`, `'Histogram mode'`, or `'Peak to peak'`.

Default: `'Histogram mode'`

RunningStateLevels

Calculation over successive calls to `step`. Set this property to `true` to enable computation of the state levels over successive calls to the `step`. Otherwise, compute the state levels of the current

input. When you set the `RunningStateLevels` property to `false` and you are using a histogram to compute your state levels, you must set the `HistogramBoundsSource` property to `'Property'`.

Methods

clone	Clones the current instance of the state levels object
getNumInputs	Number of expected inputs to the method
getNumOutputs	Number of outputs of the method
isLocked	Locked status (logical) for input attributes and nontunable properties
plot	Plot signal, state levels, and histogram
release	Allow property value and input characteristics changes
reset	Reset internal states of state levels object
step	Estimate state levels for bilevel rectangular waveform

Definitions

State

A particular level, which can be associated with an upper and lower state boundary. States are ordered from the most negative to the most positive. In a bilevel waveform, the most negative state is the low state. The most positive state is the high state.

State-Level Tolerances

Each state level can have associated lower- and upper-state boundaries. These state boundaries are defined as the state level plus or minus a scalar multiple of the difference between the high state and low state.

To provide a useful tolerance region, the scalar is typically a small number such as 2/100 or 3/100. In general, the α% tolerance region for the low state is defined as

$$S_1 \pm \tfrac{\alpha}{100}(S_2 - S_1)$$

where S_1 is the low-state level and S_2 is the high-state level. Replace the first term in the equation with S_2 to obtain the α% tolerance region for the high state.

The following figure illustrates lower and upper 2% state boundaries (tolerance regions) for a positive-polarity bilevel waveform. The estimated state levels are indicated by a dashed red line.

State Levels ± 2% Tolerance

Examples   **State Levels of 2.3 V Underdamped Noisy Clock**

Compute and plot the state levels of a 2.3 V underdamped noisy clock.

dsp.StateLevels

Load the clock data in the variable, x, and the sampling instants in the variable, t.

```
load('clockex.mat', 'x', 't');
```

Estimate the state levels.

```
 h = dsp.StateLevels;
 levels = step(h, x);
```

Plot the clock data along with the estimated state levels and histograms.

```
plot(h)
```

Algorithms

The StateLevels System object uses the histogram method to estimate the states of a bilevel waveform. The histogram method is described in [1]. To summarize the method:

1 Determine the maximum and minimum amplitudes and amplitude range of the data.

2 For the specified number of histogram bins, determine the bin width as the ratio of the amplitude range to the number of bins.

3 Sort the data values into the histogram bins.

4 Identify the lowest-indexed histogram bin, i_{low}, and highest-indexed histogram bin, i_{high}, with nonzero counts.

5 Divide the histogram into two subhistograms. The lower-histogram bins are $i_{low} \le i \le 1/2(i_{high} - i_{low})$.

The upper-histogram bins are $i_{low} + 1/2(i_{high} - i_{low}) \le i \le i_{high}$.

6 Compute the state levels by determining the mode or mean of the lower and upper histograms.

See Also   dsp.TransitionMetrics **|** dsp.PulseMetrics **|**

dsp.StateLevels.clone

Purpose   Clones the current instance of the state levels object

Syntax   clone(H)

Description   clone(H) clones the current instance of the state levels object H.

Purpose   Number of expected inputs to the step method

Syntax   N = getNumInputs(H)

Description N = getNumInputs(H) returns the number of expected inputs, N, to the step method for the state levels object H.

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

dsp.StateLevels.getNumOutputs

Purpose   Number of outputs of the `step` method

Syntax   `N = getNumOutputs(H)`

Description   `N = getNumOutputs(H)` returns the number of outputs, N, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status (logical) for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the state levels object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.StateLevels.plot

Purpose   Plot signal, state levels, and histogram

Syntax   `plot(H)`

Description   `plot(H)` plots the signal and state levels computed in the last call to the `step` method. If the `Method` property of the state levels object is set to `'Histogram mode'` or `'Histogram Mean'`, the histogram is plotted in a subplot below the signal.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.StateLevels.reset

Purpose   Reset internal states of state levels object

Syntax   reset(H)

Description   reset(H) resets the state levels object, H, to clear information
accumulated from previous calls to step.

Purpose   Estimate state levels for bilevel rectangular waveform

Syntax   LEVELS = step(H,X)
                 [LEVELS,HISTOGRAM] = step(H,X)

Description LEVELS = step(H,X) returns a 2-element row vector, LEVELS,
                 containing the estimated state levels for X. X is a real-valued column
                 vector.

                 [LEVELS,HISTOGRAM] = step(H,X) returns a double-precision column
                 vector, HISTOGRAM, containing the histogram of the sample values in
                 X. You can obtain this output only when you set the Method property
                 to either 'Histogram mean' or 'Histogram mode', and you set the
                 HistogramOutputPort property to true.

dsp.SubbandAnalysisFilter

Purpose	Decompose signal into high-frequency and low-frequency subbands

Description

The SubbandAnalysisFilter object decomposes a signal into high-frequency and low-frequency subbands.

To decompose a signal into high-frequency and low-frequency subbands:

1 Define and set up your two-channel subband analysis filter. See "Construction" on page 5-1066.

2 Call step to decompose the signal according to the properties of dsp.SubbandAnalysisFilter. The behavior of step is specific to each object in the toolbox.

Construction

H = dsp.SubbandAnalysisFilter returns a two-channel subband analysis filter, H, that decomposes the input signal into a high-frequency subband and a low-frequency subband, each with half the bandwidth of the input.

H =
dsp.SubbandAnalysisFilter('*PropertyName*',*PropertyValue*,...)
returns a two-channel subband analysis filter, H, with each specified property set to the specified value.

H = dsp.SubbandAnalysisFilter(lpc,hpc,
'*PropertyName*',*PropertyValue*,...) returns a two-channel subband analysis filter, H, with the LowpassCoefficients property set to lpc, the HighpassCoefficients property set to hpc, and other specified properties set to the specified values.

Properties

LowpassCoefficients

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of z. For the lowpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the HighpassCoefficients property. The default values of

this property specify a filter based on a third-order Daubechies wavelet.

HighpassCoefficients

Highpass FIR filter coefficient

Specify a vector of highpass FIR filter coefficients, in descending powers of *z*. For the highpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `LowpassCoefficients` property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Action to take when integer input is out of range

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Data type of the coefficients

Specify the FIR filter coefficients fixed-point data type as one of | Same word length as input | Custom |. The default is Same word length as input.

CustomCoefficientsDataType

Coefficients word and fraction lengths

Specify the FIR filter coefficients fixed-point type as a numerictype object with a Signedness of Auto. This property applies only when you set the CoefficientsDataType property to Custom. The default is numerictype([],16,15).

ProductDataType

Data type of product

Specify the product data type as one of | Full precision | Same as input | Custom |. The default is Full precision.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when you set the ProductDataType property to Custom. The default is numerictype([],32,30).

AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as one of `Full precision` | `Same as input` | `Same as product` | `Custom` |. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Data type of output

Specify the output data type as one of | `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,14)`.

Methods

clone	Create subband analysis filter object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties

dsp.SubbandAnalysisFilter

release	Allow property value and input characteristics changes
reset	Reset filter states of subband analysis filter object
step	Decompose signal into high- and low-frequency subbands

Examples

Perfectly reconstruct a signal using subband analysis and synthesis filters:

```
load dspwlets; % load the filter coefficients lod, hid, lor and hir
ha = dsp.SubbandAnalysisFilter(lod, hid);
hs = dsp.SubbandSynthesisFilter(lor, hir);
u = randn(128,1);

[hi, lo] = step(ha, u); % Two channel analysis
y = step(hs, hi, lo); % Two channel synthesis

% Plot difference between original and reconstructed signals
%  with filter latency compensated
plot(u(1:end-7)-y(8:end));
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Two-Channel Analysis Subband Filter block reference page. The object properties correspond to the block parameters, except:

- The SubbandAnalysisFilter object does not have a property that corresponds to the **Input processing** parameter of the Two-Channel Analysis Subband Filter block. The object assumes the input is frame based and always maintains the input frame rate.

- The **Rate options** block parameter is not supported by the dsp.SubbandAnalysisFilter object.

See Also

dsp.SubbandSynthesisFilter | dsp.DyadicAnalysisFilterBank

Purpose　　　Create subband analysis filter object with same property values

Syntax　　　　C = clone(H)

Description　　C = clone(H) create a SubbandAnalysisFilter object C, with the
same property values as H. The clone method creates a new unlocked
object with uninitialized states.

dsp.SubbandAnalysisFilter.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description N = getNumInputs(H) returns the number of expected inputs, N, to
the step method.

The getNumInputs method returns a positive integer that is the number
of expected inputs (not counting the object itself) to the step method.
This value will change if you alter any properties that turn inputs on or
off. You must call the step method with the number of input arguments
equal to the result of getNumInputs(*H*).

dsp.SubbandAnalysisFilter.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outpust from the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

dsp.SubbandAnalysisFilter.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the SubbandAnalysisFilter object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description   release(H) releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the release method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset filter states of subband analysis filter object

Syntax   reset(H)

Description reset(H) sets the filter states of the SubbandAnalysisFilter object H
to 0.

Purpose	Decompose signal into high- and low-frequency subbands
Syntax	[HI,LO] = step(H,SIG)
Description	[HI,LO] = step(H,SIG) decomposes the input signal, SIG, into a high-frequency subband, HI, and a low-frequency subband, LO.

> **Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

dsp.SubbandSynthesisFilter

Purpose	Reconstruct signal from high-frequency and low-frequency subbands

Description The SubbandSynthesisFilter object reconstructs a signal from high-frequency and low-frequency subbands.

To reconstruct a signal from high-frequency and low-frequency subbands:

1 Define and set up your two-channel subband synthesis filter. See "Construction" on page 5-1078.

2 Call step to reconstruct the signal according to the properties of dsp.SubbandSynthesisFilter. The behavior of step is specific to each object in the toolbox.

Construction H = dsp.SubbandSynthesisFilter returns a two-channel subband synthesis filter, H, that reconstructs a signal from its high-frequency subband and low-frequency subband. Each subband contains half the bandwidth of the original signal.

H = dsp.SubbandSynthesisFilter('*PropertyName*',*PropertyValue*,...) returns a two-channel subband synthesis filter, H, with each specified property set to the specified value.

H = dsp.SubbandSynthesisFilter(lpc,hpc, '*PropertyName*',*PropertyValue*,...) returns a two-channel subband synthesis filter, H. The object has the LowpassCoefficients property set to lpc, the HighpassCoefficients property set to hpc, and other specified properties set to the specified values.

Properties **LowpassCoefficients**

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of z. For the lowpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the HighpassCoefficients property. The default values of

this property specify a filter based on a third-order Daubechies wavelet.

HighpassCoefficients

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in descending powers of *z*. For the highpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the LowpassCoefficients property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set FullPrecisionOverride to true, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set FullPrecisionOverride to false, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor. This property applies only if the object is not in full precision mode.

OverflowAction

Action to take when integer input is out of range

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Data type of the coefficients

Specify the FIR filter coefficients fixed-point data type as one of | Same word length as input | Custom |. The default is Same word length as input.

CustomCoefficientsDataType

Coefficient word and fraction lengths

Specify the FIR filter coefficients fixed-point type as a numerictype object with a Signedness of Auto. This property applies only when you set the CoefficientsDataType property to Custom. The default is numerictype([],16,15).

ProductDataType

Data type of product

Specify the product data type as one of | Full precision | Same as input | Custom |. The default is Full precision.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when you set the ProductDataType property to Custom. The default is numerictype([],32,30).

AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as one of | `Full precision` | `Same as input` | `Same as product` | `Custom` |. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Data type of output

Specify the output data type as one of | `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,14)`.

Methods

clone	Create subband synthesis filter object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties

dsp.SubbandSynthesisFilter

release	Allow property value and input characteristics changes
reset	Reset internal states of subband synthesis filter object
step	Reconstruct signal from high- and low-frequency subbands

Examples   Perfectly reconstruct a signal using subband analysis and synthesis filters:

```
load dspwlets;  % Load filter coefficients lod,
                % hid, lor and hir
ha = dsp.SubbandAnalysisFilter(lod, hid);
hs = dsp.SubbandSynthesisFilter(lor, hir);
u = randn(128,1);

[hi, lo] = step(ha, u); % Two channel analysis
y = step(hs, hi, lo); % Two channel synthesis

% Plot difference between original and reconstructed
%  signals with filter latency compensated
plot(u(1:end-7)-y(8:end));
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Two-Channel Synthesis Subband Filter block reference page. The object properties correspond to the block parameters, except:

- The SubbandSynthesisFilter object does not have a property that corresponds to the **Input processing** parameter of the Two-Channel Synthesis Subband Filter block. The object only performs sample-based processing and always maintains the input frame rate.

- The **Rate options** block parameter is not supported by the SubbandSynthesisFilter object.

See Also   dsp.SubbandAnalysisFilter | dsp.DyadicSynthesisFilterBank

dsp.SubbandSynthesisFilter.clone

Purpose   Create subband synthesis filter object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a SubbandSynthesisFilter object C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

dsp.SubbandSynthesisFilter.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the SubbandSynthesisFilter
object H.

The isLocked method returns a logical value that indicates whether
input attributes and nontunable properties for the object are locked. The
object performs an internal initialization the first time the step method
is executed. This initialization locks nontunable properties and input
specifications, such as dimensions, complexity, and data type of the
input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset internal states of subband synthesis filter object

Syntax   reset(H)

Description   reset(H) sets the internal states of the SubbandSynthesisFilter
                   object H to their initial values.

Purpose	Reconstruct signal from high- and low-frequency subbands
Syntax	Y = step(H,HI,LO)
Description	Y = step(H,HI,LO) reconstructs a signal from a high-frequency subband, HI, and a low-frequency subband, LO.

> **Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

Purpose   Time domain signal display

Description   The TimeScope object displays time-domain signals.

To display time-domain signals in the Time Scope:

1 Define and set up your Time Scope. See "Construction" on page 5-1093.

2 Call step to display the signal in the Time Scope figure. The behavior of step is specific to each object in the toolbox.

Use the MATLAB clear function to close the Time Scope figure window.

See the following sections for information on the Time Scope System object:

- "Construction" on page 5-1093

See the following sections for information on the Time Scope Graphical User Interface:

For examples on how to use the Time Scope System object, see "Examples" on page 5-1153.

Note For information about the Time Scope block, see Time Scope.

Construction   H = dsp.TimeScope returns a Time Scope System object, H. This object displays real- and complex-valued floating and fixed-point signals in the time domain.

H = dsp.TimeScope('*PropertyName*',*PropertyValue*,...) creates a Time Scope System object, H, with each specified property *PropertyName* set to the specified value.

```
H =
dsp.TimeScope(NUMINPUTS,SAMPLERATE,'PropertyName',PropertyValue,...)
```

creates a Time Scope System object, `H`. This object has the `NumInputPorts` property set to *NUMINPUTS*, the `SampleRate` property set to *SAMPLERATE*, and other specified properties set to the specified values. *NUMINPUTS* and *SAMPLERATE* are value-only arguments. You can specify *PropertyName–PropertyValue* arguments in any order.

Properties

ActiveDisplay

Active display for display-specific properties

Specify as an integer the active display number for getting and setting relevant properties. The number of a display corresponds to its column-wise placement index. Setting this property controls which display is used for `YLimits`, `YLabel`, `LegendSource`, `Grid`, `Title`, and `MagnitudePhase`. This property is Tunable.

Default: 1

FrameBasedProcessing

Process input in frames or as samples

When you set this property to `true`, you enable frame-based processing. When you set this property to `false`, you enable sample-based processing. This property is Tunable.

Default: `true`

Grid

Option to enable or disable grid display

When you set this property to `true`, the grid appears. When you set this property to `false`, the grid does not appear. When set, `ActiveDisplay` controls which display is updated. This property is Tunable.

Default: `false`

LayoutDimensions

Layout grid dimensions

Specify the layout grid dimensions as a 2-element vector:
`[numberOfRows, numberOfColumns]`. You may use no more than
four rows or four columns. This property is Tunable.

Default: `[1,1]`

LegendSource

Source of legend

Specify the source of the legend as either `None` or `Auto`. When
you set this property to `'None'`, the Time Scope does not display
a legend. When you set this property to `'Auto'`, the Time Scope
displays a legend with automatic string labels for each input
channel. See FrameBasedProcessing for information on input
channels. This property is Tunable.

Default: `'None'`

MagnitudePhase

Plot signal as Magnitude-and-Phase

Set this property to true to plot the magnitude and phase of the
input signal on two separate axes within the same active display.
When set, `ActiveDisplay` controls which displays are updated.
The active display shows the magnitude of the input signal on the
top axes and its phase, in degrees, on the bottom axes.

This property is particularly useful for complex-valued input
signals. When the input signal is real-valued and you select this
check box, the phase will be 0 degrees when the amplitude of
the input signal is nonnegative and 180 degrees when the input
signal is negative. This property is Tunable.

Default: `false`

MaximizeAxes

Maximize axes control

Specify whether to display the Time Scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- `Auto` — In this mode, the axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.

- `On` — In this mode, the axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.

- `Off` — In this mode, none of the axes appear maximized.

This property is Tunable.

Default: `'Auto'`

Name

Caption to display on Time Scope window

Specify the caption to display on the scope window as any string. This property is Tunable.

Default: `'Time Scope'`

NumInputPorts

Number of input signals

Specify the number of input signals to display on the Time Scope as a positive integer. You must invoke the `step` method with the same number of inputs as the value of this property.

Default: 1

PlotType

Option to control the type of plot

Specify the type of plot to use for all the input signals displayed in the Time Scope GUI.

- When you set this property to `'Line'`, Time Scope displays the input signal as lines connecting each of the sampled values. This approach is similar to the functionality of the MATLAB `line` or `plot` function.

- When you set this property to `'Stairs'`, Time Scope displays the input signal as a *stairstep* graph. A stairstep graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. This approach is equivalent to the MATLAB `stairs` function. Stairstep graphs are useful for drawing time history graphs of digitally sampled data.

This property is Tunable.

Default: `'Line'`

Position

Time Scope window position in pixels

Specify, in pixels, the size and location of the Time Scope window as a 4-element double vector of the form, `[left bottom width height]`. You can place the Time Scope window in a specific position on your screen by modifying the values to this property. This property is Tunable.

Default: The default depends on your screen resolution. By default, the Time Scope window is placed in the center of your screen with a width of 410 pixels and height of 300 pixels.

ReduceUpdates

Reduce updates to improve performance

When you set this property to true, the Time Scope logs data for later use and updates the window periodically. When you set this property to false, the Time Scope updates every time the step method is called. The simulation speed is faster when this property is set to true. This property is Tunable.

You can also modify this property from the Time Scope GUI. Opening the **Simulation** menu and clearing the **Reduce Updates to Improve Performance** check box is the same as setting this property to false.

Default: true

SampleRate

Sample rate of inputs

Specify the sampling rate, in hertz, of any input signal, as a scalar or as a numeric vector with length equal to the value of NumInputPorts. The inverse of the sample rate determines the spacing between points on the *x*-axis (time axis) in the displayed signal. When you set SampleRate to a scalar value and NumInputPorts is greater than 1, the object uses the same sample rate for all inputs.

Default: 1

TimeAxisLabels

Time-axis labels

Specify how time-axis labels should appear in the Time Scope displays as one of `'All'`, `'Bottom`, or `'None'`.

- When you set this property to `'All'`, time-axis labels appear in all displays.

- When you set this property to `'Bottom'`, time-axis labels appear in the bottom display of each column.

- When you set this property to `'None'`, there are no labels in any displays.

This property is Tunable.

Default: `'All'`

TimeDisplayOffset

Time display offset

Specify the offset, in seconds, to apply to the *x*-axis (time axis). This property can be either a numeric scalar or a vector of length equal to the number of input channels. If you specify this property as a scalar, then that value is the time display offset for all channels. If you specify a vector, each vector element is the time offset for the corresponding channel. For vectors with length less than the number of input channels, the time display offsets for the remaining channels are set to 0. If a vector has a length greater than the number of input channels, the extra vector elements are ignored. This property is Tunable.

See FrameBasedProcessing for information on input channels. See `TimeSpan` and `TimeSpanSource` for information on the *x*-axis limits and time span settings.

Default: 0

TimeSpan

Specify the time span, in seconds, as a positive, numeric scalar value. This property applies when FrameBasedProcessing is false. This property also applies when FrameBasedProcessing is true and TimeSpanSource is Property. The *x*-axis limits are calculated as follows.

Minimum *x*-axis limit = min(TimeDisplayOffset)
Maximum *x*-axis limit = max(TimeDisplayOffset) + TimeSpan

where TimeDisplayOffset and TimeSpan are the values of their respective properties. This property is Tunable.

Default: 10

TimeSpanOverrunMode

Wrap or scroll when the TimeSpan value is overrun

Specify how the Time Scope displays new data beyond the visible time span as one of 'Wrap' or 'Scroll'.

- When you set this property to Wrap, the Time Scope displays new data up until it reaches the maximum *x*-axis limit. When the data reaches the maximum *x*-axis limit of the Time Scope window, the Time Scope clears the display. The Time Scope then updates the time offset value and begins displaying subsequent data points starting from the minimum *x*-axis limit.

- When you set this property to Scroll, the Time Scope scrolls old data to the left to make room for new data on the right side of the Time Scope display. This mode is graphically intensive and can affect run-time performance, but it is beneficial for debugging and for monitoring time-varying signals.

This property is Tunable.

Default: 'Wrap'

TimeSpanSource

Source of time span

Specify the source of the time span for frame-based input signals as one of 'Auto' or 'Property'. This property applies when FrameBasedProcessing is set to true. When you set this property to 'Property', the object derives the *x*-axis limits from the TimeDisplayOffset and TimeSpan properties. When you set this property to Auto, the *x*-axis limits are the following:

Minimum *x*-axis limit = min(TimeDisplayOffset)
Maximum *x*-axis limit = max(TimeDisplayOffset) + max(1/SampleRate.**FrameSize*)

where TimeDisplayOffset and SampleRate are the values of their respective properties. *FrameSize* is a vector equal to the number of rows in each input signal.

This property is Tunable.

Default: 'Property'

TimeUnits

Units of the time axis

Specify the units used to describe the time axis.

- When you set this property to 'Metric', the Time Scope converts the time axis values to the most appropriate metric units, such as microseconds, milliseconds, minutes, days, etc.

- When you set this property to 'Seconds', the Time Scope will always leave the time units as seconds.

- When you set this property to 'None', the Time Scope will not display any units on the time axis.

This property is Tunable.

Default: 'Metric'

Title

Display title

Specify the display title as a string. When set, `ActiveDisplay` controls which display is updated. This property is Tunable.

Default: `''`

YLabel

The label for the *y*-axis

Specify the *y*-axis label as a string. This property applies only when MagnitudePhase is `false`. When MagnitudePhase is `true`, the two *y*-axis labels are read-only values that are set to `'Magnitude'` and `'Phase'` for the magnitude plot and the phase plot, respectively. When set, `ActiveDisplay` controls which display is updated. This property is Tunable.

Default: `'Amplitude'` if MagnitudePhase is `false`

YLimits

The limits for the *y*-axis

Specify the *y*-axis limits as a 2-element numeric vector, `[ymin ymax]`. When set, `ActiveDisplay` controls which display is updated.

When MagnitudePhase is `true`, this property specifies the *y*-axis limits of only the magnitude plot. The *y*-axis limits of the phase plot are always `[-180, 180]`. This property is Tunable.

Default: `[-10, 10]` if MagnitudePhase is `false`, `[0, 10]` if MagnitudePhase is `true`.

Methods	clone	Create time scope object with same property values
	getNumInputs	Number of expected inputs to step method
	getNumOutputs	Number of outputs of step method
	hide	Hide time scope window
	isLocked	Locked status for input attributes and nontunable properties
	release	Allow property value and input characteristics changes
	reset	Reset internal states of time scope object
	show	Make time scope window visible
	step	Display signal in time scope figure

Displaying Multiple Signals

Multiple Signal Input

You can configure the Time Scope to show multiple signals within the same display or on separate displays. By default, the signals appear as different-colored lines on the same display. The signals can have different dimensions, sample rates, and data types. Each signal can be either real or complex valued. You can set the number of input ports on the Time Scope in the following ways:

- Set the NumInputPorts property. This property is nontunable, so you should set it before you run the step method.

- Run the show method to open the Scope window. In the Scope menu, select **File > Number of Input Ports**.

An input signal may contain multiple channels, depending on its dimensions. Multiple channels of data always appear as different-colored lines on the same display.

Multiple Displays

You can display multiple channels of data on different displays in the Scope window. In the Scope toolbar, select **View > Layout**, or select

the Layout button (⊞). This feature allows you to tile the window into a number of separate displays, up to a grid of 4 rows and 4 columns. For example, if there are three inputs to the Scope, you can display the signals in separate displays by selecting row 3, column 1, as shown in the following figure.

After you select row 3, column 1, the Scope window has three separate displays, as shown in the following figure.

Signal Display

Time Scope uses the **Time span** and **Time display offset** parameters in order to determine the time range. To change the signal display settings, select **View > Properties** to bring up the Visuals:Time Domain Options dialog box. Then, modify the values for the **Time span** and **Time display offset** parameters on the **Main** tab. For example, if you set the **Time span** to 25 seconds, the scope displays 25 seconds' worth of simulation data at a time. If you also set the **Time display offset** to 5 seconds, the scope displays values on the time axis from 5 to 30 seconds. The values on the *time*-axis of the Time Scope display remain the same throughout simulation.

To communicate the simulation time that corresponds to the current display, the scope uses the **Time units**, **Time offset**, and **Simulation time** indicators on the scope window. The following figure highlights these and other important aspects of the Time Scope window.

Time Indicators

- **Minimum time-axis limit** — The Time Scope sets the minimum *time*-axis limit using the value of the **Time display offset** parameter on the **Main** tab of the Visuals:Time Domain Options dialog box. If you specify a vector of values for the **Time display offset** parameter, the scope uses the smallest of those values to set the minimum *time*-axis limit.

- **Maximum time-axis limit** — The Time Scope sets the maximum *time*-axis limit by summing the value of **Time display offset** parameter with the value of the **Time span** parameter. If you specify a vector of values for the **Time display offset** parameter, the scope sets the maximum *time*-axis limit by summing the largest of those values with the value of the **Time span** parameter.

- **Time units** — The units used to describe the *time*-axis. The Time Scope sets the time units using the value of the **Time units** parameter on the **Main** tab of the Visuals:Time Domain Options dialog box. By default, this parameter is set to Metric (based on Time Span) and displays in metric units such as milliseconds, microseconds, minutes, days, etc. You can change it to Seconds to always display the *time*-axis values in units of seconds. You can change it to None to not display any units on the *time*-axis. When you set this parameter to None, then Time Scope shows only the word Time on the *time*-axis.

To hide both the word Time and the values on the *time*-axis, set
the **Show time-axis labels** parameter to None. To hide both the
word Time and the values on the *time*-axis in all displays except the
bottom ones in each column of displays, set this parameter to Bottom
Displays Only. This behavior differs from the Simulink Scope block,
which always shows the values but never shows a label on the *x*-axis.

For more information, see "Visuals — Time Domain Options" on page
5-1140.

Simulation Indicators

- **Simulation status** — Provides the current status of the model
  simulation. The status can be one of the following conditions:

  - Processing — Occurs after you run the step method and before
    you run the release method.

  - Stopped — Occurs after you construct the TimeScope object and
    before you first run the step method. This status also occurs after
    you run the release method.

  The **Simulation status** is part of the **Status Bar** in the Time Scope
  window. You can choose to hide or display the entire **Status Bar**.
  From the Time Scope menu, select **View > Status Bar**.

- **Time offset** — The **Time offset** value helps you determine the
  simulation times for which the scope is displaying data. The value is
  always in the range 0≤ Time offset≤ **Simulation time**.

  Suppose you set the **Time span** to 20 seconds, and you see a **Time
  offset** of 0 (secs) on the scope window. This value indicates that
  the scope is displaying data for the first 0 to 20 seconds of simulation
  time. If the **Time offset** changes to 20 (secs), the scope displays
  data for simulation times from 20 seconds to 40 seconds. The scope
  continues to update the **Time offset** value until the simulation is
  complete.

- **Simulation time** — The amount of time that has progressed since
  the Time Scope object was first constructed or reset. Every time you

call the step method, the simulation time increases by the number of rows in the input signal divided by the sample rate, as given by

the following formula: $t_{sim} = t_{sim} + \dfrac{\text{length}(x)}{SampleRate}$. You can modify the **SampleRate** parameter on the **Main options** pane of the **Spectrum Settings** panel. You can also set the sample rate using the SampleRate property.

The **Simulation time** is part of the **Status Bar** in the Time Scope window. You can choose to hide or display the entire **Status Bar**. From the Time Scope menu, select **View > Status Bar** .

Axes Maximization

You can specify whether to display the Time Scope in maximized axes mode. In this mode, the axes are expanded to fill the entire display. In each display, there is no space to show titles or axis labels. The minimum and maximum *time*-axis limits are located at the far-left and far-right edges of the display. The values at the axis tick marks appear as grid lines on top of the axes. The following figure highlights the important indicators in this mode of the Time Scope window.

To enable this mode, in the Time Scope menu, select **View > Properties** to bring up the Visuals:Time Domain Options dialog box. In the **Main** pane, you can set the **Maximize axes** parameter to one of the following options:

- Auto — In this mode, the axes appear maximized in all displays only if the **Title** and **Y-Axis label** parameters are empty for every display. If you enter any value in any display for either of these parameters, the axes are not maximized.

- On — In this mode, the axes appear maximized in all displays. Any values entered into the **Title** and **Y-Axis label** parameters are hidden.

- Off — In this mode, none of the axes appear maximized.

You can also set the MaximizeAxes property to one of the aforementioned options.

Reduce Updates to Improve Performance

By default, the Time Scope updates the displays periodically at a rate not exceeding 20 Hz. If you would like the Time Scope to update on every simulation time step, you can disable the **Reduce Updates to Improve Performance** option. In the Time Scope menu, select **Playback > Reduce Updates to Improve Performance** to clear the check box. You can also set the ReduceUpdates property to false to disable this option. However, as a recommended practice, you can leave this option enabled because doing so can significantly improve the speed of the simulation.

Toolbar   The Time Scope toolbar contains the following buttons.

Axes Control Buttons

	Tools > Zoom In	N/A	When this tool is active, you can zoom in on the scope window. To do so, click in the center of your area of interest, or click and drag your cursor to draw a rectangular area of interest inside the scope window.
	Tools > Zoom X	N/A	When this tool is active, you can zoom in on the x-axis. To do so, click inside the scope window, or click and drag your cursor along the x-axis over your area of interest.
	Tools > Zoom Y	N/A	When this tool is active, you can zoom in on the y-axis. To do so, click inside the scope window, or click and drag your cursor along the y-axis over your area of interest.
	Tools > Scale Axes Limits	Ctrl+A	Click this button to scale the axes in the active scope window. Alternatively, you can enable automatic axes scaling by selecting one of the following options from the **Tools** menu: • **Automatically Scale Axes Limits** — When you select this option, the scope scales the axes as needed during simulation. • **Scale Axes Limits at Stop** — When you select this option, the scope scales the axes each time the simulation is stopped.

Measurements Buttons

⊞	**Tools > Measurements > Cursor Measurements**	N/A	Open or close the **Cursor Measurements** panel. This panel puts screen cursors on all the displays. See the "Cursor Measurements Panel" on page 5-1114 section for more information.
◠	**Tools > Measurements > Signal Statistics**	N/A	Open or close the **Signal Statistics** panel. This panel displays the maximum, minimum, peak-to-peak difference, mean, median, RMS values of a selected signal, and the times at which the maximum and minimum occur. See the "Signal Statistics Panel" on page 5-1116 section for more information.
⊓	**Tools > Measurements > Bilevel Measurements**	N/A	Open or close the **Bilevel Measurements** panel. This panel displays information about a selected signal's transitions, overshoots or undershoots, and cycles. See the "Bilevel Measurements Panel" on page 5-1118 section for more information.
⏶	**Tools > Measurements > Peak Finder**	N/A	Open or close the **Peak Finder** panel. This panel displays maxima and the times at which they occur, allowing the settings for peak threshold, maximum number of peaks, and peak excursion to be modified.

			See the "Peak Finder Panel" on page 5-1132 section for more information.

Other Buttons

⊞	**View > Layout**	N/A	Arrange the layout of displays in the Time Scope. This feature allows you to tile your screen into a number of separate displays, up to a grid of 4 rows and 4 columns. You may find multiple displays useful when the Time Scope takes multiple input signals. The default display is 1 row and 1 column. See the "Multiple Displays" on page 5-1104 section for more information.

You can control whether this toolbar appears in the Time Scope window. From the Time Scope menu, select **View > Toolbar**.

Measurements Panels The Measurements panels are the five panels that appear to the right side of the Time Scope GUI. These panels are labeled **Trace selection**, **Cursor measurements**, **Signal statistics**, **Bilevel measurements**, and **Peak finder**.

The Time Domain Measurements panels only appear if the **Measurements** tool is enabled in the Time Scope — Tools:Plot Navigation Options dialog box. To open this dialog box, in the Time Scope menu, select **File > Configuration** and click the **Tools** pane. If you disable the tool by clearing the **Enabled** check box, the Time Domain Measurements tools no longer display in the Time Scope GUI. You can reenable the tool at any time by selecting the **Enabled** check box. See the "Tools — Plot Navigation Options" on page 5-1149 section for more information.

Measurements Panel Buttons

Each of the Measurements panels contains the following buttons that enable you to modify the appearance of the current panel.

Button	Description
	Move the current panel to the top. When you are displaying more than one panel, this action moves the current panel above all the other panels.
	Collapse the current panel. When you first enable a panel, by default, it displays one or more of its panes. Click this button to hide all of its panes to conserve space. After you click this button, it becomes the expand button.
	Expand the current panel. This button appears after you click the collapse button to hide the panes in the current panel. Click this button to display the panes in the current panel and show measurements again. After you click this button, it becomes the collapse button again.
	Undock the current panel. This button lets you move the current panel into a separate window that can be relocated anywhere on your screen. After you click this button, it becomes the dock button in the new window.
	Dock the current panel. This button appears only after you click the undock button. Click this button to put the current panel back into the right side of the Scope window. After you click this button, it becomes the undock button again.
	Close the current panel. This button lets you remove the current panel from the right side of the Scope window.

Some panels have their measurements separated by category into a number of panes. Click the pane expand button ► to show each pane that is hidden in the current panel. Click the pane collapse button ▼ to hide each pane that is shown in the current panel.

Trace Selection Panel

When you use the Scope to view multiple signals, the Trace Selection panel appears if you have more than one signal displayed and you click on any of the other Measurements panels. Choose the signal name for which you would like to display time domain measurements. See the following figure.

You can choose to hide or display the **Trace Selection** panel. In the Scope menu, select **Tools > Measurements > Trace Selection**.

Cursor Measurements Panel

The **Cursor Measurements** panel displays screen cursors. You can choose to hide or display the **Cursor Measurements** panel. In the Scope menu, select **Tools > Measurements > Cursor Measurements**. Alternatively, in the Scope toolbar, click the Cursor Measurements button.

Settings Pane

The **Settings** pane enables you to modify the type of screen cursors used to calculate time and value measurements.

- **Screen Cursors**— Shows screen cursors.

- **Horizontal**— Shows horizontal screen cursors.

- **Vertical**— Shows vertical screen cursors.

- **Waveform Cursors**— Shows cursors that attach to the input signals.

- **Lock Cursor Spacing**— Locks the time difference between the two cursors.

Measurements Pane

The **Measurements** pane shows the time and value measurements.

- **1 |**— Shows or enables you to modify the time or value at cursor number one, or both.

- **2 :**— Shows or enables you to modify the time or value at cursor number two, or both.

- **Δt**— Shows the absolute value of the difference in the times between cursor number one and cursor number two.

- **ΔV**— Shows the absolute value of the difference in signal amplitudes between cursor number one and cursor number two.

- **1/Δt**— Shows the rate, the reciprocal of the absolute value of the difference in the times between cursor number one and cursor number two.

- **ΔV/Δt**— Shows the scope, the ratio of the absolute value of the difference in signal amplitudes between cursors to the absolute value of the difference in the times between cursors.

Signal Statistics Panel

The **Signal Statistics** panel displays the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal. It also shows the times at which the maximum and minimum values occur. You can choose to hide or display the **Signal Statistics** panel. In the Scope menu, select **Tools > Measurements > Signal Statistics**. Alternatively, in the Scope toolbar, click the Signal

Statistics ![icon] button.

⊼ ▼ Signal Statistics		↗ ✕
	Value	Time (us)
Max	2.343	22.500
Min	-57.337 m	5.000
Peak to Peak	2.400	
Mean	1.150	
Median	1.152	
RMS	1.628	

Signal Statistics Measurements

The **Signal Statistics** panel shows statistics about the portion of the input signal within the *x*-axis and *y*-axis limits of the active display. The statistics shown are:

- **Max** — Shows the maximum or largest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `max` function reference.

- **Min** — Shows the minimum or smallest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `min` function reference.

- **Peak to Peak** — Shows the difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `peak2peak` function reference.

- **Mean** — Shows the average or mean of all the values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `mean` function reference.

- **Median** — Shows the median value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `median` function reference.

- **RMS** — Shows the difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `rms` function reference.

When you use the zoom options in the Scope, the Signal Statistics measurements automatically adjust to the time range shown in the display. In the Scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the *x*-axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one pulse to make the **Signal Statistics** panel display information about only that particular pulse.

The Signal Statistics measurements are valid for any units of the input signal. The letter after the value associated with each measurement represents the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

Bilevel Measurements Panel

The **Bilevel Measurements** panel shows information about a selected signal's transitions, overshoots or undershoots, and cycles. You can choose to hide or display the **Bilevel Measurements** panel. In the Scope menu, select **Tools > Measurements > Bilevel Measurements**. Alternatively, in the Scope toolbar, you can select the Bilevel Measurements button.

The **Bilevel Measurements** panel is separated into four panes, labeled **Settings**, **Transitions**, **Overshoots / Undershoots**, and **Cycles**. You can expand each pane to see the available options.

Settings Pane

The **Settings** pane enables you to modify the properties used to calculate various measurements involving transitions, overshoots, undershoots, and cycles. You can modify the high-state level, low-state level, state-level tolerance, upper-reference level, mid-reference level, and lower-reference level, as shown in the following figure.

- **Auto State Level** — When this check box is selected, the Bilevel measurements panel autodetects the high- and low- state levels of a bilevel waveform. For more information on the algorithm this option uses, see the Signal Processing Toolbox `statelevels` function

reference. When this check box is cleared, you may enter in values
for the high- and low- state levels manually.

- **High** — Used to manually specify the value that denotes a positive
  polarity, or high-state level, as shown in the following figure.

Positive Polarity Pulse

- **Low** — Used to manually specify the value that denotes a negative
  polarity, or low-state level, as shown in the following figure.

Negative Polarity Pulse

- **State Level Tolerance** — Tolerance within which the initial and final levels of each transition must be within their respective state levels. This value is expressed as a percentage of the difference between the high- and low-state levels.

- **Upper Ref Level** — Used to compute the end of the rise-time measurement or the start of the fall time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.

- **Mid Ref Level** — Used to determine when a transition occurs. This value is expressed as a percentage of the difference between the high- and low- state levels. In the following figure, the mid-reference level is shown as the horizontal line, and its corresponding mid-reference level instant is shown as the vertical line.

- **Lower Ref Level** — Used to compute the end of the fall-time measurement or the start of the rise-time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.

- **Settle Seek** — The duration after the mid-reference level instant when each transition occurs used for computing a valid settling time. This value is equivalent to the input parameter, D, which you can set when you run the settlingtime function. The settling time is displayed in the **Overshoots/Undershoots** pane.

Transitions Pane

The **Transitions** pane displays calculated measurements associated with the input signal changing between its two possible state level values, high and low.

A positive-going transition, or *rising edge*, in a bilevel waveform is a transition from the low-state level to the high-state level. A positive-going transition has a slope value greater than zero. The following figure shows a positive-going transition.

X(t)

$$\frac{dX}{dt} > 0$$

Whenever there is a plus sign (+) next to a text label, this symbol refers to measurement associated with a rising edge, a transition from a low-state level to a high-state level.

A negative-going transition, or falling edge, in a bilevel waveform is a transition from the high-state level to the low-state level. A negative-going transition has a slope value less than zero. The following figure shows a negative-going transition.

Whenever there is a minus sign (–) next to a text label, this symbol refers to measurement associated with a falling edge, a transition from a high-state level to a low-state level.

The Transition measurements assume that the amplitude of the input signal is in units of volts. You must convert all input signals to volts for the Transition measurements to be valid.

- **High** — The high-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** pane of the Visuals:Time Domain Options dialog box. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `statelevels` function reference.

- **Low** — The low-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** pane of the Visuals:Time Domain Options dialog box. For

more information on the algorithm this measurement uses, see the Signal Processing Toolbox `statelevels` function reference.

- **Amplitude** — Difference in amplitude between the high-state level and the low-state level.

- **+ Edges** — Total number of positive-polarity, or rising, edges counted within the displayed portion of the input signal.

- **+ Rise Time** — Average amount of time required for each rising edge to cross from the lower-reference level to the upper-reference level. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `risetime` function reference.

- **+ Slew Rate** — Average slope of each rising-edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal. The region in which the slew rate is calculated appears in gray in the following figure.

For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `slewrate` function reference.

- **– Edges** — Total number of negative-polarity or falling edges counted within the displayed portion of the input signal.

- **– Fall Time** — Average amount of time required for each falling edge to cross from the upper-reference level to the lower-reference level. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `falltime` function reference.

- **– Slew Rate** — Average slope of each falling edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal. For more information on the algorithm

this measurement uses, see the Signal Processing Toolbox `slewrate` function reference.

Overshoots/Undershoots

The **Overshoots/Undershoots** pane displays calculated measurements involving the distortion and damping of the input signal. *Overshoot* and *undershoot* refer to the amount that a signal respectively exceeds and falls below its final steady-state value. *Preshoot* refers to the amount prior to a transition that a signal varies from its initial steady-state value. This figure shows preshoot, overshoot, and undershoot for a rising-edge transition.

The next figure shows preshoot, overshoot, and undershoot for a falling-edge transition.

- **+ Preshoot** — Average lowest aberration in the region immediately preceding each rising transition.

- **+ Overshoot** — Average highest aberration in the region immediately following each rising transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `overshoot` function reference.

- **+ Undershoot** — Average lowest aberration in the region immediately following each rising transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `undershoot` function reference.

- **+ Settling Time** — Average time required for each rising edge to enter and remain within the tolerance of the high-state level for the remainder of the settle seek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the high-state level. This crossing is illustrated in the following figure.

You can modify the settle seek duration parameter in the **Settings** pane. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `settlingtime` function reference.

- – **Preshoot** — Average highest aberration in the region immediately preceding each falling transition.

- – **Overshoot** — Average highest aberration in the region immediately following each falling transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `overshoot` function reference.

- – **Undershoot** — Average lowest aberration in the region immediately following each falling transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `undershoot` function reference.

- – **Settling Time** — Average time required for each falling edge to enter and remain within the tolerance of the low-state level for the remainder of the settle seek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the low-state level. You can

modify the settle seek duration parameter in the **Settings** pane. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `settlingtime` function reference.

Cycles

The **Cycles** pane displays calculated measurements pertaining to repetitions or trends in the displayed portion of the input signal.

- **Period** — Average duration between adjacent edges of identical polarity within the displayed portion of the input signal. The Bilevel measurements panel calculates period as follows. It takes the difference between the mid-reference level instants of the initial transition of each positive-polarity pulse and the next positive-going transition. These mid-reference level instants appear as red dots in the following figure.

For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `pulseperiod` function reference.

- **Frequency** — Reciprocal of the average period. Whereas period is typically measured in some metric form of seconds, or seconds per cycle, frequency is typically measured in hertz or cycles per second.

- **+ Pulses** — Number of positive-polarity pulses counted.

- **+ Width** — Average duration between rising and falling edges of each positive-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `pulsewidth` function reference.

- **+ Duty Cycle** — Average ratio of pulse width to pulse period for each positive-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `dutycycle` function reference.

- **– Pulses** — Number of negative-polarity pulses counted.

- **– Width** — Average duration between rising and falling edges of each negative-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `pulsewidth` function reference.

- **– Duty Cycle** — Average ratio of pulse width to pulse period for each negative-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `dutycycle` function reference.

When you use the zoom options in the Scope, the bilevel measurements automatically adjust to the time range shown in the display. In the Scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the x-axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one rising edge to make the **Bilevel Measurements** panel display information about only that

particular rising edge. However, this feature does not apply to the **High** and **Low** measurements.

Peak Finder Panel

The **Peak Finder** panel displays maxima and the times at which they occur, allowing the settings for peak threshold, maximum number of peaks, and peak excursion to be modified. You can choose to hide or display the **Peak Finder** panel. In the Scope menu, select **Tools > Measurements > Peak Finder**. Alternatively, in the Scope toolbar, select the Peak Finder button.

The **Peak finder** panel is separated into two panes, labeled **Settings** and **Peaks**. You can expand each pane to see the available options.

Settings Pane

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input

signal. For more information on the algorithms this pane uses, see the Signal Processing Toolbox `findpeaks` function reference.

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `MINPEAKHEIGHT` parameter, which you can set when you run the `findpeaks` function.

- **Max Num of Peaks** — The maximum number of peaks to show. This setting is equivalent to the `NPEAKS` parameter, which you can set when you run the `findpeaks` function.

- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `MINPEAKDISTANCE` parameter, which you can set when you run the `findpeaks` function.

- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples. Peak excursion is illustrated alongside peak threshold in the following figure.

Whereas the peak threshold is a minimum value necessary for a sample value to be a peak, the peak excursion is the minimum difference between a peak sample and the samples to its left and right

in the time domain. In the figure, the green vertical line illustrates the lesser of the two height differences between the labeled peak and its neighboring samples. This height difference must be greater than the **Peak Excursion** value for the labeled peak to be classified as a peak. Compare this setting to peak threshold, which is illustrated by the red horizontal line. The amplitude must be above this horizontal line for the labeled peak to be classified as a peak.

The peak excursion setting is equivalent to the THRESHOLD parameter, which you can set when you run the findpeaks function.

- **Label peaks** — When this check box is selected, the Peak Finder displays the calculated peak values directly on the plot. By default, this check box is cleared and no values are displayed on the plot.

- **Sort by time** — When this check box is selected, the Peak Finder puts the largest calculated peak values in the time range shown in the display in time-sorted order. The Peak Finder displays the peak values in the **Peaks** pane. The **Max Num of Peaks** parameter still controls the number of peaks listed. By default, this check box is cleared and the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height.

Peaks Pane

The **Peaks** pane displays all of the largest calculated peak values and the times at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list. Using the **Sort by time** check box, you set the order in which the peaks are listed.

The numerical values displayed in the **Value** column are equivalent to the pks output argument returned when you run the findpeaks function. The numerical values displayed in the **Time** column are similar to the locs output argument returned when you run the findpeaks function.

When you use the zoom options in the Scope, the peak locations automatically adjust to the time range shown in the display. In the Scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the

x-axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one peak to make the **Peak Finder** panel display information about only that particular peak.

Style Dialog Box

In the **Style** dialog box, you can customize the style of displays. You are able to change the color of the figure containing the displays, the background and foreground colors of display axes, and properties of lines in a display. From the Scope menu, select **View > Style** to open this dialog box.

Properties

The **Style** dialog box allows you to modify the following properties of the Scope GUI:

Figure color

Specify the color that you want to apply to the background of the Scope GUI. By default, the figure color is gray.

Plot type

Specify the type of plot to use. The default setting is Line. Valid values for **Plot type** are:

- Line — Displays input signal as lines connecting each of the sampled values. This approach is similar to the functionality of the MATLAB line or plot function.

- Stairs — Displays input signal as a *stairstep* graph. A stairstep graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. This approach is equivalent to the MATLAB stairs function. Stairstep graphs are useful for drawing time history graphs of digitally sampled data.

- Auto — Displays input signal as a line graph if it is a continuous signal and displays input signal as a stairstep graph if it is a discrete signal.

This parameter is Tunable.

Select display

Specify the active display as a number, where a display number corresponds to the index of the input signal. The number of a display corresponds to its column-wise placement index. The default setting is 1. Set this parameter to control which display should have its axes colors, line properties, marker properties, and visibility changed. Tunable.

Axes colors

Specify the color that you want to apply to the background of the axes for the active display.

Properties for line

Specify the signal for which you want to modify the visibility, line properties, and marker properties.

Visible

Specify whether the selected signal on the active display should be visible. If you clear this check box, the line disappears.

Line

Specify the line style, line width, and line color for the selected signal on the active display.

Marker

Specify marks for the selected signal on the active display to show at data points. This parameter is similar to the Marker property for the MATLAB Handle Graphics plot objects. You can choose any of the marker symbols from the following table.

Specifier	Marker Type
none	No marker (default)
○	Circle
□	Square
×	Cross
●	Point
+	Plus sign
✳	Asterisk
◇	Diamond
▽	Downward-pointing triangle
△	Upward-pointing triangle
◁	Left-pointing triangle
▷	Right-pointing triangle

Specifier	Marker Type
☆	Five-pointed star (pentagram)
✡	Six-pointed star (hexagram)

**Core —
General
UI Options**

The Core:General UI Options dialog box controls the general settings for the Time Scope GUI. From the Time Scope menu bar, select **File > Configuration** to open the Time Scope — Configuration dialog box. Click on the **Core** pane, and the following dialog box appears.

To open the Core:General UI Options dialog box, select **General UI** and click **Options**. The following dialog box appears.

General UI Options

Open message log
Use this parameter to control when the Message Log window opens.
The Message Log window helps you debug any issues with the Time
Scope. Using the drop-down list, you can choose to open the Message
Log window under any of the following conditions:

- `for any new messages`

- `for warn/fail messages`

- `only for fail messages`

- `manually`

You can open the Message Log at any time by selecting **Help > Message
Log**. The Message Log dialog box provides a system-level record of
loaded configuration settings and registered extensions. The Message
Log displays summaries and details of each message, and you can filter
the display of messages by **Type** and **Category**.

- The **Type** parameter allows you to select which types of messages to
  display in the Message Log. You can select `All`, `Info`, `Warn`, or `Fail`.

- The **Category** parameter allows you to select the category of
  messages to display in the Message Log. You can select `All`,
  `Configuration`, or `Extension`.

- The scope uses `Configuration` messages to indicate when new configuration files are loaded.

- The scope uses `Extension` messages to indicate when components are registered. For example, you may see a `Simulink registered` message, indicating that a component has been successfully registered with Simulink and is available for configuration.

Visuals — Time Domain Options

The Time Scope — Visuals:Time Domain Options dialog box controls the visual configuration settings of the Time Scope displays. From the Time Scope menu, select **View > Properties** to open this dialog box.

Main Pane

The **Main** pane of the Time Scope — Visuals:Time Domain Options dialog box appears as follows.

Input processing

Specify whether the Time Scope should treat the input signal as
`Columns as channels (frame based)` or `Elements as channels
(sample based)`. Tunable.

Frame-based processing is only available for discrete input signals. For
more information about frame-based input channels, see the "What Is
Frame-Based Processing?" section in the *DSP System Toolbox User's
Guide*. For an example that uses the Time Scope block and frame-based
input signals, see the Display Time-Domain Data in the Time Scope
section in the *DSP System Toolbox User's Guide*.

Time span

Specify the time span, either by selecting a predefined option or by
entering a numeric value in seconds. You can select one of the following
options:

- `Auto calculate` — In this mode, the Time Scope automatically calculates the appropriate value for time span from the difference between the simulation "Start time" and "Stop time" parameters. This option is available only for the Time Scope block but not for the `dsp.TimeScope` System object.

- `One frame period` — In this mode, the Time Scope uses the frame period of the input signal to the Time Scope block. This option is only available when the **Input processing** parameter is set to `Columns as channels (frame based)`. This option is not available when you set the **Input processing** parameter to `Elements as channels (sample based)`.

- `<user defined>` — In this mode, you specify the time span by replacing the text `<user defined>` with a numeric value in seconds.

The scope sets the *time*-axis limits using the value of this parameter and the value of the **Time display offset** parameter. For example, if you set the **Time display offset** to `5e-6` and the **Time span** to `25e-6`, the scope sets the *time*-axis limits as shown in the following figure.

This parameter is Tunable.

Time span overrun

Specify how the scope displays new data beyond the visible time span. The default setting is `Wrap`. You can select one of the following options:

- Wrap — In this mode, the scope displays new data until the data reaches the maximum *time*-axis limit. When the data reaches the maximum *time*-axis limit of the scope window, the Time Scope clears the display. The Time Scope then updates the time offset value, and begins displaying subsequent data points starting from the minimum *time*-axis limit.

- Scroll — In this mode, the scope scrolls old data to the left to make room for new data on the right side of the scope display. This mode is graphically intensive and can affect run-time performance, but it is beneficial for debugging and monitoring time-varying signals.

This parameter is Tunable.

Time units

Specify the units used to describe the *time*-axis. The default setting is Metric. You can select one of the following options:

- Metric — In this mode, Time Scope converts the times on the *time*-axis to some metric units such as milliseconds, microseconds, days, etc. Time Scope chooses the appropriate metric units, based on the minimum *time*-axis limit and the maximum *time*-axis limit of the scope window.

- Seconds — In this mode, Time Scope always displays the units on the *time*-axis as seconds.

- None — In this mode, Time Scope displays no units on the *time*-axis. Time Scope shows only the word Time on the *time*-axis.

This parameter is Tunable.

Time display offset

This parameter allows you to offset the values displayed on the *time*-axis by a specified number of seconds. When you specify a scalar value, the scope offsets all channels equally. When you specify a vector of offset values, the scope offsets each channel independently. Tunable.

When you specify a **Time display offset** vector of length *N*, the scope offsets the input channels as follows:

- When *N* is equal to the number of input channels, the scope offsets each channel according to its corresponding value in the offset vector.

- When *N* is less than the number of input channels, the scope applies the values you specify in the offset vector to the first *N* input channels. The scope does not offset the remaining channels.

- When *N* is greater than the number of input channels, the scope offsets each input channel according to the corresponding value in the offset vector. The scope ignores all values in the offset vector that do not correspond to a channel of the input.

The scope computes the *time*-axis range using the values of the **Time display offset** and **Time span** parameters. For example, if you set the **Time display offset** to `5e-6` and the **Time span** to `25e-6`, the scope sets the *time*-axis limits as shown in the following figure.

Similarly, when you specify a vector of values, the scope sets the minimum *time*-axis limit using the smallest value in the vector. To set the maximum *time*-axis limit, the scope sums the largest value in the vector with the value of the **Time span** parameter. For more information, see "Signal Display" on page 2-1447.

Show time-axis labels

Specify how to display the time units used to describe the *time*-axis. The default setting is `All`. You can select one of the following options:

- All — In this mode, the *time*-axis labels appear in all displays.

- None — In this mode, the *time*-axis labels do not appear in the displays.

- Bottom Displays Only — In this mode, the *time*-axis labels appear in only the bottom row of the displays.

Tunable.

Maximize axes

Specify whether to display the Time Scope in maximized axes mode. In this mode, each of the axes are expanded to fit into the entire display. In each display, there is no space to show labels. Tick mark values are shown on top of the plotted data. The default setting is Auto. You can select one of the following options:

- Auto — In this mode, the axes appear maximized in all displays only if the **Title** and **Y-Axis label** parameters are empty for every display. If you enter any value in any display for either of these parameters, the axes are not maximized.

- On — In this mode, the axes appear maximized in all displays. Any values entered into the **Title** and **Y-Axis label** parameters are hidden.

- Off — In this mode, none of the axes appear maximized.

Display Pane

The **Display** pane of the Visuals:Time Domain Options dialog box appears as follows.

dsp.TimeScope

Select display

Specify the active display as a number, where a display number corresponds to the index of the input signal. The index of a display is its column-wise placement index. The default setting is 1. Set this parameter to control the display for which you intend to modify the title, legend, grid, *y*-axis limits, *y*-axis label, and magnitude/phase display parameters. Tunable.

Title

Specify the active display title as a string. By default, the active display has no title. Tunable.

Show legend

Select this check box to show the legend in the active display. The channel legend displays a name for each channel of each input signal. When the legend appears, you can place it anywhere inside of the scope window. To turn the legend off, clear the **Show legend** check box. Tunable.

You can edit the name of any channel in the legend. To do so, double-click the current name, and enter a new channel name. By default, the scope names each channel according to either its signal name or the name of the block from which it comes. If the signal has multiple channels, the scope uses an index number to identify each channel of that signal. For example, a 2-channel signal named `MySignal` would have the following default names in the channel legend: `MySignal:1`, `MySignal:2`.

The Time Scope does not display signal names that were labeled within an unmasked subsystem. You must label all input signals to the Scope block that originate from an unmasked subsystem.

To change the appearance of any channel of any input signal in the Scope window, from the menu, select **View > Style**.

Show grid
When you select this check box, a grid appears in the active display of the Scope. To hide the grid, clear this check box. Tunable.

Plot signal(s) as magnitude and phase
When you select this check box, the Scope splits the active display into a magnitude plot and a phase plot. By default, this check box is cleared. If the input signal is complex valued, the Scope plots the real and imaginary portions on the same axes. These real and imaginary portions appear as different-colored lines on the same axes within the same active display, as shown in the following figure.

Selecting this check box and clicking the **Apply** or **OK** button changes the active display. The magnitude of the input signal appears on the top axes and its phase, in degrees, appears on the bottom axes. See the following figure.

This feature is particularly useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box always produces the same behavior. The phase is 0 for nonnegative input and 180 degrees for negative input. Tunable.

Minimum Y-limit

Specify the minimum value of the *y*-axis. Tunable.

When you select the **Plot signal(s) as magnitude and phase** check box, the value of this parameter always applies to the magnitude plot on the top axes. The phase plot on the bottom axes is always limited to a minimum value of –180 degrees.

Maximum Y-limit

Specify the maximum value of the *y*-axis. Tunable.

When you select the **Plot signal(s) as magnitude and phase** check box, the value of this parameter always applies to the magnitude plot on the top axes. The phase plot on the bottom axes is always limited to a maximum value of 180 degrees.

Y-axis label

Specify the text for the scope to display to the left of the *y*-axis. Tunable.

This parameter becomes invisible when you select the **Plot signal(s) as magnitude and phase** check box. When you enable that parameter, the *y*-axis label always appears as Magnitude on the top axes and Phase on the bottom axes.

Tools — Plot Navigation Options

The Time Scope — Tools:Plot Navigation Options dialog box provides you with the ability to automatically zoom in on and zoom out of your data, and to scale the axes of the Time Scope. In the Time Scope menu, select **Tools > Axes Scaling Options** to open this dialog box.

Alternatively, you can open this dialog box from the Time Scope — Configuration dialog box. In the Time Scope menu, select **File > Configuration** to open the Time Scope — Configuration dialog box. Click the **Tools** pane, and the following dialog box appears.

The **Tools** pane in the Time Scope – Configuration dialog box contains the tools that appear on the Time Scope GUI. By default, the **Plot Navigation** tool is enabled. If you disable the tool by clearing the **Enabled** check box, the axes scaling and zoom tools no longer display in the Time Scope GUI. You can reenable the tool at any time by selecting the **Enabled** check box.

By default, the **Measurements** tool is also enabled. If you disable the tool by clearing the **Enabled** check box, the Time Domain Measurements tools no longer display in the Time Scope GUI. See the "Measurements Panels" on page 5-1112 section for more information. You can reenable the tool at any time by selecting the **Enabled** check box.

To open the Time Scope — Tools:Plot Navigation Options dialog box, select the **Plot Navigation** tool, and then click the **Options** button.

Parameters

The Tools:Plot Navigation Options dialog box appears as follows.

Axis Scaling

Specify when the Scope should automatically scale the axes. You can select one of the following options:

- Manual — When you select this option, the Scope does not automatically scale the axes. You can manually scale the axes in any of the following ways:

  - Select **Tools > Scale axes limits**.

  - Press the **Scale Axes Limits** toolbar button.

  - When the scope GUI is the active window, press **Ctrl+A**.

- Auto — When you select this option, the Scope scales the axes as needed, both during and after simulation. Selecting this option enables the **Do not allow Y-axis limits to shrink** check box. By default, this parameter is selected, and the Scope does not shrink the *y*-axis limits when scaling the axes.

- Once at stop — Selecting this option causes the Scope to scale the axes each time simulation is stopped. The Scope does not scale the axes during simulation.

This parameter is Tunable.

Do not allow Y-axis limits to shrink

When you select this parameter, the y-axis limits are only allowed to grow during axes scaling operations. If you clear this check box, the y-axis limits may shrink during axes scaling operations.

This parameter appears only when you select Auto for the **Axis Scaling** parameter. When you set the **Axis Scaling** parameter to Manual or Once at stop, the y-axis limits are allowed to shrink. Tunable.

Y-axis Data range (%)

Set the percentage of the y-axis that the Scope should use to display the data when scaling the axes. Valid values are between 1 and 100. For example, if you set this parameter to 100, the Scope scales the y-axis limits such that your data uses the entire y-axis range. If you then set this parameter to 30, the Scope increases the y-axis range such that your data uses only 30% of the y-axis range. Tunable.

Y-axis Align

Specify where the Scope should align your data with respect to the y-axis when it scales the axes. You can select Top, Center, or Bottom. Tunable.

Scale X-axis limits

Check this box to allow the Scope to scale the x-axis limits when it scales the axes. Tunable.

X-axis Data range (%)

Set the percentage of the x-axis that the Scope should use to display the data when scaling the axes. Valid values are between 1 and 100. For example, if you set this parameter to 100, the Scope scales the x-axis limits such that your data uses the entire$x$-axis range. If you then set this parameter to 30, the Scope increases the x-axis range such that your data uses only 30% of the x-axis range. Use the x-axis **Align** parameter to specify data placement with respect to the x-axis.

This parameter appears only when you select the **Scale X-axis limits** check box. Tunable.

X-axis Align

Specify how the Scope should align your data with respect to the *x*-axis: Left, Center, or Right. This parameter appears only when you select the **Scale X-axis limits** check box. Tunable.

**Sources —
Streaming
Options**

The Sources:Streaming Options dialog box lets you control the number of input signal samples that Time Scope holds in memory. In the Time Scope menu, select **View** > **Data History Options** to open this dialog box.

Data History Options

Data History Options

Limit data points to last: 50000

OK   Cancel   Apply

Limit data points to last

Specify the number of input signal samples that Time Scope holds in memory. The default is 50000.

Examples

The first few examples illustrate how to use the Time Scope block to view a variety of input signals in the time domain.

- "Example: Display Simple Sine Wave Input Signal" on page 5-1154
- "Example: View Sine Wave Input Signals at Different Sample Rates and Offsets" on page 5-1154
- "Example: Display Complex-valued Input Signal" on page 5-1155
- "Example: Display Variable-size Input Signal" on page 5-1157

The remaining examples demonstrate how to use the Measurements Panels in the Time Scope GUI to glean information about the input signals.

- "Example: Use Bilevel Measurements Panel with Clock Input Signal" on page 5-1158
- "Example: Find Heart Rate Using Peak Finder Panel with ECG Input Signal" on page 5-1161

Example: Display Simple Sine Wave Input Signal

Construct dsp.SineWave and dsp.TimeScope objects. Run the step method to display the signal.

```
hsin = dsp.SineWave('Frequency',100, 'SampleRate', 1000);
hsin.SamplesPerFrame = 10;
hts1 = dsp.TimeScope('SampleRate', hsin.SampleRate,'TimeSpan', 0.1);
for ii = 1:10
    x = step(hsin);
    step(hts1, x);
end
```

Run the release method to automatically scale the axes.

```
release(hts1)
```

Run the MATLAB clear function to close the Time Scope window.

```
clear hts1 hsin x;
```

Example: View Sine Wave Input Signals at Different Sample Rates and Offsets

Construct dsp.SineWave and dsp.FirDecimator objects. Use the dsp.FirDecimator object to create a new signal that equals the original signal, but decimated by a factor of 2. Construct a dsp.TimeScope object with 2 input ports. Run the step method to display the signal.

```
Fs = 1000;  % Sampling frequency
hsin1 = dsp.SineWave('Frequency',50,...
   'SampleRate',Fs, ...
   'SamplesPerFrame', 100);
% Create FIRDecimator System object to decimate by 2
```

```
hfilt = dsp.FIRDecimator;
% Create TimeScope System object with 2 input ports (channels)
hts2 = dsp.TimeScope(2, [Fs Fs/2], ...
    'TimeDisplayOffset', [O 38/Fs], ...
    'TimeSpan', 0.25, ...
    'YLimits',[-1 1], ...
    'LegendSource', 'Auto');
for ii = 1:2
     xsine = step(hsin1);
     xdec = step(hfilt,xsine);
     step(hts2, xsine, xdec);
end
```

Run the `release` method to automatically scale the axes.

```
release(hts2)
```

Run the MATLAB `clear` function to close the Time Scope window.

```
clear hts2 Fs hsin1 hfilt ii xsine xdec;
```

Example: Display Complex-valued Input Signal

Create a vector representing a complex-valued sinusoidal signal and construct a `dsp.TimeScope` object. Run the `step` method to display the signal.

```
fs = 1000; t = (0:1/fs:10)';
CxSine = cos(2*pi*0.2*t) + 1i*sin(2*pi*0.2*t);
CxSineSum = cumsum(CxSine);
figure(101); subplot(2,1,1); stairs(t,abs(CxSineSum));  % Plot magnitu
subplot(2,1,2); stairs(t,(180/pi)*angle(CxSineSum));    % Plot phase :
h1 = dsp.TimeScope(1, fs, 'TimeSpanSource', 'Auto');
step(h1,CxSineSum);
```

By default, when the input is a complex-valued signal, Time Scope plots the real and imaginary portions on the same axes. These real and imaginary portions appear as different-colored lines on the same axes within the same active display, as shown in the following figure.

Change the `MagnitudePhase` property to true.

```
set(h1,'MagnitudePhase',true);
```

Time Scope now plots the magnitude and phase of the input signal on two separate axes within the same active display. The active display changes to show the magnitude of the input signal on the top axes and its phase, in degrees, on the bottom axes, as shown in the following figure.

Run the release method to automatically scale the axes.

```
release(h1);
```

Run the MATLAB clear function to close the Time Scope window, and remove the variables you created from the workspace.

```
close(101);
clear h1 fs t CxSine CxSineSum
```

Example: Display Variable-size Input Signal

Create a vector that represents a two-channel constant signal. Create another vector that represents a three-channel constant signal. Construct a dsp.TimeScope object with 2 input ports. Run the step method to display the signal.

```
fs = 10;
```

```
sigdim2 = [ones(5*fs,1), 1+ones(5*fs,1)];                          % 2-dim 0-5s
sigdim3 = [2+ones(5*fs,1), 3+ones(5*fs,1), 4+ones(5*fs,1)]; % 3-dim 5-10s
h2 = dsp.TimeScope(2, fs, 'TimeSpanSource', 'Property');
set(h2,'PlotType','Stairs');
set(h2,'TimeSpanOverrunMode','Scroll');
set(h2,'TimeDisplayOffset',[0,0,5]);
step(h2,[sigdim2; sigdim3(:,1:2)], sigdim3(:,3));
```

In this example, the size of the input signal to the Time Scope block changes as the simulation progresses. When the simulation time is less than 5 seconds, Time Scope plots only the signal *sigdim2*, which has two channels. After 5 seconds, Time Scope also plots the signal *sigdim3*, which has three channels.

Run the `release` method to automatically scale the axes.

```
release(h2);
```

Run the MATLAB `clear` function to close the Time Scope window, and remove the variables you created from the workspace.

```
clear h2 fs sigdim2 sigdim3
```

Example: Use Bilevel Measurements Panel with Clock Input Signal

Load the clock data into the variable, *x*. Find the sample time, *ts*.

```
load clockex;
ts = t(2)-t(1);
```

Construct a `dsp.TimeScope` object. Run the `step` method to display the signal.

```
h4 = dsp.TimeScope(1, 1/ts, 'TimeSpanSource','Auto');
step(h4,x);
```

Run the `release` method to automatically scale the axes.

```
release(h4);
```

To show the **Bilevel Measurements** panel, in the Time Scope menu, select **Tools > Measurements > Bilevel Measurements**. To collapse the **Transitions** pane, click the pane collapse button (▼) next to that label. To expand the **Settings** pane and the **Overshoots / Undershoots** pane, click the pane expand button (▶) next to each label. The Time Scope figure appears as shown in the following figure.

As you can see in the figure, the value for the rising edge **Settling Time** parameter is initially not displayed. The reason for this is that the default value for the **Settle Seek** parameter is too large for this example. In this case, the settle seek time is longer than the entire simulation duration. Enter a value for settle seek of `2e-6`, and press the **Enter** key. Time Scope now displays a rising edge settling time value of `118.392 ns`.

This settling time value displayed is actually the statistical average of the settling times for all five rising edges. To show the settling time for only one rising edge, you can zoom in on that transition. In the Time

Scope toolbar, click the Zoom X button (ⁱᵂQⁱ). Then, click the display near a value of 2 microseconds on the *time*-axis. Drag to the right and release near a value of 4 microseconds on the *time*-axis. Time Scope updates the rising edge **Settling Time** value to reflect the new time window, as shown in the following figure.

Run the MATLAB `clear` function to close the Time Scope window, and remove the variables you created from the workspace.

```
clear h4 x t ts
```

Example: Find Heart Rate Using Peak Finder Panel with ECG Input Signal

First, create the electrocardiogram (ECG) signal.

```
x1 = 3.5*ecg(2700).';
y1 = sgolayfilt(kron(ones(1,13),x1),0,21);
n = (1:30000)';
del = round(2700*rand(1));
mhb = y1(n + del);
ts = 0.00025;
```

This example uses the Savitzky-Golay filter in Signal Processing Toolbox. For more information, see the sgolayfilt function reference page or run the sgolaydemo example.

Construct a dsp.TimeScope object. Run the step method to display the signal.

```
h5 = dsp.TimeScope(1, 1/ts, 'TimeSpanSource','Auto');
step(h5,mhb);
```

Run the release method to automatically scale the axes.

```
release(h5);
```

To show the **Peak Finder** panel, in the Time Scope menu, select **Tools > Measurements > Peak Finder**. To expand the **Settings** pane, click the pane expand button (▶) next to that label. Enter a value for **Max Num of Peaks** of 10, and press the **Enter** key. Time Scope now displays in the **Peaks** pane a list of 10 peak amplitude values, and the times at which they occur, as shown in the following figure.

As you can see from the list of peak values, there is a constant time difference of 0.675 seconds between each heartbeat. Therefore, the heart rate of the ECG signal is given by the following equation.

$$\frac{60\frac{\sec}{\min}}{0.675\frac{\sec}{\text{beat}}} = 88.89\frac{\text{beats}}{\min}(\text{bpm})$$

Run the MATLAB clear function to close the Time Scope window, and remove the variables you created from the workspace.

```
clear h5 x1 y1 n del mhb ts
```

See Also   Time Scope | dsp.SpectrumAnalyzer | sptool

Purpose   Create time scope object with same property values

Syntax   `C = clone(H)`

Description   `C = clone(H)` creates a `TimeScope` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

dsp.TimeScope.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   `N = getNumInputs(H)`

Description `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method. `N` equals the value of the `NumInputPorts` property.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                   method. The time scope is a sink object, so N equals 0.

                   The getNumOutputs method returns a positive integer that is the
                   number of outputs from the step method. This value will change if you
                   alter any properties that turn outputs on or off.

dsp.TimeScope.hide

Purpose   Hide time scope window

Syntax   hide(H)

Description   hide(H) hides the time scope window, associated with System object, H.

See Also   dsp.TimeScope.show

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the TimeScope object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.TimeScope.release

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description release(H) releases system resources, such as memory, file handles,
and hardware connections. This method lets you change any properties
or input characteristics.

You should call the release method after calling the step method when
there is no new data for the simulation. When you call the release
method, the axes will automatically scale in the Time Scope figure
window. After calling the release method, any non-tunable properties
can be set once again.

Note You can use the release method on a System object in code
generated from MATLAB, but once you release its resources, you cannot
use that System object again.

Examples   View a sine wave on the time scope. When you finish the simulation,
release system resources. Note that when you run the release method,
the axes automatically scale.

```
hsin = dsp.SineWave('Frequency',100, 'SampleRate', 1000);
hsin.SamplesPerFrame = 10;

hts1 = dsp.TimeScope('SampleRate', hsin.SampleRate,'TimeSpan', 0.1);
for ii = 1:10
    x = step(hsin);
    step(hts1, x);
end

release(hts1);
```

View two sine waves with different sample rates and time offsets. When you finish the simulation, release system resources. Note that when you run the release method, the axes automatically scale.

```
Fs = 1000;  % Sampling frequency

hsin1 = dsp.SineWave('Frequency',50,...
   'SampleRate',Fs, ...
   'SamplesPerFrame', 100);

% Create FIRDecimator System object to decimate by 2
hfilt = dsp.FIRDecimator;

% Create TimeScope System object with 2 input
% ports (channels)
hts2 = dsp.TimeScope(2, [Fs Fs/2], ...
   'TimeDisplayOffset', [0 38/Fs], ...
   'TimeSpan', 0.25, ...
   'YLimits',[-1 1], ...
   'LegendSource', 'Auto');

for ii = 1:2
    xsine = step(hsin1);
    xdec = step(hfilt,xsine);
    step(hts2, xsine, xdec);
end

release(hts2);
```

Algorithms   In operation, the release method is similar to the mdlTerminate function.

See Also   dsp.TimeScope.reset

dsp.TimeScope.reset

Purpose   Reset internal states of time scope object

Syntax   reset(H)

Description   reset(H) sets the internal states of the TimeScope object H to their
                initial values.

                You should call the reset method after calling the step method when
                you want to clear the Time Scope figure displays, prior to releasing
                system resources. This action enables you to start a simulation from the
                beginning. When you call the reset method, the displays will become
                blank again. In this sense, its functionality is similar to that of the
                MATLAB clf function. Do not call the reset method after calling the
                release method.

Examples   View a sine wave on the time scope. When you finish the simulation,
                pause for 5 seconds and then reset the screen. Then, view a different
                sine wave on the same time scope.

```
hsin = dsp.SineWave('Frequency', 100, 'SampleRate', 1000, 'SamplesPerFram
hsin1 = dsp.SineWave('Frequency', 50, 'SampleRate', 1000, 'SamplesPerFram

hts1 = dsp.TimeScope('SampleRate', hsin.SampleRate,'TimeSpan', 0.1);
for ii = 1:10
    x = step(hsin);
    step(hts1, x);
end

% Pause and then reset internal states
pause(5);
reset(hts1);

for ii = 1:10
    x = step(hsin1);
    step(hts1, x);
end
```

```
release(hts1);
```

Algorithms   In operation, the reset method is similar to a consecutive execution of the mdlTerminate function and the mdlInitializeConditions function.

See Also   dsp.TimeScope | dsp.TimeScope.release

dsp.TimeScope.show

Purpose   Make time scope window visible

Syntax   show(H)

Description show(H) makes the time scope window, associated with System object, H, visible.

See Also   dsp.TimeScope.hide

Purpose   Display signal in time scope figure

Syntax   `step(H,X)`
`step(H,X1,X2,...,XN)`

Description   `step(H,X)` displays the signal, `X`, in the time scope figure.

`step(H,X1,X2,...,XN)` displays the signals `X1`, `X2`,...,`XN` in the time scope figure when you set the `NumInputPorts` property to `N`. In this case, `X1`, `X2`,...,`XN` can have different data types and dimensions.

dsp.TransitionMetrics

Purpose
Transition metrics of bilevel waveforms

Description
The `TransitionMetrics` object extracts information such as duration, slew rate, and reference-level crossings for each transition found in the bilevel waveform. The `TransitionMetrics` object can additionally return preshoot, postshoot and settling metrics for the regions immediately before and after each transition.

To obtain transition metrics for a bilevel waveform:

1 Define and set up your transition metrics. See "Construction" on page 5-1174.

2 Call `step` to calculate the transition metrics according to the properties of `dsp.TransitionMetrics`. The behavior of `step` is specific to each object in the toolbox.

Construction
`H = dsp.TransitionMetrics` creates a transition metrics System object, `H`. The object computes the rise time, fall time and width of a pulse. `TransitionMetrics` additionally computes cycle metrics such as pulse separations, periods, and duty cycles.

`H = dsp.TransitionMetrics('`*PropertyName*`',`*PropertyValue*`,...)` returns a `TransitionMetrics` System object, `H`, with each specified property set to the specified value.

Properties

MaximumRecordLength

Maximum samples to preserve between calls to `step`. This property requires a positive integer that specifies the maximum number of samples to save between calls to the `step` method. When the number of samples to be saved exceeds this length, the oldest excess samples are discarded. This property applies when `RunningMetrics` is `true` and is tunable.

Default: 1000

PercentReferenceLevels

Lower-, middle-, and upper-percent reference levels. This property contains a 3-element numeric row vector that contains the lower-, middle-, and upper-percent reference levels. These reference levels are used as an offset between the low and high states of the waveform when computing the duration of each transition.

Default: [10 50 90]

PercentStateLevelTolerance

Tolerance of the state level (in percent). This property requires a scalar that specifies the maximum deviation from either the low or high state before it is considered to be outside that state. The tolerance is expressed as a percentage of the waveform amplitude.

Default: 2

PostshootOutputPort

Enable posttransition aberration metrics. If this property is set to true, overshoot and undershoot metrics are reported for a region defined immediately after each transition. The posttransition aberration region is defined as the waveform interval that begins at the end of each transition and whose duration is the value of PostshootSeekFactor times the computed transition duration. If a complete subsequent transition is detected before the interval is over, the region is truncated at the start of the subsequent transition. The metrics are computed for each transition that has a complete posttransition aberration region.

Default: false

PostshootSeekFactor

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately following each transition. The duration is expressed as a factor of the duration of the transition.

This property is enabled only when the `PostshootOutputPort` property is set to `true` and is tunable.

Default: 3

PreshootOutputPort

Enable pretransition aberration metrics. If the `PreshootOutputPort` property is set to `true`, overshoot and undershoot metrics are reported for a region defined immediately before each transition. The pretransition aberration region is defined as the waveform interval that ends at the start of each transition and whose duration is `PreshootSeekFactor` times the computed transition duration.

Default: `false`

PreshootSeekFactor

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately preceding each transition. The duration is expressed as a factor of the duration of the transition. This property is enabled only when the `PreshootOutputPort` property is set to `true` and is tunable.

Default: 3

RunningMetrics

Enable metrics over all calls to `step`. If `RunningMetrics` is set to `false`, metrics are computed for each call to `step` independently. If `RunningMetrics` is set to `true`, metrics are computed across subsequent calls to `step`. If there are not enough samples to compute metrics associated with the last transition, posttransition aberration region, or settling seek duration in the current record, the object defers reporting all transition, aberration, and settling metrics associated with the last transition until a subsequent call

to `step` is made with enough data to compute all enabled metrics for that transition.

Default: `false`

SampleRate

Sampling rate of uniformly-sampled signal. Specify the sample rate in hertz as a positive scalar. This property is used to construct the internal time values that correspond to the input sample values. Time values start with zero. This property applies when the `TimeInputPort` property is set to `false`.

Default: `1`

SettlingOutputPort

Enable settling metrics. If `SettlingOutputPort` is set to true, settling metrics are reported for each transition. The region used to compute the settling metrics starts at the midcrossing and lasts until the `SettlingSeekDuration` has elapsed. If an intervening transition occurs, or the signal has not settled within the `PercentStateLevelTolerance` of the final level, `NaN` is returned for each metric. If there are not enough samples after the last transition to complete the `SettlingSeekDuration`, no metrics are reported for the last transition. The metrics are reported for the transition the next time `step` is called if the `RunningMetrics` property is set to `true`.

Default: `false`

SettlingSeekDuration

Duration of time over which to search for settling. This property is a scalar that specifies the amount of time to inspect from the mid-reference level crossing (in seconds). If the transition has not yet settled, or a subsequent complete transition is detected within this duration, the `TransitionMetrics` object reports `NaN` for all

settling metrics. This property is tunable and applies only when you set the `SettlingOutputPort` property to `true`.

Default: `0.02`

StateLevels

Low- and high-state levels. This property is a 2-element numeric row vector that contains the low and high state levels respectively. These state levels correspond to the nominal logic low and high levels of the pulse waveform. This property is tunable.

Default: `[0 2.3]`

StateLevelsSource

Auto or manual state level computation. If the `StateLevelsSource` property is set to `'Auto'`, the first record sent to `step` is sent to `dsp.StateLevels` with the default settings to determine the state levels of the incoming waveform. If this property is set to `'Property'`, the object uses the values the user specifies in the `StateLevels` property.

Default: `'Property'`

TimeInputPort

Add input to specify sample instants. Set `TimeInputPort` to `true` to enable an additional real input column vector to `step` to specify the sample instants that correspond to the sample values. If this property is `false`, the sample instants are built internally. The sample instants start at zero and increment by the reciprocal of the `SampleRate` property for subsequent samples. The sample instants continue to increment if the `RunningMetrics` property is set to `true` and no intervening calls to the `reset` or `release` methods are encountered.

Default: `false`

Methods

clone	Clones the current instance of the transition metrics object
getNumInputs	Number of expected inputs to the method
getNumOutputs	Number of outputs of the method
isLocked	Locked status (logical) for input attributes and nontunable properties
plot	Plots signal and metrics computed in last call to
reset	Reset the running transition metrics object
step	Transition metrics of bilevel waveform

Examples

Transition and Preshoot Information of a 2.3 V Step Waveform

Compute transition and preshoot information of a 2.3 V step waveform sampled at 4 MHz

Load the data.

```
load('transitionex.mat', 'x');
```

Construct your transition metrics System object. Set the SampleRate property to 4 MHz, set the StateLevelsSource property to 'Auto' to estimate the state levels from the data, set the PreshootOutputPort property to true to output pretransition aberration metrics when you call step.

```
htm1 = dsp.TransitionMetrics('SampleRate',4e6, ...
                             'StateLevelsSource','Auto', ...
                             'PreshootOutputPort',true)
```

Call `step` to compute the transition and preshoot information. Plot the result.

```
[transition, preshoot] = step(htm1, x)
plot(htm1)
```

Transition, Postshoot, and Settling Information of a 2.3 V Step Waveform

Compute transition, postshoot, and settling information of a 2.3 V step waveform sampled at 4 MHz.

Load the data along with the sampling instants.

```
load('transitionex.mat', 'x', 't');
```

Construct your transition metrics object setting the `TimeInputPort` property to `true` and the `StateLevels` property to match waveform state levels. To output the postshoot information and settling information when you call `step`, set the `PostShootOutputPort` and `SettlingOutputPort` properties to `true`. Set the settling seek duration to 2 microseconds.

```
htm2 = dsp.TransitionMetrics('TimeInputPort',true, ...
                             'StateLevels',[O 2.3], ...
                             'PostshootOutputPort',true, ...
                             'SettlingOutputPort',true, ...
                             'SettlingSeekDuration',2e-6)
```

Compute the transition, postshoot, and settling information with `step` and plot the result.

```
[transition, postshoot, settling] = step(htm2,x,t)
plot(htm2)
```

References   [1] *IEEE Standard on Transitions, Pulses, and Related Waveforms*, IEEE Standard 181, 2003.

See Also   dsp.StateLevels **|** dsp.PulseMetrics **|**

Purpose   Clones the current instance of the transition metrics object

Syntax   clone(H)

Description   clone(H) clones the current instance of the transition metrics object H.

dsp.TransitionMetrics.getNumInputs

Purpose   Number of expected inputs to the `step` method

Syntax   `N = getNumInputs(H)`

Description `N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method for the transition metrics object `H`.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose   Number of outputs of the `step` method

Syntax   `N = getNumOutputs(H)`

Description   `N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status (logical) for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the transition metrics object H.

Purpose   Plots signal and metrics computed in last call to `step`

Syntax   `plot(H)`

Description   `plot(H)` plots the signal and metrics resulting from the last call of the step method.

By default `plot` displays

- the low and high state levels and the state-level boundaries defined by the `PercentStateLevelTolerance` property.

- the lower-, middle-, and upper-reference levels.

- the locations of the mid-reference level crossings of the positive (+) and negative (-) transitions of each detected pulse.

When you set the `TransitionOutputPort` property to `true`, the locations of the upper and lower crossings are also plotted. When the `PreshootOutputPort` or `PostShootOutputPort` properties are set to `true`, the corresponding overshoots and undershoots are plotted as inverted or non-inverted triangles. When the `SettlingOutputPort` property is set to `true`, the locations where the signal enters and remains within the upper- and lower-state boundaries over the specified seek duration are plotted.

Purpose   Reset the running transition metrics object

Syntax   reset(H)

Description

reset(H) clears information from previous calls to step.

Purpose   Transition metrics of bilevel waveform

Syntax
```
PULSE = step(H,X)
[PULSE,CYCLE] = step(H,X)
[PULSE,TRANSITION] = step(H,X)
[PULSE,PRESHOOT] = step(H,X)
[PULSE,POSTSHOOT] = step(H,X)
[PULSE,SETTLING] = step(H,X)
[...] = step(H,X,T)
```

Description   PULSE = step(H,X) returns a structure array, PULSE, whose fields
contain real-valued column vectors. The number of rows of each field
corresponds to the number of complete pulses found in the real-valued
column vector input, X. Each pulse starts with a transition of the
polarity specified by the Polarity property and ends with a transition
of the opposite polarity.

PULSE fields:

- PositiveCross — Instants where the positive-going transitions cross
  the mid-reference level of each pulse

- NegativeCross — Instants where the negative-going transitions
  cross the mid-reference level of each pulse

- Width — Absolute difference between PositiveCross and
  NegativeCross of each pulse

- RiseTime — Duration between the linearly-interpolated instants
  when the positive-going (rising) transition of each pulse crosses the
  lower- and upper-reference levels

- FallTime — Duration between the linearly-interpolated instants
  when the negative-going (falling) transition of each pulse crosses the
  upper- and lower-reference levels

[PULSE,CYCLE] = step(H,X) returns a structure array, CYCLE,
whose fields contain real-valued column vectors when you set the
CycleOutputPort property to true. The number of rows of each field

corresponds to the number of complete pulse periods found in the real-valued column vector input, X. You need at least three consecutive alternating polarity transitions that start and end with the same polarity as the value of the `Polarity` property if you want to compute cycle metrics. If the last transition found the input, X, does not match the polarity of the `Polarity` property, the pulse separation, period, frequency, and duty cycle are not reported for the last pulse. If the `RunningMetrics` property is set to `true` when this occurs, all pulse, cycle, transition, preshoot, postshoot, and settling metrics associated with the last pulse are deferred until a subsequent call to `step` detects the next transition.

`CYCLE` fields:

- `Period` — Duration between the first transition of the current pulse and the first transition of the next pulse

- `Frequency` — Reciprocal of the period

- `Separation` — Durations between the mid-reference level crossings of the second transition of each pulse and the first transition of the next pulse

- `Width` — Durations between the mid-reference level crossings of the first and second transitions of each pulse. This is equivalent to the width parameter of the `PULSE` structure.

- `DutyCycle` — Ratio of the width to the period for each pulse

`[PULSE,TRANSITION] = step(H,X)` returns a structure array, `TRANSITION`, when you set the `TransitionOutputPort` property to `true`. The fields of `TRANSITION` contain real-valued matrices with two columns which correspond to the metrics of the first and second transitions. The number of rows corresponds to the number of pulses found in the input waveform.

`TRANSITION` fields:

- `Duration` — Amount of time between the interpolated instants where the transition crosses the lower- and upper-reference levels

- `SlewRate` — Ratio of absolute difference between the upper- and lower-reference levels to the transition duration

- `MiddleCross` — Linearly-interpolated instant where the transition first crosses the mid-reference level

- `LowerCross` — Linearly-interpolated instant where the signal crosses the lower-reference level

- `UpperCross` — Linearly-interpolated instant where the signal crosses the upper-reference level

`[PULSE,PRESHOOT] = step(H,X)` returns a structure array, `PRESHOOT`, when you set the `PreshootOutputPort` property to `true`. The fields of `PRESHOOT` contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform. The field names are identical to those of the `POSTSHOOT` structure.

`[PULSE,POSTSHOOT] = step(H,X)` returns a structure array, `POSTSHOOT`, when you set the `PostshootOutputPort` property to `true`. The fields of `POSTSHOOT` contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform.

`PRESHOOT` and `POSTSHOOT` fields:

- `Overshoot` — Overshoot of the region of interest expressed as a percentage of the waveform amplitude

- `Undershoot` — Undershoot of the region of interest expressed as a percentage of the waveform amplitude

- `OvershootLevel` — Level of the overshoot

- `UndershootLevel` — Level of the undershoot

- `OvershootInstant` — Instant that corresponds to the overshoot

- `UndershootInstant` — Instant that corresponds to the undershoot

`[PULSE,SETTLING] = step(H,X)` returns a structure, `SETTLING`, when you set the `SettlingOutputPort` property to `true`. The fields of

SETTLING correspond to the settling metrics for each transition. Each field is a column vector whose elements correspond to the individual settling durations, levels, and instants.

SETTLING fields:

- Duration — Amount of time from when the signal crosses the mid-reference level to the time where the signal enters and remains within the specified PercentStateLevelTolerance of the waveform amplitude over the specified settling seek duration

- Instant — Instant in time where the signal enters and remains within the specified tolerance

- Level — Level of the waveform where it enters and remains within the specified tolerance

The above operations can be used simultaneously, provided the System object properties are set appropriately. One example of providing all possible inputs and returning all possible outputs is :

[PULSE,CYCLE,TRANSITION,PRESHOOT,POSTSHOOT,SETTLING] = step(H,X) which returns the PULSE, CYCLE, TRANSITION, PRESHOOT, POSTSHOOT, and SETTLING structure arrays when the CycleOutputPort, PreshootOutputPort, PostshootPort, and SettlingOutputPort properties are true. You may enable or disable any combination of output ports. However, the output arguments are defined in the order shown here.

[...] = step(H,X,T) performs the above metrics with respect to a sampled signal, whose sample values, X, and sample instants, T, are real-valued column vectors of the same length. The additional input T applies only when you set the TimeInputPort property to true.

Purpose   Receive UDP packets from network

Description   The UDPReceiver object receives UDP packets from the network.

To receive UDP packets from the network:

1 Define and set up your UDP receiver. See "Construction" on page 5-1191.

2 Call step to receive the UDP packets according to the properties of dsp.UDPReceiver. The behavior of step is specific to each object in the toolbox.

Construction H = dsp.UDPReceiver returns a UDP receiver System object, H, that receives UDP packets from a specified port.

H = dsp.UDPReceiver('*PropertyName*',*PropertyValue*, ...) returns a window object, H, with each property set to the specified value.

Properties   **LocalIPPort**

Local port on which to receive data

Specify the port on which to receive data. The default is 25000.

RemoteIPAddress

Address from which data was sent

Specify the remote IP address from which to receive data. The default is '0.0.0.0', which indicates that data is accepted from any remote IP address.

ReceiveBufferSize

Maximum size of internal buffer

Specify the size of the buffer that receives UDP packets, in bytes. The default is 8192.

MaximumMessageLength

Maximum size of output message

Specify the size of the output message. If received packets exceed the specified value, their contents are truncated. The default is 255.

MessageDataType

Data type of the message

Specify the data type of the message as | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | logical |. The default is uint8.

Methods

clone	Create UDP receiver object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Multiply input by window

Examples

Send some UDP packets, and calculate the number of successfully transmitted bytes:

```
hudpr = dsp.UDPReceiver;
hudps = dsp.UDPSender;

bytesSent = 0;
bytesReceived = 0;
dataLength = 128;
```

```
for k = 1:20
   dataSent = uint8(255*rand(1,dataLength));
   bytesSent = bytesSent + dataLength;
   step(hudps, dataSent);
   dataReceived = step(hudpr);
   bytesReceived = bytesReceived + length(dataReceived);
end

release(hudps);
release(hudpr);

fprintf('Bytes sent:     %d\n', bytesSent);
fprintf('Bytes received: %d\n', bytesReceived);
```

Algorithms   This object implements the algorithm, inputs, and outputs described on
the UDP Receive block reference page. The object properties correspond
to the block parameters, except:

- The **Output variable-size signal** parameter is not included in the
  System object.

- The **Sample time** parameter is not included in the System object.

See Also   dsp.UDPSender

Purpose   Create UDP receiver object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a UDP receiver object, C, with the same property values as H. The clone method creates a new unlocked object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                  the step method.

                  The getNumInputs method returns a positive integer that is the number
                  of expected inputs (not counting the object itself) to the step method.
                  This value will change if you alter any properties that turn inputs on or
                  off. You must call the step method with the number of input arguments
                  equal to the result of getNumInputs(*H*).

dsp.UDPReceiver.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the step
                method.

                The getNumOutputs method returns a positive integer that is the
                number of outputs from the step method. This value will change if you
                alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   Y = isLocked(H)

Description   Y = isLocked(H) returns the locked state, Y, of the UDP receiver object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.UDPReceiver.release

Purpose Allow property value and input characteristics changes

Syntax `release(H)`

Description `release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose Multiply input by window

Syntax P = step (H)

Description

P = step (H) receives one UDP packet, P, from the network.

Note The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

The first time you call the step method on a UDPReceiver object, the object also allocates resources and begins listening for data. As a result, the first step call may not receive data.

dsp.UDPSender

Purpose   Send UDP packets to network

Description The UDPSender object sends UDP packets to the network.

To send UDP packets to the network:

1 Define and set up your UDP sender. See "Construction" on page 5-1200.

2 Call step to send the packets according to the properties of dsp.UDPSender. The behavior of step is specific to each object in the toolbox.

Construction H = dsp.UDPSender returns a UDP sender object, H, that sends UDP packets to a specified port.

H = dsp.UDPSender('*PropertyName*',*PropertyValue*, ...) returns a UDP sender object, H, with each property set to the specified value.

Properties   **RemoteIPAddress**

Remote address to which to send data

Specify the remote (i.e., host) IP address to which the data is sent. The default is '127.0.0.1', which is the local host.

RemoteIPPort

Remote port to which to send data

Specify the port at the remote IP address to which the data is sent. The default is 25000.

LocalIPPortSource

Source of the LocalIPPort property

Specify how to determine the port on the host as | Auto | Property |. If you specify Auto, the object selects the port dynamically from the available ports. If you specify Property, the object uses the source specified in the LocalIPPort property. The default is Auto.

LocalIPPort

Local port from which to send data

Specify the port from which to send data. This property applies when you set the LocalIPPortSource property to Auto. The default is 25000.

Methods

clone	Create UDP sender object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Send a UDP packet to network

Examples

Send a number of UDP packets, and calculate the number of successfully transmitted bytes:

```
hudpr = dsp.UDPReceiver;
hudps = dsp.UDPSender;

bytesSent = 0;
bytesReceived = 0;
dataLength = 128;

for k = 1:20
   dataSent = uint8(255*rand(1,dataLength));
   bytesSent = bytesSent + dataLength;
   step(hudps, dataSent);
   dataReceived = step(hudpr);
```

```
      bytesReceived = bytesReceived + length(dataReceived);
end

release(hudps);
release(hudpr);

fprintf('Bytes sent:     %d\n', bytesSent);
fprintf('Bytes received: %d\n', bytesReceived);
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the UDP Send block reference page. The object properties correspond to the block parameters.

See Also   dsp.UDPReceiver

Purpose   Create UDP sender object with same property values

Syntax   C = clone(H)

Description C = clone(H) creates a UDP sender object, C, with the same property
                values as H. The clone method creates a new unlocked object.

dsp.UDPSender.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   getNumInputs(H)

Description getNumInputs(H) returns the number of expected inputs, N, to the step method.

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the UDP sender object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   Y = release(H)

Description   Y = release(H) releases system resources, such as memory, file
                 handles, and hardware connections. This method lets you change any
                 properties or input characteristics.

Note You can use the release method on a System object in code
generated from MATLAB, but once you release its resources, you cannot
use that System object again.

Purpose   Send a UDP packet to network

Syntax   Y = step(H,PACKET)

Description   Y = step(H,PACKET) sends one UDP packet, PACKET, to the network.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

Purpose   Decode integer input into floating-point output

Description   The UniformDecoder object decodes integer input into floating-point output. The decoder adheres to the definition for uniform decoding specified in ITU-T Recommendation G.701.

To decode an integer input into a floating-point output:

1 Define and set up your uniform decoder. See "Construction" on page 5-1209.

2 Call step to decode the input according to the properties of dsp.UniformDecoder. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.UniformDecoder returns a uniform decoder, H, that performs the inverse operation of the UniformEncoder object, reconstructing quantized floating-point values from encoded integer input.

H = dsp.UniformDecoder('*PropertyName*',*PropertyValue*,...) returns a uniform decoder, H, with each specified property set to the specified value.

H = dsp.UniformDecoder(peakvalue,numbits, '*PropertyName*',*PropertyValue*,...) returns a uniform decoder, H, with the PeakValue property set to peakvalue, the NumBits property set to numbits, and other specified properties set to the specified values.

Properties   **PeakValue**

Largest amplitude represented in encoded input

Specify the largest amplitude represented in the encoded input as a nonnegative numeric scalar. To correctly decode values encoded with the UniformEncoder object, set the PeakValue property in both objects to the same value. For more information on setting this property, see the PeakValue property description on the dsp.UniformEncoder reference page. The default is 1.

NumBits

Number of input bits used to encode data

Specify the number of bits used to encode the input data as an integer value between 2 and 32. The value of this property can be less than the total number of bits supplied by the input data type. To correctly decode values encoded with the UniformEncoder object, set the NumBits property in both objects to the same value. For more information on setting this property, see the NumBits property description on the dsp.UniformEncoder reference page. The default is 3.

OverflowAction

Action to take when integer input is out of range

Specify the behavior of the uniform decoder when the integer input is out of range as Saturate or Wrap. The value of the NumBits property specifies the representable range of the input. The default is Saturate.

OutputDataType

Output data type as single or double

Specify the data type of the output as single or double. The default is double.

Methods

clone	Create uniform decoder object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties

release	Allow property value and input characteristics changes
step	Decode integer input into quantized floating-point output

Examples   Decode an encoded sequence:

```
hue = dsp.UniformEncoder;
hue.PeakValue = 2;
hue.NumBits = 4;
hue.OutputDataType = 'Signed integer';
x = (0:0.25:2)'; % Create an input sequence
hud = dsp.UniformDecoder;
hud.PeakValue = 2;
hud.NumBits = 4;
x_encoded = step(hue, x);
% Check that the last element has been saturated.
x_decoded = step(hud, x_encoded);
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Uniform Decoder block reference page. The object properties correspond to the block parameters.

See Also   dsp.UniformEncoder

dsp.UniformDecoder.clone

Purpose Create uniform decoder object with same property values

Syntax C = clone(H)

Description C = clone(H) creates a UniformDecoder object C, with the same property values as H. The clone method creates a new unlocked object.

The clone method creates an instance of an object. The property values, but not internal states, are copied into the new instance of the object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                   the step method.

                   The getNumInputs method returns a positive integer that is the number
                   of expected inputs (not counting the object itself) to the step method.
                   This value will change if you alter any properties that turn inputs on or
                   off. You must call the step method with the number of input arguments
                   equal to the result of getNumInputs(*H*).

dsp.UniformDecoder.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the UniformDecoder object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description   release(H) releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the release method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Decode integer input into quantized floating-point output

Syntax   Y = step(H,X)

Description   Y = step(H,X) reconstructs quantized floating-point output Y from the
                   encoded integer input X. Input X can be real or complex values of the
                   following six integer data types: uint8, uint16, uint32, int8, int16, or
                   int32.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

---

dsp.UniformEncoder

Purpose   Quantize and encode floating-point input into integer output

Description   The `UniformEncoder` object quantizes floating-point input, using
                   the precision you specify in the `NumBits` property, and encodes the
                   quantized input into integer output. The operations of the uniform
                   encoder adhere to the definition for uniform encoding specified in ITU-T
                   Recommendation G.701.

                   To quantize and encode a floating-point input into an integer output:

                   1 Define and set up your uniform encoder. See "Construction" on page
                   5-1218.

                   2 Call `step` to encode the input according to the properties of
                   `dsp.UniformEncoder`. The behavior of `step` is specific to each object
                   in the toolbox.

Construction   `H = dsp.UniformEncoder` returns a uniform encoder, `H`, that quantizes
                   floating-point input samples and encodes them as integers using
                   2*N*-level quantization, where *N* is an integer.

                   `H = dsp.UniformEncoder('`*PropertyName*`',`*PropertyValue*`,...)`
                   returns an uniform encoder, `H`, with each specified property set to the
                   specified value.

                   `H = dsp.UniformEncoder(peakvalue,numbits,`
                   `'`*PropertyName*`',`*PropertyValue*`,...)` returns a uniform encoder, `H`,
                   with the `PeakValue` property set to `peakvalue`, the `NumBits` property
                   set to `numbits`, and other specified properties set to the specified values.

Properties   **PeakValue**

                   Largest input amplitude to be encoded

                   Specify the largest input amplitude to be encoded, as a
                   nonnegative numeric scalar. If the real or imaginary input are
                   outside of the interval $[-P, (1 - 2^{(1-B)})P]$, where P is the peak value
                   and B is the value of the `NumBits` property, the uniform encoder

saturates (independently for complex inputs) at those limits. The default is 1.

NumBits

Number of bits needed to represent output

Specify the number of bits needed to represent the integer output as an integer value between 2 and 32. The number of levels at which the uniform encoder quantizes the floating-point input is 2^B, where B is the number of bits. The default is 8.

OutputDataType

Data type of output

Specify the data type of the output as Unsigned integer or Signed integer. Unsigned outputs are uint8, uint16, or uint32, and signed outputs are int8, int16, or int32. The quantized inputs are linearly (uniformly) mapped to the intermediate integers in the interval $[0, 2^{(B-1)}]$ when you set this property to Unsigned integer, and in the interval $[-2^{(B-1)}, 2^{(B-1)} - 1]$ when you set this property to Signed integer. The variable B in both expressions corresponds to the value of the NumBits property.

Methods

clone	Create uniform encoder object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Quantize and encode input

dsp.UniformEncoder

Examples   Encode a sequence:

```
hue = dsp.UniformEncoder;
hue.PeakValue = 2;
hue.NumBits = 4;
hue.OutputDataType = 'Signed integer';
x = [-1:0.01:1]'; % Create an input sequence
x_encoded = step(hue, x);
plot(x, x_encoded,'.');
xlabel('Input'); ylabel('Encoded Output'); grid
```

Algorithms   This object implements the algorithm, inputs, and outputs described
on the Uniform Encoder block reference page. The object properties
correspond to the block parameters.

See Also   dsp.UniformDecoder

Purpose Create uniform encoder object with same property values

Syntax C = clone(H)

Description C = clone(H) creates a UniformEncoder object C, with the same property values as H. The clone method creates a new unlocked object.

dsp.UniformEncoder.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

dsp.UniformEncoder.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the UniformEncoder object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description   release(H) releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the release method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Quantize and encode input

Syntax   Y = step(H,X)

Description   Y = step(H,X) quantizes and encodes the input X to Y. Input X can
                   be real or complex, double-, or single-precision values. The uniform
                   encoder chooses the output data type according to the following table.

Number of Bits	Unsigned Integer	Signed Integer
2 to 8	uint8	int8
9 to 16	uint16	int16
17 to 32	uint32	int32

The row corresponds to the value of the NumBits property, and the
column corresponds to the value of the OutputDataType property.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

| **Purpose** | Solve upper-triangular matrix equation |

Description   The `UpperTriangularSolver` object solves $UX = B$ for X when U is a square, upper-triangular matrix with the same number of rows as B.

To solve $UX = B$:

1 Define and set up your linear system solver. See "Construction" on page 5-1227.

2 Call `step` to solve the equation according to the properties of `dsp.UpperTriangularSolver`. The behavior of `step` is specific to each object in the toolbox.

Construction   `H = dsp.UpperTriangularSolver` returns a linear system solver, `H`, used to solve $UX = B$ where U is an upper (or unit-upper) triangular matrix.

`H = dsp.UpperTriangularSolver('`*PropertyName*`',`*PropertyValue*`,...)` returns a linear system solver, `H`, with each specified property set to the specified value.

Properties   **OverwriteDiagonal**

Replace diagonal elements of input with ones

When you set this property to `true`, the linear system solver replaces the elements on the diagonal of the input, *U*, with ones. Set this property to either `true` or `false`. The default is `false`.

RealDiagonalElements

Indicate that diagonal of complex input is real

When you set this property to `true`, the linear system solver optimizes computation speed if the diagonal elements of complex input, *U*, are real. This property applies only when you set the `OverwriteDiagonal` property to `false`. Set this property to either `true` or `false`. The default is `false`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Data type of product

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as `Full precision`, `Same as first input`, `Same as product`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Data type of output

Specify the output data type as `Same as first input` or `Custom`. The default is `Same as first input`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create upper triangular solver object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Solve matrix equation for specified inputs

Examples

Solve an upper-triangular matrix equation:

```
huptriang = dsp.UpperTriangularSolver;
```

dsp.UpperTriangularSolver

```
u = triu(rand(4, 4));
b = rand(4, 1);
% Check that result is the solution to the linear
% equations.
x1 = inv(u)*b
x = step(huptriang, u, b)
```

Algorithms   This object implements the algorithm, inputs, and outputs described on
the Backward Substitution block reference page. The object properties
correspond to the block parameters.

See Also   dsp.LowerTriangularSolver

Purpose   Create upper triangular solver object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates an UpperTriangularSolver object C, with the
                   same property values as H. The clone method creates a new unlocked
                   object.

dsp.UpperTriangularSolver.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description N = getNumInputs(H) returns the number of expected inputs, N, to
the step method.

The getNumInputs method returns a positive integer that is the number
of expected inputs (not counting the object itself) to the step method.
This value will change if you alter any properties that turn inputs on or
off. You must call the step method with the number of input arguments
equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                     method.

                     The getNumOutputs method returns a positive integer that is the
                     number of outputs from the step method. This value will change if you
                     alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the UpperTriangularSolver object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description   release(H) releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the release method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Solve matrix equation for specified inputs

Syntax   X = step(H,U,B)

Description   X = step(H,U,B) computes the solution, *X*, of the matrix equation
                    UX = B, where *U* is a square, upper-triangular matrix with the same
                    number of rows as the matrix *B*.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

Purpose   Delay input by time-varying fractional number of sample periods

Description The `VariableFractionalDelay` object delays the input by a
                 time-varying fractional number of sample periods.

                 To delay the input by a time-varying fractional number of sample
                 periods:

                 1 Define and set up your variable fractional delay object. See
                       "Construction" on page 5-1237.

                 2 Call `step` to delay the input according to the properties of
                       `dsp.VariableFractionalDelay`. The behavior of `step` is specific to
                       each object in the toolbox.

Construction H = `dsp.VariableFractionalDelay` returns a variable fractional delay
                 System object, `H`, that delays a discrete-time input by a time-varying
                 fractional number of sample periods.

                 `H =`
                 `dsp.VariableFractionalDelay('`*PropertyName*`',`*PropertyValue*`,...)`
                 returns a variable fractional delay System object, `H`, with each
                 property set to the specified value.

Properties   **InterpolationMethod**

                 Interpolation method

                 Specify the method by which the block interpolates between
                 adjacent stored samples to obtain a value for the sample indexed
                 by the input. You can set this property to one of | `Linear` | `FIR` |
                 `Farrow` |. When you set this property to `FIR`, the object uses the
                 Signal Processing Toolbox `intfilt` function to compute an FIR
                 filter for interpolation. The default is `Linear`.

                 FilterHalfLength

                 FIR interpolation filter half-length

Specify the half-length of the FIR interpolation filter as a positive scalar integer. This property applies only when you set the `InterpolationMethod` property to `FIR`. For periodic signals, a larger value of this property (that is, a higher order filter) yields a better estimate of the delayed output sample. Setting this property to a value between `4` and `6` (that is, a 7th to 11th order filter) is usually adequate. The default is `4`.

FilterLength

Length of Farrow filter

Specify the length of the FIR filter implemented using the Farrow structure, as a positive scalar integer. This property applies only when you set the `InterpolationMethod` property to `Farrow`. The default is `4`.

InterpolationPointsPerSample

Number of interpolation points per input sample

Specify the number of interpolation points per input sample at which a unique FIR interpolation filter is computed. You must specify the number of interpolation points per input sample as a positive scalar integer. This property applies only when you set the `InterpolationMethod` property to `FIR`. The default is `10`.

Bandwidth

Normalized input bandwidth

Specify the bandwidth to which you want to constrain the interpolated output samples. You must enter the bandwidth as a scalar value between `0` and `1`. You can use this property to take advantage of the bandlimited frequency content of the input. For example, if the input signal does not have frequency content above `Fs/4` (where `Fs` is the sampling frequency), you can specify a value of `0.5` for the `Bandwidth` property. A value of `1` for the `Bandwidth` property corresponds to half the sampling frequency (`Fs`). This property applies only when you set the `InterpolationMethod`property to `FIR`. The default is `1`.

InitialConditions

Initial values in memory

Specify the values with which the object's memory is initialized. The dimensions of this property can vary depending on the setting of the `FrameBasedProcessing` property, and whether you want fixed or time-varying initial conditions. The default is `0`.

When you set the `FrameBasedProcessing` property to `false`, the object supports N-D input arrays. For an M-by-N-by-P sample-based input array `U`, you can set the `InitialConditions` property as follows:

- To specify fixed initial conditions, set the `InitialConditions` property to a scalar value. The object initializes every sample of every channel in memory using the value you specify.

- The dimensions you specify for time-varying initial conditions depend on the value of the `InterpolationMethod` property:

  - If you set the `InterpolationMethod` property to `Linear`, set the `InitialConditions` property to an array of dimension Mx-by-N-by-P-by-D. The object uses the values in this array to initialize memory samples `U(2:D+1)`, where `D` is the value of the `MaximumDelay` property.

  - If you set the `InterpolationMethod` property to either `FIR` or `Farrow`, set the `InitialConditions` property to an array of dimension M-by-N-by-P-by-(D+L). The object uses the values in this array to initialize memory samples `U(2:D+1)`, where `D` is the value of the `MaximumDelay` property. For FIR interpolation, `L` is the value of the `FilterHalfLength` property. For Farrow interpolation, `L` equals `floor` of half the value of the `FilterLength` property (`floor(FilterLength/2)`).

When you set the `FrameBasedProcessing` property to `true`, the object treats each of the N input columns as a frame containing M sequential time samples from an independent channel.

For an M-by-N frame-based input matrix U, you can set the `InitialConditions` property as follows:

- To specify fixed initial conditions, set the `InitialConditions` property to a scalar value. The object initializes every sample of every channel in memory using the value you specify.

- The dimensions you specify for time-varying initial conditions depend on the value of the `InterpolationMethod` property. To specify different time-varying initial conditions for each channel, set the `InitialConditions` property as follows:

  - If you set the `InterpolationMethod` property to `Linear`, set the `InitialConditions` property to an array of size 1-by-N-by-D, where D is the value of the `MaximumDelay` property.

  - If you set the `InterpolationMethod` property to `FIR` or `Farrow`, set the `InitialConditions` property to an array of size 1-by-N-by-(D+L), where D is the value of the `MaximumDelay` property. For FIR interpolation, L is the value of the `FilterHalfLength` property. For Farrow interpolation, L equals `floor` of half the value of the `FilterLength` property (`floor(FilterLength/2)`).

MaximumDelay

Maximum delay

Specify the maximum delay the object can produce for any sample. The maximum delay must be a positive scalar integer value. The object clips input delay values greater than the `MaximumDelay` to the `MaximumDelay`. The default is `100`.

DirectFeedthrough

Allow direct feedthrough

When you set this property to `true`, the object allows direct feedthrough. When you set this property to `false`, the object increases the minimum possible delay by one. The default is `true`.

FIRSmallDelayAction

Action for small input delay values in FIR interpolation mode

Specify the action the object should take for small input delay values when using the FIR interpolation method. You can set this property to `Clip to the minimum value necessary for centered kernel`, or `Switch to linear interpolation if kernel cannot be centered`. This property applies only when you set the `InterpolationMethod` property to `FIR`. The default is `Clip to the minimum value necessary for centered kernel`.

FarrowSmallDelayAction

Action for small input delay values in Farrow interpolation mode

Specify the action the object should take for small input delay values when using the Farrow interpolation method. You can set this property to `Clip to the minimum value necessary for centered kernel`, or `Use off-centered kernel`. This property applies only when you set the `InterpolationMethod` property to `Farrow`. The default is `Clip to the minimum value necessary for centered kernel`.

FrameBasedProcessing

Treat input as frame based or sample based

Set this property to `true` to enable frame-based processing. When you do so, the object accepts M-by-N input matrices and treats each of the `N` input columns as a frame containing `M` sequential time samples from an independent channel. Set this property to `false` to enable sample-based processing. When you do so, the object supports N-D inputs and treats each element of the input as a separate channel. The default is `true`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent`, | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Zero`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

CoefficientsDataType

Coefficient word and fraction lengths

Specify the coefficients data type as one of | `Same word length as input` | `Custom` |. The default is `Same word length as input`.

CustomCoefficientsDataType

Coefficients word length

Specify the coefficients word length as an unscaled `numerictype` object with a `Signedness` of `Auto`. If the `InterpolationMethod` is `Linear`, specify that the `numerictype` object is unsigned; otherwise the object should be signed. This property applies only when you set the `CoefficientsDataType` property to `Custom`. The default is `numerictype([],32)`.

ProductPolynomialValueDataType

Product polynomial values word and fraction lengths

Specify the product polynomial value data type as one of | `Same as first input` | `Custom` |. This property applies only when you set the `InterpolationMethod` property to `Farrow`. The default is `Same as first input`.

CustomProductPolynomialValueDataType

Product polynomial values word and

fraction lengths Specify the product polynomial values fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `InterpolationMethod` property to `Farrow` and the `ProductPolynomialValueDataType` property to `Custom`. The default is `numerictype([],32,10)`.

AccumulatorPolynomialValueDataType

Accumulator polynomial value word and fraction lengths

Specify the accumulator polynomial value data type as one of | `Same as first input` | `Custom` |. This property applies only when you set the `InterpolationMethod` property to `Farrow`. The default is `Same as first input`.

CustomAccumulatorPolynomialValueDataType

Accumulator polynomial value word and fraction lengths

Specify the data type of the accumulator polynomial values as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `InterpolationMethod` property to `Farrow` and the `AccumulatorPolynomialValueDataType` property to `Custom`. The default is `numerictype([],32,10)`.

MultiplicandPolynomialValueDataType

Multiplicand polynomial value word and fraction lengths

Specify the multiplicand polynomial values data type as one of | `Same as first input` | `Custom` |. This property applies only when you set the `InterpolationMethod` property to `Farrow`. The default is `Same as first input`.

CustomMultiplicandPolynomialValueDataType

Multiplicand polynomial value word and fraction lengths

Specify the fixed-point data type of the multiplicand polynomial values as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `InterpolationMethod` property to `Farrow` and the

MultiplicandPolynomialValueDataType property to `Custom`.
The default is `numerictype([],32,10)`.

ProductDataType

Product word and fraction lengths

Specify the product data type as one of | `Same as first input` |
`Custom` |. The default is `Same as first input`.

CustomProductDataType

Product word and fraction lengths

Specify the product data type as a scaled `numerictype` object
with a `Signedness` of `Auto`. This property applies only when
you set the `ProductDataType` property to `Custom`. The default is
`numerictype([],32,10)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator data type as one of | `Same as product`
| `Same as first input` | `Custom` |. The default is `Same as`
`product`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the fixed-point accumulator data type as a scaled
`numerictype` object with a `Signedness` of `Auto`. This property
applies only when you set the `AccumulatorDataType` property to
`Custom`. The default is `numerictype([],32,10)`.

OutputDataType

Output word and fraction lengths

Specify the output data type as one of | `Same as accumulator`
| `Same as first input` | `Custom` |. The default is `Same as`
`accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the data type of the output as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],32,10)`.

Methods

clone	Create variable fractional delay object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
info	Characteristic information about valid delay range
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of variable fractional delay object
step	Delay input by time-varying fractional number of sample periods

Examples

Delay a signal by a varying fractional number of sample periods:

```
hsr = dsp.SignalSource;
hvfd = dsp.VariableFractionalDelay;
hLog = dsp.SignalSink;

for ii = 1:10
    delayedsig = step(hvfd, step(hsr), ii/10);
     step(hLog, delayedsig);
```

dsp.VariableFractionalDelay

```
end

sigd = hLog.Buffer;

% The output sigd corresponds to the values of the delayed signal
% that are sampled at fixed-time intervals. For visualization
% purposes, we can instead plot the time instants at which the
% amplitudes of signal samples are constant by treating the
% signals as the sampling instants.

stem(hsr.Signal, 1:10, 'b')
hold on;
stem(sigd.', 1:10, 'r');
legend('Original signal',...
    'Variable fractional delayed signal', ...
    'Location','best')
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Variable Fractional Delay block reference page. The object properties correspond to the block properties, except:

When you set the `DirectFeedthrough` property of the System object to `true`, the object allows direct feedthrough. This behavior is different from the way the block behaves when you select the corresponding **Disable direct feedthrough by increasing minimum possible delay by one** check box on the block dialog. When you enable this block parameter, the block does not allow direct feedthrough.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also   dsp.VariableIntegerDelay | dsp.Delay | dsp.DelayLine

Purpose   Create variable fractional delay object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a VariableFractionalDelay System object C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

dsp.VariableFractionalDelay.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                  the step method.

                  The getNumInputs method returns a positive integer that is the number
                  of expected inputs (not counting the object itself) to the step method.
                  This value will change if you alter any properties that turn inputs on or
                  off. You must call the step method with the number of input arguments
                  equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
method.

The getNumOutputs method returns a positive integer that is the
number of outputs from the step method. This value will change if you
alter any properties that turn outputs on or off.

dsp.VariableFractionalDelay.info

Purpose   Characteristic information about valid delay range

Syntax   `S = info(H)`

Description   `S = info(H)` returns a structure, `S`, containing characteristic information about the `VariableFractionalDelay` System object, `H`. `S` has one field, `ValidDelayRange` which is a string containing the possible range of delay values based on the current property values of the `VariableFractionalDelay` object. The `ValidDelayRange` is in the format `[MinValidDelay, MaxValidDelay]`. The object clips all input delay values to be within this `ValidDelayRange`.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the VariableFractionalDelay
System object.

The isLocked method returns a logical value that indicates whether
input attributes and nontunable properties for the object are locked. The
object performs an internal initialization the first time the step method
is executed. This initialization locks nontunable properties and input
specifications, such as dimensions, complexity, and data type of the
input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Reset internal states of variable fractional delay object

Syntax   reset(H)

Description   reset(H) resets the internal states of the VariableFractionalDelay
                  System object H to their initial values.

dsp.VariableFractionalDelay.step

Purpose   Delay input by time-varying fractional number of sample periods

Syntax   Y = step(H,X,D)

Description   Y = step(H,X,D) delays the input X by D samples, where D should be less than or equal to the value specified in the MaximumDelay property.

> **Note** The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

Purpose	Delay input by time-varying integer number of sample periods
Description	The `VariableIntegerDelay` object delays input by time-varying integer number of sample periods.

To delay the input by a time-varying integer number of sample periods:

1 Define and set up your variable integer delay object. See "Construction" on page 5-1255.

2 Call `step` to delay the input according to the properties of `dsp.VariableIntegerDelay`. The behavior of `step` is specific to each object in the toolbox.

Construction   `H = dsp.VariableIntegerDelay` returns a variable integer delay System object, `H`, that delays discrete-time input by a time-varying integer number of sample periods.

```
H =
dsp.VariableIntegerDelay('PropertyName',PropertyValue,...)
```
returns a variable integer delay System object, `H`, with each property set to the specified value.

Properties   **MaximumDelay**

Maximum delay

Specify the maximum delay the object can produce for any sample. The maximum delay must be a positive scalar integer value. The object clips input delay values greater than the `MaximumDelay` to the `MaximumDelay`. The default is `100`.

InitialConditions

Initial values in memory

Specify the values with which the object's memory is initialized. The dimensions of this property can vary depending on the setting of the `FrameBasedProcessing` property, and whether you want fixed or time-varying initial conditions. The default is `0`.

When you set the `FrameBasedProcessing` property to `false`, the object supports N-D input arrays. For an M-by-N-by-P sample-based input array U, you can set the `InitialConditions` property as follows:

- To specify fixed initial conditions, set the `InitialConditions` property to a scalar value. The object initializes every sample of every channel in memory using the value you specify.

- To specify time-varying initial conditions, set the `InitialConditions` property to an array of dimension M-by-N-by-P-by-D. The object uses the values in this array to initialize memory samples `U(2:D+1)`, where D is the value of the `MaximumDelay` property.

When you set the `FrameBasedProcessing` property to `true`, the object treats each of the N input columns as a frame containing M sequential time samples from an independent channel. For an M-by-N frame-based input matrix U, you can set the `InitialConditions` property as follows:

- To specify fixed initial conditions, set the `InitialConditions` property to a scalar value. The object initializes every sample of every channel in memory using the value you specify.

- To specify different time-varying initial conditions for each channel, set the `InitialConditions` property to an array of size 1-by-N-by-D, where D is the value of the `MaximumDelay` property.

DirectFeedthrough

Allow direct feedthrough

When you set this property to `true`, the object allows direct feedthrough. When you set this property to `false`, the object increases the minimum possible delay by one. The default is `true`.

FrameBasedProcessing

Treat input as frame based or sample based

Set this property to `true` to enable frame-based processing. When you do so, the object accepts M-by-N input matrices and treats each of the N input columns as a frame containing M sequential time samples from an independent channel. Set this property to `false` to enable sample-based processing. When you do so, the object supports N-D inputs and treats each element of the input as a separate channel. The default is `true`.

Methods

clone	Create variable integer delay object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of variable integer delay object
step	Delay input by time-varying integer number of sample periods

Examples

Delay a signal by a varying integer number of sample periods:

```
h = dsp.VariableIntegerDelay;
x = 1:100;
ii = 0;
k = 0;
yout = [];

while(ii+10 <= 100)
```

```
            y = step(h, x(ii+1:ii+10)',k*ones(10,1));
            yout = [yout;y];
            ii = ii+10;
            k = k+1;
end

stem(x,'b');
hold on; stem(yout,'r');
legend('Original Signal', 'Variable Integer Delayed Signal')
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Variable Integer Delay block reference page. The object properties correspond to the block properties, except:

> When you set the `DirectFeedthrough` property of the System object to `true`, the object allows direct feedthrough. This behavior is different from the way the block behaves when you select the corresponding **Disable direct feedthrough by increasing minimum possible delay by one** check box on the block dialog. When you enable this block parameter, the block does not allow direct feedthrough.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also   dsp.VariableFractionalDelay | dsp.Delay | dsp.DelayLine

Purpose   Create variable integer delay object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a VariableIntegerDelay System object C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to the step method.

The getNumInputs method returns a positive integer that is the number of expected inputs (not counting the object itself) to the step method. This value will change if you alter any properties that turn inputs on or off. You must call the step method with the number of input arguments equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

dsp.VariableIntegerDelay.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the `VariableIntegerDelay`
                System object.

                The `isLocked` method returns a logical value that indicates whether
                input attributes and nontunable properties for the object are locked. The
                object performs an internal initialization the first time the `step` method
                is executed. This initialization locks nontunable properties and input
                specifications, such as dimensions, complexity, and data type of the
                input data. After locking, the `isLocked` method returns a `true` value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.VariableIntegerDelay.reset

Purpose   Reset internal states of variable integer delay object

Syntax   reset(H)

Description   reset(H) resets the internal states of the `VariableIntegerDelay` System object `H` to their initial values.

Purpose   Delay input by time-varying integer number of sample periods

Syntax   Y = step(H,X,D)

Description   Y = step(H,X,D) delays the input X by D samples, where D should be
less than or equal to the value specified in the MaximumDelay property
and greater than or equal to 0. The object clips delay values greater
than the MaximumDelay to the MaximumDelay, and clips values less than
zero to zero. If you enter a noninteger delay value, the object rounds
that value to the nearest integer value.

Note The object performs an initialization the first time the step
method is executed. This initialization locks nontunable properties and
input specifications, such as dimensions, complexity, and data type
of the input data. If you change a nontunable property or an input
specification, the System object issues an error. To change nontunable
properties or inputs, you must first call the release method to unlock
the object.

---

dsp.Variance

Purpose	Variance of input or sequence of inputs
Description	The Variance object computes variance for an input or sequence of inputs.

To compute the variance of an input or sequence of inputs:

1 Define and set up your variance System object. See "Construction" on page 5-1266.

2 Call step to compute the variance according to the properties of dsp.Variance. The behavior of step is specific to each object in the toolbox.

Construction   H = dsp.Variance returns a variance System object, H, that computes the variance of an input or a sequence of inputs over the specified Dimension.

H = dsp.Variance('*PropertyName*',*PropertyValue*,...) returns a variance System object, H, with each specified property set to the specified value.

Properties   **RunningVariance**

Enable calculation over time

Set this property to true to enable variance calculation over successive calls to the step method. The default is false.

ResetInputPort

Enable reset input port

Set this property to true to enable reset input port. When you set the property to true, specify a reset input for the step method. The running variance resets anytime the variance object achieves the condition you specify for the ResetCondition property. This property applies when you set the RunningVariance property to true. The default is false.

ResetCondition

Reset condition for running variance mode

Specify which event resets the running variance as one of | Rising edge | Falling edge | Either edge | Non-zero |. This property applies when you set the ResetInputPort property to true.

Dimension

Dimension to operate along

Specify how the object performs the variance calculation over the data as one of | All | Row | Column | Custom |. This property applies when you set the RunningVariance property to false. The default is Column.

CustomDimension

Numerical dimension to operate along

Specify the input signal dimension (one-based value) the object uses to compute variance. The cannot exceed the number of dimensions in the input signal. This property applies when you set the Dimension property to Custom. The default is 1.

ROIProcessing

Enable region-of-interest processing

Set this property to true to enable calculating the variance within a particular region of each image. This property applies when you set the RunningVariance property to false and the Dimension property to All. The default is false. Full ROI processing support requires a Computer Vision System Toolbox license. With only the DSP System Toolbox license, Rectangles is the only selection for the ROIForm property.

ROIForm

Define the type of region of interest.

Specify the type of region of interest as one of | Rectangles | Lines | Label matrix | Binary mask |. This property applies

when you set the `ROIProcessing` property to `true`. The default is `Rectangle`.

ROIPortion

Calculate over entire ROI or just perimeter

Specify the region over which to calculate variance as one of | `Entire ROI` | `ROI perimeter` |. This property applies when you set the `ROIForm` property to `Rectangles`. The default is `Entire ROI`.

ROIStatistics

Statistics for each ROI or one for all ROIs

Specify if statistics calculations are one of | `Individual statistics for each ROI` | `Single statistic for all ROIs` |. This property applies when `ROIForm` property is not `Binary mask`. The default is `Individual statistics for each ROI`.

ValidityOutputPort

Enable output of validity check of ROI or label numbers

Indicate whether to return the validity of the specified ROI being completely inside image when the ROIForm property is `Lines` or `Rectangles`. Indicate whether to return the validity of the specified label numbers when the ROIForm property is `Label Matrix`. This property applies when you set the ROIForm property to anything except `Binary Mask`. The default is `false`.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. This property applies when you set the `RunningVariance` property to `true`. The default is `true`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

InputSquaredProductDataType

Input-squared product word and fraction lengths

Specify the input-squared product fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

CustomInputSquaredProductDataType

Input-squared product word and fraction lengths

Specify the input-squared product fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the InputSquaredProductDataType property to Custom. The default is numerictype([],32,15).

InputSumSquaredProductDataType

Input-sum-squared product word and fraction lengths

Specify the input-sum-squared product fixed-point data type as one of | Same as input-squared product | Custom |. The default is Same as input-squared product.

CustomInputSumSquaredProductDataType

Input-sum-squared product word and fraction lengths

Specify the input-sum-squared product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `InputSumSquaredProductDataType` property to `Custom`. The default is `numerictype([],32,23)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | `Same as input-squared product` | `Same as input` | `Custom` |. The default is `Same as input-squared product`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,0)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | `Same as input-squared product` | `Same as input` | `Custom` |. The default is `Same as input-squared product`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `OutputDataType` property to `Custom`. The default is `numerictype([],16,0)`.

Methods	clone	Create variance object with same property values
	getNumInputs	Number of expected inputs to step method
	getNumOutputs	Number of outputs of step method
	isLocked	Locked status for input attributes and nontunable properties
	release	Allow property value and input characteristics changes
	reset	Reset variance to zero
	step	Variance of input

Examples Compute the running variance for a signal:

```
hvar = dsp.Variance;
hvar.RunningVariance = true;
x = randn(100,1);
y = step(hvar, x);
% y(i) is the running variance of all values in the vector x(1:i)
```

Algorithms This object implements the algorithm, inputs, and outputs described on the Variance block reference page. The object properties correspond to the block parameters, except:

- **Treat sample-based row input as a column** block parameter is not supported by the dsp.Variance object.

- **Reset port** block parameter corresponds to both the ResetCondition and the ResetInputPort object properties.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object

dsp.Variance

uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also   `dsp.Mean` | `dsp.RMS` | `dsp.StandardDeviation`

Purpose   Create variance object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a Variance System object C, with the same
                   property values as H. The clone method creates a new unlocked object
                   with uninitialized states.

dsp.Variance.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                     the step method.

                     The getNumInputs method returns a positive integer that is the number
                     of expected inputs (not counting the object itself) to the step method.
                     This value will change if you alter any properties that turn inputs on or
                     off. You must call the step method with the number of input arguments
                     equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                    method.

                    The getNumOutputs method returns a positive integer that is the
                    number of outputs from the step method. This value will change if you
                    alter any properties that turn outputs on or off.

dsp.Variance.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the Variance System object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.Variance.reset

Purpose   Reset variance to zero

Syntax   reset(H)

Description   reset(H) sets the variance to zero when the RunningVariance property
                    is true.

Purpose   Variance of input

Syntax   `Y = step(H,X)`
`Y = step(H,X,R)`
`VAR2D = step(H,X,ROI)`
`VAR2D = step(H,X,LABEL,LABELNUMBERS)`
`[VAR2D,FLAG] = step(H,X,ROI)`
`[VAR2D,FLAG] = step(H,X,LABEL,LABELNUMBERS)`

Description   `Y = step(H,X)` computes the variance, `Y`, of input `X` over successive calls to the `step` method, when the `RunningVariance` property is `true`.

`Y = step(H,X,R)` resets its state based on the value of reset signal `R`, the `ResetInputPort` property and the `ResetCondition` property. This option applies when the `RunningVariance` property is `true` and the `ResetInputPort` property is set to `true`.

`VAR2D = step(H,X,ROI)` computes the variance of input image, `X`, within the given region of interest, `ROI`, when the `ROIProcessing` property is `true` and the `ROIForm` property is `Lines`, `Rectangles` or `Binary mask`. Full `ROI` processing support requires a Computer Vision System Toolbox license. With only the DSP System Toolbox license, the `ROIForm` property only supports `Rectangles`.

`VAR2D = step(H,X,LABEL,LABELNUMBERS)` computes the variance of input image, `X`, for region labels contained in vector `LABELNUMBERS`, with matrix `LABEL` marking pixels of different regions. This option is available when the `ROIProcessing` property is `true` and the `ROIForm` property is `Label matrix`.

`[VAR2D,FLAG] = step(H,X,ROI)` returns `FLAG` which indicates whether the given region of interest is within the image bounds when both the `ROIProcessing` and `ValidityOutputPort` properties are `true` and the `ROIForm` property is set to `Lines`, `Rectangles` or `Binary mask`.

`[VAR2D,FLAG] = step(H,X,LABEL,LABELNUMBERS)` returns `FLAG` which indicates whether the input label numbers are valid when both the `ROIProcessing` and `ValidityOutputPort` properties are `true` and the `ROIForm` property is set to `Label matrix`.

> **Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose   Vector quantizer codeword for given index value

Description   The `VectorQuantizerDecoder` object returns the vector quantizer
                     codeword for a given index value. Each column of the `Codebook` property
                     is a codeword.

                     To obtain the vector quantizer codeword for a given index value:

                     1 Define and set up your vector quantizer decoder. See "Construction"
                        on page 5-1281.

                     2 Call `step` to get the vector quantizer codeword according to the
                        properties of `dsp.VectorQuantizerDecoder`. The behavior of `step` is
                        specific to each object in the toolbox.

Construction   `H = dsp.VectorQuantizerDecoder` creates a vector quantizer
                     decoder System object, `H`, that returns a vector quantizer codeword
                     corresponding to a given, zero-based index value.

                     `H = dsp.VectorQuantizerDecoder('PropertyName',PropertyValue,...)`
                     returns a vector quantizer decoder, `H`, with each specified property set
                     to the specified value.

Properties   **CodebookSource**

                     Source of codebook values

                     Specify the codebook source as `Property` or `Input port`. When
                     you select `Property`, the object reads the codebook from the
                     `codebook` property. When you select `Input port`, the object reads
                     the codebook from the input of the `step` method.

                     The default is `Property`.

                     Codebook

                     codebook

Specify quantized output values as a *k*-by-*N* matrix, where $k \geq 1$ and $N \geq 1$. Each column of the codebook matrix is a codeword, and each codeword corresponds to an index value. This property applies when you set the `CodebookSource` property to `Property`. The default is:

$$\begin{bmatrix} 1.5 \ 13.3 \ 136.4 \ 6.8 \\ 2.5 \ 14.3 \ 137.4 \ 7.8 \\ 3.5 \ 15.3 \ 138.4 \ 8.8 \end{bmatrix}$$

This property is tunable.

OutputDataType

Data type of codebook and quantized output

Specify the data type of the codebook and quantized output values as: `Same as input`, `double`, `single` or `Custom`. This property applies only when you set `CodebookSource` to `Property`. The default is `double`.

Fixed-Point Properties

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a signed or unsigned `numerictype` object. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype(true,16)`.

Methods		
	clone	Create vector quantizer decoder object with same property values
	getNumInputs	Number of expected inputs to step method
	getNumOutputs	Number of outputs of step method

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Quantized output values corresponding to input indices

Examples   Given index values as an input, determine the corresponding vector quantized codewords for a specified codebook:

```
hvqdec = dsp.VectorQuantizerDecoder;
hvqdec.Codebook = [1 10 100;2 20 200;3 30 300];
indices = uint8([1 0 2 0]);
qout = step(hvqdec, indices)
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Vector Quantizer Decoder block reference page. The object properties correspond to the block parameters, except:

There is no object property that directly corresponds to the **Action for out of range index value** block parameter. The object sets any index values less than 0 to 0 and any index values greater than or equal to *N* to *N*-1.

See Also   dsp.VectorQuantizerEncoder | dsp.ScalarQuantizerDecoder

Purpose   Create vector quantizer decoder object with same property values

Syntax

Description   C = clone(H) creates a VectorQuantizerDecoder object C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
the step method.

The getNumInputs method returns a positive integer that is the number
of expected inputs (not counting the object itself) to the step method.
This value will change if you alter any properties that turn inputs on or
off. You must call the step method with the number of input arguments
equal to the result of getNumInputs(*H*).

dsp.VectorQuantizerDecoder.getNumOutputs

Purpose Number of outputs of step method

Syntax N = getNumOutputs(H)

Description N = getNumOutputs(H) returns the number of outputs, N, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description   isLocked(H) returns the locked state of the VectorQuantizerDecoder
object H.

The isLocked method returns a logical value that indicates whether
input attributes and nontunable properties for the object are locked. The
object performs an internal initialization the first time the step method
is executed. This initialization locks nontunable properties and input
specifications, such as dimensions, complexity, and data type of the
input data. After locking, the isLocked method returns a true value.

dsp.VectorQuantizerDecoder.release

Purpose   Allow property value and input characteristics changes

Syntax   `release(H)`

Description   `release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note   You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Quantized output values corresponding to input indices

Syntax   Q = step(H,I)
                   Q = step(H,I,C)

Description   Q = step(H,I) returns the quantized output values Q corresponding to
                   the input indices I. The data type of I can be uint8, uint16, uint32,
                   int8, int16, or int32. The OutputDataType property determines the
                   data type of Q.

                   Q = step(H,I,C) uses input C as the codebook values when the
                   CodebookSource property is Input port. The data type of C can be
                   double, single, or fixed-point. The output Q has the same data type
                   as the codebook input C.

                   Note The object performs an initialization the first time the step
                   method is executed. This initialization locks nontunable properties and
                   input specifications, such as dimensions, complexity, and data type
                   of the input data. If you change a nontunable property or an input
                   specification, the System object issues an error. To change nontunable
                   properties or inputs, you must first call the release method to unlock
                   the object.

                   ---

dsp.VectorQuantizerEncoder

Purpose   Vector quantization encoding

Description   The `VectorQuantizerEncoder` object performs vector quantization
                     encoding. The object finds the nearest codeword by computing a
                     distortion based on Euclidean or weighted Euclidean distance.

                     To perform vector quantization encoding:

                     1 Define and set up your vector quantizer encoder. See "Construction"
                        on page 5-1290.

                     2 Call `step` to perform the quantization encoding according to the
                        properties of `dsp.VectorQuantizerEncoder`. The behavior of `step` is
                        specific to each object in the toolbox.

Construction   `H = dsp.VectorQuantizerEncoder` returns a vector quantizer encoder
                     System object, `H`. This object finds a zero-based index of the nearest
                     codeword for each given input column vector.

                     `H =`
                     `dsp.VectorQuantizerEncoder('`*PropertyName*`',`*PropertyValue*`,...)`
                     returns a vector quantizer encoder System object, `H`, with each specified
                     property set to the specified value.

Properties   **CodebookSource**

                        Source of codebook values

                        Specify how to determine the codebook values as `Property` or
                        `Input port`. The default is `Property`.

                     Codebook

                        Codebook

                        Specify the codebook to which the input column vector or matrix
                        is compared, as a k-by-N matrix. Each column of the codebook
                        matrix is a codeword, and each codeword corresponds to an index
                        value. The codeword vectors must have the same number of rows
                        as the input. The first codeword vector corresponds to an index

value of 0, the second codeword vector corresponds to an index value of 1, and so on. This property applies when you set the CodebookSource property to Property. The default is:

$$\begin{bmatrix} 1.5 & 13.3 & 136.4 & 6.8 \\ 2.5 & 14.3 & 137.4 & 7.8 \\ 3.5 & 15.3 & 138.4 & 8.8 \end{bmatrix}$$

This property is tunable.

DistortionMeasure

Distortion calculation method

Specify how to calculate the distortion as Squared error or Weighted squared error. If you set this property to Squared error, the object calculates the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. If you set this property to Weighted squared error, the object calculates the distortion by evaluating a weighted Euclidean distance using a weighting factor to emphasize or deemphasize certain input values. The default is Squared error.

WeightsSource

Source of weighting factor

Specify how to determine weighting factor as Property or Input port. This property applies when you set the DistortionMeasure property to Weighted squared error. The default is Property.

Weights

Weighting factor

Specify the weighting factor as a vector of length equal to the number of rows of the input. This property applies when you set the DistortionMeasure property to Weighted squared error and WeightsSource property is Property. The default is [1 1 1]. This property is tunable.

TiebreakerRule

Behavior when input column vector is equidistant from two codewords.

Specify whether to represent the input column vector by the lower index valued codeword or higher indexed valued codeword when an input column vector is equidistant from two codewords. You can set this property to `Choose the lower index` or `Choose the higher index`. The default is `Choose the lower index`.

CodewordOutputPort

Enable output of codeword value

Set this property to `true` to output the codeword vectors nearest to the input column vectors. The default is `false`.

QuantizationErrorOutputPort

Enable output of quantization error

Set this property to `true` to output the quantization error value that results when the object represents the input column vector by the nearest codeword. The default is `false`.

OutputIndexDataType

Data type of index output

Specify the data type of the index output as: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`. The default is `int32`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest` or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Same as input`, or `Custom`. The default is `Same as product`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`.

Methods

clone	Create vector quantizer encoder object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method

dsp.VectorQuantizerEncoder

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Quantization region to which input belongs

Examples

Find the indices of nearest codewords based on Euclidean distances:

```
hvqenc = dsp.VectorQuantizerEncoder(...
'Codebook', [-1 -1 1 1;1 -1 -1 1], ...
'CodewordOutputPort', true, ...
'QuantizationErrorOutputPort', true, ...
'OutputIndexDataType', 'uint8');
% Generate an input signal with some additive noise
x = sign(rand(2,40)-0.5) + 0.1*randn(2,40);
[ind, cw, err] = step(hvqenc, x);
plot(cw(1,:), cw(2,:), 'rO', x(1,:), x(2,:), 'g.');
legend('Quantized', 'Inputs', 'location', 'best');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Vector Quantizer Encoder block reference page. The object properties correspond to the block parameters.

See Also

dsp.VectorQuantizerDecoder | dsp.ScalarQuantizerEncoder

Purpose   Create vector quantizer encoder object with same property values

Syntax

Description   `C = clone(H)` creates a `VectorQuantizerEncoder` object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

dsp.VectorQuantizerEncoder.getNumInputs

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description N = getNumInputs(H) returns the number of expected inputs, N, to
                 the step method

                 The getNumInputs method returns a positive integer that is the number
                 of expected inputs (not counting the object itself) to the step method.
                 This value will change if you alter any properties that turn inputs on or
                 off. You must call the step method with the number of input arguments
                 equal to the result of getNumInputs(*H*).

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step
                   method

                   The getNumOutputs method returns a positive integer that is the
                   number of outputs from the step method. This value will change if you
                   alter any properties that turn outputs on or off.

dsp.VectorQuantizerEncoder.isLocked

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the VectorQuantizerEncoder System object H.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description   release(H) releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the release method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.VectorQuantizerEncoder.step

Purpose   Quantization region to which input belongs

Syntax
```
INDEX = step(H,INPUT)
INDEX = step(H,...,CODEBOOK)
INDEX = step(H,...,WEIGHTS)
[..., CODEWORD] = step(H, ...)
[..., QERR] = step(H, ...)
```

Description   `INDEX = step(H,INPUT)` returns `INDEX`, a scalar or column vector representing the quantization region(s) to which `INPUT` belongs. `INPUT` can be a column vector of size k-by-1 or an M multichannel matrix of dimensions k-by-M, where k is the length of each codeword in the codebook. All inputs to the object can be real floating-point or fixed-point values and must be of the same data type. The output index values can be signed or unsigned integers.

`INDEX = step(H,...,CODEBOOK)` uses the codebook given in input `CODEBOOK`, a k-by-N matrix with N codewords each of length k. This option is available when the `CodebookSource` property is `Input port`.

`INDEX = step(H,...,WEIGHTS)` uses the input vector `WEIGHTS` to emphasize or de-emphasize certain input values when calculating the distortion measure. `WEIGHTS` must be a vector of length equal to the number of rows of `INPUT`. This option is available when the `DistortionMeasure` property is `Weighted squared error` and the `WeightsSource` property is `Input port`.

`[..., CODEWORD] = step(H, ...)` outputs the `CODEWORD` values that correspond to each index value when the `CodewordOutputPort` property is `true`.

`[..., QERR] = step(H, ...)` outputs the quantization error `QERR` for each input value when the `QuantizationErrorOutputPort` property is `true`.

Note The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

.

dsp.Window

Purpose   Window object

Description   The `Window` object applies a window to an input signal.

To apply a window to an input signal:

1 Define and set up your window. See "Construction" on page 5-1302.

2 Call `step` to apply the window according to the properties of `dsp.Window`. The behavior of `step` is specific to each object in the toolbox.

Construction   `H = dsp.Window` returns a window object, `H`, that applies a Hamming window with symmetric sampling.

`H = dsp.Window('`*PropertyName*`',`*PropertyValue*`, ...)` returns a window object, `H`, with each property set to the specified value.

`H = dsp.Window(WINDOW,'`*PropertyName*`',`*PropertyValue*`, ...)` returns a window object, `H`, with the `WindowFunction` property set to `WINDOW` and other properties set to the specified values.

Properties   **WindowFunction**

Type of window

Specify the type of window to apply as `Bartlett`, `Blackman`, `Boxcar`, `Chebyshev`, `Hamming` , `Hann`, `Hanning`, `Kaiser`, `Taylor`, `Triang`. This property is tunable. The default is `Hamming`.

WeightsOutputPort

Enable the output of window weights

Set this property to `true` to output the window weights. The weights are an M-by-1 vector with M equal to the first dimension of the input. The default is `false`.

StopbandAttenuation

Level of stopband attenuation in decibels

Specify the level of stopband attenuation in decibels. This property only applies when the `WindowFunction` property is `Chebyshev`. The default is 50. This property is tunable.

Beta

Kaiser window parameter

Specify the Kaiser window parameter as a real number. Increasing the absolute value of `Beta` widens the mainlobe and decreases the amplitude of the window sidelobes in the window's frequency magnitude response. This property only applies when `WindowFunction` property is `Kaiser`. The default is 10. This property is tunable.

NumConstantSidelobes

Number of constant sidelobes

Specify the number of constant sidelobes as an integer greater than zero. This property only applies when `WindowFunction` property is `Taylor`. The default is 4. This property is tunable.

MaximumSidelobeLevel

Maximum sidelobe level relative to mainlobe

Specify, in decibels, the maximum sidelobe level relative to the mainlobe as a real number less than or equal to zero. The default is −30, which produces sidelobes with peaks 30 dB down from the mainlobe peak. This property only applies when `WindowFunction` property is `Taylor`. This property is tunable.

Sampling

Window sampling for generalized-cosine windows

Specify the window sampling for generalized-cosine windows as `Symmetric` or `Periodic`. This property only applies when `WindowFunction` property is `Blackman`, `Hamming`, `Hann`, or `Hanning`. This property is tunable.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set
`FullPrecisionOverride` to `true`, which is the default, the object
computes all internal arithmetic and output data types using full
precision rules. These rules provide the most accurate fixed-point
numerics. It also turns off the display of other fixed-point
properties because they do not apply individually. These rules
guarantee that no quantization occurs within the object. Bits are
added, as needed, to ensure that no roundoff or overflow occurs. If
you set `FullPrecisionOverride` to `false`, fixed-point data types
are controlled through individual fixed-point property settings.
For more information, see "Full Precision for Fixed-Point System
Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`,
`Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.
This property applies only if the object is not in full precision
mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The
default is `Wrap`. This property applies only if the object is not in
full precision mode.

WindowDataType

Window word and fraction lengths

Specify the window fixed-point data type as one of `Same word length as input` or `Custom`. The default is `Same word length as input`.

CustomWindowDataType

Window word and fraction lengths

Specify the window fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `WindowDataType` property to `Custom`. The default is `numerictype([],16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],16,15)`.

OutputDataType

Output data type

Specify the output fixed-point data type as one of `Same as product`, `Same as input`, `Custom`. The default is `Same as product`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you

set the `OutputDataType` property to `Custom`. The default is
`numerictype([],16,15)`.

Methods

clone	Create window object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Multiply input by window

Examples

Apply Hamming window to input signal:

```
 hwin = dsp.Window( ...
'WindowFunction', 'Hamming', ...
'WeightsOutputPort',true);
 x = rand(64,1);
[y, w] = step(hwin, x);
% View the window's time and frequency domain responses
wvtool(w);
```

Algorithms

This object implements the algorithm, inputs, and outputs described
on the Window Function block reference page. The object properties
correspond to the block parameters, except:

- **Operation** — The window object does not support the `Generate window` option.

- **Operation** — The `Generate and apply window` option on the block
  corresponds to the `WeightsOutputPort` property set to `true` on the
  window object.

- The window object only supports frame-based processing.

See Also   dsp.FFT | sigwin.bartlett | sigwin.blackman | sigwin.chebwin | sigwin.hamming | sigwin.hann | sigwin.kaiser | sigwin.taylorwin | sigwin.triang | wvtool

dsp.Window.clone

Purpose   Create window object with same property values

Syntax   C = clone(H)

Description   C = clone(H) creates a window object, C, with the same property values as H. The clone method creates a new unlocked object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   N = getNumInputs(H) returns the number of expected inputs, N, to
                   the step method.

                   The getNumInputs method returns a positive integer that is the number
                   of expected inputs (not counting the object itself) to the step method.
                   This value will change if you alter any properties that turn inputs on or
                   off. You must call the step method with the number of input arguments
                   equal to the result of getNumInputs(*H*).

dsp.Window.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of the step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose　　　Locked status for input attributes and nontunable properties

Syntax　　　　isLocked(H)

Description　　isLocked(H) returns the locked state of the window object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

dsp.Window.release

Purpose   Allow property value and input characteristics changes

Syntax   release(H)

Description release(H) releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the release method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Multiply input by window

Syntax   Y = step(H,X)
                [Y, W] = step(H,X)

Description Y = step(H,X) generates the windowed output, Y , of the input, X, using the specified window.

[Y, W] = step(H,X) returns the window values W when the WeightsOutputPort property is true.

dsp.ZeroCrossingDetector

Purpose　Zero crossing detector

Description　The `ZeroCrossingDetector` object counts the number of times the signal crosses zero, or changes sign. The zero crossing detector supports both floating-point and fixed-point data types.

To count the number of times a signal crosses zero or changes sign:

1 Define and set up your zero crossing detector. See "Construction" on page 5-1314.

2 Call `step` to count the number of times according to the properties of `dsp.ZeroCrossingDetector`. The behavior of `step` is specific to each object in the toolbox.

Construction　`H = dsp.ZeroCrossingDetector` returns a zero crossing detector object, H, that counts the number of zero crossings in the real-valued,, floating-point, or fixed-point frame-based vector or matrix.

`H = dsp.ZeroCrossingDetector('`*PropertyName*`',`*PropertyValue*`, ...)` returns a zero crossing detector object, H, with each property set to the specified value.

Properties　**FrameBasedProcessing**

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

If the `FrameBasedProcessing` property is `true`:

- The zero crossing detector treats a column vector or the columns of a matrix as single, independent channels.

- The zero crossing detector treats a length *N* row vector as *N* independent channels.

If the `FrameBasedProcessing` property is `false`:

- The zero crossing detector treats each entry of a vector or matrix as an independent channel.

Methods		
	clone	Create zero crossing detection object with same property values
	getNumInputs	Number of expected inputs to step method
	getNumOutputs	Number of outputs of step method
	isLocked	Locked status for input attributes and nontunable properties
	release	Allow property value and input characteristics changes
	step	Count zero crossings in input

Examples   Find number of zero crossings in electrocardiogram data:

```
EcgData = ecg(500)';
Hzerocross = dsp.ZeroCrossingDetector;
NumZeroCross = step(Hzerocross,EcgData);  % Equal to 4
plot(1:500,EcgData,'b',[0 500],[0 0],'r','linewidth',2);
```

Algorithms   This object implements the algorithm, inputs, and outputs described on the Zero Crossing block reference page. The object properties correspond to the block parameters.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the FrameBasedProcessing property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

dsp.ZeroCrossingDetector.clone

Purpose   Create zero crossing detection object with same property values

Syntax   C = clone(H)

Description C = clone(H) creates a zero crossing detector object, C, with the same property values as H. The clone method creates a new unlocked object.

Purpose   Number of expected inputs to step method

Syntax   N = getNumInputs(H)

Description   `N = getNumInputs(H)` returns the number of expected inputs, `N`, to
                 the `step` method.

                 The `getNumInputs` method returns a positive integer that is the number
                 of expected inputs (not counting the object itself) to the `step` method.
                 This value will change if you alter any properties that turn inputs on or
                 off. You must call the `step` method with the number of input arguments
                 equal to the result of `getNumInputs(H)`.

dsp.ZeroCrossingDetector.getNumOutputs

Purpose   Number of outputs of step method

Syntax   N = getNumOutputs(H)

Description   N = getNumOutputs(H) returns the number of outputs, N, of step method.

The getNumOutputs method returns a positive integer that is the number of outputs from the step method. This value will change if you alter any properties that turn outputs on or off.

Purpose   Locked status for input attributes and nontunable properties

Syntax   isLocked(H)

Description isLocked(H) returns the locked state of the zero crossing detector object.

The isLocked method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the isLocked method returns a true value.

Purpose	Allow property value and input characteristics changes
Syntax	`release(H)`
Description	`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

> **Note** You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose   Count zero crossings in input

Syntax   `Y = step(H,X)`

Description   `Y = step(H,X)` counts the number of zero crossings, `Y`, in the vector or matrix input `X`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

matlab.System

Purpose   Base class for System objects

Description   `matlab.System` is the base class for System objects. In your class definition file, you must subclass your object from this base class (or from another class that derives from this base class). Subclassing allows you to use the implementation and service methods provided by this base class to build your object. You use this syntax as the first line of your class definition file to directly inherit from the `matlab.System` base class, where `ObjectName` is the name of your object:

```
classdef ObjectName < matlab.System
```

Note You must set `Access=protected` for each `matlab.System` method you use in your code.

Methods

getDiscreteStateImpl	Discrete state property values
getNumInputsImpl	Number of input arguments passed to step and setup methods
getNumOutputsImpl	Number of outputs returned by method
isInactivePropertyImpl	Active or inactive flag for properties
loadObjectImpl	Load saved System object from MAT file
processTunedPropertiesImpl	Action when tunable properties change
releaseImpl	Release resources
resetImpl	Reset System object states
saveObjectImpl	Save System object in MAT file

setProperties	Set property values from name-value pair inputs
setupImpl	Initialize System object
stepImpl	System output and state update equations
validateInputsImpl	Validate inputs to step method
validatePropertiesImpl	Validate property values

Attributes   In addition to the attributes available for MATLAB objects, you can apply the following attributes to any property of a custom System object.

Nontunable	After an object is locked (after step or setup has been called), use Nontunable to prevent a user from changing that property value. By default, all properties are tunable. The Nontunable attribute is useful to lock a property that has side effects when changed. This attribute is also useful for locking a property value assumed to be constant during processing. You should always specifiy properties that affect the number of input or output ports as Nontunable.
Logical	Use Logical to limit the property value to a logical, scalar value. Any scalar value that can be converted to a logical is also valid, such as 0 or 1.
PositiveInteger	Use PositiveInteger to limit the property value to a positive integer value.
DiscreteState	Use DiscreteState to mark a property so it will display its state value when you use the getDiscreteState method.

To learn more about attributes, see "Property Attributes" in the MATLAB Object-Oriented Programming documentation.

Examples

Create a simple System object, `AddOne`, which subclasses from `matlab.System`. You place this code into a MATLAB file, `AddOne.m`.

```
classdef AddOne < matlab.System
%ADDONE Compute an output value that increments the input by one

    methods (Access=protected)
       % stepImpl method is called by the step method.
       function y = stepImpl(~,x)
           y = x + 1;
       end
    end
end
```

To use this object, create an instance of `AddOne`, provide an input, and use the `step` method:

```
hAdder = AddOne;
x = 1;
y = step(hAdder,x)
```

Assign the `Nontunable` attribute to the `InitialValue` property, which you define in your class definition file.

```
properties (Nontunable)
   InitialValue
end
```

matlab.System.getDiscreteStateImpl

Purpose   Discrete state property values

Syntax   s = getDiscreteStateImpl(obj)

Description   s = getDiscreteStateImpl(obj) returns a struct s of state values.
The field names of the struct are the object's DiscreteState property
names. To restrict or change the values returned by getDiscreteState
method, you can override this getDiscreteStateImpl method. End
users cannot specify scaled double fi objects as inputs to discrete state
properties.

getDiscreteStatesImpl is called by the getDiscreteState method,
which is called by the setup method.

Note You must set Access=protected for this method.

**Input
Arguments**

obj

    System object handle

**Output
Arguments**

s

    Struct of state values.

Examples   methods (Access=protected)
                    function s = getDiscreteState(obj)
                    end
                 end

               •

.

matlab.System.getNumInputsImpl

Purpose	Number of input arguments passed to step and setup methods
Syntax	num = getNumInputsImpl(obj)

Description   num = getNumInputsImpl(obj) returns the number of inputs num (excluding the System object handle) expected by the step method. The default implementation returns 1, which requires one input from the user, in addition to the System object handle. To specify a value other than 1, you must use include the getNumInputsImpl method in your class definition file.

getNumInputsImpl is called by the getNumInputs method and by the setup method if the number of inputs has not been determined already.

Note You must set Access=protected for this method.

Input Arguments

obj

    System object handle

Output Arguments

num

    Number of inputs expected by the step method for the specified object.

    Default: 1

Examples   Specify the number of inputs (2, in this case) expected by the step method.

```
methods (Access=protected)
   function num = getNumInputsImpl(obj)
      num = 2;
   end
end
```

Specify that the step method will not accept any inputs.

```
methods (Access=protected)
   function num = getNumInputsImpl(~)
      num = 0;
   end
end
```

See Also   setupImpl | | | | stepImpl | | | | getNumOutputsImpl | | |

How To   • "Change Number of Step Inputs or Outputs"

                 •

                 •

matlab.System.getNumOutputsImpl

Purpose	Number of outputs returned by step method
Syntax	num = getNumOutputsImpl (obj)
Description	num = getNumOutputsImpl (obj) returns the number of outputs from the step method. The default implementation returns 1 output. To specify a value other than 1, you must use include the getNumOutputsImpl method in your class definition file.
	getNumOutputsImpl is called by the getNumOutputs method, if the number of outputs has not been determined already.

> **Note** You must set Access=protected for this method.

Input Arguments	**obj**
	System object handle
Output Arguments	**num**
	Number of outputs to be returned by the step method for the specified object.
Examples	Specify the number of outputs (2, in this case) returned from the step method.

```
methods (Access=protected)
   function num = getNumOutputsImpl(obj)
      num = 2;
   end
end
```

Specify that the step method does not return any outputs.

```
methods (Access=protected)
```

```
      function num = getNumOutputsImpl(~)
         num = O;
      end
end
```

          •

matlab.System.isInactivePropertyImpl

Purpose	Active or inactive flag for properties
Syntax	`flag = isInactivePropertyImpl(obj,prop)`

Description `flag = isInactivePropertyImpl(obj,prop)` specifies whether a property is inactive for the current object configuration. An *inactive property* is a property that is not relevant to the object, given the values of other properties. Inactive properties are not shown if you use the `disp` method to display object properties. If you attempt to use public access to directly access or use `get` or `set` on an inactive property, a warning occurs.

`isInactiveProperty` is called by the `disp` method and by the `get` and `set` methods.

Note You must set `Access=protected` for this method.

Input Arguments

obj

System object handle

prop

Property name

Output Arguments

flag

Logical scalar value indicating whether the input property `prop` is inactive for the current object configuration.

Examples Display the `InitialValue` property only when the `UseRandomInitialValue` property value is `false`.

```
methods (Access=protected)
  function flag = isInactivePropertyImpl(obj,propertyName)
    if strcmp(propertyName,'InitialValue')
      flag = obj.UseRandomInitialValue;
```

```
        else
          flag = false;
        end
    end
end
```

See Also   setProperties | | |

How To   • "Hide Inactive Properties"

             •

             •

             •

matlab.System.loadObjectImpl

Purpose	Load saved System object from MAT file
Syntax	`loadObjectImpl(obj)`
Description	`loadObjectImpl(obj)` loads a saved System object, `obj`, from a MAT file. Your `loadObjectImpl` method should correspond to your `saveObjectImpl` method to ensure that all saved properties and data are loaded.
Input Arguments	**obj** System object handle

Examples   Load a saved System object. In this case, the object contains a child object, protected and private properties, and a discrete state.

```
methods(Access=protected)
  function loadObjectImpl(obj, s, wasLocked)
    % Load child System objects
    obj.child = matlab.System.loadObject(s.child);

    % Save protected & private properties
    obj.protected = s.protected;
    obj.pdependentprop = s.pdependentprop;

    % Save state only if locked when saved
    if wasLocked
      obj.state = s.state;
    end

    % Call base class method
    loadObjectImpl@matlab.System(obj,s,wasLocked);
  end
end
```

See Also   `saveObjectImpl`

How To   • "Load System Object"

• "Save System Object"

matlab.System.processTunedPropertiesImpl

Purpose   Action when tunable properties change

Syntax   processTunedPropertiesImpl(obj)

Description   processTunedPropertiesImpl(obj) specifies the actions to perform
                   when one or more tunable property values change. This method is
                   called as part of the next call to the step method after a tunable
                   property value changes. A property is tunable only if its Nontunable
                   attribute is false, which is the default.

                   processTunedPropertiesImpl is called by the step method.

                   Note You must set Access=protected for this method.

Tips   Use this method when a tunable property affects a different property
                   value. For example, two property values determine when to calculate
                   a lookup table. You want to perform that calculation when either
                   property changes. You also want the calculation to be done only once if
                   both properties change before the next call to the step method.

Input   **obj**
Arguments   System object handle

Examples   Use processTunedPropertiesImpl to recalculate the lookup table if
                   the value of either the NumNotes or MiddleC property changes.

```
methods (Access=protected)
  function processTunedPropertiesImpl(obj)
    % Generate a lookup table of note frequencies
    obj.pLookupTable = obj.MiddleC * (1+log(1:obj.NumNotes)/log(12));
  end
end
```

matlab.System.releaseImpl

Purpose   Release resources

Syntax   `releaseImpl(obj)`

Description   `releaseImpl(obj)` releases any resources used by the System object, such as file handles. This method also performs any necessary cleanup tasks. To release resources for a System object, you must use `releaseImpl` instead of a destructor.

`releaseImpl` is called by the `release` method. `releaseImpl` is also called when the object is deleted or cleared from memory, or when all references to the object have gone out of scope.

Note You must set `Access=protected` for this method.

Input Arguments

obj

System object handle

Examples   Use the `releaseImpl` method to close a file.

```
methods (Access=protected)
   function releaseImpl(obj)
     fclose(obj.pFileID);
   end
end
```

See Also   `resetImpl` | | |

How To   • "Release System Object Resources"

•

•

•

Purpose	Reset System object states
Syntax	`resetImpl(obj)`
Description	`resetImpl(obj)` defines the state reset equations for the System object. Typically you reset the states to a set of initial values.

`resetImpl` is called by the `reset` method. It is also called by the `setup` method, after the `setupImpl` method.

Note You must set `Access=protected` for this method.

Input Arguments	**obj**
	System object handle
Examples	Use the `reset` method to reset the counter `pCount` property to zero.

```
methods (Access=protected)
   function resetImpl(obj)
      obj.pCount = 0;
   end
end
```

See Also	`releaseImpl` | | |
How To	• "Reset Algorithm State"
	•
	•
	•

matlab.System.saveObjectImpl

Purpose   Save System object in MAT file

Syntax   saveObjectImpl(obj)

Description saveObjectImpl(obj) defines what System object obj property and
state values are saved in a MAT file when a user calls save on that
object. save calls saveObject, which then calls saveObjectImpl. If
you do not define a saveObjectImpl method for your System object
class, only public properties are saved. To save any private or protected
properties or state information, you must define a saveObjectImpl in
your class definition file.

You should save the state of an object only if the object is locked. When
the user loads that saved object, it loads in that locked state.

To save child object information, you use the associated saveObject
method within the saveObjectImpl method.

End users can use load, which calls loadObjectImpl to load a System
object into their workspace.

Input Arguments   **obj**

System object handle

Examples   Define what is saved for the System object. Call the base class version
of saveObjectImpl to save public properties. Then, save any child
System objects and any protected and private propertes. Finally, save
the state, if the object is locked.

```
methods(Access=protected)
    function s = saveObjectImpl(obj)
        s = saveObjectImpl@matlab.System(obj);
        s.child = matlab.System.saveObject(obj.child);
        s.protected = obj.protected;
        s.pdependentprop = obj.pdependentprop;
        if isLocked(obj)
            s.state = obj.state;
```

```
        end
    end
end
```

See Also   loadObjectImpl

How To   • "Save System Object"

               • "Load System Object"

matlab.System.setProperties

Purpose   Set property values from name-value pair inputs

Syntax   setProperties(obj,numargs,name1,value1,name2,value2,...)
                   setProperties(obj,numargs,arg1,...,argm,name1,value1,name2,
                       value2,...)

Description   setProperties(obj,numargs,name1,value1,name2,value2,...)
                   provides the name-value pair inputs to the System object constructor.
                   Use this syntax if every input must specify both name and value.

Note To allow standard name-value pair handling at construction,
define setProperties for your System object.

---

setProperties(obj,numargs,arg1,...,argm,name1,value1,name2,value2,...)
provides the value-only inputs, followed by the name-value pair inputs
to the System object during object construction. Use this syntax if you
want to allow users to specify one or more inputs by their values only.

**Input
Arguments**   **obj**

                   System object handle

                   numargs

                   Number of inputs passed in by the object constructor

                   name*

                   Name of property

                   value*

                   Value of the property

                   arg*

                   Value of property (for value-only input to the object constructor)

Examples   Set up the object so users can specify property values via name-value pairs when constructing the object.

```
methods
   function obj = MyFile(varargin)
      setProperties(obj,nargin,varargin{:});
   end
end
```

How To   • "Set Property Values at Construction Time"

•

•

•

matlab.System.setupImpl

Purpose   Initialize System object

Syntax   setupImpl(obj,input1, input2,...)

Description setupImpl(obj,input1, input2,...) sets up a System object. To acquire resources for a System object, you must use setupImpl instead of a constructor. setupImpl executes the first time the step method is called on an object after that object has been created. It also executes the next time step is called after an object has been released. . The number of inputs must match the number of inputs defined in the getNumInputsImpl method. You pass the inputs into setupImpl to use the input sizes, datatypes, etc. in the one-time calculations.

setupImpl is called by the setup method, which is done automatically as the first subtask of the step method on an unlocked System object.

Note You must set Access=protected for this method.

Tips   To validate properties or inputs use the validatePropertiesImpl, validateInputsImpl, or setProperties methods. Do not include validation in setupImpl.

Input Arguments

obj

  System object handle

input*

  Inputs to the setup method

Examples   Open a file for writing using the setupImpl method.

```
methods (Access=protected)
  function setupImpl(obj,data)
     obj.pFileID = fopen(obj.Filename, 'wb');
     if obj.pFileID < O
```

```
            error('Opening the file failed');
        end
    end
end
```

                   •

matlab.System.stepImpl

Purpose	System output and state update equations
Syntax	[output1,output2,...] = stepImpl(obj,input1,input2,...)
Description	[output1,output2,...] = stepImpl(obj,input1,input2,...) defines the algorithm to execute when you call the step method on the specified object obj. The step method calculates the outputs and updates the object's state values using the inputs, properties, and state update equations.

stepImpl is called by the step method.

Note You must set Access=protected for this method.

Tips	The number of input arguments and output arguments must match the values returned by the getNumInputsImpl and getNumOutputsImpl methods, respectively
Input Arguments	**obj**
	System object handle
	input*
	Inputs to the step method
Output Arguments	**output**
	Output returned from the step method.
Examples	Use the stepImpl method to increment two numbers.

```
methods (Access=protected)
   function [y1,y2] = stepImpl(obj,x1,x2)
      y1 = x1 + 1;
      y2 = x2 + 1;
    end
```

validateInputsImpl | | |

How To
- "Define Basic System Objects"
-
-
-
- "Change Number of Step Inputs or Outputs"
-
-
-

matlab.System.validateInputsImpl

Purpose	Validate inputs to step method
Syntax	`validateInputsImpl(obj,input1,input2,...)`
Description	`validateInputsImpl(obj,input1,input2,...)` validates inputs to the `step` method at the beginning of initialization Validation includes checking data types, complexity, cross-input validation, and validity of inputs controlled by a property value.
	`validateInputsImpl` is called by the `setup` method before `setupImpl`. `validateInputsImpl` executes only once.

Note You must set `Access=protected` for this method.

Input Arguments

obj

    System object handle

input*

    Inputs to the `setup` method

Examples

Validate that the input is numeric.

```
methods (Access=protected)
   function validateInputsImpl(~,x)
      if ~isnumeric(x)
         error('Input must be numeric');
      end
   end
end
```

·

matlab.System.validatePropertiesImpl

Purpose   Validate property values

Syntax   validatePropertiesImpl(obj)

Description   validatePropertiesImpl(obj) validates interdependent or interrelated property values at the beginning of object initialization, such as checking that the dependent or related inputs are the same size.

validatePropertiesImpl is the first method called by the setup method. validatePropertiesImpl also is called before the processTunablePropertiesImpl method.

Note You must set Access=protected for this method.

Input Arguments

obj

   System object handle

Examples   Validate that the useIncrement property is true and that the value of the increment property is greater than zero.

```
methods (Access=protected)
   function validatePropertiesImpl(obj)
      if obj.useIncrement && obj.increment < 0
         error('The increment value must be positive');
      end
    end
end
```

matlab.system.mixin.FiniteSource

Purpose   Finite source mixin class

Description `matlab.system.mixin.FiniteSource` is a class that defines the `isDone` method, which reports the state of a finite data source, such as an audio file.

To use this method, you must subclass from this class in addition to the `matlab.System` base class. You use the following syntax as the first line of your class definition file, where `ObjectName` is the name of your object:

```
classdef ObjectName < matlab.System &...
    matlab.system.mixin.FiniteSource
```

Methods   isDoneImpl   End-of-data flag

                 • Property Attributes

matlab.system.mixin.FiniteSource.isDoneImpl

Purpose   End-of-data flag

Syntax   status = isDoneImpl(obj)

Description status = isDoneImpl(obj) indicates if an end-of-data condition has
occurred. The isDone method should return false when data from a
finite source has been exhausted, typically by having read and output
all data from the source. You should also define the result of future
reads from an exhausted source in the isDoneImpl method.

isDoneImpl is called by the isDone method.

**Input
Arguments**   **obj**

    System object handle

**Output
Arguments**   **status**

    Logical value, true or false, that indicates if an end-of-data
    condition has occurred or not, respectively.

Examples   Set up isDoneImpl so the isDone method checks whether the object has
completed eight iterations.

```
methods (Access=private)
   function bdone = isDoneImpl(obj)
      bdone = obj.NumIters==8;
   end
end
```

matlab.system.StringSet

Purpose   Set of valid string values

Description   `matlab.system.StringSet` defines a list of valid string values for a property. This class validates the string in the property and enables tab completion for the property value. A *StringSet* allows only predefined or customized strings as values for the property.

A `StringSet` uses two linked properties, which you must define in the same class. One is a public property that contains the current string value. This public property is displayed to the user. The other property is a hidden property that contains the list of all possible string values. This hidden property should also have the transient attribute so its value is not saved to disk when you save the System object.

The following considerations apply when using StringSets:

- The string property that holds the current string can have any name.

- The property that holds the `StringSet` must use the same name as the string property with the suffix "Set" appended to it. The string set property is an instance of the `matlab.system.StringSet` class.

- Valid strings, defined in the `StringSet`, must be declared using a cell array. The cell array cannot be empty nor can it have any empty strings. Valid strings must be unique and are case-insensitive.

- The string property must be set to a valid `StringSet` value.

Examples   Set the string property, `Flavor`, and the `StringSet` property, `FlavorSet`, in this example.

```
properties
  Flavor='Chocolate';
end

properties (Hidden,Transient)
  FlavorSet = ...
    matlab.system.StringSet({'Vanilla','Chocolate'});
end
```

Function Reference

Adaptive Filters

Least Mean Squares

`adaptfilt.adjlms`	FIR adaptive filter that uses adjoint LMS algorithm
`adaptfilt.blms`	FIR adaptive filter that uses BLMS
`adaptfilt.blmsfft`	FIR adaptive filter that uses FFT-based BLMS
`adaptfilt.dlms`	FIR adaptive filter that uses delayed LMS
`adaptfilt.filtxlms`	FIR adaptive filter that uses filtered-x LMS
`adaptfilt.lms`	FIR adaptive filter that uses LMS
`adaptfilt.nlms`	Normalized least mean squares adaptive filter
`adaptfilt.sd`	Sign-data FIR adaptive filter
`adaptfilt.se`	FIR adaptive filter that uses sign-error algorithm
`adaptfilt.ss`	FIR adaptive filter that uses sign-sign algorithm

Recursive Least Squares

`adaptfilt.ftf`	Fast transversal LMS adaptive filter
`adaptfilt.hrls`	FIR adaptive filter that uses householder (RLS)
`adaptfilt.hswrls`	FIR adaptive filter that uses householder sliding window RLS
`adaptfilt.qrdrls`	FIR adaptive filter that uses QR-decomposition-based RLS
`adaptfilt.rls`	Recursive least-squares FIR adaptive filter
`adaptfilt.swftf`	FIR adaptive filter that uses sliding window fast transversal least squares
`adaptfilt.swrls`	FIR adaptive filter that uses window recursive least squares (RLS)

Affine Projection

`adaptfilt.ap`	FIR adaptive filter that uses direct matrix inversion
`adaptfilt.apru`	FIR adaptive filter that uses recursive matrix updating
`adaptfilt.bap`	FIR adaptive filter that uses block affine projection

Frequency Domain

`adaptfilt.fdaf`	FIR adaptive filter that uses frequency-domain with bin step size normalization
`adaptfilt.pbfdaf`	Partitioned block frequency-domain FIR adaptive filter

`adaptfilt.pbufdaf`	Partitioned block unconstrained frequency-domain adaptive filter
`adaptfilt.tdafdct`	Adaptive filter that uses discrete cosine transform
`adaptfilt.tdafdft`	Adaptive filter that uses discrete Fourier transform
`adaptfilt.ufdaf`	FIR adaptive filter that uses unconstrained frequency-domain with quantized step size normalization

Lattice

`adaptfilt.gal`	FIR adaptive filter that uses gradient lattice
`adaptfilt.lsl`	Least squares lattice adaptive filter
`adaptfilt.qrdlsl`	QR-decomposition-based least-squares lattice adaptive filter

Discrete-Time Filters

`dfilt`	Discrete-time filter
`dfilt.allpass`	Allpass filter
`dfilt.calattice`	Coupled-allpass, lattice filter
`dfilt.calatticepc`	Coupled-allpass, power-complementary lattice filter
`dfilt.cascade`	Cascade of discrete-time filters
`dfilt.cascadeallpass`	Cascade of allpass discrete-time filters
`dfilt.cascadewdfallpass`	Cascade allpass WDF filters to construct allpass WDF
`dfilt.delay`	Delay filter
`dfilt.df1`	Discrete-time, direct-form I filter
`dfilt.df1sos`	Discrete-time, SOS direct-form I filter
`dfilt.df1t`	Discrete-time, direct-form I transposed filter
`dfilt.df1tsos`	Discrete-time, SOS direct-form I transposed filter
`dfilt.df2`	Discrete-time, direct-form II filter
`dfilt.df2sos`	Discrete-time, SOS, direct-form II filter
`dfilt.df2t`	Discrete-time, direct-form II transposed filter
`dfilt.df2tsos`	Discrete-time, SOS direct-form II transposed filter
`dfilt.dfasymfir`	Discrete-time, direct-form antisymmetric FIR filter
`dfilt.dffir`	Discrete-time, direct-form FIR filter

`dfilt.dffirt`	Discrete-time, direct-form FIR transposed filter
`dfilt.dfsymfir`	Discrete-time, direct-form symmetric FIR filter
`dfilt.farrowfd`	Fractional Delay Farrow filter
`dfilt.farrowlinearfd`	Farrow Linear Fractional Delay filter
`dfilt.fftfir`	Discrete-time, overlap-add, FIR filter
`dfilt.latticeallpass`	Discrete-time, lattice allpass filter
`dfilt.latticear`	Discrete-time, lattice, autoregressive filter
`dfilt.latticearma`	Discrete-time, lattice, autoregressive, moving-average filter
`dfilt.latticemamax`	Discrete-time, lattice, moving-average filter with maximum phase
`dfilt.latticemamin`	Discrete-time, lattice, moving-average filter with minimum phase
`dfilt.parallel`	Discrete-time, parallel structure filter
`dfilt.scalar`	Discrete-time, scalar filter
`dfilt.wdfallpass`	Wave digital allpass filter

Filter Specifications — Response Types

`fdesign`	Filter specification object
`fdesign.arbgrpdelay`	Arbitrary group delay filter specification object
`fdesign.arbmag`	Arbitrary response magnitude filter specification object
`fdesign.arbmagnphase`	Arbitrary response magnitude and phase filter specification object
`fdesign.audioweighting`	Audio weighting filter specification object
`fdesign.bandpass`	Bandpass filter specification object
`fdesign.bandstop`	Bandstop filter specification object
`fdesign.ciccomp`	CIC compensator filter specification object
`fdesign.comb`	IIR comb filter specification object
`fdesign.decimator`	Decimator filter specification object
`fdesign.differentiator`	Differentiator filter specification object
`fdesign.fracdelay`	Fractional delay filter specification object
`fdesign.halfband`	Halfband filter specification object
`fdesign.highpass`	Highpass filter specification object
`fdesign.hilbert`	Hilbert filter specification object
`fdesign.interpolator`	Interpolator filter specification
`fdesign.isinchp`	Inverse sinc highpass filter specification
`fdesign.isinclp`	Inverse sinc lowpass filter specification
`fdesign.lowpass`	Lowpass filter specification
`fdesign.notch`	Notch filter specification

`fdesign.nyquist`	Nyquist filter specification
`fdesign.octave`	Octave filter specification
`fdesign.parameq`	Parametric equalizer filter specification
`fdesign.peak`	Peak filter specification
`fdesign.polysrc`	Construct polynomial sample-rate converter (POLYSRC) filter designer
`fdesign.pulseshaping`	Pulse-shaping filter specification object
`fdesign.rsrc`	Rational-factor sample-rate converter specification

Filter Specifications — Design Methods

butter	Butterworth IIR filter design using specification object
cheby1	Chebyshev Type I filter using specification object
cheby2	Chebyshev Type II filter using specification object
design	Apply design method to filter specification object
designmethods	Methods available for designing filter from specification object
designopts	Valid input arguments and values for specification object and method
ellip	Elliptic filter using specification object
equiripple	Equiripple single-rate or multirate FIR filter from specification object
fircls	FIR Constrained Least Squares filter
ifir	Interpolated FIR filter from filter specification
iirlinphase	Quasi-linear phase IIR filter from halfband filter specification
kaiserwin	Kaiser window filter from specification object
maxflat	Maxflat FIR filter
multistage	Multistage filter from specification object
validstructures	Structures for specification object with design method
window	FIR filter using windowed impulse response

Multirate Filters

`mfilt.cascade`	Cascade filter objects
`mfilt.cicdecim`	Fixed-point CIC decimator
`mfilt.cicinterp`	Fixed-point CIC interpolator
`mfilt.farrowsrc`	Sample rate converter with arbitrary conversion factor
`mfilt.fftfirinterp`	Overlap-add FIR polyphase interpolator
`mfilt.firdecim`	Direct-form FIR polyphase decimator
`mfilt.firfracdecim (Obsolete)`	Direct-form FIR polyphase fractional decimator
`mfilt.firfracinterp (Obsolete)`	Direct-form FIR polyphase fractional interpolator
`mfilt.firinterp`	FIR filter-based interpolator
`mfilt.firsrc`	Direct-form FIR polyphase sample rate converter
`mfilt.firtdecim`	Direct-form transposed FIR filter
`mfilt.holdinterp`	FIR hold interpolator
`mfilt.iirdecim`	IIR decimator
`mfilt.iirinterp`	IIR interpolator
`mfilt.iirwdfdecim`	IIR wave digital filter decimator
`mfilt.iirwdfinterp`	IIR wave digital filter interpolator
`mfilt.linearinterp`	Linear interpolator

GUIs

fdatool	Open Filter Design and Analysis Tool
filterbuilder	GUI-based filter design

Filter Analysis

autoscale	Automatic dynamic range scaling
block	Generate block from multirate or multistage filter
coeffs	Coefficients for filters
cost	Estimate cost of discrete-time or multirate filter
cumsec	Vector of SOS filters for cumulative sections
denormalize	Undo filter coefficient and gain changes caused by normalize
disp	Filter properties and values
double	Cast fixed-point filter to use double-precision arithmetic
euclidfactors	Euclid factors for multirate filter
fftcoeffs	Frequency-domain coefficients
filter	Filter data with filter object
filtstates.cic	Store CIC filter states
firtype	Type of linear phase FIR filter
freqrespest	Frequency response estimate via filtering
freqrespopts	Options for filter frequency response analysis
freqsamp	Real or complex frequency-sampled FIR filter from specification object
freqz	Frequency response of filter
grpdelay	Filter group delay
help	Help for design method with filter specification
impz	Filter impulse response

isfir	Determine whether filter is FIR
islinphase	Determine whether filter is linear phase
ismaxphase	Determine whether filter is maximum phase
isminphase	Determine whether filter is minimum phase
isreal	Determine whether filter uses real coefficients
isstable	Determine whether filter is stable
limitcycle	Response of single-rate, fixed-point IIR filter
maxstep	Maximum step size for adaptive filter convergence
measure	Measure filter magnitude response
msepred	Predicted mean-squared error for adaptive filter
msesim	Measured mean-squared error for adaptive filter
noisepsd	Power spectral density of filter output due to roundoff noise
noisepsdopts	Options for running filter output noise PSD
norm	P-norm of filter
normalize	Normalize filter numerator or feed-forward coefficients
normalizefreq	Switch filter specification between normalized frequency and absolute frequency
nstates	Number of filter states
order	Order of fixed-point filter

phasedelay	Phase delay of filter
phasez	Unwrapped phase response for filter
polyphase	Polyphase decomposition of multirate filter
qreport	Most recent fixed-point filtering operation report
realizemdl	Simulink subsystem block for filter
reffilter	Reference filter for fixed-point or single-precision filter
reorder	Rearrange sections in SOS filter
reset	Reset filter properties to initial conditions
scale	Scale sections of SOS filter
scalecheck	Check scaling of SOS filter
set2int	Configure filter for integer filtering
setspecs	Specifications for filter specification object
specifyall	Fixed-point scaling modes in direct-form FIR filter
stepz	Step response for filter
sysobj	Create filter System object from discrete-time filter or multirate filter
zerophase	Zero-phase response for filter
zplane	Zero-pole plot for filter

To see the full listing of analysis methods that apply to the adaptfilt, dfilt, or mfilt objects, enter help adaptfilt, help dfilt, or help mfilt at the MATLAB prompt.

Fixed-Point Filters

cell2sos	Convert cell array to SOS matrix
get	Properties of quantized filter
isreal	Test if filter coefficients are real
reset	Reset properties of quantized filter to initial values
scale	Scale sections of SOS filters
scalecheck	Check scaling of SOS filter
scaleopts	Scaling options for second-order section scaling
set	Properties of quantized filter
sos	Convert quantized filter to SOS form, order, and scale
sos2cell	Convert SOS matrix to cell array

Quantized Filter Analysis

freqz	Frequency response of filter
impz	Filter impulse response
isallpass	Determine whether filter is allpass
isfir	Determine whether filter is FIR
islinphase	Determine whether filter is linear phase
ismaxphase	Determine whether filter is maximum phase
isminphase	Determine whether filter is minimum phase
isreal	Determine whether filter uses real coefficients
issos	Determine whether filter is SOS form
isstable	Determine whether filter is stable
noisepsd	Power spectral density of filter output due to roundoff noise
noisepsdopts	Options for running filter output noise PSD
zplane	Zero-pole plot for filter

SOS Conversion

`cell2sos`	Convert a cell array to a second-order sections matrix
`sos`	Convert a quantized filter to second-order sections form, order, and scale
`sos2cell`	Convert a second-order sections matrix to a cell array

Filter Design

fdatool	Open Filter Design and Analysis Tool
filterbuilder	GUI-based filter design
fircband	Constrained-band equiripple FIR filter
firceqrip	Constrained equiripple FIR filter
fireqint	Equiripple FIR interpolators
firgr	Parks-McClellan FIR filter
firhalfband	Halfband FIR filter
firlpnorm	Least P-norm optimal FIR filter
firls	Least-square linear-phase FIR filter design
firminphase	Minimum-phase FIR spectral factor
firnyquist	Lowpass Nyquist (Lth-band) FIR filter
ifir	Interpolated FIR filter from filter specification
iircomb	IIR comb notch or peak filter
iirgrpdelay	Optimal IIR filter with prescribed group-delay
iirlpnorm	Least P-norm optimal IIR filter
iirlpnormc	Constrained least Pth-norm optimal IIR filter
iirnotch	Second-order IIR notch filter
iirpeak	Second-order IIR peak or resonator filter

Filter Conversion

`ca2tf`	Convert coupled allpass filter to transfer function form
`cl2tf`	Convert coupled allpass lattice to transfer function form
`convert`	Convert filter structure of discrete-time or multirate filter
`firlp2hp`	Convert FIR lowpass filter to Type I FIR highpass filter
`firlp2lp`	Convert FIR Type I lowpass to FIR Type 1 lowpass with inverse bandwidth
`iirlp2bp`	Transform IIR lowpass filter to IIR bandpass filter
`iirlp2bs`	Transform IIR lowpass filter to IIR bandstop filter
`iirlp2hp`	Transform lowpass IIR filter to highpass filter
`iirlp2lp`	Transform lowpass IIR filter to different lowpass filter
`iirpowcomp`	Power complementary IIR filter
`set2int`	Configure filter for integer filtering
`tf2ca`	Transfer function to coupled allpass
`tf2cl`	Transfer function to coupled allpass lattice

Signal Logging

`dsp.util.getLogsArray`	Return logged signal as MATLAB array
`dsp.util.getSignalPath`	Paths to logged signals
`dsp.util.SignalPath`	Properties of paths to signals

Simulink Signal Processing Functions

dsplib	Open top-level DSP System Toolbox library
dspstartup	Configure Simulink environment for signal processing systems
dsp_links	Identify whether blocks in model are current, deprecated, or obsolete
liblinks	Check model for blocks from specific DSP System Toolbox libraries
rebuffer_delay	Number of samples of delay introduced by buffering and unbuffering operations

Functions — Alphabetical List

adaptfilt

Purpose　　Adaptive filter

Syntax　　`ha = adaptfilt.`*`algorithm`*`('input1',input2,...)`

Description　　`ha = adaptfilt.`*`algorithm`*`('input1',input2,...)` returns the
adaptive filter object `ha` that uses the adaptive filtering technique
specified by *algorithm*. When you construct an adaptive filter object,
include an *algorithm* specifier to implement a specific adaptive filter.
Note that you do not enclose the algorithm option in single quotation
marks as you do for most strings. To construct an adaptive filter object
you must supply an *algorithm* string — there is no default algorithm,
although every constructor creates a default adaptive filter when you do
not provide input arguments such as `input1` or `input2` in the calling
syntax.

Algorithms

For adaptive filter (`adaptfilt`) objects, the *algorithm* string
determines which adaptive filter algorithm your `adaptfilt` object
implements. Each available algorithm entry appears in one of the tables
along with a brief description of the algorithm. Click on the algorithm in
the first column to get more information about the associated adaptive
filter technique.

Least Mean Squares (LMS) Based FIR Adaptive Filters

adaptfilt.algorithm String	Algorithm Used to Generate Filter Coefficients
adaptfilt.adjlms	Use the Adjoint LMS FIR adaptive filter algorithm
adaptfilt.blms	Use the Block LMS FIR adaptive filter algorithm
adaptfilt.blmsfft	Use the FFT-based Block LMS FIR adaptive filter algorithm
adaptfilt.dlms	Use the delayed LMS FIR adaptive filter algorithm
adaptfilt.filtxlms	Use the filtered-x LMS FIR adaptive filter algorithm
adaptfilt.lms	Use the LMS FIR adaptive filter algorithm
adaptfilt.nlms	Use the normalized LMS FIR adaptive filter algorithm
adaptfilt.sd	Use the sign-data LMS FIR adaptive filter algorithm
adaptfilt.se	Use the sign-error LMS FIR adaptive filter algorithm
adaptfilt.ss	Use the sign-sign LMS FIR adaptive filter algorithm

For further information about an adapting algorithm, refer to the reference page for the algorithm.

Recursive Least Squares (RLS) Based FIR Adaptive Filters

adaptfilt.algorithm String	Algorithm Used to Generate Filter Coefficients
adaptfilt.ftf	Use the fast transversal least squares adaptation algorithm
adaptfilt.qrdrls	Use the QR-decomposition RLS adaptation algorithm
adaptfilt.hrls	Use the householder RLS adaptation algorithm
adaptfilt.hswrls	Use the householder SWRLS adaptation algorithm
adaptfilt.rls	Use the recursive-least squares (RLS) adaptation algorithm
adaptfilt.swrls	Use the sliding window (SW) RLS adaptation algorithm
adaptfilt.swftf	Use the sliding window FTF adaptation algorithm

For more complete information about an adapting algorithm, refer to the reference page for the algorithm.

Affine Projection (AP) FIR Adaptive Filters

adaptfilt.algorithm String	Algorithm Used to Generate Filter Coefficients
adaptfilt.ap	Use the affine projection algorithm that uses direct matrix inversion
adaptfilt.apru	Use the affine projection algorithm that uses recursive matrix updating
adaptfilt.bap	Use the block affine projection adaptation algorithm

To find more information about an adapting algorithm, refer to the reference page for the algorithm.

FIR Adaptive Filters in the Frequency Domain (FD)

adaptfilt.algorithm String	Algorithm Used to Generate Filter Coefficients
adaptfilt.fdaf	Use the frequency domain adaptation algorithm
adaptfilt.pbfdaf	Use the partition block version of the FDAF algorithm
adaptfilt.pbufdaf	Use the partition block unconstrained version of the FDAF algorithm
adaptfilt.tdafdct	Use the transform domain adaptation algorithm using DCT
adaptfilt.tdafdft	Use the transform domain adaptation algorithm using DFT
adaptfilt.ufdaf	Use the unconstrained FDAF algorithm for adaptation

For more information about an adapting algorithm, refer to the reference page for the algorithm.

Lattice Based (L) FIR Adaptive Filters

adaptfilt.algorithm String	Algorithm Used to Generate Filter Coefficients
adaptfilt.gal	Use the gradient adaptive lattice filter adaptation algorithm
adaptfilt.lsl	Use the least squares lattice adaptation algorithm
adaptfilt.qrdlsl	Use the QR decomposition least squares lattice adaptation algorithm

For more information about an adapting algorithm, refer to the reference page for the algorithm.

Properties for All Adaptive Filter Objects

Each reference page for an algorithm and `adaptfilt.algorithm` object specifies which properties apply to the adapting algorithm and how to use them.

Methods for Adaptive Filter Objects

As is true with all objects, methods enable you to perform various operations on `adaptfilt` objects. To use the methods, you apply them to the object handle that you assigned when you constructed the `adaptfilt` object.

Most of the analysis methods that apply to `dfilt` objects also work with `adaptfilt` objects. Methods like `freqz` rely on the filter coefficients in the `adaptfilt` object. Since the coefficients change each time the filter adapts to data, you should view the results of using a method as an analysis of the filter at a moment in time for the object. Use caution when you apply an analysis method to your adaptive filter objects — always check that your result approached your expectation.

In particular, the Filter Visualization Tool (FVTool) supports all of the `adaptfilt` objects. Analyzing and viewing your `adaptfilt` objects is straightforward — use the `fvtool` method with the name of your object

```
fvtool(objectname)
```

to launch FVTool and work with your object.

Some methods share their names with functions in Signal Processing Toolbox software, or even functions in this toolbox. Functions that share names with methods behave in a similar way. Using the same name for more than one function or method is called *overloading* and is common in many toolboxes.

Method	Description
adaptfilt/coefficients	Return the instantaneous adaptive filter coefficients
adaptfilt/filter	Apply an adaptfilt object to your signal
adaptfilt/freqz	Plot the instantaneous adaptive filter frequency response
adaptfilt/grpdelay	Plot the instantaneous adaptive filter group delay
adaptfilt/impz	Plot the instantaneous adaptive filter impulse response.
adaptfilt/info	Return the adaptive filter information.
adaptfilt/isfir	Test whether an adaptive filter is an finite impulse response (FIR) filters.
adaptfilt/islinphase	Test whether an adaptive filter is linear phase
adaptfilt/ismaxphase	Test whether an adaptive filter is maximum phase
adaptfilt/isminphase	Test whether an adaptive filter is minimum phase
adaptfilt/isreal	True whether an adaptive filter has real coefficients
adaptfilt/isstable	Test whether an adaptive filter is stable
adaptfilt/maxstep	Return the maximum step size for an adaptive filter
adaptfilt/msepred	Return the predicted mean square error
adaptfilt/msesim	Return the measured mean square error via simulation.

Method	Description
adaptfilt/phasez	Plot the instantaneous adaptive filter phase response
adaptfilt/reset	Reset an adaptive filter to initial conditions
adaptfilt/stepz	Plot the instantaneous adaptive filter step response
adaptfilt/tf	Return the instantaneous adaptive filter transfer function
adaptfilt/zerophase	Plot the instantaneous adaptive filter zerophase response
adaptfilt/zpk	Return a matrix containing the instantaneous adaptive filter zero, pole, and gain values
adaptfilt/zplane	Plot the instantaneous adaptive filter in the Z-plane

Working with Adaptive Filter Objects

The next sections cover viewing and changing the properties of adaptfilt objects. Generally, modifying the properties is the same for adaptfilt, dfilt, and mfilt objects and most of the same methods apply to all.

Viewing Object Properties

As with any object, you can use get to view a adaptfilt object's properties. To see a specific property, use

```
get(ha,'property')
```

To see all properties for an object, use

```
get(ha)
```

Changing Object Properties

To set specific properties, use

```
set(ha,'property1',value1,'property2',value2,...)
```

You must use single quotation marks around the property name so MATLAB treats them as strings.

Copying an Object

To create a copy of an object, use `copy`.

```
ha2 = copy(ha)
```

Note Using the syntax `ha2 = ha` copies only the object handle and does not create a new object — `ha` and `ha2` are not independent. When you change the characteristics of `ha2`, those of `ha` change as well.

Using Filter States

Two properties control your adaptive filter states.

- `States` — stores the current states of the filter. Before the filter is applied, the states correspond to the initial conditions and after the filter is applied, the states correspond to the final conditions.

- `PersistentMemory` — resets the filter before filtering. The default value is `false` which causes the properties that are modified by the filter, such as `coefficients` and `states`, to be reset to the value you specified when you constructed the object, before you use the object to filter data. Setting `PersistentMemory` to `true` allows the object to retain its current properties between filtering operations, rather than resetting the filter to its property values at construction.

Examples   Construct an LMS adaptive filter object and use it to identify an unknown system. For this example, use 500 iteration of the adapting process to determine the unknown filter coefficients. Using the LMS

algorithm represents one of the most straightforward technique for adaptive filters.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
mu = 0.008;            % LMS step size.
ha = adaptfilt.lms(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');  grid on;
```

Purpose   FIR adaptive filter that uses adjoint LMS algorithm

Syntax   ha = adaptfilt.adjlms(l,step,leakage,pathcoeffs,pathest,...
                 errstates,pstates,coeffs,states)

Description ha = adaptfilt.adjlms(l,step,leakage,pathcoeffs,pathest,...
                 errstates,pstates,coeffs,states) constructs object ha, an FIR
                 adjoint LMS adaptive filter. l is the adaptive filter length (the number
                 of coefficients or taps) and must be a positive integer. l defaults to
                 10 when you omit the argument. step is the adjoint LMS step size.
                 It must be a nonnegative scalar. When you omit the step argument,
                 step defaults to 0.1.

                 leakage is the adjoint LMS leakage factor. It must be a scalar between
                 0 and 1. When leakage is less than one, you implement a leaky version
                 of the adjlms algorithm to determine the filter coefficients. leakage
                 defaults to 1 specifying no leakage in the algorithm.

                 pathcoeffs is the secondary path filter model. This vector should
                 contain the coefficient values of the secondary path from the output
                 actuator to the error sensor.

                 pathest is the estimate of the secondary path filter model. pathest
                 defaults to the values in pathcoeffs.

                 errstates is a vector of error states of the adaptive filter. It must have
                 a length equal to the filter order of the secondary path model estimate.
                 errstates defaults to a vector of zeros of appropriate length. pstates
                 contains the secondary path FIR filter states. It must be a vector of
                 length equal to the filter order of the secondary path model. pstates
                 defaults to a vector of zeros of appropriate length. The initial filter
                 coefficients for the secondary path filter compose vector coeffs. It must
                 be a length l vector. coeffs defaults to a length l vector of zeros.
                 states is a vector containing the initial filter states. It must be a vector
                 of length l+ne-1, where ne is the length of errstates. When you omit
                 states, it defaults to an appropriate length vector of zeros.

adaptfilt.adjlms

Properties In the syntax for creating the `adaptfilt` object, the input options are properties of the object created. This table lists the properties for the adjoint LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	None	Specifies the adaptive filter algorithm the object uses during adaptation
Coefficients	Length l vector with zeros for all elements	Adjoint LMS FIR filter coefficients. Should be initialized with the initial coefficients for the FIR filter prior to adapting. You need l entries in `coefficients`. Updated filter coefficients are returned in `coefficients` when you use s as an output argument.
ErrorStates	[0,...,0]	A vector of the error states for your adaptive filter, with length equal to the order of your secondary path filter.
FilterLength	10	The number of coefficients in your adaptive filter.
Leakage	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.
SecondaryPathCoeffs	No default	A vector that contains the coefficient values of your secondary path from the output actuator to the error sensor.
SecondaryPathEstimate	pathcoeffs values	An estimate of the secondary path filter model.

Property	Default Value	Description
SecondaryPathStates	Length of the secondary path filter. All elements are zeros.	The states of the secondary path filter, the unknown system
States	l+ne+1, where ne is length(errstates)	Contains the initial conditions for your adaptive filter and returns the states of the FIR filter after adaptation. If omitted, it defaults to a zero vector of length equal to l+ne+1. When you use adaptfilt.adjlms in a loop structure, use this element to specify the initial filter states for the adapting FIR filter.
Stepsize	0.1	Sets the adjoint LMS algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.

Examples   Demonstrate active noise control of a random noise signal that runs for 1000 samples.

```
x = randn(1,1000);      % Noise source
g = fir1(47,0.4);       % FIR primary path system model
```

adaptfilt.adjlms

```
n  = 0.1*randn(1,1000);  % Observation noise signal
d  = filter(g,1,x)+n;    % Signal to be canceled (desired)
b  = fir1(31,0.5);       % FIR secondary path system model
mu = 0.008;              % Adjoint LMS step size
ha = adaptfilt.adjlms(32,mu,1,b);
[y,e] = filter(ha,x,d);
plot(1:1000,d,'b',1:1000,e,'r');
title('Active Noise Control of a Random Noise Signal');
legend('Original','Attenuated');
xlabel('Time Index'); ylabel('Signal Value');  grid on;
```

Reviewing the figure shows that the adaptive filter attenuates the original noise signal as you expect.

Purpose   FIR adaptive filter that uses direct matrix inversion

Syntax   ha = adaptfilt.ap(l,step,projectord,offset,coeffs,states,...
                  errstates,epsstates)

Description   ha =
                  adaptfilt.ap(l,step,projectord,offset,coeffs,states,...
                  errstates,epsstates) constructs an affine projection FIR adaptive
                  filter ha using direct matrix inversion.

Input Arguments

Entries in the following table describe the input arguments for
adaptfilt.ap.

Input Argument	Description
l	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. l defaults to 10.
step	Affine projection step size. This is a scalar that should be a value between zero and one. Setting step equal to one provides the fastest convergence during adaptation. step defaults to 1.
projectord	Projection order of the affine projection algorithm. projectord defines the size of the input signal covariance matrix and defaults to two.
offset	Offset for the input signal covariance matrix. You should initialize the covariance matrix to a diagonal matrix whose diagonal entries are equal to the offset you specify. offset should be positive. offset defaults to one.

Input Argument	Description
coeffs	Vector containing the initial filter coefficients. It must be a length l vector, the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
states	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).
errstates	Vector of the adaptive filter error states. errstates defaults to a zero vector with length equal to (projectord - 1).
epsstates	Vector of the epsilon values of the adaptive filter. epsstates defaults to a vector of zeros with (projectord - 1) elements.

Properties   Since your adaptfilt.ap filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.ap objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps

Name	Range	Description
ProjectionOrder	1 to as large as needed.	Projection order of the affine projection algorithm. ProjectionOrder defines the size of the input signal covariance matrix and defaults to two.
OffsetCov	Matrix of values	Contains the offset covariance matrix
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector, the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).
ErrorStates	Vector of elements	Vector of the adaptive filter error states. errstates defaults to a zero vector with length equal to (projectord - 1).
EpsilonStates	Vector of elements	Vector of the epsilon values of the adaptive filter. epsstates defaults to a vector of zeros with (projectord - 1) elements.

Name	Range	Description
StepSize	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to true.

Examples   Quadrature phase shift keying (QPSK) adaptive equalization using a 32-coefficient FIR filter. Run the adaptation for 1000 iterations.

```
D  = 16;                    % Number of samples of delay
b  = exp(j*pi/4)*[-0.7 1];  % Numerator coefficients of channel
a  = [1 -0.7];              % Denominator coefficients of channel
ntr= 1000;                  % Number of iterations
s  = sign(randn(1,ntr+D)) + j*sign(randn(1,ntr+D));% Baseband Signal
n  = 0.1*(randn(1,ntr+D) + j*randn(1,ntr+D));      % Noise signal
r  = filter(b,a,s)+n;       % Received signal
x  = r(1+D:ntr+D);    % Input signal (received signal)
d  = s(1:ntr);        % Desired signal (delayed QPSK signal)
mu = 0.1;             % Step size
po = 4;               % Projection order
offset = 0.05;        % Offset for covariance matrix
ha = adaptfilt.ap(32,mu,po,offset);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
```

```
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

The four plots shown reveal the QPSK process at work.

Purpose   FIR adaptive filter that uses recursive matrix updating

Syntax   ha = adaptfilt.apru(l,step,projectord,offset,coeffs,states,
               ...errstates,epsstates)

Description   ha = adaptfilt.apru(l,step,projectord,offset,coeffs,states,
                 ...errstates,epsstates) constructs an affine projection FIR adaptive
                 filter ha using recursive matrix updating.

Input Arguments

Entries in the following table describe the input arguments for
adaptfilt.apru.

Input Argument	Description
l	Adaptive filter length (the number of coefficients or taps). It must be a positive integer. l defaults to 10.
step	Affine projection step size. This is a scalar that should be a value between zero and one. Setting step equal to one provides the fastest convergence during adaptation. step defaults to 1.
projectord	Projection order of the affine projection algorithm. projectord defines the size of the input signal covariance matrix and defaults to two.
offset	Offset for the input signal covariance matrix. You should initialize the covariance matrix to a diagonal matrix whose diagonal entries are equal to the offset you specify. offset should be positive. offset defaults to one.
coeffs	Vector containing the initial filter coefficients. It must be a length l vector, the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.

adaptfilt.apru

Input Argument	Description
states	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (1 + projectord - 2).
errstates	Vector of the adaptive filter error states. errstates defaults to a zero vector with length equal to (projectord - 1).
epsstates	Vector of the epsilon values of the adaptive filter. epsstates defaults to a vector of zeros with (projectord - 1) elements.

Properties
Since your adaptfilt.apru filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.apru objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
ProjectionOrder	1 to as large as needed.	Projection order of the affine projection algorithm. ProjectionOrder defines the size of the input signal covariance matrix and defaults to two.

Name	Range	Description
OffsetCov	Matrix of values	Contains the offset covariance matrix
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length 1 vector, the number of filter coefficients. coeffs defaults to length 1 vector of zeros when you do not provide the argument for input.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (1 + projectord - 2).
ErrorStates	Vector of elements	Vector of the adaptive filter error states. errstates defaults to a zero vector with length equal to (projectord - 1).
EpsilonStates	Vector of elements	Vector of the epsilon values of the adaptive filter. epsstates defaults to a vector of zeros with (projectord - 1) elements.

Name	Range	Description
StepSize	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to true.

Examples   Demonstrate quadrature phase shift keying (QPSK) adaptive equalization using a 32-coefficient FIR filter. This example runs the adaptation process for 1000 iterations.

```
D  = 16;                       % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];     % Numerator coefficients of channel
a  = [1 -0.7];                 % Denominator coefficients of channel
ntr= 1000;                     % Number of iterations
s  = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D)); % Baseband
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));  % Noise signal
r  = filter(b,a,s)+n;     % Received signal
x  = r(1+D:ntr+D); % Input signal (received signal)
d  = s(1:ntr);     % Desired signal (delayed QPSK signal)
mu = 0.1;                      % Step size
po = 4;                        % Projection order
offset = 0.05;                 % Offset
ha = adaptfilt.apru(32,mu,po,offset); [y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
```

```
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e])); title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

In the following component and scatter plots, you see the results of QPSK equalization.

Purpose   FIR adaptive filter that uses block affine projection

Syntax   ha = adaptfilt.bap(l,step,projectord,offset,coeffs,states)

Description   ha = adaptfilt.bap(l,step,projectord,offset,coeffs,states)
                   constructs a block affine projection FIR adaptive filter ha.

Input Arguments

Entries in the following table describe the input arguments for
adaptfilt.bap.

Input Argument	Description
l	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. l defaults to 10.
step	Affine projection step size. This is a scalar that should be a value between zero and one. Setting step equal to one provides the fastest convergence during adaptation. step defaults to 1.
projectord	Projection order of the affine projection algorithm. projectord defines the size of the input signal covariance matrix and defaults to two.
offset	Offset for the input signal covariance matrix. You should initialize the covariance matrix to a diagonal matrix whose diagonal entries are equal to the offset you specify. offset should be positive. offset defaults to one.

Input Argument	Description
coeffs	Vector containing the initial filter coefficients. It must be a length l vector, the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
states	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).

Properties   Since your adaptfilt.bap filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.bap objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
ProjectionOrder	1 to as large as needed.	Projection order of the affine projection algorithm. ProjectionOrder defines the size of the input signal covariance matrix and defaults to two.
OffsetCov	Matrix of values	Contains the offset covariance matrix

Name	Range	Description
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector, the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).
StepSize	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to true.

Examples   Show an example of quadrature phase shift keying (QPSK) adaptive equalization using a 32-coefficient FIR filter.

```
D = 16;                          % delay
```

```
b  = exp(1j*pi/4)*[-0.7 1];                % Numerator coefficients
a  = [1 -0.7];                             % Denominator coefficients
ntr= 1000;                                 % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D));% Baseband signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));    % Noise signal
r  = filter(b,a,s)+n;                      % Received signal
x  = r(1+D:ntr+D);                         % Input signal (received signal)
d  = s(1:ntr);                             % Desired signal (delayed QPSK signal)
mu = 0.5;                                  % Step size
po = 4;                                    % Projection order
offset = 1.0;                              % Offset for covariance matrix
ha = adaptfilt.bap(32,mu,po,offset);
[y,e] = filter(ha,x,d); subplot(2,2,1);
plot(1:ntr,real([d;y;e]));
title('In-Phase Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

Using the block affine projection object in QPSK results in the plots
shown here.

adaptfilt.blms

Purpose   FIR adaptive filter that uses BLMS

Syntax   ha = adaptfilt.blms(l,step,leakage,blocklen,coeffs,states)

Description   ha = adaptfilt.blms(l,step,leakage,blocklen,coeffs,states)
constructs an FIR block LMS adaptive filter ha, where l is the adaptive
filter length (the number of coefficients or taps) and must be a positive
integer. l defaults to 10.

step is the block LMS step size. You must set step to a nonnegative
scalar. You can use function maxstep to determine a reasonable range
of step size values for the signals being processed. When unspecified,
step defaults to 0.

leakage is the block LMS leakage factor. It must be a scalar between 0
and 1. If you set leakage to be less than one, you implement the leaky
block LMS algorithm. leakage defaults to 1 specifying no leakage in
the adapting algorithm.

blocklen is the block length used. It must be a positive integer and
the signal vectors d and x should be divisible by blocklen. Larger
block lengths result in faster per-sample execution times but with
poor adaptation characteristics. When you choose blocklen such that
blocklen + length(coeffs) is a power of 2, use adaptfilt.blmsfft.
blocklen defaults to l.

coeffs is a vector of initial filter coefficients. it must be a length l
vector. coeffs defaults to length l vector of zeros.

states contains a vector of your initial filter states. It must be a length
l vector and defaults to a length l vector of zeros when you do not
include it in your calling function.

Properties   In the syntax for creating the adaptfilt object, the input options are
properties of the object created. This table lists the properties for the
adjoint LMS object, their default values, and a brief description of the
property.

Property	Default Value	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
States	Vector of elements	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to l
Leakage		Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.
BlockLength	Vector of length l	Size of the blocks of data processed in each iteration

Property	Default Value	Description
StepSize	0.1	Sets the block LMS algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution. Use maxstep to determine the maximum usable step size.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.

Examples   Use an adaptive filter to identify an unknown 32nd-order FIR filter. In this example 500 input samples result in 500 iterations of the adaptation process. You see in the plot that follows the example code that the adaptive filter has determined the coefficients of the unknown system under test.

```
x  = randn(1,500);        % Input to the filter
b  = fir1(31,0.5);        % FIR system to be identified
no  = 0.1*randn(1,500);   % Observation noise signal
d  = filter(b,1,x)+no;    % Desired signal
mu = 0.008;               % Block LMS step size
n  = 5;                   % Block length
ha = adaptfilt.blms(32,mu,1,n);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
```

```
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');
grid on;
```

Based on looking at the figures here, the adaptive filter correctly identified the unknown system after 500 iterations, or fewer. In the lower plot, you see the comparison between the actual filter coefficients and those determined by the adaptation process.

adaptfilt.blmsfft

Purpose

FIR adaptive filter that uses FFT-based BLMS

Syntax

```
ha = adaptfilt.blmsfft(l,step,leakage,blocklen,coeffs,
states)
```

Description

`ha = adaptfilt.blmsfft(l,step,leakage,blocklen,coeffs, states)` constructs an FIR block LMS adaptive filter object `ha` where `l` is the adaptive filter length (the number of coefficients or taps) and must be a positive integer. `l` defaults to 10. `step` is the block LMS step size. It must be a nonnegative scalar. The function `maxstep` may be helpful to determine a reasonable range of step size values for the signals you are processing. `step` defaults to 0.

`leakage` is the block LMS leakage factor. It must also be a scalar between 0 and 1. When `leakage` is less than one, the `adaptfilt.blmsfft` implements a leaky block LMS algorithm. `leakage` defaults to 1 (no leakage). `blocklen` is the block length used. It must be a positive integer such that

```
 blocklen + length(coeffs)
```

is a power of two; otherwise, an `adaptfilt.blms` algorithm is used for adapting. Larger block lengths result in faster execution times, with poor adaptation characteristics as the cost of the speed gained. `blocklen` defaults to `l`. Enter your initial filter coefficients in `coeffs`, a vector of length `l`. When omitted, `coeffs` defaults to a length `l` vector of all zeros. `states` contains a vector of initial filter states; it must be a length `l` vector. `states` defaults to a length `l` vector of all zeros when you omit the `states` argument in the calling syntax.

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object you create. This table lists the properties for the block LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coefficients defaults to length l vector of zeros when you do not provide the argument for input.
States	Vector of elements of length l	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to l
Leakage	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.
BlockLength	Vector of length l	Size of the blocks of data processed in each iteration

Property	Default Value	Description
StepSize	0.1	Sets the block LMS algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution. Use maxstep to determine the maximum usable step size.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.

Examples   Identify an unknown FIR filter with 32 coefficients using 512 iterations of the adapting algorithm.

```
x  = randn(1,512);      % Input to the filter
b  = fir1(31,0.5);      % FIR system to be identified
no = 0.1*randn(1,512);  % Observation noise signal
d  = filter(b,1,x)+no;  % Desired signal
mu = 0.008;             % Step size
n  = 16;                % Block length
ha = adaptfilt.blmsfft(32,mu,1,n);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d(1:500);y(1:500);e(1:500)]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error'); xlabel('Time Index');
```

```
ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('actual','estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

As a result of running the adaptation process, filter object ha now matches the unknown system FIR filter b, based on comparing the filter coefficients derived during adaptation.

adaptfilt.dlms

Purpose   FIR adaptive filter that uses delayed LMS

Syntax   `ha = adaptfilt.dlms(l,step,leakage,delay,errstates,coeffs,`
`...states)`

Description   `ha = adaptfilt.dlms(l,step,leakage,delay,errstates,coeffs,`
`...states)` constructs an FIR delayed LMS adaptive filter `ha`.

Input Arguments

Entries in the following table describe the input arguments for
`adaptfilt.dlms`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	LMS step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.
`leakage`	Your LMS leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, `adaptfilt.lms` implements a leaky LMS algorithm. When you omit the `leakage` property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.
`delay`	Update delay given in time samples. This scalar should be a positive integer — negative delays do not work. `delay` defaults to 1.
`errstates`	Vector of the error states of your adaptive filter. It must have a length equal to the update delay (`delay`) in samples. `errstates` defaults to an appropriate length vector of zeros.

Input Argument	Description
coeffs	Vector of initial filter coefficients. it must be a length l vector. coeffs defaults to length l vector with elements equal to zero.
states	Vector of initial filter states for the adaptive filter. It must be a length l-1 vector. states defaults to a length l-1 vector of zeros.

Properties In the syntax for creating the adaptfilt object, the input options are properties of the object you create. This table lists the properties for the block LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input. LMS FIR filter coefficients. Should be initialized with the initial coefficients for the FIR filter prior to adapting. You need l entries in coeffs.
Delay	1	Specifies the update delay for the adaptive algorithm.

Property	Default Value	Description
ErrorStates	Vector of zeros with the number of elements equal to delay	A vector comprising the error states for the adaptive filter.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
Leakage	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.

Property	Default Value	Description
StepSize	0.1	Sets the LMS algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).

Examples   System identification of a 32-coefficient FIR filter. Refer to the figure that follows to see the results of the adapting filter process.

```
x   = randn(1,500);      % Input to the filter
b   = fir1(31,0.5);      % FIR system to be identified
n   = 0.1*randn(1,500);  % Observation noise signal
d   = filter(b,1,x)+n;   % Desired signal
mu = 0.008;              % LMS step size.
delay = 1;               % Update delay
ha = adaptfilt.dlms(32,mu,1,delay);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

Using a delayed LMS adaptive filter in the process to identify an unknown filter appears to work as planned, as shown in this figure.

Purpose	FIR adaptive filter that uses frequency-domain with bin step size normalization
Syntax	ha = adaptfilt.fdaf(l,step,leakage,delta,lambda,blocklen, offset,...coeffs,states)
Description	ha = adaptfilt.fdaf(l,step,leakage,delta,lambda,blocklen, offset,...coeffs,states) constructs a frequency-domain FIR adaptive filter ha with bin step size normalization. If you omit all the input arguments you create a default object with l = 10 and step = 1.

Input Arguments

Entries in the following table describe the input arguments for adaptfilt.fdaf.

Input Argument	Description
l	Adaptive filter length (the number of coefficients or taps). l must be a positive integer; it defaults to 10 when you omit the argument.
step	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. step defaults to 1.
leakage	Leakage parameter of the adaptive filter. If this parameter is set to a value between zero and one, you implement a leaky FDAF algorithm. leakage defaults to 1 — no leakage provided in the algorithm.
delta	Initial common value of all of the FFT input signal powers. Its initial value should be positive. delta defaults to 1.
lambda	Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the coefficient updates. lambda should lie in the range (0,1]. lambda defaults to 0.9.

Input Argument	Description
blocklen	Block length for the coefficient updates. This must be a positive integer. For faster execution, (blocklen + l) should be a power of two. blocklen defaults to l.
offset	Offset for the normalization terms in the coefficient updates. Use this to avoid divide by zeros or by very small numbers when any of the FFT input signal powers become very small. offset defaults to zero.
coeffs	Initial time-domain coefficients of the adaptive filter. coeff should be a length l vector. The adaptive filter object uses these coefficients to compute the initial frequency-domain filter coefficients via an FFT computed after zero-padding the time-domain vector by the blocklen.
states	The adaptive filter states. states defaults to a zero vector that has length equal to l.

Properties   Since your adaptfilt.fdaf filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.fdaf objects. To show you the properties that apply, this table lists and describes each property for the adaptfilt.fdaf filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation.
AvgFactor	(0, 1]	Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the coefficient updates. Same as the input argument `lambda`.
BlockLength	Any integer	Block length for the coefficient updates. This must be a positive integer. For faster execution, (blocklen + l) should be a power of two. blocklen defaults to l.
FFTCoefficients		Stores the discrete Fourier transform of the filter coefficients in `coeffs`.
FFTStates		States for the FFT operation.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
Leakage		Leakage parameter of the adaptive filter. if this parameter is set to a value between zero and one, you implement a leaky FDAF algorithm. leakage defaults to 1 — no leakage provided in the algorithm.

Name	Range	Description
Offset	Any positive real value	Offset for the normalization terms in the coefficient updates. Use this to avoid dividing by zero or by very small numbers when any of the FFT input signal powers become very small. offset defaults to zero.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
Power		A vector of 2*l elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.
StepSize	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates

Examples   Quadrature Phase Shift Keying (QPSK) adaptive equalization using 1024 iterations of a 32-coefficient FIR filter. After this example code, a figure demonstrates the equalization results.

```
D = 16;                          % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];      % Numerator coefficients of channel
a  = [1 -0.7];                   % Denominator coefficients of channel
ntr= 1024;                       % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D));  %QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));      % Noise signal
r  = filter(b,a,s)+n;            % Received signal
x  = r(1+D:ntr+D);               % Input signal (received signal)
d  = s(1:ntr);                   % Desired signal (delayed QPSK signal)
del = 1;                         % Initial FFT input powers
mu  = 0.1;                       % Step size
lam = 0.9;                       % Averaging factor
ha = adaptfilt.fdaf(32,mu,1,del,lam);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e])); title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('signal value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

`adaptfilt.blmsfft`

Purpose	FIR adaptive filter that uses filtered-x LMS
Syntax	`ha = adaptfilt.filtxlms(l,step,leakage,pathcoeffs,` `pathest,...errstates,pstates,coeffs,states)`
Description	`ha = adaptfilt.filtxlms(l,step,leakage,pathcoeffs,` `pathest,...errstates,pstates,coeffs,states)` constructs an filtered-x LMS adaptive filter `ha`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.filtxlms`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Filtered LMS step size. it must be a nonnegative scalar. `step` defaults to 0.1.
`leakage`	is the filtered-x LMS leakage factor. it must be a scalar between 0 and 1. If it is less than one, a leaky version of `adaptfilt.filtxlms` is implemented. `leakage` defaults to 1 (no leakage).
`pathcoeffs`	is the secondary path filter model. this vector should contain the coefficient values of the secondary path from the output actuator to the error sensor.
`pathest`	is the estimate of the secondary path filter model. `pathest` defaults to the values in `pathcoeffs`.
`fstates`	is a vector of filtered input states of the adaptive filter. `fstates` defaults to a zero vector of length equal to (`l` - 1).

Input Argument	Description
pstates	are the secondary path FIR filter states. it must be a vector of length equal to the (length(pathcoeffs) - 1). pstates defaults to a vector of zeros of appropriate length.
coeffs	is a vector of initial filter coefficients. it must be a length l vector. coeffs defaults to length l vector of zeros.
states	Vector of initial filter states. states defaults to a zero vector of length equal to the larger of (length(pathcoeffs) - 1) and (length(pathest) - 1).

Properties   In the syntax for creating the adaptfilt object, the input options are properties of the object created. This table lists the properties for the adjoint LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.

Property	Default Value	Description
FilteredInputStates	l-1	Vector of filtered input states with length equal to l - 1.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
States	Vector of elements	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2)
SecondaryPathCoeffs	No default	A vector that contains the coefficient values of your secondary path from the output actuator to the error sensor
SecondaryPathEstimate	pathcoeffs values	An estimate of the secondary path filter model
SecondaryPathStates	Vector of size (length (pathcoeffs) -1) with all elements equal to zero.	The states of the secondary path FIR filter — the unknown system
StepSize	0.1	Sets the filtered-x algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the

Property	Default Value	Description
		adaptive filter converges to the filter solution.

Examples   Demonstrate active noise control of a random noise signal over 1000 iterations.

As the figure that follows this code demonstrates, the filtered-x LMS filter successfully controls random noise in this context.

```
x  = randn(1,1000);      % Noise source
g  = fir1(47,0.4);       % FIR primary path system model
n  = 0.1*randn(1,1000);  % Observation noise signal
d  = filter(g,1,x)+n;    % Signal to be cancelled
b  = fir1(31,0.5);       % FIR secondary path system model
mu = 0.008;              % Filtered-X LMS step size
ha = adaptfilt.filtxlms(32,mu,1,b);
[y,e] = filter(ha,x,d); plot(1:1000,d,'b',1:1000,e,'r');
title('Active Noise Control of a Random Noise Signal');
legend('Original','Attenuated');
xlabel('Time Index'); ylabel('Signal Value');  grid on;
```

Purpose   Fast transversal LMS adaptive filter

Syntax   `ha = adaptfilt.ftf(l,lambda,delta,gamma,gstates,coeffs,`
`states)`

Description   `ha = adaptfilt.ftf(l,lambda,delta,gamma,gstates,coeffs,`
`states)` constructs a fast transversal least squares adaptive filter
object `ha`.

Input Arguments

Entries in the following table describe the input arguments for
`adaptfilt.ftf`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`lambda`	RLS forgetting factor. This is a scalar that should lie in the range (1-0.5/l, 1]. `lambda` defaults to 1.
`delta`	Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. `delta` defaults to one.
`gamma`	Conversion factor. `gamma` defaults to one specifying soft-constrained initialization.
`gstates`	States of the Kalman gain updates. `gstates` defaults to a zero vector of length `l`.
`coeffs`	Length `l` vector of initial filter coefficients. `coeffs` defaults to a length `l` vector of zeros.
`states`	Vector of initial filter States. `states` defaults to a zero vector of length (l-1).

Properties

Since your `adaptfilt.ftf` filter is an object, it has properties that define its operating behavior. Note that many of the properties are also input arguments for creating `adaptfilt.ftf` objects. To show you the properties that apply, this table lists and describes each property for the fast transversal least squares filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
BkwdPrediction		Returns the predicted samples generated during adaptation. Refer to [2] in the bibliography for details about linear prediction.
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
ConversionFactor		Conversion factor. Called gamma when it is an input argument, it defaults to the matrix [1 -1] that specifies soft-constrained initialization.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
ForgettingFactor		RLS forgetting factor. This is a scalar that should lie in the range (1-0.5/l, 1]. lambda defaults to 1.

Name	Range	Description
FwdPrediction		Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.
InitFactor		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. delta defaults to one.
KalmanGain		Empty when you construct the object, this gets populated after you run the filter.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).

Examples   System Identification of a 32-coefficient FIR filter by running the identification process for 500 iterations.

```
x   = randn(1,500);    % Input to the filter
b   = fir1(31,0.5);    % FIR system to be identified
n   = 0.1*randn(1,500);% Observation noise signal
d   = filter(b,1,x)+n; % Desired signal
N   = 31;              % Adaptive filter order
lam = 0.99;            % RLS forgetting factor
del = 0.1;             % Soft-constrained initialization factor
ha = adaptfilt.ftf(32,lam,del);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('signal value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated'); grid on;
xlabel('coefficient #'); ylabel('Coefficient Value');
```

For this example of identifying an unknown system, the figure shows that the adaptation process identifies the filter coefficients for the unknown FIR filter within the first 150 iterations.

Purpose   FIR adaptive filter that uses gradient lattice

Syntax   ha = adaptfilt.gal(l,step,leakage,offset,rstep,delta,
lambda,...rcoeffs,coeffs,states)

Description   ha = adaptfilt.gal(l,step,leakage,offset,rstep,delta,
lambda,...rcoeffs,coeffs,states) constructs a gradient adaptive
lattice FIR filter ha.

Input Arguments

Entries in the following table describe the input arguments for
adaptfilt.gal.

Input Argument	Description
l	Length of the joint process filter coefficients. It must be a positive integer and must be equal to the length of the reflection coefficients plus one. l defaults to 10.
step	Joint process step size of the adaptive filter. This scalar should be a value between zero and one. step defaults to 0.
leakage	Leakage factor of the adaptive filter. It must be a scalar between 0 and 1. Setting leakage less than one implements a leaky algorithm to estimate both the reflection and the joint process coefficients. leakage defaults to 1 (no leakage).
offset	Specifies an optional offset for the denominator of the step size normalization term. It must be a scalar greater or equal to zero. A non-zero offset is useful to avoid divide-by-near-zero conditions when the input signal amplitude becomes very small. offset defaults to 1.

Input Argument	Description
rstep	Reflection process step size of the adaptive filter. This scalar should be a value between zero and one. rstep defaults to step.
delta	Initial common value of the forward and backward prediction error powers. It should be a positive value. 0.1 is the default value for delta.
lambda	Specifies the averaging factor used to compute the exponentially windowed forward and backward prediction error powers for the coefficient updates. lambda should lie in the range (0, 1]. lambda defaults to the value (1 - step).
rcoeffs	Vector of initial reflection coefficients. It should be a length (l-1) vector. rcoeffs defaults to a zero vector of length (l-1).
coeffs	Vector of initial joint process filter coefficients. It must be a length l vector. coeffs defaults to a length l vector of zeros.
states	Vector of the backward prediction error states of the adaptive filter. states defaults to a zero vector of length (l-1).

Properties   Since your adaptfilt.gal filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.gal objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
AvgFactor		Specifies the averaging factor used to compute the exponentially-windowed forward and backward prediction error powers for the coefficient updates. Same as the input argument lambda.
BkwdPredErrorPower		Returns the minimum mean-squared prediction error. Refer to [2] in the bibliography for details about linear prediction
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
FwdPredErrorPower		Returns the minimum mean-squared prediction error in the forward direction. Refer to [2] in the bibliography for details about linear prediction.

Name	Range	Description
Leakage	0 to 1	Leakage parameter of the adaptive filter. If this parameter is set to a value between zero and one, you implement a leaky GAL algorithm. leakage defaults to 1 — no leakage provided in the algorithm.
Offset		Offset for the normalization terms in the coefficient updates. Use this to avoid dividing by zero or by very small numbers when input signal amplitude becomes very small. offset defaults to one.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
ReflectionCoeffs		Coefficients determined for the reflection portion of the filter during adaptation.

Name	Range	Description
ReflectionCoeffsStep		Size of the steps used to determine the reflection coefficients.
States	Vector of elements	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (1 + projectord - 2).
StepSize	0 to 1	Specifies the step size taken between filter coefficient updates

Examples

Perform a Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient adaptive filter over 1000 iterations.

```
D  = 16;                    % Number of delay samples
b  = exp(1j*pi/4)*[-0.7 1];  % Numerator coefficients
a  = [1 -0.7];              % Denominator coefficients
ntr= 1000;                  % Number of iterations
s  = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D)); % QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));    % Noise signal
r  = filter(b,a,s)+n;       % Received signal
x  = r(1+D:ntr+D);          % Input signal (received signal)
d  = s(1:ntr);              % Desired signal (delayed QPSK signal)
L = 32;                     % filter length
mu = 0.007;                 % Step size
ha = adaptfilt.gal(L,mu);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
```

```
subplot(2,2,3); plot(x(ntr-100:ntr),'.');  axis([-3 3 -3 3]);
title('Received Signal Scatter Plot');  axis('square');
xlabel('Real[x]'); ylabel('Imag[x]');  grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');  grid on;
```

To see the results, look at this figure.

Purpose	FIR adaptive filter that uses householder (RLS)
Syntax	ha = adaptfilt.hrls(l,lambda,sqrtinvcov,coeffs,states)

Description   ha = adaptfilt.hrls(l,lambda,sqrtinvcov,coeffs,states)
constructs an FIR householder RLS adaptive filter ha.

Input Arguments

Entries in the following table describe the input arguments for
adaptfilt.hrls.

Input Argument	Description
l	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. l defaults to 10.
lambda	RLS forgetting factor. This is a scalar and should lie in the range (0, 1]. lambda defaults to 1 meaning the adaptation process retains infinite memory.
sqrtinvcov	Square-root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
coeffs	Vector of initial filter coefficients. It must be a length l vector. coeffs defaults to being a length l vector of zeros.
states	Vector of initial filter states. It must be a length l-1 vector. states defaults to a length l-1 vector of zeros.

Properties   Since your adaptfilt.hrls filter is an object, it has properties that
define its behavior in operation. Note that many of the properties are
also input arguments for creating adaptfilt.hrls objects. To show you
the properties that apply, this table lists and describes each property
for the affine projection filter object.

adaptfilt.hrls

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
ForgettingFactor	Scalar	RLS forgetting factor. This is a scalar and should lie in the range (0, 1]. Same as input argument lambda. It defaults to 1 meaning the adaptation process retains infinite memory.
KalmanGain	Vector of size (l,1)	Empty when you construct the object, this gets populated after you run the filter.

Name	Range	Description
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. Defaults to false.
SqrtInvCov	Matrix of doubles	Square root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l - 1).

Examples   Use 500 iterations of an adaptive filter object to identify a 32-coefficient FIR filter system. Both the example code and the resulting figure show the successful filter identification through adaptive filter processing.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
G0 = sqrt(10)*eye(32); % Initial sqrt correlation matrix inverse
lam = 0.99;            % RLS forgetting factor
ha = adaptfilt.hrls(32,lam,G0);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
```

```
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated'); grid on;
 xlabel('Coefficient #'); ylabel('Coefficient Value');
```

See Also   adaptfilt.hswrls | adaptfilt.qrdrls | adaptfilt.rls

Purpose   FIR adaptive filter that uses householder sliding window RLS

Syntax   ha = adaptfilt.hswrls(l,lambda,sqrtinvcov,swblocklen,
                 dstates,coeffs,states)

Description ha = adaptfilt.hswrls(l,lambda,sqrtinvcov,swblocklen,
                 dstates,coeffs,states) constructs an FIR householder sliding
                 window recursive-least-square adaptive filter ha.

Input Arguments

Entries in the following table describe the input arguments for
adaptfilt.hswrls.

Input Argument	Description
l	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. l defaults to 10.
lambda	Recursive least square (RLS) forgetting factor. This is a scalar and should lie in the range (0, 1]. lambda defaults to 1 meaning the adaptation process retains infinite memory.
sqrtinvcov	Square-root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
swblocklen	Block length of the sliding window. This integer must be at least as large as the filter length. swblocklen defaults to 16.
dstates	Desired signal states of the adaptive filter. dstates defaults to a zero vector with length equal to (swblocklen - 1).

Input Argument	Description
coeffs	Vector of initial filter coefficients. It must be a length l vector. coeffs defaults to being a length l vector of zeros.
states	Vector of initial filter states. It must be a length (l + swblocklen - 2) vector. states defaults to a length (l + swblocklen -2) vector of zeros.

Properties

Since your adaptfilt.hswrls filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.hswrls objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
DesiredSignalStates	Vector	Desired signal states of the adaptive filter. dstates defaults to a zero vector with length equal to (swblocklen - 1).

Name	Range	Description
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
ForgettingFactor	Scalar	Root-least-square (RLS) forgetting factor. This is a scalar and should lie in the range (0, 1]. Same as input argument `lambda`. It defaults to 1 meaning the adaptation process retains infinite memory.
KalmanGain	(1,1) vector	Empty when you construct the object, this gets populated after you run the filter.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. Defaults to `false`.
SqrtInvCov	1-by-1 Matrix	Square-root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.

Name	Range	Description
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).
SwBlockLength	Integer	Block length of the sliding window. This integer must be at least as large as the filter length. swblocklen defaults to 16.

Examples   System Identification of a 32-coefficient FIR filter.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
G0 = sqrt(10)*eye(32); % Initial sqrt correlation matrix inverse
lam = 0.99;            % RLS forgetting factor
N  = 64;               % block length
ha = adaptfilt.hswrls(32,lam,G0,N);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

In the pair of plots shown in the figure you see the comparison of the desired and actual output for the adapting filter and the coefficients of both filters, the unknown and the adapted.

adaptfilt.lms

Purpose   FIR adaptive filter that uses LMS

Syntax   `ha = adaptfilt.lms(l,step,leakage,coeffs,states)`

Description   `ha = adaptfilt.lms(l,step,leakage,coeffs,states)` constructs an FIR LMS adaptive filter object `ha`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.lms`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	LMS step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.1.
`leakage`	Your LMS leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, `adaptfilt.lms` implements a leaky LMS algorithm. When you omit the `leakage` property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.
`coeffs`	Vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector with elements equal to zero.
`states`	Vector of initial filter states for the adaptive filter. It must be a length l-1 vector. `states` defaults to a length l-1 vector of zeros.

Properties   In the syntax for creating the adaptfilt object, the input options are properties of the object created. This table lists the properties for the adaptfilt.lms object, their default values, and a brief description of the property.

Property	Range	Property Description
Algorithm	None	Reports the adaptive filter algorithm the object uses during adaptation
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to a length l vector of zeros when you do not provide the vector as an input argument.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
Leakage	0 to 1	LMS leakage factor. It must be a scalar between zero and one. When it is less than one, a leaky NLMS algorithm results. leakage defaults to 1 (no leakage).

Property	Range	Property Description
PersistentMemory	false or true	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to false.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l - 1).
StepSize	0 to 1	LMS step size. It must be a scalar between zero and one. Setting this step size value to one provides the fastest convergence. step defaults to 0.1.

Examples
Use 500 iterations of an adapting filter system to identify and unknown 32nd-order FIR filter.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
mu = 0.008;            % LMS step size.
ha = adaptfilt.lms(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
```

```
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');  grid on;
```

Using LMS filters in an adaptive filter architecture is a time honored means for identifying an unknown filter. By running the example code provided you can demonstrate one process to identify an unknown FIR filter.

adaptfilt.lsl

Purpose
Least squares lattice adaptive filter

Syntax
`ha = adaptfilt.lsl(l,lambda,delta,coeffs,states)`

Description
`ha = adaptfilt.lsl(l,lambda,delta,coeffs,states)` constructs a least squares lattice adaptive filter ha.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.lsl`.

Input Argument	Description
l	Length of the joint process filter coefficients. It must be a positive integer and must be equal to the length of the prediction coefficients plus one. L defaults to 10.
lambda	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. lambda defaults to 1. lambda = 1 denotes infinite memory while adapting to find the new filter.
delta	Soft-constrained initialization factor in the least squares lattice algorithm. It should be positive. delta defaults to 1.
coeffs	Vector of initial joint process filter coefficients. It must be a length l vector. coeffs defaults to a length l vector of all zeros.
states	Vector of the backward prediction error states of the adaptive filter. states defaults to a length l vector of all zeros, specifying soft-constrained initialization for the algorithm.

Properties
Since your `adaptfilt.lsl` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are

also input arguments for creating `adaptfilt.lsl` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation.
BkwdPrediction		Returns the predicted samples generated during adaptation. Refer to [2] in the bibliography for details about linear prediction.
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
ForgettingFactor		Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting forgetting factor = 1 denotes infinite memory while adapting to find the new filter. Note that this is the lambda input argument.

Name	Range	Description
FwdPrediction		Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.
InitFactor		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. delta defaults to one.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to l.

Examples   Demonstrate Quadrature Phase Shift Keying (QPSK) adaptive
equalization using a 32-coefficient adaptive filter running for 1000
iterations. After you review the example code, the figure shows the
results of running the example to use QPSK adaptive equalization with
a 32nd-order FIR filter. The error between the in-phase and quadrature
components, as shown by the errors plotted in the upper plots, falls to
near zero. Also, the equalized signal shows the clear quadrature nature.

```
D  = 16;                       % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];    % Numerator coefficients of channel
a  = [1 -0.7];                 % Denominator coefficients of channel
ntr= 1000;                     % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D)); % QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));     % Noise signal
r  = filter(b,a,s)+n;          % Received signal
x  = r(1+D:ntr+D);             % Input signal (received signal)
d  = s(1:ntr);                 % Desired signal (delayed QPSK signal)
lam = 0.995;                   % Forgetting factor
del = 1;                       % initialization factor
ha = adaptfilt.lsl(32,lam,del);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');  axis([-3 3 -3 3]);
title('Received Signal Scatter Plot');  axis('square');
xlabel('Real[x]'); ylabel('Imag[x]');  grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.');  axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot');  grid on;
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');
```

adaptfilt.lsl

adaptfilt.rls

Purpose   Normalized least mean squares adaptive filter

Syntax   `ha = adaptfilt.nlms(l,step,leakage,offset,coeffs,states)`

Description `ha = adaptfilt.nlms(l,step,leakage,offset,coeffs,states)`
constructs a normalized least-mean squares (NLMS) FIR adaptive filter
object named `ha`.

Input Arguments

Entries in the following table describe the input arguments for
`adaptfilt.nlms`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	NLMS step size. It must be a scalar between 0 and 2. Setting this step size value to one provides the fastest convergence. `step` defaults to 1.
`leakage`	NLMS leakage factor. It must be a scalar between zero and one. When it is less than one, a leaky NLMS algorithm results. `leakage` defaults to 1 (no leakage).
`offset`	Specifies an optional offset for the denominator of the step size normalization term. You must specify offset to be a scalar greater than or equal to zero. Nonzero offsets can help avoid a divide-by-near-zero condition that causes errors. Use this to avoid dividing by zero (or by very small numbers) when the square of the input data norm becomes very small (when the input signal amplitude becomes very small). When you omit it, `offset` defaults to zero.

Input Argument	Description
coeffs	Vector composed of your initial filter coefficients. Enter a length l vector. coeffs defaults to a vector of zeros with length equal to the filter order.
states	Your initial adaptive filter states appear in the states vector. It must be a vector of length l-1. states defaults to a length l-1 vector with zeros for all of the elements.

Properties

In the syntax for creating the adaptfilt object, the input options are properties of the object you create. This table lists the properties for normalized LMS objects, their default values, and a brief description of the property.

Property	Range	Property Description
Algorithm	None	Reports the adaptive filter algorithm the object uses during adaptation
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps

Property	Range	Property Description
Leakage	0 to 1	NLMS leakage factor. It must be a scalar between zero and one. When it is less than one, a leaky NLMS algorithm results. leakage defaults to 1 (no leakage).
Offset	0 or greater	Specifies an optional offset for the denominator of the step size normalization term. You must specify offset to be a scalar greater than or equal to zero. Nonzero offsets can help avoid a divide-by-near-zero condition that causes errors. Use this to avoid dividing by zero (or by very small numbers) when the square of the input data norm becomes very small (when the input signal amplitude becomes very small). When you omit it, offset defaults to zero.
PersistentMemory	false or true	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to false.

Property	Range	Property Description
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l - 1).
StepSize	0 to 1	NLMS step size. It must be a scalar between zero and one. Setting this step size value to one provides the fastest convergence. step defaults to one.

Examples   To help you compare this algorithm's performance to other LMS-based algorithms, such as BLMS or LMS, this example demonstrates the NLMS adaptive filter in use to identify the coefficients of an unknown FIR filter of order equal to 32 — an example used in other adaptive filter examples.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
mu = 1;                % NLMS step size
offset = 50;           % NLMS offset
ha = adaptfilt.nlms(32,mu,1,offset);
[y,e] = filter(ha,x,d);
subplot(2,1,1);
plot(1:500,[d;y;e]);
legend('Desired','Output','Error');
title('System Identification of FIR Filter');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2);
stem([b', ha.coefficients']);
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

As you see from the figure, the nlms variant again closely matches the actual filter coefficients in the unknown FIR filter.

adaptfilt.pbfdaf

Purpose   Partitioned block frequency-domain FIR adaptive filter

Syntax   `ha = adaptfilt.pbfdaf(l,step,leakage,delta,lambda,blocklen,`
                                `offset,coeffs,states)`

Description   `ha = adaptfilt.pbfdaf(l,step,leakage,delta,lambda,blocklen,`
`offset,coeffs,states)` constructs a partitioned block
frequency-domain FIR adaptive filter `ha` that uses bin step size
normalization during adaptation.

Input Arguments

Entries in the following table describe the input arguments for
`adaptfilt.pbfdaf`.

Input Argument	Description
l	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. L defaults to 10.
step	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. `step` defaults to 1.
leakage	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. `leakage` defaults to 1— no leakage.
delta	Initial common value of all of the FFT input signal powers. Its initial value should be positive. `delta` defaults to 1.
lambda	Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. `lambda` should lie in the range (0,1]. `lambda` defaults to 0.9.

Input Argument	Description
blocklen	Block length for the coefficient updates. This must be a positive integer such that (l/blocklen) is also an integer. For faster execution, blocklen should be a power of two. blocklen defaults to two.
offset	Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small. offset defaults to zero.
coeffs	Initial time-domain coefficients of the adaptive filter. It should be a vector of length l. The PBFDAF algorithm uses these coefficients to compute the initial frequency-domain filter coefficient matrix via FFTs.
states	Specifies the filter initial conditions. states defaults to a zero vector of length l.

Properties   Since your adaptfilt.pbfdaf filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.pbfdaf objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation.
AvgFactor		Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. AvgFactor should lie in the range (0,1]. AvgFactor defaults to 0.9. Called lambda as an input argument.
BlockLength		Block length for the coefficient updates. This must be a positive integer such that (1/blocklen) is also an integer. For faster execution, blocklen should be a power of two. blocklen defaults to two.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
FFTCoefficients		Stores the discrete Fourier transform of the filter coefficients in coeffs.
FFTStates		States for the FFT operation.

Name	Range	Description
Leakage	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. leakage defaults to 1 — no leakage.
Offset		Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small. offset defaults to zero.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.

Name	Range	Description
Power		A vector of 2*1 elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.
StepSize	0 to 1	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. step defaults to 1.

Examples

An example of Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient FIR filter.

```
D   = 16;                         % Number of samples of delay
b   = exp(1j*pi/4)*[-0.7 1];      % Numerator coefficients of channel
a   = [1 -0.7];                   % Denominator coefficients of channel
ntr = 1000;                       % Number of iterations
s   = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D)); % Baseband QPSK signal
n   = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));     % Noise signal
r   = filter(b,a,s)+n;    % Received signal
x   = r(1+D:ntr+D);               % Input signal (received signal)
d   = s(1:ntr);                   % Desired signal (delayed QPSK signal)
del = 1;                          % Initial FFT input powers
mu  = 0.1;                        % Step size
lam = 0.9;                        % Averaging factor
N   = 8;                          % Block size
ha = adaptfilt.pbfdaf(32,mu,1,del,lam,N);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
```

```
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');  axis([-3 3 -3 3]);
 title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]');  grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.');  axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');  grid on;subplot(2,2,4); plot(y(ntr
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');  grid on;
```

In the figure shown, the four subplots provide the details of the results of the QPSK process used in the equalization for this example.

adaptfilt.pbfdaf

See Also adaptfilt.fdaf | adaptfilt.pbufdaf | adaptfilt.blmsfft

Purpose   Partitioned block unconstrained frequency-domain adaptive filter

Syntax   ha = adaptfilt.pbufdaf(l,step,leakage,delta,lambda,
blocklen,...offset,coeffs,states)

Description   ha = adaptfilt.pbufdaf(l,step,leakage,delta,lambda,
blocklen,...offset,coeffs,states) constructs a partitioned block
unconstrained frequency-domain FIR adaptive filter ha with bin step
size normalization.

Input Arguments

Entries in the following table describe the input arguments for
adaptfilt.pbufdaf.

Input Argument	Description
l	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. L defaults to 10.
step	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. step defaults to 1.
leakage	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. leakage defaults to 1 — no leakage.
delta	Initial common value of all of the FFT input signal powers. Its initial value should be positive. delta defaults to 1.
lambda	Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. lambda should lie in the range (0,1]. lambda defaults to 0.9.

Input Argument	Description
blocklen	Block length for the coefficient updates. This must be a positive integer such that (1/blocklen) is also an integer. For faster execution, blocklen should be a power of two. blocklen defaults to two.
offset	Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small. offset defaults to zero.
coeffs	Initial time-domain coefficients of the adaptive filter. It should be a vector of length l. The PBFDAF algorithm uses these coefficients to compute the initial frequency-domain filter coefficient matrix via FFTs.
states	Specifies the filter initial conditions. states defaults to a zero vector of length l.

Properties   Since your adaptfilt.pbufdaf filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.pbufdaf objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
AvgFactor		Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. AvgFactor should lie in the range (0,1]. AvgFactor defaults to 0.9. Called lambda as an input argument.
BlockLength		Block length for the coefficient updates. This must be a positive integer such that (l/blocklen) is also an integer. For faster execution, blocklen should be a power of two. blocklen defaults to two.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
FFTCoefficients		Stores the discrete Fourier transform of the filter coefficients in coeffs.
FFTStates		States for the FFT operation.

Name	Range	Description
Leakage	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. leakage defaults to 1 — no leakage.
Offset		Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small.voffset defaults to zero.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.

Name	Range	Description
Power	2*1 element vector	A vector of 2*1 elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.
StepSize	0 to 1	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. step defaults to 1.

Examples   Demonstrating Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient FIR filter. To perform the equalization, this example runs for 1000 iterations.

```
D  = 16;       % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1]; % Numerator coefficients of channel
a  = [1 -0.7];              % Denominator coefficients of channel
ntr= 1000;                 % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D)); % Baseband QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D)); % Noise signal
r  = filter(b,a,s)+n;       % Received signal
x  = r(1+D:ntr+D);          % Input signal (received signal)
d  = s(1:ntr);              % Desired signal (delayed QPSK signal)
del = 1;                    % Initial FFT input powers
mu  = 0.1;                  % Step size
lam = 0.9;                  % Averaging factor
N   = 8;                    % Block size
ha = adaptfilt.pbufdaf(32,mu,1,del,lam,N);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
```

adaptfilt.pbufdaf

```
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

You can compare this algorithm to another, such as the `pbfdaf` version. Use the same example of QPSK adaptation. The following figure shows the results.

adaptfilt.qrdlsl

Purpose	QR-decomposition-based least-squares lattice adaptive filter
Syntax	ha = adaptfilt.qrdlsl(l,lambda,delta,coeffs,states)
Description	ha = adaptfilt.qrdlsl(l,lambda,delta,coeffs,states) returns a QR-decomposition-based least squares lattice adaptive filter ha.

Input Arguments

Entries in the following table describe the input arguments for adaptfilt.qrdlsl.

Input Argument	Description
l	Length of the joint process filter coefficients. It must be a positive integer and must be equal to the length of the prediction coefficients plus one. L defaults to 10.
lambda	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. lambda defaults to 1. lambda = 1 denotes infinite memory while adapting to find the new filter.
delta	Soft-constrained initialization factor in the least squares lattice algorithm. It should be positive. delta defaults to 1.
coeffs	Vector of initial joint process filter coefficients. It must be a length l vector. coeffs defaults to a length l vector of all zeros.
states	Vector of the angle normalized backward prediction error states of the adaptive filter

Properties   Since your adaptfilt.qrdlsl filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.qrdlsl objects. To

show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
BkwdPrediction		Returns the predicted samples generated during adaptation. Refer to [2] in the bibliography for details about linear prediction.
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
ForgettingFactor		Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting forgetting factor = 1 denotes infinite memory while adapting to find the new filter. Note that this is the lambda input argument.

adaptfilt.qrdlsl

Name	Range	Description
FwdPrediction		Returns the predicted samples generated during adaptation in the forward direction. Refer to [2] in the bibliography for details about linear prediction.
InitFactor		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. delta defaults to one.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to l -1

Examples   Implement Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient adaptive filter. To see the results of

the equalization process in this example, look at the figure that follows the example code.

```
D  = 16;                          % Number of samples of delay
b = exp(1j*pi/4)*[-0.7 1];      % Numerator coefficients of channel
a  = [1 -0.7];                    % Denominator coefficients of channel
ntr= 1000;                        % Number of iterations
s = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D)); % Baseband  QPSK signal
n = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));   % Noise signal
r  = filter(b,a,s)+n;      % Received signal
x = r(1+D:ntr+D);          % Input signal (received signal)
d = s(1:ntr);              % Desired signal (delayed QPSK signal)
lam = 0.995;               % Forgetting factor
del = 1;                   % Soft-constrained initialization factor
ha = adaptfilt.qrdlsl(32,lam,del);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

`adaptfilt.lsl`

Purpose   FIR adaptive filter that uses QR-decomposition-based RLS

Syntax   ha = adaptfilt.qrdrls(l,lambda,sqrtcov,coeffs,states)

Description   ha = adaptfilt.qrdrls(l,lambda,sqrtcov,coeffs,states)
                  constructs an FIR QR-decomposition-based recursive-least squares
                  (RLS) adaptive filter object ha.

Input Arguments

Entries in the following table describe the input arguments for
adaptfilt.qrdrls.

Input Argument	Description
l	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. l defaults to 10.
lambda	RLS forgetting factor. This is a scalar and should lie within the range (0, 1]. lambda defaults to 1.
sqrtcov	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.
coeffs	Vector of initial filter coefficients. It must be a length l vector. coeffs defaults to length l vector whose elements are zeros.
states	Vector of initial filter states. It must be a length l-1 vector. states defaults to a length l-1 vector of zeros.

Properties   Since your adaptfilt.qrdrls filter is an object, it has properties that
                  define its behavior in operation. Note that many of the properties
                  are also input arguments for creating adaptfilt.qrdrls objects. To
                  show you the properties that apply, this table lists and describes each
                  property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	Vector of length l	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
ForgettingFactor	Scalar	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting forgetting factor = 1 denotes infinite memory while adapting to find the new filter. Note that this is the lambda input argument.

Name	Range	Description
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
SqrtCov	Square matrix with each dimension equal to the filter length l	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.
States	Vector of elements	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).

Examples   System Identification of a 32-coefficient FIR filter (500 iterations).

```
x  = randn(1,500);      % Input to the filter
b  = fir1(31,0.5);      % FIR system to be identified
n  = 0.1*randn(1,500);  % Observation noise signal
d  = filter(b,1,x)+n;   % Desired signal
G0 = sqrt(.1)*eye(32);  % Initial sqrt correlation matrix
```

```
lam = 0.99;              % RLS forgetting factor
ha = adaptfilt.qrdrls(32,lam,G0);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

Using this variant of the RLS algorithm successfully identifies the unknown FIR filter, as shown here.

adaptfilt.rls | adaptfilt.hrls | adaptfilt.hswrls | adaptfilt.swrls

Purpose   Recursive least-squares FIR adaptive filter

Syntax   ha = adaptfilt.rls(l,lambda,invcov,coeffs,states)

Description ha = adaptfilt.rls(l,lambda,invcov,coeffs,states) constructs
                 an FIR direct form RLS adaptive filter ha.

Input Arguments

Entries in the following table describe the input arguments for
adaptfilt.rls.

Input Argument	Description
l	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. l defaults to 10.
lambda	RLS forgetting factor. This is a scalar and should lie in the range (0, 1]. lambda defaults to 1.
invcov	Inverse of the input signal covariance matrix. For best performance, you should initialize this matrix to be a positive definite matrix.
coeffs	Vector of initial filter coefficients. it must be a length l vector. coeffs defaults to length l vector with elements equal to zero.
states	Vector of initial filter states for the adaptive filter. It must be a length l-1 vector. states defaults to a length l-1 vector of zeros.

Properties Since your adaptfilt.rls filter is an object, it has properties that
                define its behavior in operation. Note that many of the properties are
                also input arguments for creating adaptfilt.rls objects. To show you
                the properties that apply, this table lists and describes each property
                for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation.
Coefficients	Vector containing l elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps. Remember that filter length is filter order + 1.
ForgettingFactor	Scalar	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting forgetting factor = 1 denotes infinite memory while adapting to find the new filter. Note that this is the lambda input argument.
InvCov	Matrix of size l-by-l	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.
KalmanGain	Vector of size (l,1)	Empty when you construct the object, this gets populated after you run the filter.

Name	Range	Description
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. Defaults to false.
States	Double array	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (1 + projectord - 2).

Examples   System Identification of a 32-coefficient FIR filter over 500 adaptation iterations.

```
x  = randn(1,500);    % Input to the filter
b  = fir1(31,0.5);    % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n; % Desired signal
P0 = 10*eye(32); % Initial sqrt correlation matrix inverse
lam = 0.99;           % RLS forgetting factor
ha = adaptfilt.rls(32,lam,P0);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient valUe');  grid on;
```

adaptfilt.rls

In this example of adaptive filtering using the RLS algorithm to update the filter coefficients for each iteration, the figure shown reveals the fidelity of the derived filter after adaptation.

See Also   adaptfilt.hrls | adaptfilt.hswrls | adaptfilt.qrdrls

Purpose   Sign-data FIR adaptive filter

Syntax   `ha = adaptfilt.sd(l,step,leakage,coeffs,states)`

Description `ha = adaptfilt.sd(l,step,leakage,coeffs,states)` constructs an
FIR sign-data adaptive filter object `ha`.

Input Arguments

Entries in the following table describe the input arguments for
`adaptfilt.sd`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	SD step size. It must be a nonnegative scalar. `step` defaults to 0.1
`leakage`	Your SD leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, `adaptfilt.sd` implements a leaky SD algorithm. When you omit the `leakage` property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.
`coeffs`	Vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector with elements equal to zero.
`states`	Vector of initial filter states for the adaptive filter. It must be a length `l`-1 vector. `states` defaults to a length `l`-1 vector of zeros.

Properties   In the syntax for creating the `adaptfilt` object, the input options are
properties of the object you create. This table lists the properties for

sign-data objects, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	Sign-data	Defines the adaptive filter algorithm the object uses during adaptation.
Coefficients	zeros(1,l)	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input. Should be initialized with the initial coefficients for the FIR filter prior to adapting. You need l entries in coefficients.
FilterLength	10	Reports the length of the filter, the number of coefficients or taps.
Leakage	0	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1. Defaults to 0.

Property	Default Value	Description
PersistentMemory	false or true	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to false.
States	zeros(l-1,1)	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l - 1).
StepSize	0.1	Sets the SD algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.

Examples   Adaptive line enhancement using a 32-coefficient FIR filter to perform the enhancement. This example runs for 5000 iterations, as you see in property iter.

```
d  = 1;                      % Number of samples of delay
ntr= 5000;                   % Number of iterations
v  = sin(2*pi*0.05*[1:ntr+d]); % Sinusoidal signal
n  = randn(1,ntr+d);         % Noise signal
```

```
x  = v(1:ntr)+n(1:ntr);          % Input signal
d  = v(1+d:ntr+d)+n(1+d:ntr+d);  % Desired signal
mu = 0.0001;                     % Sign-data step size.
ha = adaptfilt.sd(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:ntr,[d;y;v(1:end-1)]);
axis([ntr-100 ntr -3 3]);
title('Adaptive Line Enhancement of a Noisy Sinusoidal Signal');
legend('Observed','Enhanced','Original');
 xlabel('Time Index'); ylabel('Signal Value');
[pxx,om] = pwelch(x(ntr-1000:ntr));
 pyy = pwelch(y(ntr-1000:ntr));
subplot(2,1,2);
plot(om/pi,10*log10([pxx/max(pxx),pyy/max(pyy)]));
axis([0 1 -60 20]); legend('Observed','Enhanced');
xlabel('Normalized Frequency (\times \pi rad/sample)');
ylabel('Power Spectral Density'); grid on;
```

Each of the variants — sign-data, sign-error, and sign-sign — uses the same example. You can compare the results by viewing the figure shown for each adaptive filter method — adaptfilt.sd, adaptfilt.se, and adaptfilt.ss.

adaptfilt.se

Purpose FIR adaptive filter that uses sign-error algorithm

Syntax `ha = adaptfilt.se(l,step,leakage,coeffs,states)`

Description `ha = adaptfilt.se(l,step,leakage,coeffs,states)` constructs an FIR sign-error adaptive filter `ha`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.se`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	SE step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.1
`leakage`	Your SE leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, `adaptfilt.se` implements a leaky SE algorithm. When you omit the `leakage` property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.
`coeffs`	Vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector with elements equal to zero.
`states`	Vector of initial filter states for the adaptive filter. It must be a length `l-1` vector. `states` defaults to a length `l-1` vector of zeros.

Properties   In the syntax for creating the adaptfilt object, the input options are properties of the object you create. This table lists the properties for the sign-error SD object, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	Sign-error	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	zeros(1,l)	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input. Should be initialized with the initial coefficients for the FIR filter prior to adapting.
FilterLength	10	Reports the length of the filter, the number of coefficients or taps
Leakage	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1. Defaults to one if omitted.

Property	Default Value	Description
PersistentMemory	false or true	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to false.
States	zeros(l-1,1)	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l -1).
StepSize	0.1	Sets the SE algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.

Use inspect(ha) to view or change the object properties graphically using the MATLAB Property Inspector.

Examples   Adaptive line enhancement using a 32-coefficient FIR filter running over 5000 iterations.

```
d = 1;                      % Number of samples of delay
ntr= 5000;                  % Number of iterations
v = sin(2*pi*0.05*(1:ntr+d));    % Sinusoidal signal
n = randn(1,ntr+d);         % Noise signal
```

```
x = v(1:ntr)+n(1:ntr);        % Input signal --(delayed desired signal)
d = v(1+d:ntr+d)+n(1+d:ntr+d);  % Desired signal
mu = 0.0001;                    % Sign-error step size
ha = adaptfilt.se(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1);
plot(1:ntr,[d;y;v(1:end-1)]);
axis([ntr-100 ntr -3 3]);
title('Adaptive Line Enhancement of Noisy Sinusoid');
legend('Observed','Enhanced','Original');
xlabel('Time Index'); ylabel('Signal Value');
HWelch = spectrum.welch;
InputPsd = psd(HWelch,x(ntr-1000:ntr));
OutputPsd = psd(HWelch,y(ntr-1000:ntr));
CompPsdEst = [InputPsd.Data/max(InputPsd.Data), OutputPsd.Data/max(OutputPsd.Data)];
subplot(2,1,2); plot(InputPsd.Frequencies/pi,10*log10(CompPsdEst));
axis([0 1 -60 20]); legend('Observed','Enhanced');
xlabel('Normalized Frequency (\times \pi rad/sample)');
ylabel('Power Spectral Density'); grid on;
```

Compare the figure shown here to the ones for `adaptfilt.sd` and
`adaptfilt.ss` to see how the variants perform on the same example.

See Also   adaptfilt.sd | adaptfilt.ss | adaptfilt.lms

Purpose   FIR adaptive filter that uses sign-sign algorithm

Syntax   ha = adaptfilt.ss(l,step,leakage,coeffs,states)

Description   ha = adaptfilt.ss(l,step,leakage,coeffs,states) constructs an
FIR sign-error adaptive filter ha.

Input Arguments

Entries in the following table describe the input arguments for
adaptfilt.ss.

Input Argument	Description
l	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. l defaults to 10.
step	SS step size. It must be a nonnegative scalar. step defaults to 0.1.
leakage	Your SS leakage factor. It must be a scalar between 0 and 1. When leakage is less than one, adaptfilt.lms implements a leaky SS algorithm. When you omit the leakage property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.
coeffs	Vector of initial filter coefficients. it must be a length l vector. coeffs defaults to length l vector with elements equal to zero.
states	Vector of initial filter states for the adaptive filter. It must be a length l -1 vector. states defaults to a length l-1 vector of zeros.

adaptfilt.ss can be called for a block of data, when x and d are vectors,
or in "sample by sample mode" using a For-loop with the method filter:

```
for n = 1:length(x)
```

```
ha = adaptfilt.ss(25,0.9);
[y(n),e(n)] = filter(ha,(x(n),d(n),s));
end
```

Properties

In the syntax for creating the adaptfilt object, most of the input options are properties of the object you create. This table lists the properties for sign-sign objects, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	Sign-sign	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	zeros(1,l)	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input. Should be initialized with the initial coefficients for the FIR filter prior to adapting.
FilterLength	10	Reports the length of the filter, the number of coefficients or taps

Property	Default Value	Description
Leakage	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1. 1 is the default value.
PersistentMemory	false or true	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to false.
States	zeros(l-1,1)	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l-1).
StepSize	0.1	Sets the SE algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.

Examples   Demonstrating adaptive line enhancement using a 32-coefficient FIR
filter provides a good introduction to the sign-sign algorithm.

```
d = 1;                          % Number of samples of delay
ntr= 5000;                      % Number of iterations
v = sin(2*pi*0.05*(1:ntr+d));    % Sinusoidal signal
n = randn(1,ntr+d);          % Noise signal
x = v(1:ntr)+n(1:ntr);        % Input signal --(delayed desired signal)
d = v(1+d:ntr+d)+n(1+d:ntr+d);  % Desired signal
mu = 0.0001;                      % Sign-error step size
ha = adaptfilt.ss(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1);
plot(1:ntr,[d;y;v(1:end-1)]);
axis([ntr-100 ntr -3 3]);
title('Adaptive Line Enhancement of Noisy Sinusoid');
legend('Observed','Enhanced','Original');
xlabel('Time Index'); ylabel('Signal Value');
HWelch = spectrum.welch;
InputPsd = psd(HWelch,x(ntr-1000:ntr));
OutputPsd = psd(HWelch,y(ntr-1000:ntr));
CompPsdEst = [InputPsd.Data/max(InputPsd.Data), OutputPsd.Data/max(OutputPsd.Data)];
subplot(2,1,2); plot(InputPsd.Frequencies/pi,10*log10(CompPsdEst));
axis([0 1 -60 20]); legend('Observed','Enhanced');
xlabel('Normalized Frequency (\times \pi rad/sample)');
ylabel('Power Spectral Density'); grid on;
```

This example is the same as the ones used for the sign-data and
sign-error examples. Comparing the figures shown for each of the
others lets you assess the performance of each for the same task.

adaptfilt.swftf

Purpose   FIR adaptive filter that uses sliding window fast transversal least squares

Syntax   ha = adaptfilt.swftf(l,delta,blocklen,gamma,gstates,
                dstates,...coeffs,states)

Description ha = adaptfilt.swftf(l,delta,blocklen,gamma,gstates,
                dstates,...coeffs,states) constructs a sliding window fast
                transversal least squares adaptive filter ha.

Input Arguments

Entries in the following table describe the input arguments for
adaptfilt.swftf.

Input Argument	Description
l	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. l defaults to 10.
delta	Soft-constrained initialization factor. This scalar should be positive and sufficiently large to maintain stability. delta defaults to 1.
blocklen	Block length of the sliding window. This must be an integer at least as large as the filter length l, which is the default value.
gamma	Conversion factor. gamma defaults to the matrix [1 -1] that specifies soft-constrained initialization.
gstates	States of the Kalman gain updates. gstates defaults to a zero vector of length (l + blocklen - 1).
dstates	Desired signal states of the adaptive filter. dstates defaults to a zero vector of length equal to (blocklen - 1). For a default object, dstates is (l-1).

Input Argument	Description
coeffs	Vector of initial filter coefficients. It must be a length l vector. coeffs defaults to length l vector of all zeros.
states	Vector of initial filter states. states defaults to a zero vector of length equal to (l + blocklen - 2).

Properties

Since your adaptfilt.swftf filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.swftf objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
BkwdPredictions		Returns the predicted samples generated during adaptation. Refer to [2] in the bibliography for details about linear prediction.
BlockLength		Block length of the sliding window. This must be an integer at least as large as the filter length l, which is the default value.
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.

Name	Range	Description
ConversionFactor		Conversion factor. Called gamma when it is an input argument, it defaults to the matrix [1 -1] that specifies soft-constrained initialization.
DesiredSignal States		Desired signal states of the adaptive filter. dstates defaults to a zero vector with length equal to (blocklen - 1).
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
FwdPrediction		Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.
InitFactor		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. delta defaults to one.
KalmanGain		Empty when you construct the object, this gets populated after you run the filter.
KalmanGainStates		Contains the states of the Kalman gains for the adaptive algorithm. Initialized to a vector of double data type entries.

Name	Range	Description
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (1 + projectord - 2).

Examples

Over 500 iterations, perform a system identification of a 32-coefficient FIR filter.

```
x = randn(1,500);      % Input to the filter
b = fir1(31,0.5);      % FIR system to be identified
n = 0.1*randn(1,500);  % Observation noise signal
d = filter(b,1,x)+n;   % Desired signal
L = 32;                % Adaptive filter length
del = 0.1;             % Soft-constrained initialization factor
N = 64;                % block length
ha = adaptfilt.swftf(L,del,N);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
```

adaptfilt.swftf

```
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');  grid on;
```

Review the figure for the results of the example. When you evaluate the example you should get the same results, within the differences in the random noise signal you use.

Purpose   FIR adaptive filter that uses window recursive least squares (RLS)

Syntax   ha = adaptfilt.swrls(l,lambda,invcov,swblocklen,
                dstates,...coeffs,states)

Description ha = adaptfilt.swrls(l,lambda,invcov,swblocklen,
                dstates,...coeffs,states) constructs an FIR sliding window RLS
                adaptive filter ha.

Input Arguments

Entries in the following table describe the input arguments for
adaptfilt.swrls.

Input Argument	Description
l	Adaptive filter length (the number of coefficients or taps). It must be a positive integer. l defaults to 10.
lambda	RLS forgetting factor. This is a scalar and should lie within the range (0, 1]. lambda defaults to 1.
invcov	Inverse of the input signal covariance matrix. You should initialize invcov to a positive definite matrix.
swblocklen	Block length of the sliding window. This integer must be at least as large as the filter length. swblocklen defaults to 16.
dstates	Desired signal states of the adaptive filter. dstates defaults to a zero vector with length equal to (swblocklen - 1).
coeffs	Vector of initial filter coefficients. It must be a length l vector. coeffs defaults to length l vector of all zeros.
states	Vector of initial filter states. states defaults to a zero vector of length equal to (l + swblocklen - 2).

adaptfilt.swrls

Properties   Since your `adaptfilt.swrls` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.swrls` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	Any vector of l elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. `coeffs` defaults to length l vector of zeros when you do not provide the argument for input.
DesiredSignalStates	Vector	Desired signal states of the adaptive filter. `dstates` defaults to a zero vector with length equal to (`swblocklen` - 1).
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps

Name	Range	Description
ForgettingFactor	Scalar	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting forgetting factor = 1 denotes infinite memory while adapting to find the new filter. Note that this is the lambda input argument.
InvCov	Matrix	Square matrix with each dimension equal to the filter length l.
KalmanGain	Vector with dimensions (l,1)	Empty when you construct the object, this gets populated after you run the filter.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. Defaults to false.

adaptfilt.swrls

Name	Range	Description
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (1 + swblocklen - 2)
SwBlockLength	Integer	Block length of the sliding window. This integer must be at least as large as the filter length. swblocklen defaults to 16.

Examples   System Identification of a 32-coefficient FIR filter. Use 500 iterations to adapt to the unknown filter. After the example code, you see a figure that plots the results of the running the code.

```
x  = randn(1,500);      % Input to the filter
b  = fir1(31,0.5);      % FIR system to be identified
n  = 0.1*randn(1,500);  % Observation noise signal
d  = filter(b,1,x)+n;   % Desired signal
P0 = 10*eye(32);        % Initial correlation matrix inverse
lam = 0.99;             % RLS forgetting factor
N  = 64;                % Block length
ha = adaptfilt.swrls(32,lam,P0,N);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
 title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');  grid on;
```

In the figure you see clearly that the adaptive filter process successfully identified the coefficients of the unknown FIR filter. You knew it

had to or many things that you take for granted, such as modems on computers, would not work.

adaptfilt.tdafdct

Purpose   Adaptive filter that uses discrete cosine transform

Syntax   ha = adaptfilt.tdafdct(l,step,leakage,offset,delta,lambda,
                 coeffs,states)

Description ha = adaptfilt.tdafdct(l,step,leakage,offset,delta,lambda,
                 coeffs,states) constructs a transform-domain adaptive filter ha object
                 that uses the discrete cosine transform to perform filter adaptation.

Input Arguments

Entries in the following table describe the input arguments for
adaptfilt.tdafdct.

Input Argument	Description
l	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. l defaults to 10.
step	Adaptive filter step size. It must be a nonnegative scalar. You can use maxstep to determine a reasonable range of step size values for the signals being processed. step defaults to 0.
leakage	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the TDAFDCT algorithm. leakage defaults to 1 — no leakage.
offset	Offset for the normalization terms in the coefficient updates. You can use this argument to avoid dividing by zero or by very small numbers when any of the FFT input signal powers become very small. offset defaults to zero.

Input Argument	Description
delta	Initial common value of all of the transform domain powers. Its initial value should be positive. delta defaults to 5.
lambda	Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. lambda should lie between zero and one. For default filter objects, lambda equals (1 - step).
coeffs	Initial time domain coefficients of the adaptive filter. Set it to be a length l vector. coeffs defaults to a zero vector of length l.
states	Initial conditions of the adaptive filter. states defaults to a zero vector with length equal to (l - 1).

Properties   Since your adaptfilt.tdafdct filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.tdafdct objects. To show you the properties that apply, this table lists and describes each property for the transform domain filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation.
AvgFactor		Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. AvgFactor

Name	Range	Description
		should lie between zero and one. For default filter objects, `AvgFactor` equals (1 - `step`). `lambda` is the input argument that represent `AvgFactor`.
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. `coeffs` defaults to length l vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
Leakage	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the TDAFDFT algorithm. `leakage` defaults to 1 — no leakage.
Offset		Offset for the normalization terms in the coefficient updates. You can use this argument to avoid dividing by zeros or by very small numbers when any of the FFT input signal powers become very small. `offset` defaults to zero.

Name	Range	Description
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
Power	2*l element vector	A vector of 2*l elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).
StepSize	0 to 1	Step size. It must be a nonnegative scalar, greater than zero and less than or equal to 1. You can use maxstep to determine a reasonable range of step size values for the signals being processed. step defaults to 0.

For checking the values of properties for an adaptive filter object, use get(ha) or enter the object name, without a trailing semicolon, at the MATLAB prompt.

Examples   Using 1000 iterations, perform a Quadrature Phase Shift Keying
(QPSK) adaptive equalization using a 32-coefficient FIR filter.

```
D  = 16;                         % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];       % Numerator coefficients of channel
a  = [1 -0.7];                   % Denominator coefficients of channel
ntr= 1000;                       % Number of iterations
s  = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D)); %QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D)); % Noise signal
r  = filter(b,a,s)+n;            % Received signal
x  = r(1+D:ntr+D);               % Input signal (received signal)
d  = s(1:ntr);                   % Desired signal (delayed QPSK signal)
L  = 32;                         % filter length
mu = 0.01;                       % Step size
ha = adaptfilt.tdafdct(L,mu);
[y,e] = filter(ha,x,d);
subplot(2,2,1);
plot(1:ntr,real([d;y;e])); title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); grid on;
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');
```

Compare the plots shown in this figure to those in the other time
domain filter variations. The comparison should help you select and
understand how the variants differ.

adaptfilt.tdafdft

Purpose   Adaptive filter that uses discrete Fourier transform

Syntax   ha = adaptfilt.tdafdft(l,step,leakage,offset,
                 delta,lambda,...coeffs,states)

Description ha = adaptfilt.tdafdft(l,step,leakage,offset,
                 delta,lambda,...coeffs,states) constructs a transform-domain
                 adaptive filter object ha using a discrete Fourier transform.

Input Arguments

Entries in the following table describe the input arguments for
adaptfilt.tdafdft.

Input Argument	Description
l	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. l defaults to 10.
step	Adaptive filter step size. It must be a nonnegative scalar. You can use maxstep to determine a reasonable range of step size values for the signals being processed. step defaults to 0.
leakage	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the TDAFDFT algorithm. leakage defaults to 1 — no leakage.
offset	Offset for the normalization terms in the coefficient updates. You can use this argument to avoid dividing by zeros or by very small numbers when any of the FFT input signal powers become very small. offset defaults to zero.

Input Argument	Description
delta	Initial common value of all of the transform domain powers. Its initial value should be positive. delta defaults to 5.
lambda	Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. lambda should lie between zero and one. For default filter objects, LAMBDA equals (1 - step).
coeffs	Initial time domain coefficients of the adaptive filter. Set it to be a length l vector. coeffs defaults to a zero vector of length l.
states	Initial conditions of the adaptive filter. states defaults to a zero vector with length equal to (l - 1).

Properties   Since your adaptfilt.tdafdft filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.tdafdft objects. To show you the properties that apply, this table lists and describes each property for the transform domain filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
AvgFactor		Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. AvgFactor

adaptfilt.tdafdft

Name	Range	Description
		should lie between zero and one. For default filter objects, AvgFactor equals (1 - step). lambda is the input argument that represent AvgFactor.
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
Leakage	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the TDAFDFT algorithm. leakage defaults to 1 — no leakage.
Offset		Offset for the normalization terms in the coefficient updates. You can use this argument to avoid dividing by zeros or by very small numbers when any of the FFT input signal powers become very small. offset defaults to zero.

Name	Range	Description
PersistentMemory	false or true	Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
Power	2*l element vector	A vector of 2*l elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).
StepSize	0 to 1	Step size. It must be a nonnegative scalar, greater than zero and less than or equal to 1. step defaults to 0.

Examples   Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient FIR filter (1000 iterations).

```
D = 16;                        % Number of samples of delay
b = exp(1j*pi/4)*[-0.7 1];      % Numerator coefficients of channel
a = [1 -0.7];                  % Denominator coefficients of channel
ntr= 1000;                     % Number of iterations
```

```
s  = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D));% Baseband QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));      % Noise signal
r  = filter(b,a,s)+n;           % Received signal
x  = r(1+D:ntr+D);              % Input signal (received signal)
d  = s(1:ntr);                  % Desired signal (delayed QPSK signal)
L  = 32;                        % filter length
mu = 0.01;                      % Step size
ha = adaptfilt.tdafdft(L,mu);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');
 axis([-3 3 -3 3]); title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

All of the time domain adaptive filter reference pages use this QPSK example. By comparing the results for each variation you get an idea of the differences in the way each one performs.

This figure demonstrates the results of running the example code shown.

adaptfilt.ufdaf

Purpose	FIR adaptive filter that uses unconstrained frequency-domain with quantized step size normalization
Syntax	`ha = adaptfilt.ufdaf(l,step,leakage,delta,lambda,blocklen, offset,coeffs,states)`
Description	`ha = adaptfilt.ufdaf(l,step,leakage,delta,lambda,blocklen, offset,coeffs,states)`

constructs an unconstrained frequency-domain FIR adaptive filter `ha` with quantized step size normalization.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.ufdaf`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Adaptive filter step size. It must be a nonnegative scalar. `step` defaults to 0.
`leakage`	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the UFDAF algorithm. `leakage` defaults to 1 — no leakage.
`delta`	Initial common value of all of the FFT input signal powers. the initial value of delta should be positive, and it defaults to 1.

Input Argument	Description
lambda	Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the coefficient updates. lambda should lie in the range (0,1]. For default UFDAF filter objects, lambda defaults to 0.9.
blocklen	Block length for the coefficient updates. This must be a positive integer. For faster execution, (blocklen l) should be a power of two. blocklen defaults to l.
offset	Offset for the normalization terms in the coefficient updates. This can help you avoid divide by zero conditions, or divide by very small numbers conditions, when any of the FFT input signal powers become very small. Default value is zero.
coeffs	Initial time-domain coefficients of the adaptive filter. It should be a length l vector. The filter object uses these coefficients to compute the initial frequency-domain filter coefficients via an FFT computed after zero-padding the time-domain vector by blocklen.
states	Adaptive filter states. states defaults to a zero vector with length equal to l.

Properties   Since your adaptfilt.ufdaf filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.ufdaf objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
AvgFactor		Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the coefficient updates. AvgFactor should lie in the range (0,1]. For default UFDAF filter objects, AvgFactor defaults to 0.9. Note that AvgFactor and lambda are the same thing — lambda is an input argument and AvgFactor a property of the object.
BlockLength		Block length for the coefficient updates. This must be a positive integer. For faster execution, (blocklen + 1) should be a power of two. blocklen defaults to 1.
FFTCoefficients		Stores the discrete Fourier transform of the filter coefficients in coeffs.
FFTStates		States for the FFT operation.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps

Name	Range	Description
Leakage	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the UFDAF algorithm. leakage defaults to 1 — no leakage.
Offset		Offset for the normalization terms in the coefficient updates. This can help you avoid divide by zero conditions, or divide by very small numbers conditions, when any of the FFT input signal powers become very small. Default value is zero.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.

Name	Range	Description
Power	2*1 element vector	A vector of 2*1 elements, each initialized with the value `delta` from the input arguments. As you filter data, `Power` gets updated by the filter process.
StepSize	0 to 1	Adaptive filter step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.

Examples

Show an example of Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient adaptive filter. For fidelity, use 1024 iterations. The figure that follows the code provides the information you need to assess the performance of the equalization process.

```
D  = 16;                        % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];      % Numerator coefficients of channel
a  = [1 -0.7];                   % Denominator coefficients of channel
ntr= 1024;                       % Number of iterations
s = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D));% Baseband QPSK signal
n = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));
r = filter(b,a,s)+n;% Received signal
x = r(1+D:ntr+D);   % Input signal (received signal)
d = s(1:ntr);        % Desired signal (delayed QPSK signal)
del = 1;            %Initial FFT input powers
mu  = 0.1;           % Step size
lam = 0.9;           % Averaging factor
ha = adaptfilt.ufdaf(32,mu,1,del,lam);
[y,e] = filter(ha,x,d);
subplot(2,2,1);  plot(1:1000,real([d(1:1000);y(1:1000);e(1:1000)])));
```

```
title('In-Phase Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

allpassbpc2bpc

Purpose   Allpass filter for complex bandpass transformation

Syntax   [AllpassNum,AllpassDen] = allpassbpc2bpc(Wo,Wt)

Description   [AllpassNum,AllpassDen] = allpassbpc2bpc(Wo,Wt) returns the
numerator, AllpassNum, and the denominator, AllpassDen, of the
first-order allpass mapping filter for performing a complex bandpass
to complex bandpass frequency transformation. This transformation
effectively places two features of an original filter, located at frequencies
W_{o1} and W_{o2}, at the required target frequency locations W_{t1} and W_{t2}.
It is assumed that W_{t2} is greater than W_{t1}. In most of the cases the
features selected for the transformation are the band edges of the
filter passbands. In general it is possible to select any feature; e.g.,
the stopband edge, the DC, the deep minimum in the stopband, or
other ones.

Relative positions of other features of an original filter do not change in
the target filter. This means that it is possible to select two features of
an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still
precede F_2 after the transformation. However, the distance between F_1
and F_2 will not be the same before and after the transformation.

This transformation can also be used for transforming other types of
filters; e.g., complex notch filters or resonators can be repositioned at
two distinct desired frequencies at any place around the unit circle.
This is very attractive for adaptive systems.

Examples   Design the allpass mapping filter changing the complex bandpass filter
with the band edges at W_{o1}=0.2 and W_{o2}=0.4 to the new band edges
of W_{t1}=0.3 and W_{t2}=0.6. Find the frequency response of the allpass
mapping filter:

```
Wo = [0.2, 0.4]; Wt = [0.3, 0.6];
[AllpassNum, AllpassDen] = allpassbpc2bpc(Wo, Wt);
[ha, f] = freqz(AllpassNum, AllpassDen,'whole');
plot(f/pi,angle(ha)/pi, Wt, Wo, 'ro'); title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

Arguments

Variable	Description
Wo	Frequency values to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

allpasslp2bp

Purpose   Allpass filter for lowpass to bandpass transformation

Syntax   `[AllpassNum,AllpassDen] = allpasslp2bp(Wo,Wt)`

Description   `[AllpassNum,AllpassDen] = allpasslp2bp(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the second-order allpass mapping filter for performing a real lowpass to real bandpass frequency transformation. This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. This transformation implements the "DC mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of W_t.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and repositioned at two distinct desired frequencies.

Examples   Design the allpass mapping filter changing the lowpass filter with cutoff frequency at W_o=0.5 to the real–valued bandpass filter with cutoff frequencies at W_{t1}0.25 and W_{t2}=0.375.

Compute the frequency response and plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = [0.25, 0.375];
[AllpassNum, AllpassDen] = allpasslp2bp(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter

allpasslp2bp

Variable	Description
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Purpose   Allpass filter for lowpass to complex bandpass transformation

Syntax   [AllpassNum,AllpassDen] = allpasslp2bpc(Wo,Wt)

Description [AllpassNum,AllpassDen] = allpasslp2bpc(Wo,Wt) returns the
numerator, AllpassNum, and the denominator, AllpassDen, of the
first-order allpass mapping filter for performing a real lowpass to
complex bandpass frequency transformation. This transformation
effectively places one feature of an original filter, located at frequency
-W_o, at the required target frequency location, W_{t1}, and the second
feature, originally at +W_o, at the new location, W_{t2}. It is assumed that
W_{t2} is greater than W_{t1}.

Relative positions of other features of an original filter do not change in
the target filter. This means that it is possible to select two features of
an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still
precede F_2 after the transformation. However, the distance between F_1
and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation
is not restricted only to the cutoff frequency of an original lowpass filter.
In general it is possible to select any feature; e.g., the stopband edge,
the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming
other types of filters; e.g., real notch filters or resonators can be doubled
and positioned at two distinct desired frequencies at any place around
the unit circle forming a pair of complex notches/resonators. This
transformation can be used for designing bandpass filters for radio
receivers from the high-quality prototype lowpass filter.

Examples   Design the allpass mapping filter changing the real lowpass filter with
the cutoff frequency of W_o=0.5 into a complex bandpass filter with band
edges of W_{t1}=0.2 and W_{t2}=0.4 precisely defined. Calculate the frequency
response of the mapping filter in the full range:

```
Wo = 0.5; Wt = [0.2,0.4];
[AllpassNum, AllpassDen] = allpasslp2bpc(Wo, Wt);
```

allpasslp2bpc

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

See Also   iirlp2bpc | zpklp2bpc

Purpose   Allpass filter for lowpass to bandstop transformation

Syntax   [AllpassNum,AllpassDen] = allpasslp2bs(Wo,Wt)

Description [AllpassNum,AllpassDen] = allpasslp2bs(Wo,Wt) returns the
numerator, AllpassNum, and the denominator, AllpassDen, of the
second-order allpass mapping filter for performing a real lowpass to real
bandstop frequency transformation. This transformation effectively
places one feature of an original filter, located at frequency $-W_o$, at
the required target frequency location, W_{t1}, and the second feature,
originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater
than W_{t1}. This transformation implements the "Nyquist Mobility," which
means that the DC feature stays at DC, but the Nyquist feature moves
to a location dependent on the selection of W_o and W_t.

Relative positions of other features of an original filter change in the
target filter. This means that it is possible to select two features
of an original filter, F_1 and F_2, with F_1 preceding F_2. After the
transformation feature F_2 will precede F_1 in the target filter. However,
the distance between F_1 and F_2 will not be the same before and after
the transformation.

Choice of the feature subject to the lowpass to bandstop transformation
is not restricted only to the cutoff frequency of an original lowpass filter.
In general it is possible to select any feature; e.g., the stopband edge,
the DC, the deep minimum in the stopband, or other ones.

Examples   Design the allpass filter changing the lowpass filter with cutoff
frequency at W_o=0.5 to the real bandstop filter with cutoff frequencies
at W_{t1}=0.25 and W_{t2}=0.375:

```
Wo = 0.5; Wt = [0.25, 0.375];
[AllpassNum, AllpassDen] = allpasslp2bs(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

In the figure, you find the mapping filter function as determined by the example. Note the response is normalized to π:

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

allpasslp2bsc

Purpose   Allpass filter for lowpass to complex bandstop transformation

Syntax   `[AllpassNum,AllpassDen] = allpasslp2bsc(Wo,Wt)`

Description   `[AllpassNum,AllpassDen] = allpasslp2bsc(Wo,Wt)` returns the
                  numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the
                  first-order allpass mapping filter for performing a real lowpass to
                  complex bandstop frequency transformation. This transformation
                  effectively places one feature of an original filter, located at frequency
                  $-W_o$, at the required target frequency location, W_{t1}, and the second
                  feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed
                  that W_{t2} is greater than W_{t1}. Additionally the transformation swaps
                  passbands with stopbands in the target filter.

                  Relative positions of other features of an original filter do not change in
                  the target filter. This means that it is possible to select two features of
                  an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still
                  precede F_2 after the transformation. However, the distance between F_1
                  and F_2 will not be the same before and after the transformation.

                  Choice of the feature subject to the lowpass to bandstop transformation
                  is not restricted only to the cutoff frequency of an original lowpass filter.
                  In general it is possible to select any feature; e.g., the stopband edge,
                  the DC, the deep minimum in the stopband, or other ones.

                  Lowpass to bandpass transformation can also be used for transforming
                  other types of filters; e.g., real notch filters or resonators can be doubled
                  and positioned at two distinct desired frequencies at any place around
                  the unit circle forming a pair of complex notches/resonators. This
                  transformation can be used for designing bandstop filters for band
                  attenuation or frequency equalizers, from the high-quality prototype
                  lowpass filter.

Examples   Design the allpass filter changing the real lowpass filter with the cutoff
                  frequency of W_o=`0.5` into a complex bandstop filter with band edges of
                  W_{t1}=`0.2` and W_{t2}=`0.4` precisely defined:

                  `Wo = 0.5; Wt = [0.2,0.4];`

```
[AllpassNum, AllpassDen] = allpasslp2bsc(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

See Also   iirlp2bsc | zpklp2bsc

allpasslp2hp

Purpose	Allpass filter for lowpass to highpass transformation
Syntax	`[AllpassNum,AllpassDen] = allpasslp2hp(Wo,Wt)`

Description   `[AllpassNum,AllpassDen] = allpasslp2hp(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a real lowpass to real highpass frequency transformation. This transformation effectively places one feature of an original filter, located originally at frequency, W_o, at the required target frequency location, W_t, at the same time rotating the whole frequency response by half of the sampling frequency. Result is that the DC and Nyquist features swap places.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. After the transformation feature F_2 will precede F_1 in the target filter. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to highpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband.

Lowpass to highpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way by using the lowpass to highpass transformation.

Examples   Design the allpass filter changing the lowpass filter to the highpass filter with its cutoff frequency moved from W_o=0.5 to W_t=0.25.

Plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpasslp2hp(Wo, Wt);
```

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt');
ylabel('Old Frequency, Wo');
```

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

allpasslp2lp

Purpose   Allpass filter for lowpass to lowpass transformation

Syntax   `[AllpassNum,AllpassDen] = allpasslp2lp(Wo,Wt)`

Description   `[AllpassNum,AllpassDen] = allpasslp2lp(Wo,Wt)` returns the
numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the
first-order allpass mapping filter for performing a real lowpass to real
lowpass frequency transformation. This transformation effectively
places one feature of an original filter, located originally at frequency
W_o, at the required target frequency location, W_t.

Relative positions of other features of an original filter do not change in
the target filter. This means that it is possible to select two features of
an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still
precede F_2 after the transformation. However, the distance between F_1
and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to lowpass transformation
is not restricted to the cutoff frequency of an original lowpass filter. In
general it is possible to select any feature; e.g., the stopband edge, the
DC, the deep minimum in the stopband and so on.

Lowpass to lowpass transformation can also be used for transforming
other types of filters; e.g., notch filters or resonators can change
their position in a simple way by applying the lowpass to lowpass
transformation.

Examples   Design the allpass filter changing the lowpass filter cutoff frequency
originally at W_o=0.5 to W_t=0.25. Plot the phase response normalized to
π, which is in effect the mapping function $W_o(W_t)$. Please note that the
transformation works in the same way for both positive and negative
frequencies:

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpasslp2lp(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
```

```
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

As shown in the figure, `allpasslp2lp` generates a mapping function that converts your prototype lowpass filter to a target lowpass filter with different passband specifications.

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter

allpasslp2lp

Variable	Description
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Purpose　　Allpass filter for lowpass to M-band transformation

Syntax　　　[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt)
[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt,Pass)

Description　[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the Mth-order allpass mapping filter for performing a real lowpass to real multipassband frequency transformation. Parameter M is the number of times an original feature is replicated in the target filter. This transformation effectively places one feature of an original filter, located at frequency W_o, at the required target frequency locations, $W_{t1},...,W_{tM}$. By default the DC feature is kept at its original location.

[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt,Pass) allows you to specify an additional parameter, Pass, which chooses between using the "DC Mobility" and the "Nyquist Mobility." In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is movable.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations without redesigning them. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

allpasslp2mb

Examples   Design the allpass filter changing the real lowpass filter with the cutoff frequency of W_o=0.5 into a real multiband filter with band edges of W_t=[1:2:9]/10 precisely defined. Plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = [1:2:9]/10;
[AllpassNum, AllpassDen] = allpasslp2mb(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
Pass	Choice ('pass'/'stop') of passband/stopband at DC, 'pass' being the default
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

allpasslp2mbc

Purpose   Allpass filter for lowpass to complex M-band transformation

Syntax   [AllpassNum,AllpassDen] = allpasslp2mbc(Wo,Wt)

Description   [AllpassNum,AllpassDen] = allpasslp2mbc(Wo,Wt) returns the
                   numerator, AllpassNum, and the denominator, AllpassDen, of the
                   Mth-order allpass mapping filter for performing a real lowpass to
                   complex multipassband frequency transformation. Parameter M is the
                   number of times an original feature is replicated in the target filter.
                   This transformation effectively places one feature of an original filter,
                   located at frequency W_o, at the required target frequency locations,
                   $W_{t1},...,W_{tM}$.

                   Relative positions of other features of an original filter do not change in
                   the target filter. This means that it is possible to select two features of
                   an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still
                   precede F_2 after the transformation. However, the distance between F_1
                   and F_2 will not be the same before and after the transformation.

                   Choice of the feature subject to this transformation is not restricted
                   to the cutoff frequency of an original lowpass filter. In general it is
                   possible to select any feature; e.g., the stopband edge, the DC, the deep
                   minimum in the stopband, or other ones.

                   This transformation can also be used for transforming other types of
                   filters; e.g., notch filters or resonators can be easily replicated at a
                   number of required frequency locations without the need to design them
                   again. A good application would be an adaptive tone cancellation circuit
                   reacting to the changing number and location of tones.

Examples   Design the allpass filter changing the real lowpass filter with the cutoff
                   frequency of Wo=0.5 into a complex multiband filter with band edges of
                   Wt=[-3+1:2:9]/10 precisely defined:

                   ```
                   Wo = 0.5; Wt = [-3+1:2:9]/10;
                   [AllpassNum, AllpassDen] = allpasslp2mbc(Wo, Wt);
                   ```

                   Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
plot(f/pi, angle(h)/pi, Wt, Wo, 'ro');
 title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

In this example, the resulting mapping function converts real filters to multiband complex filters.

allpasslp2mbc

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

See Also   iirlp2mbc | zpklp2mbc

Purpose   Allpass filter for lowpass to complex N-point transformation

Syntax   `[AllpassNum,AllpassDen] = allpasslp2xc(Wo,Wt)`

Description `[AllpassNum,AllpassDen] = allpasslp2xc(Wo,Wt)` returns the
numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the
`Nth`-order allpass mapping filter, where `N` is the allpass filter order,
for performing a real lowpass to complex multipoint frequency
transformation. Parameter `N` also specifies the number of replicas of the
prototype filter created around the unit circle after the transformation.
This transformation effectively places `N` features of the, original filter
located at frequencies $W_{o1},...,W_{oN}$, at the required target frequency
locations, $W_{t1},...,W_{tM}$.

Relative positions of other features of an original filter are the same
in the target filter for the Nyquist mobility and are reversed for the
DC mobility. For the Nyquist mobility this means that it is possible to
select two features of an original filter, F_1 and F_2, with F_1 preceding F_2.
Feature F_1 will still precede F_2 after the transformation. However,
the distance between F_1 and F_2 will not be the same before and after
the transformation. For DC mobility feature F_2 will precede F_1 after
the transformation.

Choice of the feature subject to this transformation is not restricted
to the cutoff frequency of an original lowpass filter. In general it is
possible to select any feature; e.g., the stopband edge, the DC, the deep
minimum in the stopband, or other ones. The only condition is that the
features must be selected in such a way that when creating `N` bands
around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of
filters; e.g., notch filters or resonators can be easily replicated at a
number of required frequency locations. A good application would be
an adaptive tone cancellation circuit reacting to the changing number
and location of tones.

Examples   Design the allpass filter moving four features of an original complex
filter given in `W`o to the new independent frequency locations `W`t. Please

note that the transformation creates N replicas of an original filter around the unit circle, where N is the order of the allpass mapping filter:

```
Wo = [-0.2, 0.3, -0.7, 0.4]; Wt = [0.3, 0.5, 0.7, 0.9];
[AllpassNum, AllpassDen] = allpasslp2xc(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Arguments

Variable	Description
Wo	Frequency values to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

See Also   iirlp2xc | zpklp2xc

Purpose   Allpass filter for lowpass to N-point transformation

Syntax   [AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt)
                  [AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt,Pass)

Description   [AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt) returns the
                  numerator, AllpassNum, and the denominator, AllpassDen, of the
                  Nth-order allpass mapping filter, where N is the allpass filter order, for
                  performing a real lowpass to real multipoint frequency transformation.
                  Parameter N also specifies the number of replicas of the prototype
                  filter created around the unit circle after the transformation. This
                  transformation effectively places N features of an original filter, located
                  at frequencies $W_{o1},...,W_{oN}$, at the required target frequency locations,
                  $W_{t1},...,W_{tM}$. By default the DC feature is kept at its original location.

                  [AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt,Pass) allows
                  you to specify an additional parameter, Pass, which chooses between
                  using the "DC Mobility" and the "Nyquist Mobility." In the first case
                  the Nyquist feature stays at its original location and the DC feature is
                  free to move. In the second case the DC feature is kept at an original
                  frequency and the Nyquist feature is movable.

                  Relative positions of other features of an original filter are the same
                  in the target filter for the Nyquist mobility and are reversed for the
                  DC mobility. For the Nyquist mobility this means that it is possible to
                  select two features of an original filter, F_1 and F_2, with F_1 preceding F_2.
                  Feature F_1 will still precede F_2 after the transformation. However,
                  the distance between F_1 and F_2 will not be the same before and after
                  the transformation. For DC mobility feature F_2 will precede F_1 after
                  the transformation.

                  Choice of the feature subject to this transformation is not restricted
                  to the cutoff frequency of an original lowpass filter. In general it is
                  possible to select any feature; e.g., the stopband edge, the DC, the deep
                  minimum in the stopband, or other ones. The only condition is that the
                  features must be selected in such a way that when creating N bands
                  around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations without the need of designing them again. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Arguments

Variable	Description
Wo	Frequency values to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
Pass	Choice ('pass'/'stop') of passband/stopband at DC, 'pass' being the default
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

allpassrateup

Purpose	Allpass filter for integer upsample transformation

Syntax   `[AllpassNum,AllpassDen] = allpassrateup(N)`

Description   `[AllpassNum,AllpassDen] = allpassrateup(N)` returns the
numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the
Nth-order allpass mapping filter for performing the rateup frequency
transformation, which creates `N` equal replicas of the prototype filter
frequency response.

Relative positions of other features of an original filter do not change in
the target filter. This means that it is possible to select two features of
an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still
precede F_2 after the transformation. However, the distance between F_1
and F_2 will not be the same before and after the transformation.

Examples   Design the allpass filter creating the effect of upsampling the digital
filter four times:

Choose any feature from an original filter, say at W_o=`0.2`:

```
N = 4;
Wo = 0.2; Wt = Wo/N + 2*[0:N-1]/N;
[AllpassNum, AllpassDen] = allpassrateup(N);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Arguments

Variable	Description
N	Frequency replication ratio (upsampling ratio)
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

See Also   `iirrateup` | `zpkrateup`

7-187

allpassshift

Purpose   Allpass filter for real shift transformation

Syntax   `[AllpassNum,AllpassDen] = allpassshift(Wo,Wt)`

Description   `[AllpassNum,AllpassDen] = allpassshift(Wo,Wt)` returns the
numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the
second-order allpass mapping filter for performing a real frequency shift
transformation. This transformation places one selected feature of an
original filter, located at frequency W_o, at the required target frequency
location, W_t. This transformation implements the "DC mobility," which
means that the Nyquist feature stays at Nyquist, but the DC feature
moves to a location dependent on the selection of W_o and W_t.

Relative positions of other features of an original filter do not change in
the target filter. This means that it is possible to select two features of
an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still
precede F_2 after the transformation. However, the distance between F_1
and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the real shift transformation is not
restricted to the cutoff frequency of an original lowpass filter. In general
it is possible to select any feature; e.g., the stopband edge, the DC, the
deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types
of filters; e.g., notch filters or resonators can be moved to a different
frequency by applying a shift transformation. In such a way you can
avoid designing the filter from the beginning.

Examples   Design the allpass filter precisely shifting one feature of the lowpass
filter originally at W_o=`0.5` to the new frequencies of W_t=`0.25`:

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpassshift(Wo, Wt);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

allpassshift

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

See Also   iirshift | zpkshift

Purpose   Allpass filter for complex shift transformation

Syntax   [AllpassNum,AllpassDen] = allpassshiftc(Wo,Wt)
                   [AllpassNum,AllpassDen] = allpassshiftc(0,0.5)
                   [AllpassNum,AllpassDen] = allpassshiftc(0,-0.5)

Description   [AllpassNum,AllpassDen] = allpassshiftc(Wo,Wt) returns the
                   numerator, AllpassNum, and denominator, AllpassDen, vectors of the
                   allpass mapping filter for performing a complex frequency shift of the
                   frequency response of the digital filter by an arbitrary amount.

                   [AllpassNum,AllpassDen] = allpassshiftc(0,0.5) calculates
                   the allpass filter for doing the Hilbert transformation, a 90 degree
                   counterclockwise rotation of an original filter in the frequency domain.

                   [AllpassNum,AllpassDen] = allpassshiftc(0,-0.5) calculates the
                   allpass filter for doing an inverse Hilbert transformation, i.e. a 90
                   degree clockwise rotation of an original filter in the frequency domain.

Examples   Design the allpass filter precisely rotating the whole filter by the
                  amount defined by the location of the selected feature from an original
                  filter, W_o=0.5, and its required position in the target filter, W_t=0.25:

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpassshiftc(Wo, Wt);
```

                  Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter

allpassshiftc

Variable	Description
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

Purpose   Automatic dynamic range scaling

Syntax   autoscale(hd,x)
                hnew = autoscale(hd,x)

Description autoscale(hd,x) provides dynamic range scaling for each node of the
                filter hd. This method runs signal x through hd in floating-point to
                simulate filtering. autoscale uses the maximum and minimum data
                obtained from that simulation at each filter node to set fraction lengths
                to cover the simulation full range and maximize the precision. Word
                lengths are not changed during autoscaling.

                hnew = autoscale(hd,x) If you request an output, autoscale returns
                a new filter with the scaled fraction lengths. The original filter is not
                changed.

                For introductory demonstrations of the automatic scale process, refer to
                the following demos in the toolbox:

                • Fixed-Point Scaling of an Elliptic IIR Filter

                • Floating-Point to Fixed-Point Conversion of IIR Filters

                • Floating-Point to Fixed-Point Conversion of FIR Filters

Examples   Demonstrate dynamic range scaling in a lattice ARMA filter:

```
hd = design(fdesign.bandpass,'ellip');
hd = convert(hd,'latticearma');
hd.arithmetic = 'fixed';
rng(4); x = rand(100,10); % Training input data.
hd(2) = autoscale(hd,x);
hfvt = fvtool(hd,'Analysis','magestimate','Showreference','off');
legend(hfvt, 'Before Autoscaling', 'After Autoscaling')
```

Purpose   Generate block from multirate or multistage filter

Syntax   block(hm)
                  block(hm,'propertyname1',propertyvalue1,'propertyname2',
                      propertyvalue2,...)

Description   block(hm) generates a DSP System Toolbox block equivalent to hm.

block(hm,'propertyname1',propertyvalue1,'propertyname2',propertyvalue2
generates a DSP System Toolbox block using the options specified in
the property name/property value pairs. The valid properties
and their values are

Property Name	Property Values	Description and Values
Destination	'current' (default), 'new', or *Subsystemname*.	Determine which Simulink model gets the block. Enter 'current', 'new', or specify the name of an existing subsystem with *subsystemname*. 'current' adds the block to your current Simulink model. Specifying 'new' opens a new model and adds the block. Specifying 'new' opens a new model and adds the block. If you provide the name of a subsystem in *subsystemname*, block adds the new block to your specified subsystem.
Blockname	'filter' (default)	Specify the name of the generated block. The name appears below the block in the model. When you do not specify a block name, the default is filter.

Property Name	Property Values	Description and Values
OverwriteBlock	'off' (default), or 'on'.	Tell block whether to overwrite an existing block of the same name, or create a new block. 'off' is the default setting—block does not overwrite existing blocks with matching names. Switching from 'off' to 'on' directs block to overwrite existing blocks.
MapStates	'off' (default), or 'on'.	Specify whether to apply the current filter states to the new block. This lets you save states from a filter object you may have used or configured in a specific way. The default setting of 'off' means the states are not transferred to the block. Choosing 'on' preserves the current filter states in the block.
Link2Obj	'off' (default), or 'on'.	Specify how to set the **Coefficient source** in the block mask. The default setting is 'off' and the **Coefficient source** is set to **Dialog parameters**. Setting Link2Obj to 'on' sets the **Coefficient source** to **Discrete-time filter object (DFILT)**. The Link2Obj and MapCoeffstoPorts cannot be simultaneously 'on'.

Property Name	Property Values	Description and Values
MapCoeffstoPorts	'off' (default) or 'on'	Specify whether to map the coefficients of the filter to the ports of the block. The Link2Obj and MapCoeffstoPorts cannot be simultaneously 'on'. See mfilt for a list of supported filter objects.
CoeffNames	{'Num'} (default FIR) {'Num','Den'} (default direct form IIR) {'Num','Den','g'} (default IIR SOS), {'K'} (default form lattice)	Specify the coefficient variable names as string variables in a cell array. MapCoeffsToPorts must be set to 'on' for this property to apply.
InputProcessing	'columns as channels' (default), 'elements as channels' , or 'inherited'	Specify sample-based (elements as channels) or frame-based (columns as channels) processing. The Inherited (this choice will be removed - see release notes) option will be removed in a future release.
RateOption	'enforce single rate' (default) or 'allow multirate'	Specify how the block adjusts the rate at the output to accommodate the reduced number of samples. This parameter applies only when InputProcessing is 'columns as channels'.

block

Using block to Realize Fixed-Point Multirate Filters

When the source filter hm is fixed-point, the input word and fraction lengths for the block are derived from the block input signal. The realization process issues a warning and ignores the input word and input fraction lengths that are part of the source filter object, choosing to inherit the settings from the input data. Other fixed-point properties map directly to settings for word and fraction length in the realized block.

Examples

Two examples of using block demonstrate the syntax capabilities. Both examples start from an mfilt object with interpolation factor of three. In the first example, use block with the default syntax, letting the function determine the block name and configuration.

```
hm = mfilt.firdecim(3);
```

Now use the default syntax to create a block.

```
block(hm);
```

In this second example, define the block name to meet your needs by using the property name/property value pair input arguments.

```
block(hm, 'blockname', 'firdecim');
```

The figure below shows the blocks in a Simulink model. When you try these examples, you see that the second block writes over the first block location. You can avoid this by moving the first block before you generate the second, always naming your block with the blockname property, or setting the Destination property to new which puts the filter block in a new Simulink model.

How To   • "Realize Filters as Simulink Subsystem Blocks"

butter

Purpose	Butterworth IIR filter design using specification object
Syntax	hd = design(d,'butter') hd = design(d,'butter',designoption,value...)
Description	hd = design(d,'butter') designs a Butterworth IIR digital filter using the specifications supplied in the object d. hd = design(d,'butter',designoption,value...) returns a Butterworth IIR filter where you specify a design option and value. To determine the available design options, use designopts with the specification object and the design method as input arguments as shown. designopts(d,'method') For complete help about using butter, refer to the command line help system. For example, to get specific information about using butter with d, the specification object, enter the following at the MATLAB prompt. help(d,'butter')

Examples	Construct a default lowpass filter specification object and design a Butterworth filter:
	
	d = fdesign.lowpass;
	hd = design(d,'butter','matchexactly','stopband');
	
	Construct a highpass filter specification object and design a Butterworth filter:
	
	%Order 8 and 3 dB frequency 0.6*pi radians/sample
	d = fdesign.highpass('N,F3dB',8,.6);
	hd = design(d,'butter');
	fvtool(hd)

Purpose   Convert coupled allpass filter to transfer function form

Syntax   `[b,a]=ca2tf(d1,d2)`
                     `[b,a]=ca2tf(d1,d2,beta)`
                     `[b,a,bp]=ca2tf(d1,d2)`
                     `[b,a,bp]=ca2tf(d1,d2,beta)`

Description   `[b,a]=ca2tf(d1,d2)` returns the vector of coefficients b and the vector of
                     coefficients a corresponding to the numerator and the denominator of
                     the transfer function

$$H(z) = B(z)\,/\,A(z) = \frac{1}{2}\big[H1(z) + H2(z)\big]$$

d1 and d2 are real vectors corresponding to the denominators of the
allpass filters H1(z) and H2(z).

`[b,a]=ca2tf(d1,d2,beta)` where d1, d2 and beta are complex, returns
the vector of coefficients b and the vector of coefficients a corresponding
to the numerator and the denominator of the transfer function

$$H(z) = B(z)\,/\,A(z) = \frac{1}{2}\big[-(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z)\big]$$

`[b,a,bp]=ca2tf(d1,d2)`, where d1 and d2 are real, returns the vector
bp of real coefficients corresponding to the numerator of the power
complementary filter G(z)

$$G(z) = Bp(z)\,/\,A(z) = \frac{1}{2}\big[H1(z) - H2(z)\big]$$

`[b,a,bp]=ca2tf(d1,d2,beta)`, where d1, d2 and beta are complex,
returns the vector of coefficients bp of real or complex coefficients that
correspond to the numerator of the power complementary filter G(z)

$$G(z) = Bp(z)\,/\,A(z) = \frac{1}{2_j}\big[-(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z)\big]$$

Examples   Create a filter, convert the filter to coupled allpass form, and convert the
result back to the original structure (create the power complementary
filter as well).

```
[b,a]=cheby1(10,.5,.4);
[d1,d2,beta]=tf2ca(b,a);        % tf2ca returns the %
                                  denominators of the %
                                  allpasses.
[num,den,numpc]=ca2tf(d1,       % Reconstruct the original
d2,beta);                       % filter plus the power %
                                  complementary one.
[h,w,s]=freqz(num,den);
hpc = freqz(numpc,den);
s.plot = 'mag';
s.yunits = 'sq';
freqzplot([h hpc],w,s);         % Plot the mag response of
                                  the % original filter and
                                  the % power complementary
                                  one.
```

cheby1

Purpose	Chebyshev Type I filter using specification object

Syntax

```
hd = design(d,'cheby1')
hd = design(d,'cheby1',designoption,value,designoption,
value,...)
```

Description

`hd = design(d,'cheby1')` designs a type I Chebyshev IIR digital filter using the specifications supplied in the object `d`. Depending on the filter specification object, `cheby1` may or may not be a valid design. Use `designmethods` with the filter specification object to determine if a Chebyshev type I filter design is possible.

`hd = design(d,'cheby1',designoption,value,designoption, value,...)` returns a type I Chebyshev IIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `cheby1`, refer to the command line help system. For example, to get specific information about using `cheby1` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'cheby1')
```

Examples

These examples use filter specification objects to construct Chebyshev type I filters. In the first example, you use the `matchexactly` option to ensure the performance of the filter in the passband.

```
d = fdesign.lowpass; designopts(d,'cheby1');
hd = design(d,'cheby1','matchexactly','passband');
```

Specify the filter order, passband edge frequency, and the passband ripple to get the filter exactly as required.

```
d = fdesign.highpass('n,fp,ap',7,20,.4,50);
hd = design(d,'cheby1');
```

Use fvtool to view the resulting filter.

```
fvtool(hd)
```

By design, cheby1 returns filters that use second-order sections (SOS). For many applications, and for most fixed-point applications, SOS filters are particularly well-suited.

cheby2

Purpose	Chebyshev Type II filter using specification object

Syntax	`hd = design(d,'cheby2')`
	`hd = design(d,'cheby2',designoption,value,designoption,`
	`value,...)`

Description	`hd = design(d,'cheby2')` designs a Chebyshev II IIR digital filter using the specifications supplied in the object `d`.
	
	`hd = design(d,'cheby2',designoption,value,designoption,`
	`value,...)` returns a Chebyshev II IIR filter where you specify design options as input arguments.
	
	To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.
	
	`designopts(d,'method')`
	
	For complete help about using `cheby1`, refer to the command line help system. For example, to get specific information about using `cheby2` with `d`, the specification object, enter the following at the MATLAB prompt.
	
	`help(d,'cheby2')`

Examples	These examples use filter specification objects to construct Chebyshev type I filters. In the first example, you use the `matchexactly` option to ensure the performance of the filter in the passband.
	
	`d = fdesign.lowpass;`
	`hd = design(d,'cheby2','matchexactly','passband');`
	
	`cheby2` also designs highpass, bandpass, and bandstop filters. Here is a highpass filter where you specify the filter order, the stopband edge frequency. and the stopband attenuation to get the filter exactly as required.
	
	`d = fdesign.highpass('n,fst,ast',5,20,55,50);`

```
hd=design(d,'cheby2');
```

The Filter Visualization Tool shows the highpass filter meets the specifications.

```
fvtool(hd)
```

By design, cheby2 returns filters that use second-order sections. For many applications, and for most fixed-point applications, SOS filters are particularly well-suited for use.

cl2tf

Purpose
Convert coupled allpass lattice to transfer function form

Syntax
```
[b,a] = cl2tf(k1,k2)
[b,a] = cl2tf(k1,k2,beta)
[b,a,bp] = cl2tf(k1,k2)
[b,a,bp] = cl2tf(k1,k2,beta)
```

Description
`[b,a] = cl2tf(k1,k2)` returns the numerator and denominator vectors of coefficients b and a corresponding to the transfer function

$$H(z) = B(z) / A(z) = \frac{1}{2}\big[H1(z) + H2(z)\big]$$

where *H1(z)* and *H2(z)* are the transfer functions of the allpass filters determined by `k1` and `k2`, and `k1` and `k2` are real vectors of reflection coefficients corresponding to allpass lattice structures.

`[b,a] = cl2tf(k1,k2,beta)` where `k1`, `k2` and `beta` are complex, returns the numerator and denominator vectors of coefficients b and a corresponding to the transfer function

$$H(z) = B(z) / A(z) = \frac{1}{2}\big[-(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z)\big]$$

`[b,a,bp] = cl2tf(k1,k2)` where `k1` and `k2` are real, returns the vector bp of real coefficients corresponding to the numerator of the power complementary filter *G(z)*

$$G(z) = Bp(z) / A(z) = \frac{1}{2}\big[H1(z) - H2(z)\big]$$

`[b,a,bp] = cl2tf(k1,k2,beta)` where `k1`, `k2` and `beta` are complex, returns the vector of coefficients bp of possibly complex coefficients corresponding to the numerator of the power complementary filter *G(z)*

$$G(z) = Bp(z) / A(z) = \frac{1}{2}_j \left[-(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z) \right]$$

Examples

```
[b,a]=cheby1(10,.5,.4);  %TF2CL returns the reflection coeffs
[k1,k2,beta]=tf2cl(b,a); % Reconstruct the original filter
% plus the power complementary one.
[num,den,numpc]=cl2tf(k1,k2,beta);
[h,w]=freqz(num,den); hpc = freqz(numpc,den);
% and the power complementary one.
subplot(211);
plot(w./pi,20*log10(abs(h)),'k'); hold on; grid on;
plot(w./pi,20*log10(abs(hpc)),'b');
xlabel('Normalized Frequency (x \pi radians/sample)');
ylabel('dB');
legend('Original Filter','Power Complementary Filter',...
    'Location','best');
subplot(212);
plot(w./pi,unwrap(angle(h)),'k'); hold on; grid on;
xlabel('Normalized Frequency (x \pi radians/sample)');
ylabel('Phase (radians)');
plot(w./pi,unwrap(angle(hpc)),'b');
```

Purpose	Coefficients for filters

Syntax

```
s = coeffs(ha)
s = coeffs(hd)
s = coeffs(hm)
s = coeffs(hs)
s = coeffs(hs,Name,Value)
```

Description   s = coeffs(ha) returns a structure containing the coefficients of the adaptive filter ha.

s = coeffs(hd) returns a structure containing the coefficients of the discrete-time filter hd.

s = coeffs(hm) returns a structure containing the coefficients of the multirate filter hm.

s = coeffs(hs) returns filter coefficients for the filter System object hs.

s = coeffs(hs,Name,Value) returns filter coefficients for the filter System object hs with additional options specified by one or more Name,Value pair arguments.

Input Arguments

ha

Adaptive adaptfilt filter object.

hd

Discrete-time dfilt filter object.

hm

Multirate mfilt filter object. CIC-based filters do not have coefficients, so the function does not support CIC filter structures such as mfilt.cicdecim.

hs

coeffs

Filter System object. The function supports the following filter structures.

- `dsp.FIRFilter`

- `dsp.BiquadFilter`

- `dsp.FIRInterpolator`

- `dsp.FIRDecimator`

- `dsp.FIRRateConverter`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Arithmetic

`double' | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

Output Arguments

s

Structure with a single field, Numerator, containing filter coefficients. For adaptive filters, s contains the instantaneous frequency response available at the time you use the function.

Examples

coeffs works the same way for all filters. This example uses a multirate filter hm to demonstrate the function.

```
hm=mfilt.firdecim(3);
s=coeffs(hm);
stem(s.Numerator)
```

The filter coefficients may be extracted by typing s.Numerator at the command prompt.

coeread

Purpose	Read Xilinx COE file
Syntax	hd = coeread(filename)
Description	hd = coeread(filename) extracts the Distributed Arithmetic FIR filter coefficients defined in the XILINX CORE Generator .COE file specified by filename. It returns a dfilt object, the fixed-point filter hd. If you do not provide the file type extension .coe with the filename, the function assumes the .coe extension.
See Also	coewrite | dfilt | dfilt.dffir

Purpose   Write Xilinx COE file

Syntax
```
coewrite(hd)
coewrite(hd,radix)
coewrite(...,filename)
```

Description   coewrite(hd) writes a XILINX Distributed Arithmetic FIR filter
coefficient .COE file which can be loaded into the XILINX CORE
Generator. The coefficients are extracted from the fixed-point dfilt
object hd. Your fixed-point filter must be a direct form FIR structure
dfilt object with one section and whose Arithmetic property is set
to fixed. You cannot export single-precision, double-precision, or
floating-point filters as .coe files, nor multiple-section filters. To enable
you to provide a name for the file, coewrite displays a dialog box where
you fill in the file name. If you do not specify the name of the output
file, the default file name is untitled.coe.

coewrite(hd,radix) indicates the radix (number base) used to specify
the FIR filter coefficients. Valid radix values are 2 for binary, 10 for
decimal, and 16 for hexadecimal (default).

coewrite(...,filename) writes a XILINX.COE file to filename. If
you omit the file extension, coewrite adds the .coe extension to the
name of the file.

The coewrite function always generates the XILINX.COE file in your
current folder. To use this function, you must have write permission in
your current folder.

Examples   coewrite generates an ASCII text file that contains the filter
coefficients in a format the XILINX CORE Generator can read and load.
In this example, you create a 30th-order fixed-point filter and generate
the .coe file that includes the filter coefficients as well as associated
information about the filter.

```
b = firceqrip(30,0.4,[0.05 0.03]); hq = dfilt.dffir(b);
set(hq,'arithmetic','fixed'); coewrite(hq,10,'mycoefile');
```

The coewrite function generates the output file, mycoefile.coe, in your current folder. The .coe file contains the radix, coefficient width, and filter coefficients. The file reports the filter coefficients in column-major order. The radix, coefficient width, and filter coefficients are the minimum set of data needed in a .coe file.

See Also   coeread | dfilt | dfilt.dffir

Purpose   Constrain coefficient wordlength

Syntax

```
Hq = constraincoeffwl(Hd,wordlength)
Hq = constraincoeffwl(Hd,wordlength,'Ntrials',N)
Hq = constraincoeffwl(Hd,wordlength,...,'NoiseShaping',
    NSFlag)
Hq = constraincoeffwl(Hd,wordlength,...,'Apasstol',Apasstol)
Hq = constraincoeffwl(Hd,wordlength,...,'Astoptol',Astoptol)
```

Description   `Hq = constraincoeffwl(Hd,wordlength)` returns a fixed-point filter `Hq` meeting the design specifications of the single-stage or multistage FIR filter object `Hd` with a wordlength of at most `wordlength` bits. For multistage filters, `wordlength` can either be a scalar or vector. If `wordlength` is a scalar, the same wordlength is used for all stages. If `wordlength` is a vector, each stage uses the corresponding element in the vector. The vector length must equal the number of stages. `Hd` must be generated using `fdesign` and `design`. `constraincoeffwl` uses a stochastic noise-shaping procedure by default to minimize the wordlength. To obtain repeatable results on successive function calls, initialize the uniform random number generator `rand`

`Hq = constraincoeffwl(Hd,wordlength,'Ntrials',N)` specifies the number of Monte Carlo trials to use. `Hq` is first filter among the trials to meet the specifications in `Hd` with a wordlength of at most `wordlength`.

`Hq = constraincoeffwl(Hd,wordlength,...,'NoiseShaping',NSFlag)` enables or disables the stochastic noise-shaping procedure in the constraint of the wordlength. By default `NSFlag` is `true`. Setting `NSFlag` to `false` constrains the wordlength without using noise-shaping.

`Hq = constraincoeffwl(Hd,wordlength,...,'Apasstol',Apasstol)` specifies the passband ripple tolerance in dB. `'Apasstol'` defaults to `1e-4`.

`Hq = constraincoeffwl(Hd,wordlength,...,'Astoptol',Astoptol)` specifies the stopband tolerance in dB. `'Astoptol'` defaults to `1e-2`

constraincoeffwl

You must have the Fixed-Point Toolbox software installed to use this function.

Examples   Design fixed-point filter with a wordlength of at most 11 bits:

```
Hf = fdesign.lowpass('Fp,Fst,Ap,Ast',.4,.5,1,60);
Hd = design(Hf,'equiripple'); % 43 coefficients
Hq = constraincoeffwl(Hd,11); % 45 11-bit coefficients
hfvt = fvtool(Hd,Hq,'showreference','off');
legend(hfvt,'Floating-point Filter','Fixed-point Filter');
```

See Also   design | fdesign | maximizestopband | minimizecoeffwl | measure
| rand

Tutorials   • "Fixed-Point Data Types"

Purpose   Convert filter structure of discrete-time or multirate filter

Syntax   ```
                hq = convert(hq,newstruct)
                hm = convert(hm,newstruct)
                ```
Description   **Discrete-Time Filters**

hq = convert(hq,newstruct) returns a quantized filter whose structure has been transformed to the filter structure specified by string newstruct. You can enter any one of the following quantized filter structures:

- 'antisymmetricfir': Antisymmetric finite impulse response (FIR)

- 'df1': Direct form I

- 'df1t': Direct form I transposed

- 'df1sos': Direct-Form I, Second-Order Sections

- 'df1tsos': Direct-Form I Transposed, Second-Order Sections

- 'df2': Direct form II

- 'df2t': Direct form II transposed. Default filter structure

- 'df2sos': Direct-Form II, Second-Order Sections

- 'df2tsos': Direct-Form II Transposed, Second-Order Sections

- 'dffir': FIR

- 'dffirt': Direct form FIR transposed

- 'latcallpass': Lattice allpass

- 'latticeca': Lattice coupled-allpass

- 'latticecapc': Lattice coupled-allpass power-complementary

- 'latticear': Lattice autoregressive (AR)

- 'latticemamax': Lattice moving average (MA) maximum phase

- 'latticemamin': Lattice moving average (MA) minimum phase

- `'latticearma'`: Lattice ARMA
- `'statespace'`: Single-input/single-output state-space
- `'symmetricfir'`: Symmetric FIR. Even and odd forms

All filters can be converted to the following structures:

- `'df1'`: Direct form I
- `'df1t'`: Direct form I transposed
- `'df1sos'`: Direct-Form I, Second-Order Sections
- `'df1tsos'`: Direct-Form I Transposed, Second-Order Sections
- `'df2'`: Direct form II
- `'df2t'`: Direct form II transposed. Default filter structure
- `'df2sos'`: Direct-Form II, Second-Order Sections
- `'df2tsos'`: Direct-Form II Transposed, Second-Order Sections
- `'statespace'`: Single-input/single-output state-space
- `'symmetricfir'`: Symmetric FIR. Even and odd forms

For the following filter classes, you can specify other conversions as well:

- Minimum phase FIR filters can be converted to `latticemamin`
- Maximum phase FIR filters can be converted to `latticemamax`
- Allpass filters can be converted to `latcallpass`

`convert` generates an error when you specify a conversion that is not possible.

Multirate Filters

`hm = convert(hm,newstruct)` returns a multirate filter whose structure has been transformed to the filter structure specified by string `newstruct`. You can enter any one of the following multirate filter structures, defined by the strings shown, for `newstruct`:

Cascaded Integrator-Comb Structure

- `cicdecim` — CIC-based decimator

- `cicinterp` — CIC-based interpolator

FIR Structures

- `firdecim` — FIR decimator

- `firtdecim` — transposed FIR decimator

- `firfracdecim` — FIR fractional decimator

- `firinterp` — FIR interpolator

- `firfracinterp` — FIR fractional interpolator

- `firsrc` — FIR sample rate change filter

- `firholdinterp` — FIR interpolator that uses hold interpolation between input samples

- `firlinearinterp` — FIR interpolator that uses linear interpolation between input samples

- `fftfirinterp` — FFT-based FIR interpolator

You cannot convert between the FIR and CIC structures.

Examples   `[b,a]=ellip(5,3,40,.7); hq = dfilt.df2t(b,a);`
`hq2 = convert(hq,'df1');`

For an example of changing the structure of a multirate filter, try the following conversion from a CIC interpolator to a CIC interpolator with zero latency.

`hm = mfilt.cicinterp(2,2,3,8,8);`

> **Note** The above example will generate a warning:
>
> ```
> Warning: Using reference filter for structure conversion.
> Fixed-point attributes will not be converted.
> ```
>
> Since CIC interpolators only use fixed-point arithmetic, the user may disregard this warning. The fixed-point structure will not be lost on conversion.

See Also   mfilt | dfilt

Purpose   Estimate cost of discrete-time or multirate filter

Syntax   ```
c = cost(hd)
c = cost(hm)
c = cost(hs)
c = cost(hs,Name,Value)
```

**Description**  `c = cost(hd)` returns a cost estimate `c` for the discrete-time filter `hd`.

`c = cost(hm)` return a cost estimate `c` for the multirate filter `hm`.

`c = cost(hs)` returns a cost estimate `c` for the filter System object `hs`.

`c = cost(hs,Name,Value)` returns a cost estimate `c` for the filter System object `hs` with additional options specified by one or more `Name,Value` pair arguments.

**Input Arguments**

**hd**

Discrete-time `dfilt` filter object.

**hm**

Multirate `mfilt` filter object.

**hs**

Filter System object. The function supports the following filter structures.

- `dsp.FIRFilter`
- `dsp.BiquadFilter`
- `dsp.FIRInterpolator`
- `dsp.CICInterpolator`
- `dsp.FIRDecimator`
- `dsp.CICDecimator`
- `dsp.FIRRateConverter`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Arithmetic
`` `double' | 'single' | 'fixed' ``

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

### Details for Fixed-Point Arithmetic

| System Object State | Coefficient Data Type | Rule |
| --- | --- | --- |
| Unlocked | `'Same as input'` | The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption. |
| Unlocked | `'Custom'` | The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property. |

| System Object State | Coefficient Data Type | Rule |
|---|---|---|
| Locked | `'Same as input'` | When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption. |
| Locked | `'Custom'` | The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property. |

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

**Output Arguments**

`c`

Cost estimate. `c` has the following fields.

**cost**

| Estimated Value | Field Name | Description |
|---|---|---|
| Number of Multiplications | nmult | Number of multiplications during the filter run. nmult ignores multiplications by -1, 0, and 1 in the total multiple. |
| Number of Additions | nadd | Number of additions during the filter run. |
| Number of States | nstates | Number of states the filter uses. |
| Multiplications per Input Sample | multperinputsample | Number of multiplication operations performed for each input sample |
| Additions per Input Sample | addperinputsample | Number of addition operations performed for each input sample |

**Examples**   These examples show you the cost method applied to dfilt and mfilt objects.

```
hd = design(fdesign.lowpass);
c = cost(hd);
```

When you are using a multirate filter object, cost works the same way.

```
d = fdesign.decimator(4,'cic');
hm = design(d,'multisection');
```

Purpose   Vector of SOS filters for cumulative sections

Syntax
```
h = cumsec(hd)
h = cumsec(hd,indices)
h = cumsec(hd,indices,secondary)
cumsec(hd,...)
h = cumsec(hs)
h = cumsec(hs,Name,Value)
```

Description   `h = cumsec(hd)` returns a vector `h` of SOS filter objects with the cumulative sections. Each element in `h` is a filter with the structure of the original filter. The first element is the first filter section of `hd`. The second element of `h` is a filter that represents the combination of the first and second sections of `hd`. The third element of `h` is a filter which combines sections 1, 2, and 3 of `hd`. This pattern continues until the final element of `h` contains all the sections of `hd` and should be identical to `hd`.

`h = cumsec(hd,indices)` returns a vector `h` of SOS filter objects whose indices into the original filter are in the vector `indices`.

`h = cumsec(hd,indices,secondary)` uses the secondary scaling points `secondary` in the sections to determine where the sections should be split.

`cumsec(hd,...)` uses FVTool to plot the magnitude response of the cumulative sections.

`h = cumsec(hs)` returns the cumulative sections of the `dsp.BiquadFilter` filter System object `hs`. You can also use the optional input arguments `indices` and `secondary` with this syntax. You can also omit the output argument `h` to use FVTool to plot the magnitude response of the cumulative sections.

`h = cumsec(hs,Name,Value)` returns the cumulative sections of the filter System object `hs` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments	**hd**

Discrete-time `dfilt.df1sos`, `dfilt.df2tsos`, `dfilt.df2sos`, or `dfilt.df1tsos`filter object.

hs

`dsp.BiquadFilter` filter System object.

indices

Filter indices. Use `indices` to specify the filter sections `cumsec` uses to compute the cumulative responses.

secondary

This option applies only when `hd` is a `df2sos` and `df1tsos` filter. For these second-order section structures, the secondary scaling points refer to the scaling locations between the recursive and the nonrecursive parts of the section (the "middle" of the section). Argument `secondary` accepts either `true` or `false`. By default, `secondary` is `false`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Arithmetic

`double' | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

Examples   To demonstrate how `cumsec` works, this example plots the relative responses of the sections of a sixth-order filter SOS filter with three sections. Each curve adds one more section to form the filter response.

```
hs = fdesign.lowpass('n,fc',6,.4); hd = butter(hs);
h = cumsec(hd); hfvt = fvtool(h);
legend(hfvt,'First Section','First Two Sections','Overall  Filter');
```

See Also   scale | scalecheck

Purpose   Undo filter coefficient and gain changes caused by normalize

Syntax   denormalize(hq)

Description denormalize(hq) reverses the coefficient changes you make when you
use normalize with hq. The filter coefficients do not change if you call
denormalize(hq) before you use normalize(hq). Calling denormalize
more than once on a filter does not change the coefficients after the
first denormalize call.

Examples   Make a quantized filter hq and normalize the filter coefficients. After
normalizing the coefficients, restore them to their original values by
reversing the effects of the normalize function.

```
d=fdesign.highpass('n,F3dB',14,0.45);
hd =design(d,'butter');
hd.arithmetic='fixed';
normalize(hd)
NormSOSMatrix = hd.sosMatrix;
denormalize(hd)
eqSOSMatrices = isequal(NormSOSMatrix,hd.sosMatrix);
% returns a 0
```

See Also   normalize

design

Purpose	Apply design method to filter specification object
Syntax	H = design(D) H = design(D,METHOD) H = design(D,METHOD,PARAM1,VALUE1,PARAM2,VALUE2,...) H = design(D,METHOD,OPTS) Hs = design(D,...,'SystemObject',*sysobjflag*)

Description   H = design(D) uses the filter specifications object D to generate a filter H. When you do not provide a design method as an input argument, design uses a default design method. Use designmethods(D,'default') to see the default design method for your filter specifications object.

H = design(D,METHOD) forces the design method specified by the string METHOD. METHOD must be one of the strings returned by designmethods. Use designmethods(D,'default') to determine which algorithm is used by default.

The design method you provide as the designmethod input argument must be one of the methods returned by

designmethods(d)

To help you design filters more quickly, the input argument METHOD accepts a variety of special keywords that force design to behave in different ways. The following table presents the keywords you can use for METHOD and how design responds to the keyword.

Designmethod Keyword	Description of the design Response
'FIR'	Forces design to produce an FIR filter. When no FIR design method exists for object D, design returns an error.
'IIR'	Forces design to produce an IIR filter. When no IIR design method exists for object D, design returns an error.

Designmethod Keyword	Description of the design Response
`'ALLFIR'`	Produces filters from every applicable FIR design method for the specifications in D, one filter for each design method. As a result, `design` returns multiple filters in the output object.
`'ALLIIR'`	Produces filters from every applicable IIR design method for the specifications in D, one filter for each design method. As a result, `design` returns multiple filters in the output object.
`'ALL'`	Designs filters using all applicable design methods for the specifications object D. As a result, `design` returns multiple filters, one for each design method. `design` uses the design methods in the order that `designmethods(D)` returns them.

Keywords are not case sensitive

When `design` returns multiple filters in the output object, use indexing to see the individual filters. For example, to see the third filter in H, enter

`H(3)`

`H = design(D,METHOD,PARAM1,VALUE1,PARAM2,VALUE2,...)` specifies design-method options. Use `help(D,METHOD)` for complete information on which design-method-specific options are available. You can also use `designopts(D,METHOD)` for a less-detailed listing of the design-method-specific options.

`H = design(D,METHOD,OPTS)` specifies design-method options using the structure `OPTS`. `OPTS` is usually obtained from `designopts` and then specified as an input to `design`. Use `help(D,METHOD)` for more information on optional inputs.

`Hs = design(D,...,'SystemObject',`*sysobjflag*`)` uses the filter specifications object D to generate a filter System object Hs when

sysobjflag is `true`. To generate System objects, you must have the DSP System Toolbox product installed. When *sysobjflag* is `false`, the function generates a `dfilt` or `mfilt` object H, as described previously. Design methods and design options for filter System objects are not necessarily the same as those for `dfilt` and `mfilt` objects. To check design methods for System objects, use `designmethods` with the `'SystemObject'`,*sysobjflag* syntax.

If you are specifying design-method-specific options using OPTS, you can also set OPTS.SystemObject to `true` instead of calling `design` with the `'SystemObject'`,*sysobjflag* syntax.

Examples

Design an FIR equiripple lowpass filter. The passband edge frequency is 0.2π radians/sample, and the stopband edge frequency is 0.25π radians/sample. The passband ripple is 0.5 dB, and the stopband attenuation is 40 dB.

```
D = fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.25,0.5,40);
H = design(D); % Uses the default equiripple method.
```

If you have the DSP System Toolbox software installed, you can design a minimum-phase FIR equripple filter. Design a minimum–phase filter and compare the pole-zero plots of the original and minimum-phase designs.

```
Hmin = design(D,'equiripple','MinPhase',true);
hfvt = fvtool([H Hmin],'analysis','polezero');
legend(hfvt,'Original Design','Minimum Phase Design');
```

Design a Butterworth lowpass filter. The passband edge frequency is 0.2π radians/sample, and the stopband edge frequency is 0.25π radians/sample. The passband ripple is 0.5 dB, and the stopband attenuation is 40 dB. Obtain help on the design options specific to the Butterworth design method. Design the filter with the "MatchExactly' option set to 'Passband'.

```
D = fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.25,0.5,40);
% Query design-method-specific options
```

```
help(D,'butter')
% Match passband exactly
H = design(D,'butter','MatchExactly','passband');
```

If you have the DSP System Toolbox software, you can specify the *P*-th norm scaling on the second-order sections. Use L-infinity norm scaling in the time domain.

```
H = design(D,'butter','MatchExactly','passband','SOSScaleNorm','linf')
```

If you have the DSP System Toolbox software, you can create a filter System object.

```
Hs = design(D,'SystemObject',true);
```

See Also   designmethods | designopts

designmethods

Purpose　　　Methods available for designing filter from specification object

Syntax　　　　
```
M = designmethods(D)
M = designmethods(D,'default')
M = designmethods(D,TYPE)
M = designmethods(D,'full')
Ms = designmethods(D,...,'SystemObject',sysobjflag)
```

Description　　`M = designmethods(D)` returns the available design methods for the filter specification object, `D`, and the current value of the `Specification` property.

`M = designmethods(D,'default')` returns the default design method for the filter specification object `D` and the current value of the `Specification` property.

`M = designmethods(D,TYPE)` returns either the TYPE design methods that apply to D. TYPE can be either `'FIR'` or `'IIR'`.

`M = designmethods(D,'full')` returns the full name for each of the available design methods. For example, `designmethods` with the `'full'` argument returns `Butterworth` for the `butter` method.

`Ms = designmethods(D,...,'SystemObject',sysobjflag)` returns the available design methods for designing filter System objects when *sysobjflag* is `true`. To use System objects, you must have the DSP System Toolbox product installed. When *sysobjflag* is `false`, the function checks methods for creating `dfilt` and `mfilt` objects, as described previously. Design methods and design options for filter System objects are not necessarily the same as those for `dfilt` and `mfilt` objects.

Examples　　　Construct a lowpass filter specification object and determine the valid design methods. Obtain detailed command line help on the Chebyshev type I design method.

```
D =fdesign.lowpass('Fp,Fst,Ap,Ast',500,600,0.5,60,1e4);
M = designmethods(D)
help(D,M{2})
```

The last line of the example is equivalent to `help(D,'cheby1')`.

If you have DSP System Toolbox software installed, use the `'SystemObject',`*sysobjflag* syntax to return design methods for a filter System object:

```
Ms = designmethods(D,'SystemObject',true);
```

See Also   design | designopts | fdesign

designopts

Purpose	Valid input arguments and values for specification object and method
Syntax	OPTS = designopts(D,METHOD)
Description	OPTS = designopts(D,METHOD) returns a structure array with the default design parameters used by the design method METHOD. METHOD must be one of the strings returned by designmethods.
	Use help(D,METHOD) to get a description of the design parameters.
	If you have DSP System Toolbox software installed, OPTS has the SystemObject property if at least one of the structures available for that design method is supported by System objects. However, not all structures for that design method are supported by System objects.
Examples	Create a lowpass filter with a numerator and denominator order of 10 and a 3-dB frequency of 0.2π radians/sample. Obtain the default design parameters for a Butterworth design, and test whether the filter structure is a direct-form II biquad.

```
D = fdesign.lowpass('Nb,Na,F3dB',10,10,0.2);
OPTS = designopts(D,'butter');
if (OPTS.FilterStructure == 'df2sos')
    fprintf('The default filter structure is Direct-Form II\n');
    fprintf('with second-order sections.\n');
end
```

If you have DSP System Toolbox software installed, OPTS has the SystemObject property.

See Also design | designmethods | fdesign | validstructures

Purpose   Discrete-time filter

Syntax   hd = dfilt.*structure*(input1,...)
                 hd = [dfilt.*structure*(input1,...), dfilt.*structure*(input1,
                    ...),...]
                 hd = design(d,'designmethod')

Description   hd = dfilt.*structure*(input1,...) returns a discrete-time filter, hd,
                 of type *structure*. Each structure takes one or more inputs. When you
                 specify a dfilt.*structure* with no inputs, a default filter is created.

Note You must use a *structure* with dfilt.

---

hd = [dfilt.*structure*(input1,...),
dfilt.*structure*(input1,...),...] returns a vector containing
dfilt filters.

Structures

Structures for dfilt.structure specify the type of filter structure.
Available types of structures for dfilt are shown below.

dfilt.structure	Description	Coefficient Mapping Support in realizemdl
dfilt.allpass	Allpass filter	Supported
dfilt.cascadeallpass	Cascade of allpass filter sections	Supported
dfilt.cascadewdfallpass	Cascade of allpass wave digital filters	Supported
dfilt.delay	Delay	Not supported
dfilt.df1	Direct-form I	Supported
dfilt.df1sos	Direct-form I, second-order sections	Supported

dfilt.structure	Description	Coefficient Mapping Support in realizemdl
dfilt.df1t	Direct-form I transposed	Supported
dfilt.df1tsos	Direct-form I transposed, second-order sections	Supported
dfilt.df2	Direct-form II	Supported
dfilt.df2sos	Direct-form II, second-order sections	Supported
dfilt.df2t	Direct-form II transposed	Supported
dfilt.df2tsos	Direct-form II transposed, second-order sections	Supported
dfilt.dffir	Direct-form FIR	Supported
dfilt.dffirt	Direct-form FIR transposed	Supported
dfilt.dfsymfir	Direct-form symmetric FIR	Supported
dfilt.dfasymfir	Direct-form antisymmetric FIR	Supported
dfilt.farrowfd	Generic fractional delay Farrow filter	Supported
dfilt.farrowlinearfd	Linear fractional delay Farrow filter	Not supported
dfilt.fftfir	Overlap-add FIR	Not supported
dfilt.latticeallpass	Lattice allpass	Supported
dfilt.latticear	Lattice autoregressive (AR)	Supported
dfilt.latticearma	Lattice autoregressive moving-average (ARMA)	Supported
dfilt.latticemamax	Lattice moving-average (MA) for maximum phase	Supported
dfilt.latticemamin	Lattice moving-average (MA) for minimum phase	Supported

dfilt.structure	Description	Coefficient Mapping Support in realizemdl
dfilt.calattice	Coupled, allpass lattice	Supported
dfilt.calatticepc	Coupled, allpass lattice with power complementary output	Supported
dfilt.statespace	State-space	Supported
dfilt.scalar	Scalar gain object	Supported
dfilt.wdfallpass	Allpass wave digital filter object	Supported
dfilt.cascade	Filters arranged in series	Supported
dfilt.parallel	Filters arranged in parallel	Supported

For more information on each structure, refer to its reference page.

hd = design(d,'designmethod') returns the dfilt object hd resulting from the filter specification object d and the design method you specify in *designmethod*. When you omit the designmethod argument, design uses the default design method to construct a filter from the object d.

With this syntax, you design filters by:

1 Specifying the filter specifications, such as the response shape (perhaps highpass) and details (passband edges and attenuation).

2 Selecting a method (such as equiripple) to design the filter.

3 Applying the method to the specifications object with design(d,'designmethod).

Using the specification-based technique can be more effective than the coefficient-based filter design techniques.

Design Methods for Design Syntax

When you use the hd = design(d,'*designmethod*') syntax, you have a range of design methods available depending on d, the filter

specification object. The next table lists all of the design methods in the toolbox.

Design Method String	Filter Design Result
butter	Butterworth IIR
cheby1	Chebyshev Type I IIR
cheby2	Chebyshev Type II IIR
ellip	Elliptic IIR
equiripple	Equiripple with the same ripple in the pass and stopbands
firls	Least-squares FIR
freqsamp	Frequency-Sampled FIR
ifir	Interpolated FIR
iirlpnorm	Least Pth norm IIR
iirls	Least-Squares IIR
kaiserwin	Kaiser-windowed FIR
lagrange	Fractional delay filter
multistage	Multistage FIR
window	Windowed FIR

As the specifications object d changes, the available methods for designing filters from d also change. For instance, if d is a lowpass filter with the default specification 'Fp,Fst,Ap,Ast', the applicable methods are:

```
% Create an object to design a lowpass filter.
d=fdesign.lowpass;
designmethods(d) % What design methods apply to object d?
```

If you change the specification string to `'N,F3dB'`, the available design methods change:

```
d=fdesign.lowpass('N,F3dB');
designmethods(d)
```

Analysis Methods

Methods provide ways of performing functions directly on your `dfilt` object without having to specify the filter parameters again. You can apply these methods directly on the variable you assigned to your `dfilt` object.

For example, if you create a `dfilt` object, `hd`, you can check whether it has linear phase with `islinphase(hd)`, view its frequency response plot with `fvtool(hd),` or obtain its frequency response values with `h = freqz(hd)`. You can use all of the methods described here in this way.

Note If your variable `hd` is a 1-D array of `dfilt` filters, the method is applied to each object in the array. Only `freqz`, `grpdelay`, `impz`, `is*`, `order`, and `stepz` methods can be applied to arrays. The `zplane` method can be applied to an array only if `zplane` is used without outputs.

Some of the methods listed here have the same name as functions in Signal Processing Toolbox software. They behave similarly.

Method	Description
addstage	Adds a stage to a cascade or parallel object, where a stage is a separate, modular filter. Refer to dfilt.cascade and dfilt.parallel.
block	block(hd) creates a block of the dfilt object. The block method can specify these properties and values:
	'Destination' indicates where to place the block. 'Current' places the block in the current Simulink model. 'New' creates a new model. Default value is 'Current'.
	'Blockname' assigns the entered string to the block name. Default name is 'Filter'.
	'OverwriteBlock' indicates whether to overwrite the block generated by the block method ('on') and defined by Blockame. Default is 'off'.
	'MapStates' specifies initial conditions in the block ('on'). Default is 'off'. Refer to "Using Filter States" in Signal Processing Toolbox documentation.
cascade	Returns the series combination of two dfilt objects. Refer to dfilt.cascade.
coeffs	Returns the filter coefficients in a structure containing fields that use the same property names as those in the original dfilt.
convert	Converts a dfilt object from one filter structure, to another filter structure.

Method	Description
fcfwrite	Writes a filter coefficient ASCII file. The file can contain a single filter or a vector of objects. The file can contain multirate filters (mfilt) or adaptive filters (adaptfilt). The default file name is untitled.fcf.
	fcfwrite(hd,filename) writes to a disk file named filename in the current working folder. The .fcf extension is added automatically.
	fcfwrite(...,fmt) writes the coefficients in the format fmt, where valid fmt strings are:
	'hex' for hexadecimal
	'dec' for decimal
	'bin' for binary representation
fftcoeffs	Returns the frequency-domain coefficients used when filtering with a dfilt.fftfir
filter	Performs filtering using the dfilt object.
firtype	Returns the type (1-4) of a linear phase FIR filter.
freqz	Plots the frequency response in fvtool. Unlike the freqz function, this dfilt freqz method has a default length of 8192.
grpdelay	Plots the group delay in fvtool.
impz	Plots the impulse response in fvtool.
impzlength	Returns the length of the impulse response.
info	Displays dfilt information, such as filter structure, length, stability, linear phase, and, when appropriate, lattice and ladder length.

Method	Description
isallpass	Returns a logical 1 (i.e., true) if the dfilt object in an allpass filter or a logical 0 (i.e., false) if it is not.
iscascade	Returns a logical 1 if the dfilt object is cascaded or a logical 0 if it is not.
isfir	Returns a logical 1 if the dfilt object has finite impulse response (FIR) or a logical 0 if it does not.
islinphase	Returns a logical 1 if the dfilt object is linear phase or a logical 0 if it is not.
ismaxphase	Returns a logical 1 if the dfilt object is maximum-phase or a logical 0 if it is not.
isminphase	Returns a logical 1 if the dfilt object is minimum-phase or a logical 0 if it is not.
isparallel	Returns a logical 1 if the dfilt object has parallel stages or a logical 0 if it does not.
isreal	Returns a logical 1 if the dfilt object has real-valued coefficients or a logical 0 if it does not.
isscalar	Returns a logical 1 if the dfilt object is a scalar or a logical 0 if it is not scalar.
issos	Returns a logical 1 if the dfilt object has second-order sections or a logical 0 if it does not.
isstable	Returns a logical 1 if the dfilt object is stable or a logical 0 if it are not.

Method	Description
nsections	Returns the number of sections in a second-order sections filter. If a multistage filter contains stages with multiple sections, using nsections returns the total number of sections in all the stages (a stage with a single section returns 1).
nstages	Returns the number of stages of the filter, where a stage is a separate, modular filter.
nstates	Returns the number of states for an object.
order	Returns the filter order. If hd is a single-stage filter, the order is given by the number of delays needed for a minimum realization of the filter. If hd has multiple stages, the order is given by the number of delays needed for a minimum realization of the overall filter.
parallel	Returns the parallel combination of two dfilt filters. Refer to dfilt.parallel.
phasez	Plots the phase response in fvtool.
realizemdl	(Available only with Simulink.) realizemdl(hd) creates a Simulink model containing a subsystem block realization of your dfilt. realizemdl(hd,p1,v1,p2,v2,...) creates the block using the properties p1, p2,... and values v1, v2,... specified. The following properties are available: 'Blockname' specifies the name of the block. The default value is 'Filter'. 'Destination' specifies whether to add the block to a current Simulink model or create a

Method	Description
	new model. Valid values are `'Current'` and `'New'`.
	`'OverwriteBlock'` specifies whether to overwrite an existing block that was created by realizemdl or create a new block. Valid values are `'on'` and `'off'`. Only blocks created by realizemdl are overwritten.
	The following properties optimize the block structure. Specifying `'on'` turns the optimization on and `'off'` creates the block without optimization. The default for each block is `'off'`.
	`'OptimizeZeros'` removes zero-gain blocks.
	`'OptimizeOnes'` replaces unity-gain blocks with a direct connection.
	`'OptimizeNegOnes'` replaces negative unity-gain blocks with a sign change at the nearest summation block.
	`'OptimizeDelayChains'` replaces delay chains made up of n unit delays with a single delay by n.
removestage	Removes a stage from a cascade or parallel dfilt. Refer to dfilt.cascade and dfilt.parallel.
setstage	Overwrites a stage of a cascade or parallel dfilt. Refer to dfilt.cascade and dfilt.parallel.

Method	Description
sos	Converts the dfilt to a second-order sections dfilt. If hd has a single section, the returned filter has the same class.
	sos(hd,flag) specifies the ordering of the second-order sections. If flag='UP', the first row contains the poles closest to the origin, and the last row contains the poles closest to the unit circle. If flag='down', the sections are ordered in the opposite direction. The zeros are always paired with the poles closest to them.
	sos(hd,flag,scale) specifies the scaling of the gain and the numerator coefficients of all second-order sections. scale can be 'none', 'inf' (infinity-norm), or 'two' (2-norm). Using infinity-norm scaling with up ordering minimizes the probability of overflow in the realization. Using 2-norm scaling with down ordering minimizes the peak roundoff noise.
ss	Converts the dfilt to state-space. To see the separate A,B,C,D matrices for the state-space model, use [A,B,C,D]=ss(hd).
stepz	Plots the step response in fvtool
	stepz(hd,n) computes the first n samples of the step response.
	stepz(hd,n,Fs) separates the time samples by T = 1/Fs, where Fs is assumed to be in hertz.
sysobj	Converts the dfilt to a filter System object. See the reference page for a list of supported objects.

dfilt

Method	Description
tf	Converts the dfilt to a transfer function.
zerophase	Plots the zero-phase response in fvtool.
zpk	Converts the dfilt to zeros-pole-gain form.
zplane	Plots a pole-zero plot in fvtool.

Viewing Properties

As with any object, use get to view a dfilt properties. To see a specific property, use

```
get(hd,'property')
```

To see all properties for an object, use

```
get(hd)
```

Note dfilt objects include an arithmetic property. You can change the internal arithmetic of the filter from double- precision to single-precision using: hd.arithmetic = 'single'.

If you have Fixed-Point Toolbox software, you can change the arithmetic property to fixed-point using: hd.arithmetic = 'fixed'

Changing Properties

To set specific properties, use

```
set(hd,'property1',value,'property2',value,...)
```

You must use single quotation marks around the property name. Use single quotation marks around the value argument when the value is a string, such as specifyall or fixed.

Copying an Object

To create a copy of an object, use the copy method.

```
h2 = copy(hd)
```

Note Using the syntax H2 = hd copies only the object handle and does not create a new, independent object.

Converting Between Filter Structures

To change the filter structure of a `dfilt` object `hd`, use

```
hd2 = convert(hd,'structure_string');
```

where `structure_string` is any valid structure name in single quotation marks. If `hd` is a `cascade` or `parallel` structure, each stage is converted to the new structure.

Using Filter States

Two properties control the filter states:

- `states` — Stores the current states of the filter. Before the filter is applied, the states correspond to the initial conditions and after the filter is applied, the states correspond to the final conditions. For `df1`, `df1t`, `df1sos` and `df1tsos` structures, `states` returns a `filtstates` object.

- `PersistentMemory` — Controls whether filter `states` are saved. The default value is `'false'`, which causes the initial conditions to be reset to zero before filtering and turns off the display of `states` information. Setting `PersistentMemory` to `'true'` allows the filter to use your initial conditions or to reuse the final conditions from a previous filtering operation as the initial conditions of the next filtering operation. The `true` setting also displays information about the filter `states`.

Note If you set the `states` and want to use them for filtering, you must set `PersistentMemory` to `'true'` before you use the filter.

---

dfilt

Examples

Create a direct-form I filter, and use a method to see if it is stable.

```
[b,a] = butter(8,0.25);
hd = dfilt.df1(b,a);
isstable(hd)
```

If a dfilt's numerator values do not fit on a single line, a description of the vector is displayed. To see the specific numerator values for this example, use

```
B = get(hd,'numerator');
% or
B1 = hd.numerator;
```

Create an array containing two dfilt objects, apply a method and verify that the method acts on both objects. Use a method to test whether the objects are FIR objects.

```
b = fir1(5,.5);
hd = dfilt.dffir(b);         % Create an FIR filter object
[b,a] = butter(5,.5);        % Create IIR filter
hd(2) = dfilt.df2t(b,a);      % Create DF2T object and place
                              % in the second column of hd.
[h,w] = freqz(hd);
test_fir = isfir(hd)
% hd(1) is FIR and hd(2) is not.
```

Refer to the reference pages for each structure for more examples.

Purpose   Allpass filter

Syntax   hd = dfilt.allpass(c)

Description hd = dfilt.allpass(c) constructs an allpass filter with the minimum number of multipliers from the elements in vector c. To be valid, c must contain one, two, three, or four real elements. The number of elements in c determines the order of the filter. For example, c with two elements creates a second-order filter and c with four elements creates a fourth-order filter.

The transfer function for the allpass filter is defined by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \ldots + z^{-n}}{1 + c(1)z^{-1} + \ldots + c(n)z^{-n}}$$

given the coefficients in c.

To construct a cascade of allpass filter objects, use dfilt.cascadeallpass. For more information about creating cascades of allpass filters, refer to dfilt.cascadeallpass.

Properties The following table provides a list of all the properties associated with an allpass dfilt object.

Property Name	Brief Description
AllpassCoefficients	Contains the coefficients for the allpass filter object
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.

dfilt.allpass

Property Name	Brief Description
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.

Examples This example constructs and displays the information about a second-order allpass filter that uses the minimum number of multipliers.

```
c = [1.5, 0.7];
% Create a second-order dfilt object.
hd = dfilt.allpass(c);
```

See Also dfilt | dfilt.cascadeallpass | dfilt.cascadewdfallpass | dfilt.latticeallpass | mfilt.iirdecim | mfilt.iirinterp

Purpose   Coupled-allpass, lattice filter

Syntax
```
hd = dfilt.calattice(k1,k2,beta)
hd = dfilt.calattice
```

Description   `hd = dfilt.calattice(k1,k2,beta)` returns a discrete-time, coupled-allpass, lattice filter object `hd`, which is two allpass, lattice filter structures coupled together. The lattice coefficients for each structure are vectors `k1` and `k2`. Input argument `beta` is shown in the diagram below.

`hd = dfilt.calattice` returns a default, discrete-time coupled-allpass, lattice filter object, `hd`. The default values are `k1 = k2 = []`, which is the default value for `dfilt.latticeallpass`, and `beta = 1`. This filter passes the input through to the output unchanged.

**calattice
(Coupled–Allpass Lattice)**

dfilt.calattice

Examples   Specify a third-order lattice coupled-allpass filter structure for a `dfilt` filter, `hd` with the following code.

```
k1 = [0.9511 + 1j*0.3088; 0.7511 + 1j*0.1158];
k2 = 0.7502 - 1j*0.1218;
beta = 0.1385 + 1j*0.9904;
hd = dfilt.calattice(k1,k2,beta);
```

The `Allpass1` and `Allpass2` properties store vectors of coefficients.

See Also   dfilt.calatticepc | dfilt | dfilt.latticeallpass | dfilt.latticear | dfilt.latticearma | dfilt.latticemamax | dfilt.latticemamin

Purpose   Coupled-allpass, power-complementary lattice filter

Syntax   hd = dfilt.calatticepc(k1,k2)
                 hd = dfilt.calatticepc

Description hd = dfilt.calatticepc(k1,k2) returns a discrete-time,
                 coupled-allpass, lattice filter object hd, with power-complementary
                 output. This object is two allpass lattice filter structures coupled
                 together to produce complementary output. The lattice coefficients for
                 each structure are vectors, k1 and k2, respectively. beta is shown in the
                 following diagram.

                 hd = dfilt.calatticepc returns a default, discrete-time,
                 coupled-allpass, lattice filter object hd, with power-complementary
                 output. The default values are k1 = k2 = [], which is the default value
                 for the dfilt.latticeallpass. The default for beta = 1. This filter
                 passes the input through to the output unchanged.

dfilt.calatticepc

calatticepc
(Coupled Allpass Lattice, Power Complementary output)

Examples

Specify a third-order lattice coupled-allpass power complementary filter structure for a filter `hd` with the following code. You see from the returned properties that `Allpass1` and `Allpass2` contain vectors of coefficients for the constituent filters.

```
k1 = [0.9511 + 0.3088i; 0.7511 + 0.1158i];
k2 = 0.7502 - 0.1218i;
beta = 0.1385 + 0.9904i;
hd = dfilt.calatticepc(k1,k2,beta);
```

To see the coefficients for `Allpass1`, check the property values.

```
get(hd,'Allpass1')
```

See Also   dfilt.calattice | dfilt | dfilt.latticeallpass |
                dfilt.latticear | dfilt.latticearma | dfilt.latticemamax |
                dfilt.latticemamin

dfilt.cascade

Purpose   Cascade of discrete-time filters

Syntax   Refer to `dfilt.cascade` in Signal Processing Toolbox documentation for more information.

Description `hd = dfilt.cascade(filterobject1,filterobject2,...)` returns a discrete-time filter object `hd` of type `cascade`, which is a serial interconnection of two or more filter objects `filterobject1`, `filterobject2`, and so on. `dfilt.cascade` accepts any combination of `dfilt` objects (discrete time filters) to cascade, as well as Farrow filter objects.

You can use the standard notation to cascade one or more filters:

```
cascade(hd1,hd2,...)
```

where `hd1`, `hd2`, and so on can be mixed types, such as `dfilt` objects and `mfilt` objects.

`hd1`, `hd2`, and so on can be fixed-point filters. All filters in the cascade must be the same arithmetic format — `double`, `single`, or `fixed`. `hd`, the filter object returned, inherits the format of the cascaded filters.

Examples   Cascade a lowpass filter and a highpass filter to produce a bandpass filter.

```
[b1,a1]=butter(8,0.6);     % Lowpass
[b2,a2]=butter(8,0.4,'high');  % Highpass
h1=dfilt.df2t(b1,a1);
h2=dfilt.df2t(b2,a2);
hcas=dfilt.cascade(h1,h2);   % Bandpass with passband 0.4-0.6
% View stage 1 with hcas.Stage(1)
```

See Also   `dfilt` | `dfilt.parallel` | `dfilt.scalar`

Purpose   Cascade of allpass discrete-time filters

Syntax   `hd = dfilt.cascadeallpass(c1,c2,...)`

Description   `hd = dfilt.cascadeallpass(c1,c2,...)` constructs a cascade of allpass filters, each of which uses the minimum number of multipliers, given the filter coefficients provided in `c1`, `c2`, and so on.

Each vector `c` represents one section in the cascade filter. `c` vectors must contain one, two, three, or four elements as the filter coefficients for each section. As a result of the design algorithm, each section is a `dfilt.allpass` structure whose coefficients are given in the matching `c` vector, such as the `c1` vector contains the coefficients for the first stage.

States for each section are shared between sections.

Vectors `c` do not have to be the same length. You can combine various length vectors in the input arguments. For example, you can cascade fourth-order sections with second-order sections, or first-order sections.

For more information about the vectors `ci` and about the transfer function of each section, refer to `dfilt.allpass`.

Generally, you do not construct these allpass cascade filters directly. Instead, they result from the design process for an IIR filter. Refer to the first example in Examples for more about using `dfilt.cascadeallpass` to design an IIR filter.

Properties   In the next table, the row entries are the filter properties and a brief description of each property.

Property Name	Brief Description
AllpassCoefficients	Contains the coefficients for the allpass filter object
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.

Examples

Two examples show how dfilt.cascadeallpass works in very different applications — designing a halfband IIR filter and constructing an allpass cascade of dfilt objects.

First, design the IIR halfband filter using cascaded allpass filters. Each branch of the parallel cascade construction is a cascadeallpass filter object.

```
tw = 100;  % Transition width of filter to be designed, 100 Hz.
ast = 80;  % Stopband attenuation of filter to be designed, 80dB.
fs = 2000; % Sampling frequency of signal to be filtered.
% Store halfband design specs in the specifications object d.
d = fdesign.halfband('tw,ast',tw,ast,fs);
```

Now perform the actual filter design. hd contains two
dfilt.cascadeallpass objects.

```
hd = design(d,'ellip','filterstructure','cascadeallpass');
% Get summary information about one dfilt.cascadeallpass stage.
StageInfo = hd.Stage(1).Stage(1);
```

This second example constructs a dfilt.cascadeallpass filter object
directly given allpass coefficients for the input vectors.

```
section1 = 0.8;
section2 = [1.2,0.7];
section3 = [1.3,0.9];
hd = dfilt.cascadeallpass(section1,section2,section3);
% Get information about the filter
% return informatio in character array
S = info(hd);
```

See Also   dfilt | dfilt.allpass | dfilt.cascadewdfallpass |
                  mfilt.iirdecim | mfilt.iirinterp

dfilt.cascadewdfallpass

Purpose	Cascade allpass WDF filters to construct allpass WDF

Syntax

`hd = dfilt.cascadewdfallpass(c1,c2,...)`

Description

`hd = dfilt.cascadewdfallpass(c1,c2,...)` constructs a cascade of allpass wave digital filters given the allpass coefficients in the vectors `c1`, `c2`, and so on.

Each `c` vector contains the coefficients for one section of the cascaded filter. `C` vectors must have one, two, or four elements (coefficients). Three element vectors are not supported.

When the `c` vector has four elements, the first and third elements of the vector must be 0. Each section of the cascade is an allpass wave digital filter, from `dfilt.wdfallpass`, with the coefficients given by the corresponding c vector. That is, the first section has coefficients from vector `c1`, the second section coefficients come from `c2`, and on until all of the `c` vectors are used.

You can mix the lengths of the `c` vectors. They do not need to be the same length. For example, you can cascade several fourth-order sections (`length(c)` = 4) with first or second-order sections.

Wave digital filters are usually used to create other filters. This toolbox uses them to implement halfband filters, which the first example in Examples demonstrates. They are most often building blocks for filters.

Generally, you do not construct these WDF allpass cascade filters directly. Instead, they result from the design process for an IIR filter. Refer to the first example in Examples for more about using `dfilt.cascadewdfallpass` to design an IIR filter.

For more information about the `c` vectors and the transfer function for the allpass filters, refer to `dfilt.wdfallpass`.

Properties

In the next table, the row entries are the filter properties and a brief description of each property.

Property Name	Brief Description
AllpassCoefficients	Contains the coefficients for the allpass wave digital filter object
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.

Examples   To demonstrate two approaches to using dfilt.cascadewdfallpass to design a filter, these examples show both direct construction and construction as part of another filter.

The first design shown creates an IIR halfband filter that uses lattice wave digital filters. Each branch of the parallel connection in the lattice is an allpass cascade wave digital filter.

```
tw = 100;  % Transition width of filter, 100 Hz.
ast = 80;  % Stopband attenuation of filter, 80 dB.
fs = 2000; % Sampling frequency of signal to filter.
% Store halfband specs.
d = fdesign.halfband('tw,ast',tw,ast,fs);
```

Now perform the actual halfband design process. `hd` contains two `dfilt.cascadewdfallpass` filters.

```
hd = design(d,'ellip','filterstructure','cascadewdfallpass');
% Summary info on dfilt.cascadewdfallpass.
StageSummary = hd.stage(1).stage(2);
```

This example demonstrates direct construction of a `dfilt.cascadewdfallpass` filter with allpass coefficients.

```
section1 = 0.8;
section2 = [1.5,0.7];
section3 = [1.8,0.9];
hd = dfilt.cascadewdfallpass(section1,section2,section3);
```

See Also   dfilt | dfilt.wdfallpass

dfilt.delay

Purpose Delay filter

Syntax
```
Hd = dfilt.delay
Hd = dfilt.delay(latency)
```

Description `Hd = dfilt.delay` returns a discrete-time filter, `Hd`, of type `delay`, which adds a single delay to any signal filtered with `Hd`. The filtered signal has its values shifted by one sample.

`Hd = dfilt.delay(latency)` returns a discrete-time filter, `Hd`, of type `delay`, which adds the number of delay units specified in `latency` to any signal filtered with `Hd`. The filtered signal has its values shifted by the `latency` number of samples. The values that appear before the shifted signal are the filter states.

Examples Create a `delay` filter with a `latency` of 4 and filter a simple signal to view the impact of applying a delay.

```
h = dfilt.delay(4);
Fs = 1000;
t = 0:1/Fs:1;
sig = cos(2*pi*100*t);
y = filter(h,sig);
subplot(211);
stem(sig,'markerfacecolor',[0 0 1]);
axis([0 20 -2 2]);
title('Input Signal');
subplot(212);
stem(y,'markerfacecolor',[0 0 1]);
axis([0 20 -2 2]);
title('Delayed Signal');
```

See Also   dfilt

dfilt.df1

Purpose   Discrete-time, direct-form I filter

Syntax   Refer to `dfilt.df1` in Signal Processing Toolbox documentation.

Description   `hd = dfilt.df1` returns a default discrete-time, direct-form I filter object that uses double-precision arithmetic. By default, the numerator and denominator coefficients b and a are set to 1. With these coefficients the filter passes the input to the output without changes.

Make this filter a fixed-point or single-precision filter by changing the value of the Arithmetic property for the filter hd as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property Arithmetic, refer to "Arithmetic" on page 8-19.

Note a(1), the leading denominator coefficient, cannot be 0. To allow you to change the arithmetic setting to fixed or single, a(1) must be equal to 1.

Fixed-Point Filter Structure   The following figure shows the signal flow for the direct-form I filter implemented by dfilt.df1. To help you see how the filter processes the coefficients, input, output, and states of the filter, as well as numerical operations, the figure includes the locations of the arithmetic and data type format elements within the signal flow.

Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word "format." In this use, "format" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFormat	`AccumWordLength`	`DenAccumFracLength`	`AccumMode,` `CastBeforeSum`
DenFormat	`CoeffWordLength`	`DenFracLength`	`CoeffAutoScale ,` `SignedDenominator`
DenProdFormat	`CoeffWordLength`	`DenProdFracLength`	`ProductMode,` `ProductWordLength`
InputFormat	`InputWordLength`	`InputFracLength`	None
NumAccumFormat	`AccumWordLength`	`NumAccumFracLength`	`AccumMode,` `CastBeforeSum`
NumFormat	`CoeffWordLength`	`NumFracLength`	`CoeffAutoScale,` `Signed, Numerator`
NumProdFormat	`CoeffWordLength`	`NumProdFracLength`	`ProductWordLength,` `ProductMode`
OutputFormat	`OutputWordLength`	`OutputFracLength`	`OutputMode`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFormat, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFormat refers to the properties `ProdWordLength`, `ProductMode` and `DenProdFracLength` that fully define the denominator format after multiply (or product) operations.

Properties   In this table you see the properties associated with df1 implementations of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use `get(hd)` where hd is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 8-2.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (`FullPrecision`), or whether to keep the most significant bits (`KeepMSB`) or least significant bits (`KeepLSB`) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set `AccumMode` to `SpecifyPrecision`.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.

Property Name	Brief Description
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength and DenFracLength properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length the filter algorithm uses to interpret the results of product operations involving denominator coefficients. You can change the value for this property when you set AccumMode to SpecifyPrecision.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
Denominator	Stores the denominator coefficients for the IIR filter.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.

Property Name	Brief Description
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
Numerator	Holds the numerator coefficient values for the filter.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputWordLength	Determines the word length used for the output data.

Property Name	Brief Description
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.

Property Name	Brief Description
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.

Property Name	Brief Description
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.

Examples   Specify a second-order direct-form I structure for a dfilt object, hd, with the following code:

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df1(b,a);
% Convert hd to fixed-point filter
set(hd,'arithmetic','fixed')
```

See Also   dfilt | dfilt.df1t | dfilt.df2 | dfilt.df2t

Purpose   Discrete-time, SOS direct-form I filter

Syntax   Refer to `dfilt.df1sos` in Signal Processing Toolbox documentation.

Description   `hd = dfilt.df1sos(s)` returns a discrete-time, second-order section, direct-form I filter object `hd`, with coefficients given in the `s` matrix.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  `set(hd,'arithmetic','single');`

- To change to fixed-point filtering, enter

  `set(hd,'arithmetic','fixed');`

For more information about the property `Arithmetic`, refer to "Arithmetic" on page 8-19.

`hd = dfilt.df1sos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form I filter object `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, and so on.

`hd = dfilt.df1sos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. When you do not specify `g`, all gains default to one.

`hd = dfilt.df1sos` returns a default, discrete-time, second-order section, direct-form I filter object, `hd`. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

dfilt.df1sos

Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form I filter implemented in second-order sections by `dfilt.df1sos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters "frmt" (format). In this use, "frmt" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Similarly consider NumFrmt, which refers to the word and fraction lengths

(CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
DenStateFrmt	DenStateWordLength	DenStateFracLength	CastBeforeSum, States
InputFrmt	InputWordLength	InputFracLength	None
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
NumStateFrmt	NumStateWordLength	NumStateFracLength	States
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode
ScaleValueFrmt	CoeffWordLength	ScaleValueFracLength	CoeffAutoScale, ScaleValues

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with

product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

Properties
In this table you see the properties associated with SOS implementation of direct-form I dfilt objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

get(hd)

where hd is a filter.

For further information about the properties of this filter or any dfilt object, refer to "Fixed-Point Filter Properties" on page 8-2.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output

Property Name	Brief Description
	from the accumulator, set `AccumMode` to `SpecifyPrecision`.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` and `DenFracLength` properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set `AccumMode` to `SpecifyPrecision`.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. `DenFracLength` is always available, but it is read-only until you set `CoeffAutoScale` to `false`.

Property Name	Brief Description
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
DenStateFracLength	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
DenStateWordLength	Specifies the word length used to represent the states associated with denominator coefficients in the filter.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumStateFracLength	Specifies the fraction length used to interpret the states associated with numerator coefficient operations in the filter.

Property Name	Brief Description
NumWordFracLength	Specifies the word length used to interpret the states associated with numerator coefficient operations in the filter.
OptimizeScaleValues	When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length applied for the output data.

Property Name	Brief Description
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.

Property Name	Brief Description
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
ScaleValueFracLength	Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable AutoScaleMode by setting it to false.

Property Name	Brief Description
ScaleValues	Scaling for the filter objects in SOS filters.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
SosMatrix	Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/section datatype]. A [15x6 double] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type double to represent the coefficients.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

Examples   Specify a fixed-point, second-order section, direct-form I dfilt object with the following code:

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df1sos(b,a);
% Convert to fixed-point filter
hd.arithmetic = 'fixed';
```

See Also   dfilt | dfilt.df2tsos

Purpose Discrete-time, direct-form I transposed filter

Syntax Refer to `dfilt.df1t` in Signal Processing Toolbox documentation.

Description `hd = dfilt.df1t(b,a)` returns a discrete-time, direct-form I transposed filter object hd, with numerator coefficients `b` and denominator coefficients `a`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter hd as follows:

- To change to single-precision filtering, enter

  `set(hd,'arithmetic','single');`

- To change to fixed-point filtering, enter

  `set(hd,'arithmetic','fixed');`

For more information about the property `Arithmetic`, refer to "Arithmetic" on page 8-19.

`hd = dfilt.df1t` returns a default, discrete-time, direct-form I transposed filter object hd, with `b=1` and `a=1`. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

Fixed-Point Filter Structure The following figure shows the signal flow for the transposed direct-form I filter implemented by `dfilt.df1t`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters "frmt" (format). In this use, "frmt" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	`AccumWordLength`	`DenAccumFracLength`	`AccumMode`, `CastBeforeSum`
DenFrmt	`CoeffWordLength`	`DenFracLength`	`CoeffAutoScale`, , `Signed`, `Denominator`
DenProdFrmt	`CoeffWordLength`	`DenProdFracLength`	`ProductMode`, `ProductWordLength`
DenStateFrmt	`DenStateWordLength`	`DenStateFracLength`	`CastBeforeSum`, `States`
InputFrmt	`InputWordLength`	`InputFracLength`	None
Multiplicandfrmt	`Multiplicand-WordLength`	`Multiplicand-FracLength`	`CastBeforeSum`
NumAccumFrmt	`AccumWordLength`	`NumAccumFracLength`	`AccumMode`, `CastBeforeSum`
NumFrmt	`CoeffWordLength`	`NumFracLength`	`CoeffAutoScale`, `Signed`, `Numerator`
NumProdFrmt	`CoeffWordLength`	`NumProdFracLength`	`ProductWordLength`, `ProductMode`
NumStateFrmt	`NumStateWord-Length`	`NumStateFrac-Length`	`States`
OutputFrmt	`OutputWordLength`	`OutputFracLength`	`OutputMode`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From

reviewing the table, you see that the DenProdFrmt refers to the properties `ProdWordLength`, `ProductMode` and `DenProdFracLength` that fully define the denominator format after multiply (or product) operations.

Properties   In this table you see the properties associated with df1t implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where hd is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 8-2.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (`FullPrecision`), or whether to keep the most significant bits (`KeepMSB`) or least significant bits (`KeepLSB`) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set `AccumMode` to `SpecifyPrecision`.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.

Property Name	Brief Description
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength and DenFracLength properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set AccumMode to SpecifyPrecision.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
Denominator	Holds the denominator coefficients for the filter.

Property Name	Brief Description
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
DenStateFracLength	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
MultiplicandFracLength	Sets the fraction length for values (multiplicands) used in multiply operations in the filter.
MultiplicandWordLength	Sets the word length applied to the values input to a multiply operation (the multiplicands).
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.

Property Name	Brief Description
Numerator	Holds the numerator coefficient values for the filter.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
NumStateFracLength	For IIR filters, this defines the binary point location applied to the numerator states of the filter. Specifies the fraction length used to interpret the states associated with numerator coefficient operations in the filter.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.

Property Name	Brief Description
	• SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.

Property Name	Brief Description
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.

Property Name	Brief Description
	The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateAutoScale	Setting autoscaling for filter states to true reduces the possibility of overflows occurring during fixed-point operations. Set to false, StateAutoScale lets the filter select the fraction length to limit the overflow potential.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

Examples   Specify a second-order direct-form I transposed filter structure for a dfilt object, hd, with the following code:

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df1t(b,a);
% Convert filter to single-precision arithmetic
set(hd,'arithmetic','single')
```

See Also   dfilt | dfilt.df1 | dfilt.df2 | dfilt.df2t

Purpose   Discrete-time, SOS direct-form I transposed filter

Syntax   Refer to `dfilt.df1tsos` in Signal Processing Toolbox documentation.

Description   `hd = dfilt.df1tsos(s)` returns a discrete-time, second-order section, direct-form I, transposed filter object `hd`, with coefficients given in the `s` matrix.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to .

`hd = dfilt.df1tsos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form I, transposed filter object `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, etc.

`hd = dfilt.df1tsos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. If `g` is not specified, all gains default to one.

`hd = dfilt.df1tsos` returns a default, discrete-time, second-order section, direct-form I, transposed filter object, `hd`. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

dfilt.df1tsos

Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form I transposed filter implemented using second-order sections by `dfilt.df1tsos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters "frmt" (format). In this use, "frmt" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
DenStateFrmt	DenStateWordLength	DenStateFracLength	CastBeforeSum, States
InputFrmt	InputWordLength	InputFracLength	None
MultiplicandFrmt	Multiplicand-WordLength	Multiplicand-FracLength	CastBeforeSum
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
NumStateFrmt	NumStateWordLength	NumStateFracLength	States
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode
ScaleValueFrmt	CoeffWordLength	ScaleValue-FracLength	CoeffAutoScale, ScaleValues

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties `ProdWordLength`, `ProductMode` and `DenProdFracLength` that fully define the denominator format after multiply (or product) operations.

Properties In this table you see the properties associated with SOS implementation of transposed direct-form I `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

`get(hd)`

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 8-2.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength and DenFracLength properties to specify the precision used.

Property Name	Brief Description
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set AccumMode to SpecifyPrecision.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
DenStateFracLength	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.

Property Name	Brief Description
InputWordLength	Specifies the word length applied to interpret input data.
MultiplicandFracLength	Sets the fraction length for values (multiplicands) used in multiply operations in the filter.
MultiplicandWordLength	Sets the word length applied to the values input to a multiply operation (the multiplicands)
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
Numerator	Holds the numerator coefficient values for the filter.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
NumStateFracLength	For IIR filters, this defines the binary point location applied to the numerator states of the filter. Specifies the fraction length used to interpret the states associated with numerator coefficient operations in the filter.

Property Name	Brief Description
NumStateWordLength	For IIR filters, this defines the word length applied to the numerator states of the filter. Specifies the word length used to interpret the states associated with numerator coefficient operations in the filter.
OptimizeScaleValues	When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.

Property Name	Brief Description
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.

Property Name	Brief Description
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity.

Property Name	Brief Description
	• round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.
	The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
ScaleValueFracLength	Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable AutoScaleMode by setting it to false.
ScaleValues	Scaling for the filter objects in SOS filters.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.

Property Name	Brief Description
SosMatrix	Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/sectiondatatype]. A [15x6 double] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type double to represent the coefficients.
StateAutoScale	Setting autoscaling for filter states to true reduces the possibility of overflows occurring during fixed-point operations. Set to false, StateAutoScale lets the filter select the fraction length to limit the overflow potential.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

Examples   With the following code, this example specifies a second-order section, direct-form I transposed dfilt object for a filter. Then convert the filter to fixed-point operation.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df1tsos(b,a);
set(hd,'arithmetic','fixed')
```

See Also   dfilt | dfilt.df1sos | dfilt.df2sos | dfilt.df2tsos

Purpose	Discrete-time, direct-form II filter
Syntax	Refer to `dfilt.df2` in Signal Processing Toolbox documentation.
Description	`hd = dfilt.df2(b,a)` returns a discrete-time, direct-form II filter object `hd`, with numerator coefficients `b` and denominator coefficients `a`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to "Arithmetic" on page 8-19.

`hd = dfilt.df2` returns a default, discrete-time, direct-form II filter object `hd`, with `b = 1` and `a = 1`. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form II filter implemented by `dfilt.df2`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters"frmt" (format). In this use, "frmt" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
InputFrmt	InputWordLength	InputFracLength	None
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode
StateFrmt	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

Properties   In this table you see the properties associated with the df2
implementation of dfilt objects.

Note The table lists all the properties that a filter can have. Many of
the properties are dynamic, meaning they exist only in response to the
settings of other properties. You might not see all of the listed properties
all the time. To view all the properties for a filter at any time, use

get(hd)

where hd is a filter.

For further information about the properties of this filter or any dfilt
object, refer to "Fixed-Point Filter Properties" on page 8-2.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.

Property Name	Brief Description
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength and DenFracLength properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set AccumMode to SpecifyPrecision.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
Denominator	Holds the denominator coefficients for IIR filters.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.

Property Name	Brief Description
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
Numerator	Holds the numerator coefficient values for the filter.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.

Property Name	Brief Description
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.

Property Name	Brief Description
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative

dfilt.df2

Property Name	Brief Description
	numbers, and toward positive infinity for positive numbers.

The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision. |
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

Examples   Specify a second-order direct-form II filter structure for a dfilt object, hd, with the following code:

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df2(b,a);
% Change filter to fixed-point
set(hd,'arithmetic','fixed')
```

See Also   dfilt | dfilt.df1 | dfilt.df1t | dfilt.df2t

Purpose　　　Discrete-time, SOS, direct-form II filter

Syntax　　　Refer to `dfilt.df2sos` in Signal Processing Toolbox documentation.

Description　`hd = dfilt.df2sos(s)` returns a discrete-time, second-order section, direct-form II filter object `hd`, with coefficients given in the `s` matrix.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to "Arithmetic" on page 8-19.

`hd = dfilt.df2sos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form II object, `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, etc.

`hd = dfilt.df2sos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. If `g` is not specified, all gains default to one.

`hd = dfilt.df2sos` returns a default, discrete-time, second-order section, direct-form II filter object, `hd`. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

dfilt.df2sos

Fixed-Point Filter Structure

The figure below shows the signal flow for the direct-form II filter implemented with second-order sections by dfilt.df2sos. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters "frmt" (format). In this use, "frmt" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The frmt properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths

(`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	`AccumWordLength`	`DenAccumFracLength`	`AccumMode,` `CastBeforeSum`
DenFrmt	`CoeffWordLength`	`DenFracLength`	`CoeffAutoScale,` `Signed, sosMatrix`

DenProdFrmt	`CoeffWordLength`	`DenProdFracLength`	`ProductMode,`
			`ProductWordLength,`
			`sosMatrix`

InputFrmt	`InputWordLength`	`InputFracLength`	None
NumAccumFrmt	`AccumWordLength`	`NumAccumFracLength`	`AccumMode,` `CastBeforeSum`
NumFrmt	`CoeffWordLength`	`NumFracLength`	`CoeffAutoScale,` `Signed, sosMatrix`
NumProdFrmt	`CoeffWordLength`	`NumProdFracLength`	`ProductWordLength,` `ProductMode`
OutputFrmt	`OutputWordLength`	`OutputFracLength`	`OutputMode`

StateFrmt	`StateWordLength`	`StateFracLength`	`CastBeforeSum,` `States`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties `ProdWordLength`, `ProductMode` and `DenProdFracLength` that fully define the denominator format after multiply (or product) operations.

Properties   In this table you see the properties associated with second-order section implementation of direct-form II `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

`get(hd)`

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 8-2.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength and DenFracLength properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.

Property Name	Brief Description
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set AccumMode to SpecifyPrecision.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.

Property Name	Brief Description
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
OptimizeScaleValues	When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.

Property Name	Brief Description
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.

Property Name	Brief Description
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
ScaleValueFracLength	Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable AutoScaleMode by setting it to false.

Property Name	Brief Description
ScaleValues	Scaling for the filter objects in SOS filters.
SectionInputAutoScale	Tells the filter whether to set the stage input data format to minimize the occurrence of overflow conditions.
SectionInputFracLength	Lets you set the fraction length for section inputs in SOS filters, if you set `SectionInputAutoScale` to `false`.
SectionInputWordLength	Lets you set the word length for section inputs in SOS filters, if you set `SectionInputAutoScale` to `false`.
SectionOutputAutoScale	Tells the filter whether to set the section output data format to minimize the occurrence of overflow conditions.
SectionOutputFracLength	Lets you set the fraction length for section outputs in SOS filters, if you set `SectionOutputAutoScale` to `off`.
SectionOutputWordLength	Lets you set the word length for section outputs in SOS filters, if you set `SectionOutputAutoScale` to `false`.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
SosMatrix	Holds the filter coefficents as property values. Displays the matrix in the format [sections x coefficients/section datatype]. A [15x6 double] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type `double` to represent the coefficients.

Property Name	Brief Description
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

Examples   Specify a second-order section, direct-form II dfilt object for a Butterworth filter converted to second-order sections, with the following code:

```
[z,p,k] = butter(30,0.5);
[s,g] = zp2sos(z,p,k);
hd = dfilt.df2sos(s,g);
% Convert filter to fixed-point
hd.arithmetic='fixed';
```

See Also   dfilt | dfilt.df1sos | dfilt.df1tsos | dfilt.df2tsos

dfilt.df2t

Purpose	Discrete-time, direct-form II transposed filter
Syntax	Refer to dfilt.df2t in Signal Processing Toolbox documentation.
Description	hd = dfilt.df2t(b,a) returns a discrete-time, direct-form II transposed filter object hd, with numerator coefficients b and denominator coefficients a.

Make this filter a fixed-point or single-precision filter by changing the value of the Arithmetic property for the filter hd as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property Arithmetic, refer to "Arithmetic" on page 8-19.

hd = dfilt.df2t returns a default, discrete-time, direct-form II transposed filter object hd, with b = 1 and a = 1. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator a(1) cannot be 0. To allow you to change the arithmetic setting to fixed or single, a(1) must be equal to 1.

Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form II transposed filter implemented by dfilt.df2t. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters "frmt." In this use, "frmt" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The

format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	`AccumWordLength`	`DenAccumFracLength`	`AccumMode, CastBeforeSum`
DenFrmt	`CoeffWordLength`	`DenFracLength`	`CoeffAutoScale,Signed, Denominator`
DenProdFrmt	`CoeffWordLength`	`DenProdFracLength`	`ProductMode, ProductWordLength`
InputFrmt	`InputWordLength`	`InputFracLength`	None
NumAccumFrmt	`AccumWordLength`	`NumAccumFracLength`	`AccumMode, CastBeforeSum`
NumFrmt	`CoeffWordLength`	`NumFracLength`	`CoeffAutoScale, Signed, Numerator`
NumProdFrmt	`CoeffWordLength`	`NumProdFracLength`	`ProductWordLength, ProductMode`
OutputFrmt	`OutputWordLength`	`OutputFracLength`	None
StateFrmt	`StateWordLength`	`StateFracLength`	`States`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the

properties `ProdWordLength`, `ProductMode` and `DenProdFracLength` that fully define the denominator format after multiply (or product) operations.

Properties   In this table you see the properties associated with `df2t` implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

`get(hd)`

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 8-2.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (`FullPrecision`), or whether to keep the most significant bits (`KeepMSB`) or least significant bits (`KeepLSB`) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set `AccumMode` to `SpecifyPrecision`.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.

Property Name	Brief Description
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength and DenFracLength properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set AccumMode to SpecifyPrecision.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
Denominator	Holds the denominator coefficients for IIR filters.

Property Name	Brief Description
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
Numerator	Holds the numerator coefficient values for the filter.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
OutputFracLength	Determines how the filter interprets the filter output data.
OutputWordLength	Determines the word length used for the output data.

Property Name	Brief Description
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (`FullPrecision`), or whether to keep the most significant bit (`KeepMSB`) or least significant bit (`KeepLSB`) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set `ProductMode` to `SpecifyPrecision`.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set `ProductMode` to `SpecifyPrecision`.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. `False` is the default setting.

Property Name	Brief Description
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.

Property Name	Brief Description
StateAutoScale	Setting autoscaling for filter states to true reduces the possibility of overflows occurring during fixed-point operations. Set to false, StateAutoScale lets the filter select the fraction length to limit the overflow potential.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

Examples   Create a fixed-point filter by specifying a second-order direct-form II transposed filter structure for a dfilt object, and then converting the double-precision arithmetic setting to fixed-point.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df2t(b,a);
% Convert filter to fixed-point
set(hd,'arithmetic','fixed')
```

See Also   dfilt | dfilt.df1 | dfilt.df1t | dfilt.df2

Purpose   Discrete-time, SOS direct-form II transposed filter

Syntax   Refer to `dfilt.df2tsos` in Signal Processing Toolbox documentation.

Description `hd = dfilt.df2tsos(s)` returns a discrete-time, second-order section, direct-form II, transposed filter object `hd`, with coefficients given in the matrix `s`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

• To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

• To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to "Arithmetic" on page 8-19.

`hd = dfilt.df2tsos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form II, transposed filter object `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, etc.

`hd = dfilt.df2tsos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. If `g` is not specified, all gains default to one.

`hd = dfilt.df2tsos` returns a default, discrete-time, second-order section, direct-form II, transposed filter object, `hd`. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

Fixed-Point Filter Structure

The figure below shows the signal flow for the second-order section transposed direct-form II filter implemented by dfilt.dftsos. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters "frmt" (format). In this use, "frmt" indicates the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	`AccumWordLength`	`DenAccumFracLength`	`AccumMode`, `CastBeforeSum`
DenFrmt	`CoeffWordLength`	`DenFracLength`	`CoeffAutoScale`, `Signed`, `Denominator`
DenProdFrmt	`CoeffWordLength`	`DenProdFracLength`	`ProductMode`, `ProductWordLength`
InputFrmt	`InputWordLength`	`InputFracLength`	None
NumAccumFrmt	`AccumWordLength`	`NumAccumFracLength`	`AccumMode`, `CastBeforeSum`
NumFrmt	`CoeffWordLength`	`NumFracLength`	`CoeffAutoScale`, `SignedNumerator`

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
NumProdFrmt	`CoeffWordLength`	`NumProdFracLength`	`ProductWordLength,` `ProductMode`
OutputFrmt	`OutputWordLength`	`OutputFracLength`	`OutputMode`
ScaleValueFrmt	`CoeffWordLength`	`ScaleValueFracLength`	`CoeffAutoScale,` `ScaleValues`
SectionInputFormt	`SectionInput-` `WordLength`	`SectionInput-` `FracLength`	
SectionOutputFrmt	`SectionOutput-` `WordLength`	`SectionOutput-` `FracLength`	
StateFrmt	`StateWordLength`	`StateFracLength`	`States`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties `ProdWordLength`, `ProductMode` and `DenProdFracLength` that fully define the denominator format after multiply (or product) operations.

Properties   In this table you see the properties associated with second-order section implementation of transposed direct-form II `dfilt` objects.

> **Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use
>
> get(hd)
>
> where hd is a filter.

For further information about the properties of this filter or any dfilt object, refer to "Fixed-Point Filter Properties" on page 8-2.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.

dfilt.df2tsos

Property Name	Brief Description
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` and `DenFracLength` properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set `AccumMode` to `SpecifyPrecision`.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. `DenFracLength` is always available, but it is read-only until you set `CoeffAutoScale` to `false`.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set `ProductMode` to `SpecifyPrecision`.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set `AccumMode` to `SpecifyPrecision`.

Property Name	Brief Description
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
OptimizeScaleValues	When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.

Property Name	Brief Description
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.

Property Name	Brief Description
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
ScaleValueFracLength	Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable AutoScaleMode by setting it to false.
ScaleValues	Scaling for the filter objects in SOS filters.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.

Property Name	Brief Description
SosMatrix	Holds the filter coefficients as property values — you use set and get to modify them. Displays the matrix in the format [sections x coefficients/section data type].
SectionInputFracLength	Lets you set the fraction length for section inputs in SOS filters, if you set SectionInputAutoScale to false.
SectionInputWordLength	Lets you set the word length for section inputs in SOS filters, if you set SectionInputAutoScale to false.
SectionOutputFracLength	Lets you set the fraction length for section outputs in SOS filters, if you set SectionOutputAutoScale to off.
SectionOutputWordLength	Lets you set the word length for section outputs in SOS filters, if you set SectionOutputAutoScale to false.
StateAutoScale	Setting autoscaling for filter states to true reduces the possibility of overflows occurring during fixed-point operations. Set to false, StateAutoScale lets the filter select the fraction length to limit the overflow potential.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

Examples   Construct a second-order section Butterworth filter for fixed-point filtering. Start by specifying a Butterworth filter, and then convert the filter to second-order sections, with the following code:

```
[z,p,k] = butter(30,0.5);
```

```
[s,g] = zp2sos(z,p,k);
hd = dfilt.df2tsos(s,g);
% convert filter to fixed-point
hd.arithmetic='fixed';
```

See Also   dfilt | dfilt.df1sos | dfilt.df1tsos | dfilt.df2sos

Purpose	Discrete-time, direct-form antisymmetric FIR filter
Syntax	Refer to `dfilt.dfasymfir` in Signal Processing Toolbox documentation.
Description	`hd = dfilt.dfasymfir(b)` returns a discrete-time, direct-form, antisymmetric FIR filter object `hd`, with numerator coefficients `b`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  `set(hd,'arithmetic','single');`

- To change to fixed-point filtering, enter

  `set(hd,'arithmetic','fixed');`

For more information about the property `Arithmetic`, refer to "Arithmetic" on page 8-19.

`hd = dfilt.dfasymfir` returns a default, discrete-time, direct-form, antisymmetric FIR filter object `hd`, with b=1. This filter passes the input through to the output unchanged.

Note Only the coefficients in the first half of vector `b` are used because `dfilt.dfasymfir` assumes the coefficients in the second half are antisymmetric to those in the first half. For example, in the figure coefficients, b(4) = -b(3), b(5) = -b(2), and b(6) = -b(1).

Fixed-Point Filter Structure

The following figure shows the signal flow for the odd-order antisymmetric FIR filter implemented by `dfilt.dfasymfir`. The even-order filter uses similar flow. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word "format." In this use, "format" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

dfilt.dfasymfir

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	`AccumWordLength`	`AccumFracLength`	None
InputFormat	`InputWordLength`	`InputFracLength`	None
NumFormat	`CoeffWordLength`	`NumFracLength`	`CoeffAutoScale`, , `Signed`, `Numerator`
OutputFormat	`OutputWordLength`	`OutputFracLength`	None
ProductFormat	`ProductWordLength`	`ProductFracLength`	None
TapSumFormat	`InputWordLength`	`InputFracLength`	`InputFormat`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties `ProductFracLength` and `ProductWordLength` that fully define the coefficient format after multiply (or product) operations.

Properties   In this table you see the properties associated with an antisymmetric FIR implementation of `dfilt` objects.

> **Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use
>
> ```
> get(hd)
> ```
>
> where hd is a filter.

For further information about the properties of this filter or any dfilt object, refer to "Fixed-Point Filter Properties" on page 8-2.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits [27]	Specifies the fraction length used to interpret data output by the accumulator.
AccumWordLength	Any integer number of bits[33]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to fixed allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.

dfilt.dfasymfir

Name	Values	Description
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data. Also controls TapSumFracLength.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data. Also determines TapSumWordLength.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [29]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilerInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [33]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.

Name	Values	Description
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductFracLength	Any positive or negative integer number of bits [27]	Specifies the fraction length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
ProductWordLength	Any integer number of bits [33]	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
RoundMode	[convergent], ceil, fix, floor, nearest, round	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero.

Name	Values	Description
		• `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	`fi` object to match the filter arithmetic setting	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Toolbox documentation.

Examples   **Odd Order**

Specify a fifth-order direct-form antisymmetric FIR filter structure for a `dfilt` object, hd, with the following code:

```
b = [-0.008 0.06 -0.44 0.44 -0.06 0.008];
hd = dfilt.dfasymfir(b);
```

Even Order

Specify a fourth-order direct-form antisymmetric FIR filter structure for dfilt object hd, with the following code:

```
b = [-0.01 0.1 0.0 -0.1 0.01];
hd = dfilt.dfasymfir(b);
hd.arithmetic='fixed';
FilterCoefs = get(hd,'numerator');
% or equivalently
FilterCoefs = hd.numerator;
```

See Also   dfilt | dfilt.dffir | dfilt.dffirt | dfilt.dfsymfir

dfilt.dffir

Purpose   Discrete-time, direct-form FIR filter

Syntax   Refer to `dfilt.dffir` in Signal Processing Toolbox documentation.

Description   `hd = dfilt.dffir(b)` returns a discrete-time, direct-form finite impulse response (FIR) filter object `hd`, with numerator coefficients `b`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to "Arithmetic" on page 8-19.

`hd = dfilt.dffir` returns a default, discrete-time, direct-form FIR filter object `hd`, with `b=1`. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure   The following figure shows the signal flow for the direct-form FIR filter implemented by `dfilt.dffir`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters "frmt" (format). In this use, "frmt" indicates the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

dfilt.dffir

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFrmt	AccumWordLength	AccumFracLength	None
InputFrmt	InputWordLength	InputFracLength	None
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
OutputFrmt	OutputWordLength	OutputFracLength	None
ProductFrmt	ProductWordLength	ProductFracLength	None

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFrmt, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFrmt refers to the properties ProductFracLength and ProductWordLength that fully define the coefficient format after multiply (or product) operations.

Properties   In this table you see the properties associated with direct-form FIR implementation of dfilt objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

get(hd)

where hd is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 8-2.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits [30]	Specifies the fraction length used to interpret data output by the accumulator.
AccumWordLength	Any integer number of bits[34]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to `fixed` allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. `SpecifyPrecision` makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.

Name	Values	Description
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilerInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.

Name	Values	Description
ProductFracLength	Any positive or negative integer number of bits [30]	Specifies the fraction length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
ProductWordLength	Any integer number of bits [32]	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
RoundMode	[convergent], ceil, fix, floor, nearest, round	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient

Name	Values	Description
		and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object to match the filter arithmetic setting	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Toolbox documentation.

Examples   Specify a second-order direct-form FIR filter structure for a dfilt object hd, with the following code that constructs the filter in double-precision format and then converts the filter to fixed-point operation:

```
b = [0.05 0.9 0.05];
hd = dfilt.dffir(b);
% Create fixed-point filter
hd.arithmetic='fixed';
% Change FilterInternals property to
% SpecifyPrecision enabling other properites
hd.FilterInternals='SpecifyPrecision';
```

See Also   dfilt | dfilt.dfasymfir | dfilt.dffirt | dfilt.dfsymfir

Purpose   Discrete-time, direct-form FIR transposed filter

Syntax   Refer to dfilt.dffirt in Signal Processing Toolbox documentation.

Description hd = dfilt.dffirt(b) returns a discrete-time, direct-form FIR transposed filter object hd, with numerator coefficients b.

Make this filter a fixed-point or single-precision filter by changing the value of the Arithmetic property for the filter hd as follows:

• To change to single-precision filtering, enter

  set(hd,'arithmetic','single');

• To change to fixed-point filtering, enter

  set(hd,'arithmetic','fixed');

For more information about the property Arithmetic, refer to "Arithmetic" on page 8-19.

hd = dfilt.dffirt returns a default, discrete-time, direct-form FIR transposed filter object hd, with b = 1. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure   The following figure shows the signal flow for the transposed direct-form FIR filter implemented by dfilt.dffirt. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word "format." In this use, "format" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	AccumWordLength	AccumFracLength	None
InputFormat	InputWordLength	InputFracLength	None
NumFormat	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
OutputFormat	OutputWordLength	OutputFracLength	None
ProductFormat	ProductWordLength	ProductFracLength	None

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties ProductFracLength and ProductWordLength that fully define the coefficient format after multiply (or product) operations.

Properties   In this table you see the properties associated with the transposed direct-form FIR implementation of dfilt objects.

> **Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use
>
> ```
> get(hd)
> ```
>
> where hd is a filter.

For further information about the properties of this filter or any dfilt object, refer to "Fixed-Point Filter Properties" on page 8-2.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits [30]	Specifies the fraction length used to interpret data output by the accumulator.
AccumWordLength	Any integer number of bits[34]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to fixed allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.

Name	Values	Description
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [30]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilerInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [34]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.

dfilt.dffirt

Name	Values	Description
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
RoundMode	[convergent], ceil, fix, floor, nearest, round	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.

Name	Values	Description
		The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	`fi` object to match the filter arithmetic setting	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Toolbox documentation.

Examples   Specify a second-order direct-form FIR transposed filter structure for a
`dfilt` object, hd, with the following code:

```
b = [0.05 0.9 0.05];
hd = dfilt.dffirt(b);
set(hd,'arithmetic','fixed')
```

See Also   dfilt | dfilt.dffir | dfilt.dfasymfir | dfilt.dfsymfir

Purpose	Discrete-time, direct-form symmetric FIR filter
Syntax	Refer to dfilt.dfsymfir in Signal Processing Toolbox documentation.
Description	hd = dfilt.dfsymfir(b) returns a discrete-time, direct-form symmetric FIR filter object hd, with numerator coefficients b.

Make this filter a fixed-point or single-precision filter by changing the value of the Arithmetic property for the filter hd as follows:

- To change to single-precision filtering, enter

  set(hd,'arithmetic','single');

- To change to fixed-point filtering, enter

  set(hd,'arithmetic','fixed');

For more information about the property Arithmetic, refer to "Arithmetic" on page 8-19.

hd = dfilt.dfsymfir returns a default, discrete-time, direct-form symmetric FIR filter object hd, with b=1. This filter passes the input through to the output unchanged.

Note Only the coefficients in the first half of vector b are used because dfilt.dfsymfir assumes the coefficients in the second half are symmetric to those in the first half. In the following figure, for example, b(3) = 0, b(4) = b(2) and b(5) = b(1).

Fixed-Point Filter Structure

In the following figure you see the signal flow diagram for the symmetric FIR filter that dfilt.dfsymfir implements.

Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters "frmt" (format). In this use, "frmt" indicates the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFrmt	AccumWordLength	AccumFracLength	None
InputFrmt	InputWordLength	InputFracLength	None
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
OutputFrmt	OutputWordLength	OutputFracLength	None
ProductFrmt	ProductWordLength	ProductFracLength	None
TapSumFrmt	InputWordLength	InputFracLength	None

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFrmt, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFrmt refers to the properties ProductFracLength and ProductWordLength that fully define the coefficient format after multiply (or product) operations.

Properties   In this table you see the properties associated with the symmetric FIR implementation of dfilt objects.

> **Note** The table lists all the properties that a filter can have. Many of
> the properties are dynamic, meaning they exist only in response to the
> settings of other properties. You might not see all of the listed properties
> all the time. To view all the properties for a filter at any time, use

For further information about the properties of this filter or any `dfilt`
object, refer to "Fixed-Point Filter Properties" on page 8-2.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits [27]	Specifies the fraction length used to interpret data output by the accumulator.
AccumWordLength	Any integer number of bits[33]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to `fixed` allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.

Name	Values	Description
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [29]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilerInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [33]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.

Name	Values	Description
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductFracLength	Any positive or negative integer number of bits [29]	Specifies the fraction length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
ProductWordLength	Any integer number of bits [33]	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.

Name	Values	Description
RoundMode	[convergent], ceil, fix, floor, nearest, round	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.

Name	Values	Description
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object to match the filter arithmetic setting	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Toolbox documentation.

Examples　　**Odd Order**

Specify a fifth-order direct-form symmetric FIR filter structure for a dfilt object hd, with the following code:

```
b = [-0.008 0.06 0.44 0.44 0.06 -0.008];
hd = dfilt.dfsymfir(b);
% Create fixed-point filter
set(hd,'arithmetic','fixed')
% Change FilterInternals property to
% SpecifyPrecision
hd.Filterinternals='SpecifyPrecision';
```

Even Order

Specify a fourth-order, fixed-point, direct-form symmetric FIR filter structure for a dfilt object hd, with the following code:

```
b = [-0.01 0.1 0.8 0.1 -0.01];
hd = dfilt.dfsymfir(b);
set(hd,'arithmetic','fixed');
```

See Also　　dfilt | dfilt.dfasymfir | dfilt.dffir | dfilt.dffirt

dfilt.farrowfd

Purpose   Fractional Delay Farrow filter

Syntax   Hd = dfilt.farrowd(D, COEFFS)

Description   Hd = dfilt.farrowd(D, COEFFS)

Constructs a discrete-time fractional delay Farrow filter with COEFFS coefficients and D delay.

Examples   Farrow filters can be designed with the dfilt.farrowfd filter designer.

```
coeffs = [-1/6 1/2 -1/3 0;1/2 -1 -1/2 1;
-1/2 1/2 1 0;1/6 0 -1/6 0];
Hd = dfilt.farrowfd(0.5, coeffs);
```

Design a cubic fractional delay filter with the Lagrange method.

```
fdelay = .2; % Fractional delay
d = fdesign.fracdelay(fdelay,'N',3);
Hd = design(d, 'lagrange', 'FilterStructure', 'farrowfd');
fvtool(Hd, 'Analysis', 'grpdelay');
```

For more information about fractional delay filter implementations, see the "Fractional Delay Filters Using Farrow Structures" example, farrowdemo.

How To   • dfilt

dfilt.farrowlinearfd

Purpose	Farrow Linear Fractional Delay filter
Syntax	Hd = DFILT.FARROWLINEARFD(D)

Description   Hd = DFILT.FARROWLINEARFD(D)

Constructs a discrete-time linear fractional delay Farrow filter with the delay D.

Examples   Farrow linear fractional delay filter with 1/2 sample delay:

```
 Hd = dfilt.farrowlinearfd(0.5);
n = cos(pi/10*(0:159));
y = filter(Hd,x);
stem(x(1:40));
axis([0 40 -2 2]);
hold on;
stem(y(1:40),'color',[1 0 0],'markerfacecolor',[1 0 0 ]);
legend('Orignal Signal','Filtered Signal','Location','best');
```

For more information about fractional delay filter implementations, see the "Fractional Delay Filters Using Farrow Structures" example, farrowdemo.

How To   • dfilt

Purpose   Discrete-time, overlap-add, FIR filter

Syntax   Hd = dfilt.fftfir(b,len)
                   Hd = dfilt.fftfir(b)
                   Hd = dfilt.fftfir

Description   This object uses the overlap-add method of block FIR filtering, which is
                   very efficient for streaming data.

                   Hd = dfilt.fftfir(b,len) returns a discrete-time, FFT, FIR filter,
                   Hd, with numerator coefficients, b and block length, len. The block
                   length is the number of input points to use for each overlap-add
                   computation.

                   Hd = dfilt.fftfir(b) returns a discrete-time, FFT, FIR filter, Hd,
                   with numerator coefficients, b and block length, len=100.

                   Hd = dfilt.fftfir returns a default, discrete-time, FFT, FIR filter,
                   Hd, with the numerator b=1 and block length, len=100. This filter
                   passes the input through to the output unchanged.

                   Note When you use a dfilt.fftfir object to filter, the input signal
                   length must be an integer multiple of the object's block length, len. The
                   resulting number of FFT points = (filter length + the block length - 1).
                   The filter is most efficient if the number of FFT points is a power of 2.

                   The fftfir uses an overlap-add block processing algorithm, which is
                   represented as follows,

where len is the block length and M is the length of the numerator-1, (length(b)-1), which is also the number of states. The output of each convolution is a block that is longer than the input block by a tail of (length(b)-1) samples. These tails overlap the next block and are added to it. The states reported by dfilt.fftfir are the tails of the final convolution.

Examples   Create an FFT FIR discrete-time filter with coefficients from a 30th order lowpass equiripple design:

```
b = firpm(30,[0 .1 .2 .5]*2,[1 1 0 0]);
Hd = dfilt.fftfir(b);
% To obtain frequency domain coefficients
% used in filtering
Coeffs = fftcoeffs(Hd);
```

See Also   dfilt | dfilt.dffir | dfilt.dfasymfir | dfilt.dffirt | dfilt.dfsymfir

Purpose	Discrete-time, lattice allpass filter
Syntax	Refer to `dfilt.latticeallpass` in Signal Processing Toolbox documentation.
Description	`hd = dfilt.latticeallpass(k)` returns a discrete-time, lattice allpass filter object `hd`, with lattice coefficients, `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to "Arithmetic" on page 8-19.

`hd = dfilt.latticeallpass` returns a default, discrete-time, lattice allpass filter object `hd`, with `k=[ ]`. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure

The following figure shows the signal flow for the allpass lattice filter implemented by `dfilt.latticeallpass`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

dfilt.latticeallpass

Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word "format." In this use, "format" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	AccumWordLength	AccumFracLength	AccumMode
InputFormat	InputWordLength	InputFracLength	None
LatticeFormat	CoeffWordLength	LatticeFracLength	CoeffAutoScale
OutputFormat	OutputWordLength	OutputFracLength	OutputMode
ProductFormat	ProductWordLength	ProductFracLength	ProductMode
StateFormat	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties ProductFracLength, ProductWordLength, and ProductMode that fully define the coefficient format after multiply (or product) operations.

Properties   In this table you see the properties associated with the allpass lattice implementation of dfilt objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

get(hd)

where hd is a filter.

---

dfilt.latticeallpass

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 8-2.

Property Name	Brief Description
AccumFracLength	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties —`DenAccumFracLength` and `NumAccumFracLength` — that let you set the precision for numerator and denominator operations separately.
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (`FullPrecision`), or whether to keep the most significant bits (`KeepMSB`) or least significant bits (`KeepLSB`) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set `AccumMode` to `SpecifyPrecision`.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.

Property Name	Brief Description
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the LatticeFracLength property value to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
Lattice	Any lattice structure coefficients. No default value.
LatticeFracLength	Sets the fraction length applied to the lattice coefficients.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.

dfilt.latticeallpass

Property Name	Brief Description
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductFracLength	For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.

Property Name	Brief Description
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity.

Property Name	Brief Description
	• nearest - Round toward nearest. Ties round toward positive infinity.
	• round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.
	The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

Examples   Specify a third-order lattice allpass filter structure for a dfilt object hd, with the following code:

```
k = [.66 .7 .44];
hd=dfilt.latticeallpass(k);
% convert to fixed-point arithmetic
hd.arithmetic = 'fixed';
```

See Also   dfilt | dfilt.latticear | dfilt.latticearma |
                   dfilt.latticemamax | dfilt.latticemamin

dfilt.latticear

Purpose   Discrete-time, lattice, autoregressive filter

Syntax   Refer to `dfilt.latticear` in Signal Processing Toolbox documentation.

Description `hd = dfilt.latticear(k)` returns a discrete-time, lattice autoregressive filter object `hd`, with lattice coefficients, `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to "Arithmetic" on page 8-19.

`hd = dfilt.latticear` returns a default, discrete-time, lattice autoregressive filter object `hd`, with `k=[ ]`. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure

The following figure shows the signal flow for the autoregressive lattice filter implemented by `dfilt.latticear`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word "format." In this use, "format" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	`AccumWordLength`	`AccumFracLength`	`AccumMode`
InputFormat	`InputWordLength`	`InputFracLength`	None

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
LatticeFormat	CoeffWordLength	LatticeFracLength	CoeffAutoScale
OutputFormat	OutputWordLength	OutputFracLength	OutputMode
ProductFormat	ProductWordLength	ProductFracLength	ProductMode
StateFormat	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties ProductFracLength, ProductWordLength, and ProductMode that fully define the coefficient format after multiply (or product) operations.

Properties   In this table you see the properties associated with the autoregressive lattice implementation of dfilt objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

get(hd)

where hd is a filter.

For further information about the properties of this filter or any dfilt object, refer to "Fixed-Point Filter Properties" on page 8-2.

Property Name	Brief Description
AccumFracLength	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.

Property Name	Brief Description
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the LatticeFracLength to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
Lattice	Any lattice structure coefficients.
LatticeFracLength	Sets the fraction length applied to the lattice coefficients.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.

Property Name	Brief Description
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductFracLength	For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.

Property Name	Brief Description
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity.

Property Name	Brief Description
	• nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

Examples   Specify a third-order lattice autoregressive filter structure for a dfilt object, hd, with the following code that creates a fixed-point filter.

dfilt.latticear

```
k = [.66 .7 .44];
hd1=dfilt.latticear(k);
hd1.arithmetic='fixed';
specifyall(hd1);
```

See Also   dfilt | dfilt.latticeallpass | dfilt.latticearma |
                dfilt.latticemamax | dfilt.latticemamin

Purpose　Discrete-time, lattice, autoregressive, moving-average filter

Syntax　Refer to `dfilt.latticearma` in Signal Processing Toolbox documentation.

Description　`hd = dfilt.latticearma(k)` returns a discrete-time, lattice moving-average autoregressive filter object `hd`, with lattice coefficients, `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

• To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

• To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to "Arithmetic" on page 8-19.

`hd dfilt.latticearma` returns a default, discrete-time, lattice moving-average, autoregressive filter object `hd`, with `k = [ ]`. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure　The following figure shows the signal flow for the autoregressive lattice filter implemented by `dfilt.latticearma`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

dfilt.latticearma

Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word "format." In this use, "format" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
InputFormat	InputWordLength	InputFracLength	None
LadderAccumFormat	AccumWordLength	LadderAccumFracLength	AccumMode
LadderFormat	CoeffWordLength	LadderFracLength	CoeffAutoScale
LadderProdFormat	ProductWordLength	LadderProdFracLength	ProductMode
LatticeAccumFormat	AccumWordLength	LatticeAccum-FracLength	AccumMode
LatticeFormat	CoeffWordLength	LatticeFracLength	CoeffAutoScale
LatticeProdFormat	ProductWordLength	LatticeProdFracLength	ProductMode
OutputFormat	OutputWordLength	OutputFracLength	OutputMode
StateFormat	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label LatticeProdFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that lattice coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the LatticeProdFormat refers to the properties ProductWordLength, LatticeProdFracLength, and ProductMode that fully define the coefficient format after multiply (or product) operations.

Properties   In this table you see the properties associated with the autoregressive moving-average lattice implementation of dfilt objects.

> **Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use
>
> get(hd)
>
> where hd is a filter.

For further information about the properties of this filter or any dfilt object, refer to "Fixed-Point Filter Properties" on page 8-2.

Property Name	Brief Description
AccumFracLength	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.

Property Name	Brief Description
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the LatticeFracLength property to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
Ladder	Stores the ladder coefficients for lattice ARMA (dfilt.latticearma) filters.

Property Name	Brief Description
LadderAccumFracLength	Sets the fraction length used to interpret the output from sum operations that include the ladder coefficients. You can change this property value after you set AccumMode to SpecifyPrecision.
LadderFracLength	Determines the precision used to represent the ladder coefficients in ARMA lattice filters.
Lattice	Stores the lattice structure coefficients.
LatticeFracLength	Sets the fraction length applied to the lattice coefficients.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.

Property Name	Brief Description
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductFracLength	For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.

Property Name	Brief Description
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set `ProductMode` to `SpecifyPrecision`.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. `False` is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic.

Property Name	Brief Description
	Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

dfilt.latticemamax

Purpose	Discrete-time, lattice, moving-average filter with maximum phase
Syntax	Refer to `dfilt.latticemamax` in Signal Processing Toolbox documentation.
Description	`hd = dfilt.latticemamax(k)` returns a discrete-time, lattice, moving-average filter object `hd`, with lattice coefficients `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to "Arithmetic" on page 8-19.

Note When the `k` coefficients define a maximum phase filter, the resulting filter in this structure is maximum phase. When your coefficients do not define a maximum phase filter, placing them in this structure does not produce a maximum phase filter.

`hd = dfilt.latticemamax` returns a default discrete-time, lattice, moving-average filter object `hd`, with `k = [ ]`. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure

The following figure shows the signal flow for the maximum phase implementation of a moving-average lattice filter implemented by `dfilt.latticemamax`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical

operations, the figure includes the locations of the formatting objects within the signal flow.

Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word "format." In this use, "format" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	AccumWordLength	AccumFracLength	AccumMode
InputFormat	InputWordLength	InputFracLength	None
LatticeFormat	CoeffWordLength	LatticeFracLength	CoeffAutoScale
OutputFormat	OutputWordLength	OutputFracLength	OutputMode
ProductFormat	ProductWordLength	ProductFracLength	ProductMode
StateFormat	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties ProductFracLength, ProductWordLength, and ProductMode that fully define the coefficient format after multiply (or product) operations.

Properties   In this table you see the properties associated with the maximum phase, moving average lattice implementation of dfilt objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

get(hd)

where hd is a filter.

For further information about the properties of this filter or any dfilt object, refer to "Fixed-Point Filter Properties" on page 8-2.

Property Name	Brief Description
AccumFracLength	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.

dfilt.latticemamax

Property Name	Brief Description
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the LatticeFracLength property to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
Lattice	Any lattice structure coefficients.
LatticeFracLength	Sets the fraction length applied to the lattice coefficients.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.

Property Name	Brief Description
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductFracLength	For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.

Property Name	Brief Description
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity.

Property Name	Brief Description
	• nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

Examples Specify a fourth-order lattice, moving-average, maximum phase filter structure for a dfilt object, hd, with the following code:

```
k = [.66 .7 .44 .33];
hd = dfilt.latticemamax(k);
```

See Also   dfilt | dfilt.latticeallpass | dfilt.latticear |
               dfilt.latticearma | dfilt.latticemamin

dfilt.latticemamin

Purpose   Discrete-time, lattice, moving-average filter with minimum phase

Syntax   Refer to `dfilt.latticemamin` in Signal Processing Toolbox
                  documentation.

Description   `hd = dfilt.latticemamin(k)` returns a discrete-time, lattice,
                  moving-average, minimum phase, filter object `hd`, with lattice
                  coefficients `k`.

                  Make this filter a fixed-point or single-precision filter by changing the
                  value of the `Arithmetic` property for the filter `hd` as follows:

                  • To change to single-precision filtering, enter

                    `set(hd,'arithmetic','single');`

                  • To change to fixed-point filtering, enter

                    `set(hd,'arithmetic','fixed');`

                  For more information about the property `Arithmetic`, refer to
                  "Arithmetic" on page 8-19.

                  Note When the `k` coefficients define a minimum phase filter, the
                  resulting filter in this structure is minimum phase. When your
                  coefficients do not define a minimum phase filter, placing them in this
                  structure does not produce a minimum phase filter.

                  `hd = dfilt.latticemamin` returns a default discrete-time, lattice,
                  moving-average, minimum phase, filter object `hd`, with k=[ ]. This filter
                  passes the input through to the output unchanged.

Fixed-Point   The following figure shows the signal flow for the minimum phase
Filter   implementation of a moving-average lattice filter implemented by
Structure   `dfilt.latticemamin`. To help you see how the filter processes the
                  coefficients, input, and states of the filter, as well as numerical

dfilt.latticemamin

operations, the figure includes the locations of the formatting objects within the signal flow.

Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word "format." In this use, "format" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	AccumWordLength	AccumFracLength	AccumMode
InputFormat	InputWordLength	InputFracLength	None
LatticeFormat	CoeffWordLength	LatticeFracLength	CoeffAutoScale
OutputFormat	OutputWordLength	OutputFracLength	OutputMode
ProductFormat	ProductWordLength	ProductFracLength	ProductMode
StateFormat	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties ProductFracLength, ProductWordLength, and ProductMode that fully define the coefficient format after multiply (or product) operations.

Properties   In this table you see the properties associated with the minimum phase, moving average lattice implementation of dfilt objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

get(hd)

where hd is a filter.

---

dfilt.latticemamin

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 8-2.

Property Name	Brief Description
AccumFracLength	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — `DenAccumFracLength` and `NumAccumFracLength` — that let you set the precision for numerator and denominator operations separately.
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (`FullPrecision`), or whether to keep the most significant bits (`KeepMSB`) or least significant bits (`KeepLSB`) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set `AccumMode` to `SpecifyPrecision`.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.

Property Name	Brief Description
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the LatticeFracLength property to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
Lattice	Any lattice structure coefficients.
LatticeFracLength	Sets the fraction length applied to the lattice coefficients.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.

Property Name	Brief Description
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductFracLength	For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.

Property Name	Brief Description
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity.

minimal# dfilt.latticemamin

Property Name	Brief Description
	• nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

Examples   Specify a third-order lattice, moving-average, minimum phase, filter structure for a dfilt object, hd, with the following code:

```
k = [.66 .7 .44];
hd = dfilt.latticemamin(k);
```

                 dfilt.latticearma | dfilt.latticemamax

dfilt.parallel

Purpose   Discrete-time, parallel structure filter

Syntax   Refer to `dfilt.parallel` in Signal Processing Toolbox documentation.

Description   `hd = dfilt.parallel(hd1,hd2,...)` returns a discrete-time filter object `hd`, which is a structure of two or more `dfilt` filter objects, `hd1`, `hd2`, and so on arranged in parallel.

You can also use the standard notation to combine filters into a parallel structure.

`parallel(hd1,hd2,...)`

In this syntax, `hd1`, `hd2`, and so on can be a mix of `dfilt` objects, `mfilt` objects, and `adaptfilt` objects.

`hd1`, `hd2`, and so on can be fixed-point filters. All filters in the parallel structure must be the same arithmetic format — double, single, or fixed. `hd`, the filter returned, inherits the format of the individual filters.

See Also   `dfilt` | `dfilt.cascade` | `parallel` | `dfilt.cascade` | `dfilt.parallel`

Purpose   Discrete-time, scalar filter

Syntax   Refer to dfilt.scalar in Signal Processing Toolbox documentation.

Description dfilt.scalar(g) returns a discrete-time, scalar filter object with gain g, where g is a scalar.

Make this filter a fixed-point or single-precision filter by changing the value of the Arithmetic property for the filter hd as follows:

• To change to single-precision filtering, enter

  set(hd,'arithmetic','single');

• To change to fixed-point filtering, enter

  set(hd,'arithmetic','fixed');

For more information about the property Arithmetic, refer to "Arithmetic" on page 8-19.

dfilt.scalar returns a default, discrete-time scalar gain filter object hd, with gain 1.

Properties In this table you see the properties associated with the scalar implementation of dfilt objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

get(hd)

where hd is a filter.

For further information about the properties of this filter or any dfilt object, refer to "Fixed-Point Filter Properties" on page 8-2.

Property Name	Brief Description
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the CoeffFracLength property to specify the precision used.
CoeffFracLength	Set the fraction length the filter uses to interpret coefficients. CoeffFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
Gain	Returns the gain for the scalar filter. Scalar filters do not alter the input data except by adding gain.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.

Property Name	Brief Description
InputWordLength	Specifies the word length applied to interpret input data.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.

Property Name	Brief Description
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.

Property Name	Brief Description
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.

Examples   Create a direct-form I filter object hd_filt and a scalar object with a gain of 3 hd_gain and cascade them together.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd_filt = dfilt.df1(b,a);
hd_gain = dfilt.scalar(3);
hd_cascade=cascade(hd_gain,hd_filt);
fvtool_handle = fvtool(hd_filt,hd_gain,hd_cascade);
legend(fvtool_handle,'IIR Filter (direct form I)',...
'Gain','Cascaded Filter');
```

To view the stages of the cascaded filter, use

hd.Stage(1)

and

hd.Stage(2)

See Also   dfilt | dfilt.cascade

Purpose   Wave digital allpass filter

Syntax   hd = dfilt.wdfallpass(c)

Description   hd = dfilt.wdfallpass(c) constructs an allpass wave digital filter structure given the allpass coefficients in vector c.

Vector c must have, one, two, or four elements (filter coefficients). Filters with three coefficients are not supported. When you use c with four coefficients, the first and third coefficients must be 0.

Given the coefficients in c, the transfer function for the wave digital allpass filter is defined by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \ldots + z^{-n}}{1 + c(1)z^{-1} + \ldots + c(n)z^{-n}}$$

Internally, the allpass coefficients are converted to wave digital filters for filtering. Note that dfilt.wdfallpass allows only stable filters. Also note that the leading coefficient in the denominator, a 1, does not need to be included in vector c.

Use the constructor dfilt.cascadewdfallpass to cascade wdfallpass filters.

To compare these filters to other similar filters, dfilt.wdfallpass and dfilt.cascadewdfallpass filters have the same number of multipliers as the non-wave digital filters dfilt.allpass and dfilt.cascadeallpass. However, the wave digital filters use fewer states and they may require more adders in the filter structure.

Wave digital filters are usually used to create other filters. This toolbox uses them to implement halfband filters, which the first example in Examples demonstrates. They are most often building blocks for filters.

Properties   In the next table, the row entries are the filter properties and a brief description of each property.

dfilt.wdfallpass

Property Name	Brief Description
AllpassCoefficients	Contains the coefficients for the allpass wave digital filter object
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. `False` is the default setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to `filtstates` in Signal Processing Toolbox documentation or in the Help system.

Filter Structure

When you change the order of the wave digital filters in the cascade, the filter structure changes as well.

As shown in this example, `realizemdl` lets you see the filter structure used for your filter, if you have Simulink installed.

```
section11=0.8;
section12=[1.5,0.7];
section13=[1.8,0.9];
hd1=dfilt.cascadewdfallpass(section11,section12,section13);

section21=[0.8,0.4];
section22=[0,1.5,0,0.7];
```

```
section23=[0,1.8,0,0.9];
hd2=dfilt.cascadewdfallpass(section21,section22,section23);
% If you have Simulink
realizemdl(hd2)
```

hd1 has this filter structure with three sections.

The filter structure for `hd2` is somewhat different, with the different orders and interconnections between the three sections.

Examples   Construct a second-order wave digital allpass filter with two coefficients. Note that to use realizemdl, you must have Simulink.

```
c = [1.5,0.7];
hd = dfilt.wdfallpass(c);
```

With Simulink installed, realizemdl returns this structure for hd.

See Also   dfilt | dfilt.allpass | dfilt.latticeallpass | dfilt.cascadewdfallpass | dfilt.cascadeallpass | mfilt.iirdecim | mfilt.iirinterp

disp

Purpose	Filter properties and values

Syntax	`disp(hd)`
	`disp(ha)`
	`disp(hm)`

Description	Similar to omitting the closing semicolon from an expression on the command line, except that `disp` does not display the variable name. `disp` lists the property names and property values for any filter object, such as a `dfilt` object or `adaptfilt` object. The following examples illustrate the default display for an adaptive filter `ha` and a multirate filter `hm`.

```
ha=adaptfilt.rls;
fprintf('Displaying properties for default RLS adaptive filter:\n');
fprintf('\n');
disp(ha)
pause(2);
hm=mfilt.cicdecim(6);
fprintf('Displaying properties for cascaded integrator-comb decimator\n')
fprintf('with a decimation factor of 6:\n');
fprintf('\n');
disp(hm)
```

See Also	`set`

Purpose   Cast fixed-point filter to use double-precision arithmetic

Syntax   hd = double(h)

Description hd = double(h) returns a new filter hd that has the same structure
and coefficients as h, but whose arithmetic property is set to double
to use double-precision arithmetic for filtering. double(h) is not the
same as the reffilter(h) function:

- hd, the filter returned by double has the quantized coefficients of h
  represented in double-precision floating-point format

- The reference filter returned by reffilter has double-precision,
  floating-point coefficients that have not been quantized.

You might find double(h) useful to isolate the effects of quantizing the
coefficients of a filter by using double to create a filter hd that operates
in double-precision but uses the quantized filter coefficients.

Examples   Use the same filter, once with fixed-point arithmetic and once with
floating-point, to compare fixed-point filtering with double-precision
floating-point filtering.

```
h = dfilt.dffir(firgr(27,[0 .4 .6 1],...
[1 1 0 0]));                    % Lowpass filter.
% Set h to use fixed-point arithmetic to filter.
% Quantize the coeffs.
h.arithmetic = 'fixed';
% Cast h to double-precision
hd = double(h);
% Set up an input signal.
n = 0:99; x = sin(0.7*pi*n(:));
y = filter(h,x);                % Fixed-point output.
yd = filter(hd,x);              % Floating-point output.
FixedFloatNormDiff=norm(yd-double(y),inf);
```

dsp.util.getLogsArray

Purpose	Return logged signal as MATLAB array

Syntax

```
Array = dsp.util.getLogsArray(LogObject,Format2D,
    'SignalPath',PATH)
Array = dsp.util.getLogsArray(LogObject,Format2D,
    'SignalName',NAME)
```

Description

Array =
dsp.util.getLogsArray(LogObject,Format2D,'SignalPath',PATH)
returns a MATLAB array that contains a signal in `LogObject`. You
must specify the `PATH` to the signal in `LogObject` using the
`Name,Value` pair argument.

Array =
dsp.util.getLogsArray(LogObject,Format2D,'SignalName',NAME)
returns a MATLAB array that contains a signal in `LogObject`. You
must specify the `NAME` of the signal in `LogObject` using the
`Name,Value` pair argument.

Input Arguments

LogObject

Specify the name of the object that contains your logged signals. Valid
classes for `LogObject` depend on the syntax you use:

- When you specify PATH as a `dsp.util.SignalPath` object,
  `LogObject` can be either a `Simulink.SimulationData.Dataset` or
  `Simulink.SimulationData.Signal` object.

- When you specify PATH as the full path to a block in a Simulink
  model, `LogObject` must be a `Simulink.SimulationData.Dataset`
  object.

- When you specify the NAME of a signal in
  `LogObject`, `LogObject` can be an object of class
  `timeseries`, `Simulink.SimulationData.Dataset`, or
  `Simulink.SimulationData.Signal`.

Format2D

Specify a logical value to determine whether the function formats 3-D logged signals as a 2-D or 3-D MATLAB array. When you set this property to `true`, the function uses the following formula to format the 3-D logged signal into a 2-D MATLAB array:

```
dim = size(signal);
ntimes = dim(1)*dim(3);
Array = reshape(permute(signal,[1 3 2]),[ntimes dim(2)]);
```

When you set this property to `false`, the function returns the logged signal without any reformatting.

PATH

Specify the path to the logged signal in `LogObject`. You can specify the path using a `dsp.util.SignalPath` object, or you can provide the full path to a block in your Simulink model. To get the full path to a block in your Simulink model, use the `gcb` command.

NAME

Specify the name of the signal in `LogObject`.

Output Arguments

Array

The output `Array` is a MATLAB array that contains the specified logged signal. When the input is a 3-D logged signal, the dimensions of `Array` depend on the value you specify for `Format2D`:

- When `Format2D` is `true`, `Array` is a 2-D MATLAB array.

- When `Format2D` is `false`, `Array` is a 3-D MATLAB array.

When the input is not a 3-D signal, the dimensions of the output `Array` match those of the input.

dsp.util.getLogsArray

Examples

> **Note** To run the following examples, you must first load
> ex_logsout.mat which contains a `Simulink.SimulationData.Dataset`
> object. Alternatively, you can open and simulate the ex_log_utils
> Simulink model. Doing so will log signals and generate the necessary
> `ex_logsout` object.

Extract a unique signal named Signal3x4 from ex_logsout.

```
dsp.util.getLogsArray(ex_logsout, true, 'SignalName','Signal3x4')
```

Extract a unique signal named Signal3x4 from ex_logsout as a 3-D array.

```
dsp.util.getLogsArray(ex_logsout, false, 'SignalName','Signal3x4')
```

Find and extract a specific signal from multiple signals that have the same name.

Because ex_logsout contains multiple signals named Signal2x4, you
must use the `dsp.util.getSignalPath` function to find the paths to
each of those signals.

```
paths = dsp.util.getSignalPath(ex_logsout, 'Signal2x4')
% paths is a 2x1 array of dsp.util.SignalPath objects. Next, examine
% the BlockPath property of each paths object.
paths.BlockPath
% Find the signal path that corresponds to the logged signal you are
% interested in. For example paths(2). You can then use the
% dsp.util.getLogsArray function and provide the 'SignalPath' name-value
% pair argument.
dsp.util.getLogsArray(ex_logsout, true, 'SignalPath', paths(2))
```

Find and extract a signal from a bus.

Use the `dsp.util.getSignalPath` function to get paths to all the
signals in the bus named Bus1.

```
buspaths = dsp.util.getSignalPath(ex_logsout, 'Bus1')
% buspaths is a 2x1 array of dsp.util.SignalPath objects. Examine the
% BusElement property of each buspaths object.
buspaths.BusElement
% Select a signal path. For example buspaths(1). This is the path to t
% signal named 'Signal3x4' in bus 'Bus' that is contained in bus 'Bus
% Now that you have the path to the signal, call dsp.util.getLogsArray
% using the 'SignalPath' name-value pair argument.
dsp.util.getLogsArray(ex_logsout, true, 'SignalPath', buspaths(1))
```

Simulink.SimulationData.Signal | timeseries

How To   • "Export Signal Data Using Signal Logging"

• "Configure a Signal for Signal Logging"

• "Specify the Signal Logging Data Format"

dsp.util.getSignalPath

Purpose	Paths to logged signals
Syntax	`Path = dsp.util.getSignalPath(LogObject, SignalName)`
Description	`Path = dsp.util.getSignalPath(LogObject, SignalName)` returns all paths to signals in `LogObject` with name `SignalName`. The output `Path` is a `dsp.util.SignalPath` object or an array of `dsp.util.SignalPath` objects.
Tips	• To return the path to an unnamed signal in `LogObject`, set `SignalName` to the empty string (`''`).

Input Arguments

LogObject

Specify the name of the object that contains your logged signals. `LogObject` must be a `Simulink.SimulationData.Dataset` or `Simulink.SimulationData.Signal` object.

SignalName

Specify the name of a logged signal in `LogObject`.

Output Arguments

Path

The output `Path` contains the path to all signals named `SignalName` in `LogObject`.

- If `LogObject` contains a unique signal with name `SignalName`, the function returns a single `dsp.util.SignalPath` object.

- If `LogObject` contains more than one signal with the specified name, the function returns an array of `dsp.util.SignalPath` objects.

Examples

Note To run the following examples, you must first load
ex_logsout.mat which contains a Simulink.SimulationData.Dataset
object. Alternatively, you can open and simulate the ex_log_utils
Simulink model. Doing so will log signals and generate the necessary
ex_logsout object.

Find and extract a specific signal from multiple signals that have the same name.

Because ex_logsout contains multiple signals named Signal2x4, you
must use the dsp.util.getSignalPath function to find the paths to
each of those signals.

```
paths = dsp.util.getSignalPath(ex_logsout, 'Signal2x4')
% paths is a 2x1 array of dsp.util.SignalPath objects. Next, examine
% the BlockPath property of each paths object.
paths.BlockPath
% Find the signal path that corresponds to the logged signal you are
% interested in. For example paths(2). You can then use the
% dsp.util.getLogsArray function and provide the 'SignalPath' name-val
% pair argument.
dsp.util.getLogsArray(ex_logsout, true, 'SignalPath', paths(2))
```

Find and extract a signal from a bus.

Use the dsp.util.getSignalPath function to get paths to all the
signals in the bus named Bus1.

```
buspaths = dsp.util.getSignalPath(ex_logsout, 'Bus1')
% buspaths is a 2x1 array of dsp.util.SignalPath objects. Examine the
% BusElement property of each buspaths object.
buspaths.BusElement
% Select a signal path. For example buspaths(1). This is the path to t
% signal named 'Signal3x4' in bus 'Bus' that is contained in bus 'Bus'
% Now that you have the path to the signal, call dsp.util.getLogsArray
% using the 'SignalPath' name-value pair argument.
dsp.util.getLogsArray(ex_logsout, true, 'SignalPath', buspaths(1))
```

dsp.util.getSignalPath

See Also
dsp.util.getLogsArray | dsp.util.SignalPath
| Simulink.SimulationData.Dataset
| Simulink.SimulationData.Signal |
Simulink.SimulationData.updateDatasetFormatLogging

How To
- "Export Signal Data Using Signal Logging"
- "Configure a Signal for Signal Logging"
- "Specify the Signal Logging Data Format"

Purpose   Properties of paths to signals

Description   `dsp.util.SignalPath` objects contain path information for
                  signals in `Simulink.SimulationData.Dataset` objects. You get
                  `Simulink.SimulationData.Dataset` objects when you use `Dataset`
                  logging to log signals from a Simulink model.

Construction `dsp.util.SignalPath` objects are returned by the
                  `dsp.util.getSignalPath` function and can be used as input
                  to the `dsp.util.getLogsArray` function.

Properties   **SignalName**

                  Contains the name of the signal output by the block at the
                  specified `BlockPath`.

                  BlockPath

                  Provides the `Simulink.SimulationData.BlockPath` to the block
                  in the Simulink model from which the signal originates.

                  PortIndex

                  Provides the output port index of the block from which the logged
                  signal `SignalName` originates.

                  BusElement

                  Provides a string description of a signal in a logged bus. When
                  `SignalPath` is not a logged bus, this property will be an empty
                  string.

                  If the `SignalPath` object is a logged bus signal, the `BusElement`
                  string will be formatted as follows:

                  • When the bus contains a nonbus signal, `BusElement` is the
                    name of that signal.

                  • When the bus contains a nested bus that contains a nonbus
                    signal, `BusElement` will be a dot-separated string consisting of

the name of the nested bus followed by the name of the non-bus signal. For example: `nestbus.signal1`

- When the bus contains nested busses within nested busses to any depth, `BusElement` will be a dot-separated string. This string contains each of the nested bus names, and ends with the nonbus signal name. For example: `outernestedbus.innernestedbus.signal1`

Simulink.SimulationData.Dataset

Purpose	Identify whether blocks in model are current, deprecated, or obsolete
Syntax	`dsp_links` `dsp_links('modelname')`
Description	`dsp_links` returns a structure with three elements that identify whether the DSP System Toolbox blocks in the current model are current, deprecated, or obsolete. Each element is one of the three block categories and contains a cell array of strings. Each string is the name of a library block in the current model. `dsp_links('modelname')` returns the three-element structure for the specified model.

Definitions

Obsolete Blocks

Obsolete blocks are blocks that the toolbox no longer supports. In some cases, these blocks no longer function properly.

Deprecated Blocks

Deprecated blocks are blocks that the toolbox still supports but are likely to become obsolete in a future release. Refer to the block reference page for suggested replacements.

Current Blocks

Current blocks are blocks that the toolbox supports and that represent the latest block functionality.

Examples

Display block support information for the specified model, and then find the name of the first current block:

```
sys = 'dspcochlear';
load_system(sys)     % Load the dspcochlear model
links = dsp_links(sys) % Run dsp_links on the model
links.current{1}     % Find the name of the first current block
```

See Also   `liblinks`

dsplib

Purpose   Open top-level DSP System Toolbox library

Syntax   `dsplib`

Description   `dsplib` opens the top-level DSP System Toolbox block library model.

Examples   View and gain access to the DSP System Toolbox blocks:

`dsplib`

Alternatives   To view and gain access to the DSP System Toolbox blocks using the Simulink library browser:

- Type `simulink` at the MATLAB command line, and then expand the DSP System Toolbox node in the library browser.

- Click the Simulink icon from the MATLAB Toolstrip.

Purpose   Configure Simulink environment for signal processing systems

Syntax   dspstartup

Description   dspstartup configures Simulink environment parameters with settings
                   appropriate for a typical signal processing project. You can use the
                   dspstartup function in the following ways:

- At the MATLAB command line. Doing so configures the Simulink
  environment in your current session for signal processing projects.

- By adding a call to the dspstartup function from your startup.m file.
  When you do so, MATLAB configures your Simulink environment for
  typical signal processing projects each time you launch MATLAB.

When the function successfully configures your Simulink environment,
MATLAB displays the following message in the command window.

```
Changed default Simulink settings for signal processing
systems (dspstartup.m).
```

The dspstartup.m file executes the following commands. See
set_param in the Simulink documentation.

```
set_param(0, ...
          'SingleTaskRateTransMsg','error', ...
          'multiTaskRateTransMsg', 'error', ...
          'Solver',                'fixedstepdiscrete', ...
          'SolverMode',            'SingleTasking', ...
          'StartTime',             '0.0', ...
          'StopTime',              'inf', ...
          'FixedStep',             'auto', ...
          'SaveTime',              'off', ...
          'SaveOutput',            'off', ...
          'AlgebraicLoopMsg',      'error', ...
          'SignalLogging',         'off');
```

dspstartup

Examples
Add a call to the dspstartup function from your startup.m file:

1 To find out if there is a startup.m file on your MATLAB path, run the following code at the MATLAB command line:

```
which startup.m
```

2 If MATLAB returns 'startup.m' not found., see "Startup Options" in the MATLAB documentation to learn more about the startup.m file.

If MATLAB returns a path to your startup.m file, open that file for editing.

```
edit startup.m
```

3 Add a call to the dspstartup function. Your startup.m file now resembles the following code sample:

```
%STARTUP    Startup file
%    This file is executed when MATLAB starts up, if it exists
%    anywhere on the path.  In this case, the startup.m file
%    runs the dspstartup.m file to configure the Simulink
%    environment with settings appropriate for typical
%    signal processing projects.

dspstartup;
```

How To
• "Configure the Simulink Environment for Signal Processing Models"

Purpose   Elliptic filter using specification object

Syntax   hd = design(d,'ellip')
               hd = design(d,'ellip',designoption,value,designoption,...
               value,...)

Description   hd = design(d,'ellip') designs an elliptical IIR digital filter using
               the specifications supplied in the object h.

               hd = design(d,'ellip',designoption,value,designoption,...
               value,...) returns an elliptical or Cauer FIR filter where you specify
               design options as input arguments.

               To determine the available design options, use designopts with the
               specification object and the design method as input arguments as
               shown.

               designopts(d,'method')

               For complete help about using ellip, refer to the command line help
               system. For example, to get specific information about using ellip with
               d, the specification object, enter the following at the MATLAB prompt.

               help(d,'ellip')

Examples   These examples demonstrate how to use ellip to design filters based
               on filter specification objects.

               Example 1

               Construct the default bandpass filter specification object and design
               an elliptic filter.

               d = fdesign.bandpass;
               hd = design(d,'ellip','matchexactly','both');

Example 2

Construct a lowpass object with order, passband-edge frequency, stopband-edge frequency, and passband ripple specifications, and then design an elliptic filter.

```
d = fdesign.lowpass('n,fp,fst,ap',6,20,25,.8,80);
design(d,'ellip'); % Starts FVtool to display the filter.
```

Example 3

Construct a lowpass object with filter order, passband edge frequency, passband ripple, and stopband attenuation specifications, and then design an elliptic filter.

```
d = fdesign.lowpass('n,fp,ap,ast',6,20,.8,60,80);
design(d,'ellip'); % Starts FVTool to display the filter.
```

euclidfactors

Purpose   Euclid factors for multirate filter

Syntax   `[lo,mo] = euclidfactors(hm)`

Description   `[lo,mo] = euclidfactors(hm)` returns integer factors `lo` and `mo` such that (`lo*L`)-(`mo*M`) = -1. L and M are relatively prime and represent the interpolation and decimation factors of the multirate filter `hm`.

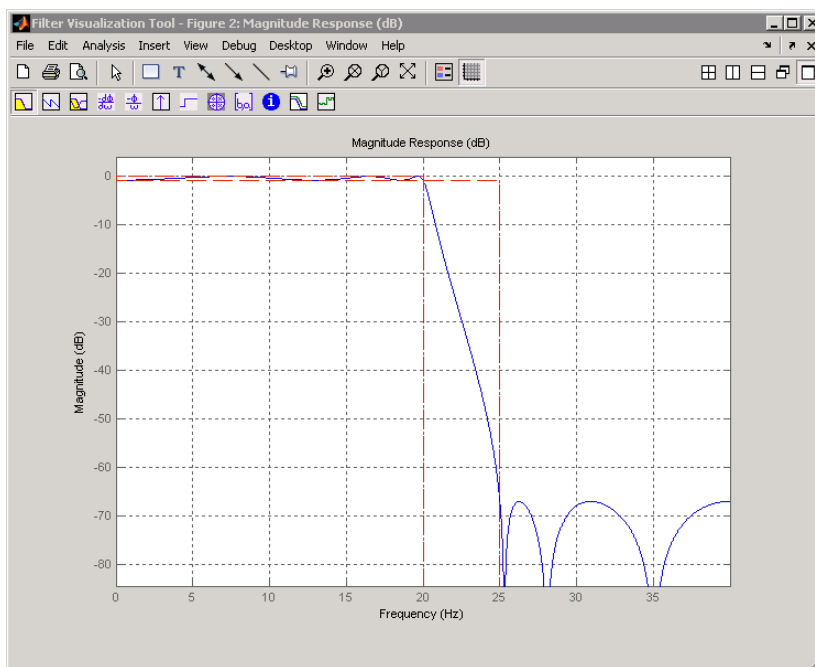
`euclidfactors` works with the multirate filters `mfilt.firfracdecim` and `mfilt.firfracinterp`. You cannot return `lo` and `mo` for decimators or interpolators.

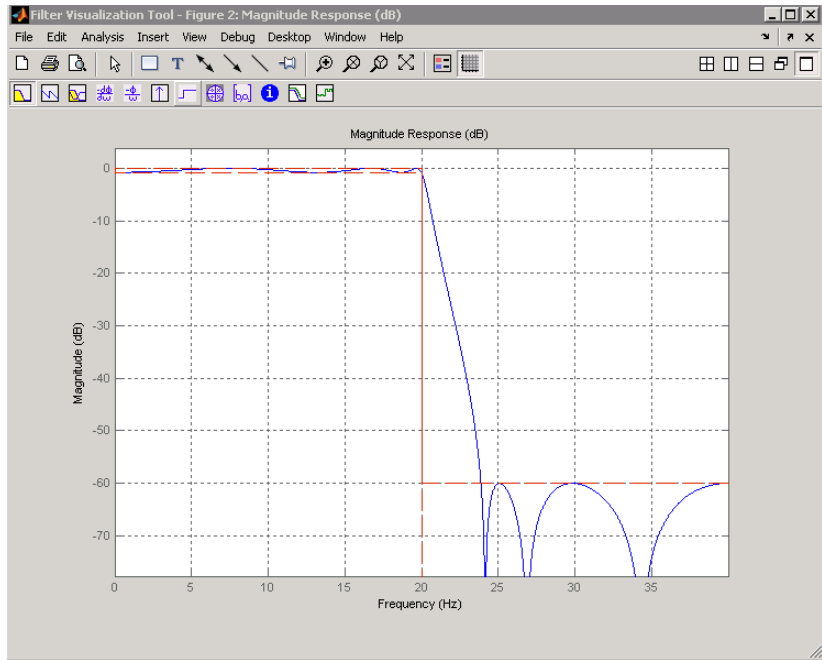
Examples   Use an FIR fractional decimator, with L = 5 and M = 7, to show what `euclidfactors` does.

Indeed, (`lo*L`)-(`mo*M`) = (4*5)-(3*7) = -1.

See Also   `polyphase` | `nstates`

Purpose   Equiripple single-rate or multirate FIR filter from specification object

Syntax   ```
hd = design(d,'equiripple')
hd = design(d,'equiripple',designoption,value,designoption,
...value,...)
```




Description   `hd = design(d,'equiripple')` designs an equiripple FIR digital
filter or multirate filter using the specifications supplied in the object
`d`. Equiripple filter designs minimize the maximum ripple in the
passbands and stopbands.

hd is either a `dfilt` object (a single-rate digital filter) or an `mfilt` object
(a multirate digital filter) depending on the `Specification` property
of the filter specification object `d` and the specifications object type —
halfband or interpolator.

When you use `equiripple` with Nyquist filter specification objects, you
might encounter design cases where the filter design does not converge.
Convergence errors occur mostly at large filter orders, or small
transition widths, or large stopband attenuations. These specifications,
alone or combined, can cause design failures. For more information,
refer to `fdesign.nyquist` in the online Help system.

`hd = design(d,'equiripple',designoption,value,designoption,
...value,...)` returns an equiripple FIR filter where you specify
design options as input arguments.

To determine the available design options, use `designopts` with the
specification object and the design method as input arguments as
shown.

```
designopts(d,'method')
```

For complete help about using `equiripple`, refer to the command line
help system. For example, to get specific information about using
`equiripple` with `d`, the specification object, enter the following at the
MATLAB prompt.

```
help(d,'equiripple')
```

equiripple

Examples

Here is an example of designing a single-rate equiripple filter from a halfband filter specification object. Notice the help command used to learn about the options for the specification object and method.

```
d = fdesign.halfband('tw,ast',0.1,80);
designmethods(d)
help(d,'equiripple')
designopts(d,'equiripple')
hd = design(d,'equiripple','stopbandshape','flat');
fvtool(hd);
```

Displaying the filter in FVTool shows the equiripple nature of the filter.
equiripple also designs multirate filters. This example generates a halfband interpolator filter.

```
d = fdesign.interpolator(2); % Interpolation factor = 2.
hd = design(d,'equiripple');
```

This final example designs an equiripple filter with a direct-form structure by specifying the **filterstructure** argument. To set the design options for the filter, use the designopts method and options object opts.

```
d = fdesign.lowpass('fp,fst,ap,ast');
opts=designopts(d,'equiripple')
opts.FilterStructure='dffirt'
opts.MinPhase=1;
opts.DensityFactor=20;
opts
hd=design(d,'equiripple',opts)
```

Note The MaxPhase design option for equripple FIR filters is currently only available for lowpass, highpass, bandpass, and bandstop filters.

fcfwrite

Purpose   Write file containing filter coefficients

Syntax
```
fcfwrite(h)
fcfwrite(h,filename)
fcfwrite(...,'fmt')
```

Description   fcfwrite(h) writes a filter coefficient ASCII file in a folder you choose, or your current MATLAB working folder. h can be a single filter object or a vector of filter objects. On execution, fcfwrite opens the **Export Filter Coefficients to .FCF File** dialog box to let you assign a file name for the output file. You can choose the destination folder within this dialog as well.

The default file name is untitled.fcf. When you have DSP System Toolbox software, you can use fcfwrite(h) to write filter coefficient files for multirate filters, adaptive filters, and discrete-time filters.

fcfwrite(h,filename) writes the filter coefficients and general information to a text file called filename in your present MATLAB working folder and opens the file in the MATLAB editor for you to review or modify.

If you do not include a file extension in filename, fcfwrite adds the extension fcf to filename.

fcfwrite(...,'fmt') writes the filter coefficients in the format specified by the input argument fmt. Valid fmt values are hex for hexadecimal, dec for decimal, or bin for binary representation of the filter coefficients.

Examples   To demonstrate fcfwrite, create a fixed-point IIR filter at the command line, and then write the filter coefficients to a file named iirfilter.fcf.

```
d=fdesign.lowpass;
hd=design(d,'butter');
set(hd,'arithmetic','fixed');
fcfwrite(hd,'iirfilter.fcf');
```

Here is the output from `fcfwrite` as it appears in the MATLAB editor. Not shown here is the filename — `iirfilter.fcf` as specified and some comments at the top of the file.

```

Purpose   Open Filter Design and Analysis Tool

Syntax   `fdatool`

Description `fdatool` opens the Filter Design and Analysis Tool (FDATool). Use this tool to:

- Design filters

- Quantize filters (with DSP System Toolbox software installed)

- Analyze filters

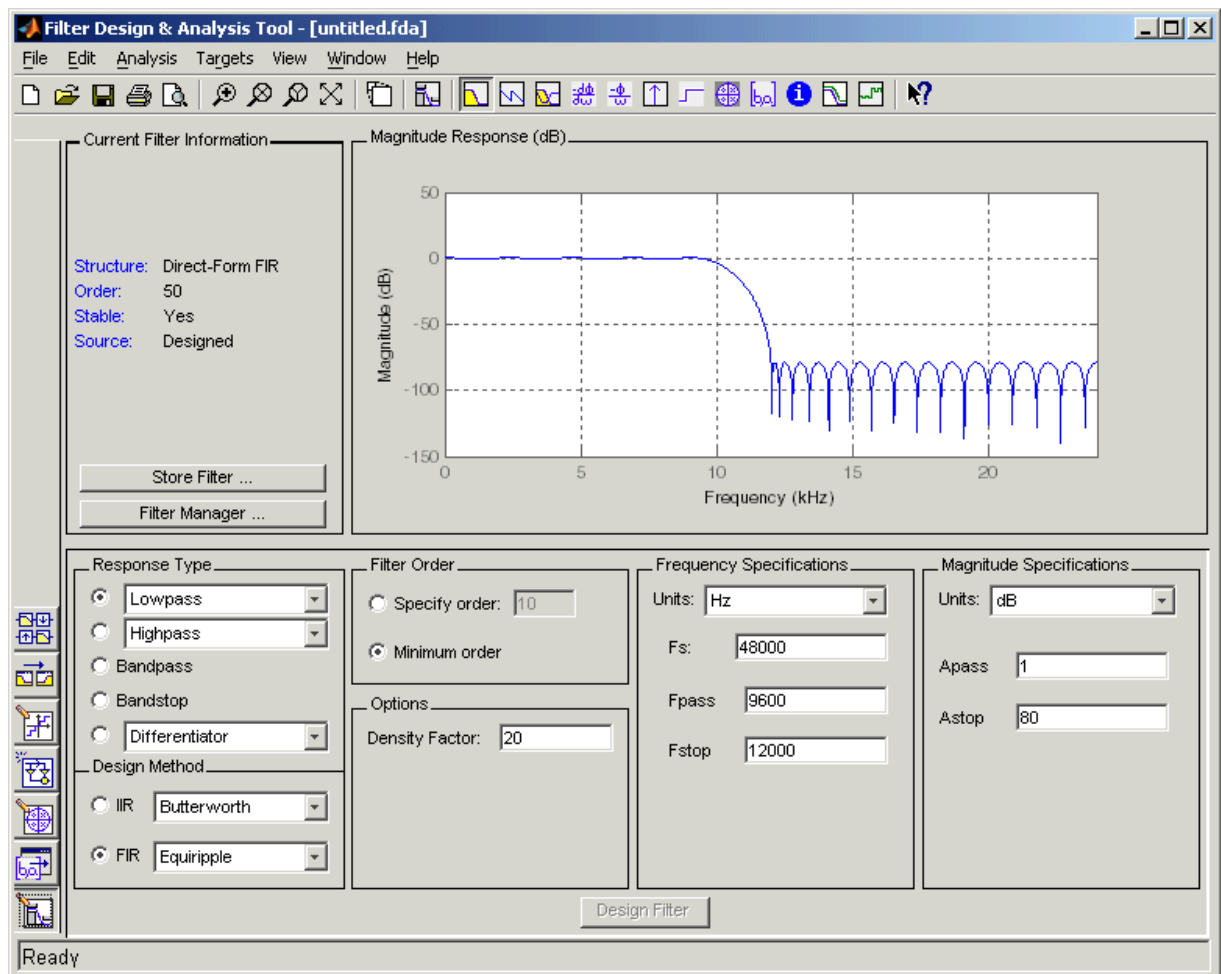
- Modify existing filter designs

- Create multirate filters (with DSP System Toolbox software installed)

- Realize Simulink models of quantized, direct-form, FIR filters (with DSP System Toolbox software installed)

- Perform digital frequency transformations of filters (with DSP System Toolbox software installed)

Refer to "Use FDATool with DSP System Toolbox Software" for more information about using the analysis, design, and quantization features of FDATool. For general information about using FDATool, refer to "FDATool" in Signal Processing Toolbox documentation.

When you open FDATool and you have DSP System Toolbox software installed, FDATool incorporates features that are added by DSP System Toolbox software. With DSP System Toolbox software installed, FDATool lets you design and analyze quantized filters, as well as convert quantized filters to various filter structures, transform filters, design multirate filters, and realize models of filters.


fdatool

Use the buttons on the sidebar to configure the design area to use various tools in FDATool.

Set Quantization Parameters — provides access to the properties of the quantizers that compose a quantized filter. When you click **Set Quantization Parameters**, you see FDATool displaying the

quantization options at the bottom of the dialog box (the design area), as shown in the figure.

Transform Filter — clicking this button opens the *Frequency Transformations* pane so you can use digital frequency transformations to change the magnitude response of your filter.

Create a multirate filter — clicking this button switches FDATool to multirate filter design mode so you can design interpolators, decimators, and fractional rate change filters.

Realize Model — starting from your quantized, direct-form, FIR filter, clicking this button creates a Simulink model of your filter structure in new model window.
Other options in the menu bar let you convert the filter structure to a new structure, change the order of second-order sections in a filter, or change the scaling applied to the filter, among many possibilities.

Tips
By incorporating many advanced filter design methods from DSP System Toolbox software, FDATool provides more design methods than the SPTool Filter Designer.

Purpose   Filter specification object

Syntax
```
d = fdesign.response
d = fdesign.response(spec)
d = fdesign.response(...,Fs)
d = fdesign.response(...,magunits)
```

Description   **Filter Specification Objects**

d = fdesign.*response* returns a filter specification object d, of filter response *response*. To create filters from d, use one of the design methods listed in "Using Filter Design Methods with Specification Objects" on page 7-484

Note Several of the filter response types described below are only available if your installation includes the DSP System Toolbox. The DSP System Toolbox significantly expands the functionality available for the specification, design, and analysis of filters.

Here is how you design filters using fdesign.

1 Use fdesign.*response* to construct a filter specification object.

2 Use designmethods to determine which filter design methods work for your new filter specification object.

3 Use design to apply your filter design method from step 2 to your filter specification object to construct a filter object.

4 Use FVTool to inspect and analyze your filter object.

fdesign

> **Note** fdesign does not create filters. fdesign returns a filter specification object that contains the specifications for a filter, such as the passband cutoff or attenuation in the stopband. To design a filter hd from a filter specification object d, use d with a filter design method such as butter —hd = design(d,'butter').

For more guidance about using fdesign, refer to the examples in "Getting Started". Alternatively, type the following at the MATLAB prompt for more information:

```
help fdesign
```

response can be one of the entries in the following table that specify the filter response desired, such as a bandstop filter or an interpolator.

fdesign Response String	Description
arbgrpdelay	fdesign.arbgrpdelay creates an object to specify allpass arbitrary group delay filters. Requires the DSP System Toolbox
arbmag	fdesign.arbmag creates an object to specify IIR filters that have arbitrary magnitude responses defined by the input arguments.
arbmagnphase	fdesign.arbmagnphase creates an object to specify IIR filters that have arbitrary magnitude and phase responses defined by the input arguments. Requires the DSP System Toolbox.
audioweighting	fdesign.audioweighting creates a filter specification object for audio weighting filters. The supported audio weighting types are: A, C, C-message, ITU-T 0.41, and ITU-R 468-4 weighting. Requires the DSP System Toolbox

fdesign Response String	Description
bandpass	fdesign.bandpass creates an object to specify bandpass filters.
bandstop	fdesign.bandstop creates an object to specify bandstop filters.
ciccomp	fdesign.ciccomp creates an object to specify filters that compensate for the CIC decimator or interpolator response curves. Requires the DSP System Toolbox.
comb	fdesign.comb creates an object to specify a notching or peaking comb filter. Requires the DSP System Toolbox.
decimator	fdesign.decimator creates an object to specify decimators. Requires the DSP System Toolbox
differentiator	fdesign.differentiator creates an object to specify an FIR differentiator filter.
fracdelay	fdesign.fracdelay creates an object to specify fractional delay filters. Requires the DSP System Toolbox.
halfband	fdesign.halfband creates an object to specify halfband filters. Requires the DSP System Toolbox.
highpass	fdesign.highpass creates an object to specify highpass filters.
hilbert	fdesign.hilbert creates an object to specify an FIR Hilbert transformer.
interpolator	fdesign.interpolator creates an object to specify interpolators. Requires the DSP System Toolbox.

fdesign Response String	Description
isinchp	fdesign.isinchp creates an object to specify an inverse sinc highpass filter. Requires the DSP System Toolbox.
isinclp	fdesign.isinclp creates an object to specify an inverse sinc lowpass filters. Requires the DSP System Toolbox.
lowpass	fdesign.lowpass creates an object to specify lowpass filters.
notch	fdesign.notch creates an object to specify notch filters. Requires the DSP System Toolbox.
nyquist	fdesign.nyquist creates an object to specify nyquist filters. Requires the DSP System Toolbox.
octave	fdesign.octave creates an object to specify octave and fractional octave filters. Requires the DSP System Toolbox.
parameq	fdesign.parameq creates an object to specify parametric equalizer filters. Requires the DSP System Toolbox.
peak	fdesign.peak creates an object to specify peak filters. Requires the DSP System Toolbox.
polysrc	fdesign.polysrc creates an object to specify polynomial sample-rate converter filters. Requires the DSP System Toolbox.
pulseshaping	fdesign.pulseshaping creates an object to specify pulse-shaping filters.
rsrc	fdesign.rsrc creates an object to specify rational-factor sample-rate convertors. Requires the DSP System Toolbox.

Use the `doc fdesign.`*`response`* syntax at the MATLAB prompt to get help on a specific structure. Using `doc` in a syntax like

```
doc fdesign.lowpass
doc fdesign.bandstop
```

gets more information about the lowpass or bandstop structure objects.

Each `response` has a property `Specification` that defines the specifications to use to design your filter. You can use defaults or specify the `Specification` property when you construct the specifications object.

With the strings for the `Specification` property, you provide filter constraints such as the filter order or the passband attenuation to use when you construct your filter from the specification object.

Properties   `fdesign` returns a filter specification object. Every filter specification object has the following properties.

Property Name	Default Value	Description
Response	Depends on the chosen type	Defines the type of filter to design, such as an interpolator or bandpass filter. This is a read-only value.
Specification	Depends on the chosen type	Defines the filter characteristics used to define the desired filter performance, such as the cutoff frequency Fc or the filter order N.

fdesign

Property Name	Default Value	Description
Description	Depends on the filter type you choose	Contains descriptions of the filter specifications used to define the object, and the filter specifications you use when you create a filter from the object. This is a read-only value.
NormalizedFrequency	Logical true	Determines whether the filter calculation uses normalized frequency from 0 to 1, or the frequency band from 0 to Fs/2, the sampling frequency. Accepts either true or false without single quotation marks. Audio weighting filters do not support normalized frequency.

In addition to these properties, filter specification objects may have other properties as well, depending on whether they design dfilt objects or mfilt objects.

Added Properties for mfilt Objects	Description
DecimationFactor	Specifies the amount to decrease the sampling rate. Always a positive integer.
InterpolationFactor	Specifies the amount to increase the sampling rate. Always a positive integer.
PolyphaseLength	Polyphase length is the length of each polyphase subfilter that composes the decimator or interpolator or rate-change

Added Properties for mfilt Objects	Description
	factor filters. Total filter length is the product of `pl` and the rate change factors. `pl` must be an even integer.

`d = fdesign.`*`response`*`(spec)`. In `spec`, you specify the variables to use that define your filter design, such as the passband frequency or the stopband attenuation. The specifications are applied to the filter design method you choose to design your filter.

For example, when you create a default lowpass filter specification object, `fdesign.lowpass` sets the passband frequency `Fp`, the stopband frequency `Fst`, the stopband attenuation `Ast`, and the passband ripple `Ap` :

```
H = fdesign.lowpass
% Without a terminating semicolon
% the filter specifications are displayed
```

The default specification `'Fp,Fst,Ap,Ast'` is only one of the possible specifications for `fdesign.lowpass`. To see all available specifications:

```
H = fdesign.lowpass;
set(H,'specification')
```

The DSP System Toolbox software supports all available specification strings. The Signal Processing Toolbox supports a subset of the specification strings. See the reference pages for the filter specification object to determine which specification strings your installation supports.

One important note is that the specification string you choose determines which design methods apply to the filter specifications object.

Specifications that do not contain the filter order result in minimum order designs when you invoke the `design` method:

```
d = fdesign.lowpass;
% Specification is Fp,Fst,Ap,Ast
Hd = design(d,'equiripple');
length(Hd.Numerator) % returns 43
% Filter order is 42
fvtool(Hd) %view magnitude
```

d = fdesign.*response*(...,Fs) specifies the sampling frequency in Hz to use in the filter specifications. The sampling frequency is a scalar trailing all other input arguments. If you specify a sampling frequency, all frequency specifications are in Hz.

d = fdesign.*response*(...,magunits) specifies the units for any magnitude specification you provide in the input arguments. magunits can be one of the following strings:

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in decibels
- 'squared' — specify the magnitude in power units

When you omit the magunits argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Using Filter Design Methods with Specification Objects

After you create a filter specification object, you use a filter design method to implement your filter with a selected algorithm. Use designmethods to determine valid design methods for your filter specification object.

```
d = fdesign.lowpass('N,Fc,Ap,Ast',10,0.2,0.5,40);
designmethods(d)
% Design FIR equiripple filter
hd = design(d,'equiripple');
```

When you use any of the design methods without providing an output argument, the resulting filter design appears in FVTool by default.

Along with filter design methods, `fdesign` works with supporting methods that help you create filter specification objects or determine which design methods work for a given specifications object.

Supporting Function	Description
`setspecs`	Set all of the specifications simultaneously.
`designmethods`	Return the design methods.
`designopts`	Return the input arguments and default values that apply to a specifications object and method

You can set filter specification values by passing them after the `Specification` argument, or by passing the values without the `Specification` string.

Filter object constructors take the input arguments in the same order as `setspecs` and the order in the strings for `Specification`. Enter `doc setspecs` at the prompt for more information about using `setspecs`.

When the first input to `fdesign` is not a valid `Specification` string like 'n,fc', `fdesign` assumes that the input argument is a filter specification and applies it using the default `Specification` string —fp,fst,ap,ast for a lowpass object, for example.

Examples   The following examples require only the Signal Processing Toolbox.

Example 1–Bandstop Filter

A bandstop filter specification object for data sampled at 8 kHz. The stopband between 2 and 2.4 kHz is attenuated at least 80 dB:

```
H = fdesign.bandstop('Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2',...
          1600,2000,2400,2800,1,80,1,8000);
```

Example 2–Lowpass Filter

A lowpass filter specification object for data sampled at 10 kHz. The passband frequency is 500 Hz and the stopband frequency is 750 Hz.

The passband ripple is set to 1 dB and the required attenuation in the stopband is 80 dB.

```
H = fdesign.lowpass('Fp,Fst,Ap,Ast',500,750,1,80,10000);
```

Example 3—Highpass Filter

A default highpass filter specification object.

```
H = fdesign.highpass % Creates specifications object.
H.Description
```

Notice the correspondence between the property values in `Specification` and `Description` — in `Description` you see in words the definitions of the variables shown in `Specification`.

Example 4—Filter Specification and Design

Lowpass Butterworth filter specification object

Use a filter specification object to construct a lowpass Butterworth filter with default `Specification` `'Fp,Fst,Ap,Ast'`. Set the passband edge frequency to 0.4π radians/sample, a stopband frequency of 0.5π radians/sample, a passband ripple of 1 dB, and 80 dB of stopband attenuation.

```
d = fdesign.lowpass(0.4,0.5,1,80);
```

Determine which design methods apply to `d`.

```
designmethods(d)
```

You can use `d` and the `butter` design method to design a Butterworth filter.

```
hd = design(d,'butter','matchexactly','passband');
fvtool(hd);
```

The resulting filter magnitude response shown by FVTool appears in the following figure.
If you have the DSP System Toolbox software installed, the preceding figure appears with the filter specification mask.

fdesign.arbgrpdelay

Purpose   Arbitrary group delay filter specification object

Syntax
```
D = fdesign.arbgrpdelay(SPEC)
D = fdesign.arbgrpdelay(SPEC,SPEC1,SPEC2,...)
D = fdesign.arbgrpdelay(N,F,Gd)
D = fdesign.arbgrpdelay(...,Fs)
```

Description   Arbitrary group delay filters are allpass filters you can use for correcting phase distortion introduced by other filters. `fdesign.arbgrpdelay` uses an iterative least *p*-th norm optimization procedure to minimize the phase response error [1].

D = fdesign.arbgrpdelay(SPEC) specifies an allpass arbitrary group delay filter with the `Specification` property set to `SPEC`. See "Input Arguments" on page 7-489 for a description of supported specifications.

D = fdesign.arbgrpdelay(SPEC,SPEC1,SPEC2,...) initializes the allpass arbitrary group delay filter specification object with specifications `SPEC1,SPEC2,...`. See SPEC for a description of supported specifications.

D = fdesign.arbgrpdelay(N,F,Gd) specifies an allpass arbitrary group delay filter. The filter order is equal to `N`, frequency vector equal to `F`, and group delay vector equal to `Gd`. See SPEC for a description of the filter order, frequency vector, and group delay vector inputs. See the example Allpass Filter with Arbitrary Group Delay for an example using this syntax.

D = fdesign.arbgrpdelay(...,Fs) specifies the sampling frequency in hertz as a trailing scalar. If you do not specify a sampling frequency, all frequencies are normalized frequencies and group delay values are in samples. If you specify a sampling frequency, group delay values are in seconds.

Tips   If your arbitrary group delay design produces the error `Poorly conditioned Hessian matrix`, attempt one or more of the following:

- Set the `MaxPoleRadius` IIR lp norm design option to some number less than 1. Set this option when you `design` your filter with the syntax:

  ```
  design(d,'iirlpnorm','MaxPoleRadius',0.95)
  ```

  See the Frequency Dispersion and Multiband Delay Equalization examples for the use of the `MaxPoleRadius` design option.

- Reduce the order of your filter design.

Input Arguments

SPEC

Specification string. `SPEC` is one of the following two strings. The entries are not case sensitive.

- `'N,F,Gd'`

- `'N,B,F,Gd'`

The string entries are defined as follows:

- `N` — Filter order. This value must be an even positive integer. The numerator and denominator orders are both equal to `N`. "Allpass Systems" on page 7-491 explains why the numerator and denominator filter orders are equal and the order must be even in `fdesign.arbgrpdelay`.

- `F` — Frequency vector for the group delay specifications. The elements of the frequency vector must increase monotonically. If you do not specify a sampling frequency, `Fs`, in hertz, the frequencies are normalized frequencies. For a single-band design, the first element of the normalized frequency vector must be zero and the last element must be 1. These correspond to 0 and π radians/sample respectively. For multiband designs, the union of the frequency vectors must range from [0,1].

  If you specify a sampling frequency, `Fs`, the first element of the frequency vector in a single-band design must be 0. The last element must be the Nyquist frequency, Fs/2. For multiband designs, the union of the frequency vectors must range from [0,Fs/2].

fdesign.arbgrpdelay

- Gd — Group delay vector. A vector with nonnegative elements equal in length to the frequency vector, F. The elements of Gd specify the nonnegative group delay at the corresponding element of the frequency vector, F.

  If you do not specify a sampling frequency, Fs, in Hertz, the group delays are in samples. If you specify a sampling frequency, the group delays are in seconds.

- B — Number of frequency bands. If you use this specification, you must specify a frequency and group delay vector for each band. The union of the frequency vectors must range from [0,1] in normalized frequency, or [0,Fs/2] when a sampling frequency is specified. The elements in the union of the frequency bands must be monotonically increasing.

  For example:

  ```
  filtorder = 14;
  freqband1 = [0 0.1 0.4]; grpdelay1 = [1 2 3];
  freqband2 = [0.5 0.8 1]; grpdelay2 = [3 2 1];
  D = fdesign.arbgrpdelay('N,B,F,Gd',filtorder,2,freqband1,grpdelay1,freq
  ```

  Default: `'N,F,Gd'`

Fs

Sampling frequency. Specify the sampling frequency as a trailing positive scalar after all other input arguments. Specifying a sampling frequency forces the group delay units to be in seconds. If you specify a sampling frequency, the first element of the frequency vector must be 0. The last element must be the Nyquist frequency, Fs/2.

Output Arguments

D

Filter specification object. An allpass arbitrary group delay filter specification object containing the following modifiable properties: Specification, NormalizedFrequency, FilterOrder, Frequencies, and GroupDelay.

Use the `normalizefreq` method to change the `NormalizedFrequency` property after construction.

Definitions   ### Group Delay in Discrete-Time Filter Design

The frequency response of a rational discrete-time filter is:

$$H(e^{j\omega}) = \frac{B(e^{j\omega})}{A(e^{j\omega})}$$

The argument of the frequency response as a function of the angle, ω, is referred to as the *phase response*.

The negative of the first derivative of the argument with respect to ω is the group delay.

$$\tau(\omega) = -\frac{d}{d\omega} Arg(H(e^{j\omega}))$$

Systems with nonlinear phase responses have nonconstant group delay, which causes dispersion of the frequency components of the signal. You may not want this phase distortion even if the magnitude distortion introduced by the filter produces the desired effect. See Frequency Dispersion for an illustration of frequency dispersion resulting from nonconstant group delay.

In these cases, you can cascade the frequency-selective filter with an allpass filter that compensates for the group delay. This process is often referred to as *delay equalization*.

Allpass Systems

The general form of an allpass system function with a real-valued impulse response is:

$$H_{ap}(z) = \prod_{k=1}^{M} \frac{z^{-1} - d_k}{1 - d_k z^{-1}} \prod_{k=1}^{N} \frac{(z^{-1} - c_k)(z^{-1} - c_k^*)}{(1 - c_k z^{-1})(1 - c_k^* z^{-1})}$$

where the d_k denote the real-valued poles and the c_k denote the complex-valued poles, which occur in conjugate pairs.

The preceding equation demonstrates that allpass systems with real-valued impulse responses have *2N+M* zeros and poles. The poles and zeros occur in pairs with reciprocal magnitudes. The filter order is always the same for the numerator and denominator.

Because `fdesign.arbgrpdelay` uses robust second-order section (biquad) filter structures to implement the allpass arbitrary group delay filter, the filter order must be even.

Examples   Construct a signal consisting of two discrete-time windowed sinusoids (wave packets) with disjoint time support to illustrate frequency dispersion. One discrete-time sinusoid has a frequency of π/2 radians/sample and the other has a frequency of π/4 radians/sample. There are 9 periods of the higher–frequency sinusoid that precede 5 periods of the lower–frequency signal.

Create the signal.

```
x = zeros(300,1);
x(1:36) = cos(pi/2*(0:35)).*hamming(36)';
x(40:40+39) = cos(pi/4*(0:39)).*hamming(40)';
```

Create an arbitrary group delay filter that delays the higher–frequency wave packet by approximately 100 samples.

```
N = 18;
f = 0:.1:1;
gd = ones(size(f));
% Delay pi/2 radians/sample by 100 samples
gd(6) = 100;
d = fdesign.arbgrpdelay(N,f,gd);
Hd = design(d,'iirlpnorm','MaxPoleRadius',0.9);
% Visualize the group delay
fvtool(Hd,'analysis','grpdelay');
```
Filter the input signal with the arbitrary group delay filter and illustrate the frequency dispersion. The high–frequency wave packet, which initially preceded the low–frequency wave packet, now occurs later because of the nonconstant group delay.

```
y = filter(Hd,x);
subplot(211)
plot(x); title('Input Signal');
grid on; ylabel('Amplitude');
subplot(212);
plot(y); title('Output Signal'); grid on;
```

```
xlabel('Samples'); ylabel('Amplitude');
```

Design an allpass filter with an arbitrary group delay.

```
N = 10;
f = [0 0.02 0.04 0.06 0.08 0.1 0.25 0.5 0.75 1];
g = [5 5 5 5 5 5 4 3 2 1];
w = [2 2 2 2 2 2 1 1 1 1];
hgd = fdesign.arbgrpdelay(N,f,g);
Hgd = design(hgd,'iirlpnorm','Weights',w,'MaxPoleRadius',0.95);
```

```
fvtool(Hgd,'Analysis','grpdelay') ;
```

Perform multiband delay equalization outside the stopband.

```
Fs = 1e3;
Hcheby2 = design(fdesign.bandstop('N,Fst1,Fst2,Ast',10,150,400,60,Fs);
f1 = 0.0:0.5:150; % Hz
g1 = grpdelay(Hcheby2,f1,Fs).'/Fs; % seconds
f2 = 400:0.5:500; % Hz
g2 = grpdelay(Hcheby2,f2,Fs).'/Fs; % seconds
```

```
maxg = max([g1 g2]);
% Design an arbitrary group delay allpass filter to equalize the group
% delay of the bandstop filter. Use an order 18 multiband design and spec
% two bands.
hgd = fdesign.arbgrpdelay('N,B,F,Gd',18,2,f1,maxg-g1,f2,maxg-g2,Fs);
Hgd = design(hgd,'iirlpnorm','MaxPoleRadius',0.95);
Hcascade = cascade(Hcheby2,Hgd);
hft = fvtool(Hcheby2,Hgd,Hcascade,'Analysis','grpdelay','Fs',Fs);
    legend(hft,'Original Bandstop Filter','Allpass Arbitrary Group Delay
    'Delay Equalization', 'Location','North');
```
Algorithms   `fdesign.arbgrpdelay` uses a least *p*-th norm iterative optimization described in [1].

References   [1] Antoniou, A. *Digital Signal Processing: Signals, Systems, and Filters.*, New York:McGraw-Hill, 2006, pp. 719–771.

Alternatives   `iirgrpdelay` — Returns an allpass arbitrary group delay filter. The `iirgrpdelay` function returns the numerator and denominator coefficients. This behavior differs from that of `fdesign.arbgrpdelay`, which returns the filter in second-order sections. `iirgrpdelay` accepts only normalized frequencies.

How To   • "Design a Filter in Fdesign — Process Overview"

fdesign.arbmag

Purpose	Arbitrary response magnitude filter specification object

Syntax

```
D= fdesign.arbmag
D= fdesign.arbmag(SPEC)
D = fdesign.arbmag(SPEC,specvalue1,specvalue2,...)
D = fdesign.arbmag(specvalue1,specvalue2,specvalue3)
D = fdesign.arbmag(...,Fs)
```

Description D= fdesign.arbmag constructs an arbitrary magnitude filter specification object D.

D= fdesign.arbmag(SPEC) initializes the Specification property to SPEC. The input argument SPEC must be one of the strings shown in the following table. Specification strings are not case sensitive.

Note Specifications strings marked with an asterisk require the DSP System Toolbox software.

- 'N,F,A' — Single band design (default)
- 'F,A,R' — Single band minimum order design *
- 'N,B,F,A' — Multiband design
- 'N,B,F,A,C' — Constrained multiband design *
- 'B,F,A,R' — Multiband minimum order design *
- 'Nb,Na,F,A' — Single band design *
- 'Nb,Na,B,F,A' — Multiband design *

The string entries are defined as follows:

- A — Amplitude vector. Values in A define the filter amplitude at frequency points you specify in f, the frequency vector. If you use A, you must use F as well. Amplitude values must be real. For complex values designs, use fdesign.arbmagnphase.

- B — Number of bands in the multiband filter

- C — Constrained band flag. This enables you to constrain the passband ripple in your multiband design. You cannot constrain the passband ripple in all bands simultaneously.

- F — Frequency vector. Frequency values in specified in F indicate locations where you provide specific filter response amplitudes. When you provide F, you must also provide A.

- N — Filter order for FIR filters and the numerator and denominator orders for IIR filters.

- Nb — Numerator order for IIR filters

- Na — Denominator order for IIR filter designs

- R — Ripple

By default, this method assumes that all frequency specifications are supplied in normalized frequency.

Specifying Frequency and Amplitude Vectors

F and A are the input arguments you use to define the filter response desired. Each frequency value you specify in F must have a corresponding response value in A. The following table shows how F and A are related.

Define the frequency vector F as [0 0.25 0.3 0.4 0.5 0.6 0.7 0.75 1.0]

Define the response vector A as [1 1 0 0 0 0 0 1 1]

These specifications connect F and A as shown here:

F (Normalized Frequency)	A (Response Desired at F)
0	1
0.25	1
0.3	0
0.4	0

F (Normalized Frequency)	A (Response Desired at F)
0.5	0
0.6	0
0.7	0
0.75	1
1.0	1

Different specifications can have different design methods available. Use `designmethods` to get a list of design methods available for a given specification string and filter specification object.

Use `designopts` to get a list of design options available for a filter specification object and a given design method. Enter `help(D,METHOD)` to get detailed help on the available design options for a given design method.

`D = fdesign.arbmag(SPEC,specvalue1,specvalue2,...)` initializes the specifications with `specvalue1`, `specvalue2`. Use `get(D,'Description')` for descriptions of the various specifications `specvalue1`, `specvalue2`, ... `specvalueN`.

`D = fdesign.arbmag(specvalue1,specvalue2,specvalue3)` uses the default specification string `'N,F,A'`, setting the filter order, filter frequency vector, and the amplitude vector to the values `specvalue1`, `specvalue2`, and `specvalue3`.

`D = fdesign.arbmag(...,Fs)` specifies the sampling frequency in Hz. All other frequency specifications are also assumed to be in Hz when you specify `Fs`.

Examples   **Design of a multiband arbitrary-magnitude filter**

Use fdesign.arbmag to design a 3–band filter.

Use the given frequency and amplitude vectors in "Specifying Frequency and Amplitude Vectors" on page 7-499.

```
N = 150;
B = 3;
F = [0 .25 .3 .4 .5 .6 .7 .75 1];
A = [1 1 0 0 0 0 0 1 1];
A1 = A(1:2);
A2 = A(3:7);
A3 = A(8:end);
F1 = F(1:2);
F2 = F(3:7);
F3 = F(8:end);
d = fdesign.arbmag('N,B,F,A',N,B,F1,A1,F2,A2,F3,A3);
Hd = design(d);
fvtool(Hd)
```

A response with two passbands — one roughly between 0 and 0.25 and the second between 0.75 and 1 — results from the mapping between F and A.
Design of a single band arbitrary-magnitude filter

Use fdesign.arbmag to design a single band equiripple filter.

```
n = 120;
f = linspace(0,1,100);  % 100 frequency points.
as = ones(1,100)-f*0.2;
absorb = [ones(1,30),(1-0.6*bohmanwin(10))',...
ones(1,5), (1-0.5*bohmanwin(8))',ones(1,47)];
a = as.*absorb;
d = fdesign.arbmag('N,F,A',n,f,a);
hd1 = design(d,'equiripple');
```

If you have the DSP System Toolbox, you can design a minimum-phase equiripple filter.

```
hd2 = design(d,'equiripple','MinPhase',true);
hfvt = fvtool([hd1 hd2],'analysis','polezero');
legend(hfvt,'Equiripple Filter','Minimum-phase Equiripple Filter');
```

Design of a multiband minimum order arbitrary-magnitude filter

Use fdesign.arbmag to design a multiband minimum order filter.

This example requires the DSP System Toolbox.

Place the notches at 0.25π and 0.55π radians/sample

```
d = fdesign.arbmag('B,F,A,R');
d.NBands = 5;
d.B1Frequencies = [0 0.2];
d.B1Amplitudes = [1 1];
d.B1Ripple = 0.25;
d.B2Frequencies = 0.25;
d.B2Amplitudes = 0;
d.B3Frequencies = [0.3 0.5];
d.B3Amplitudes = [1 1];
d.B3Ripple = 0.25;
d.B4Frequencies = 0.55;
d.B4Amplitudes = 0;
d.B5Frequencies = [0.6 1];
d.B5Amplitudes = [1 1];
d.B5Ripple = 0.25;
Hd = design(d,'equiripple');
fvtool(Hd)
```
Design of a multiband constrained arbitrary-magnitude filter

Use fdesign.arbmag to design a multiband constrained FIR filter.

This example requires the DSP System Toolbox.

Force the frequency response at 0.15π radians/sample to 0 dB.

```
d = fdesign.arbmag('N,B,F,A,C',82,2);
d.B1Frequencies = [0 0.06 .1];
d.B1Amplitudes = [0 0 0];
d.B2Frequencies = [.15 1];
d.B2Amplitudes = [1 1];
```

```
% Design a filter with no constraints
Hd1 = design(d,'equiripple','B2ForcedFrequencyPoints',0.15);
% Add a constraint to the first band to increase attenuation
d.B1Constrained = true;
d.B1Ripple = .001;
Hd2 = design(d,'equiripple','B2ForcedFrequencyPoints',0.15);
hfvt = fvtool(Hd1,Hd2);
legend(hfvt,'Original Design','Design with Constrained Stopband Ripple
```

See Also   design | designmethods | fdesign

fdesign.arbmagnphase

Purpose   Arbitrary response magnitude and phase filter specification object

Syntax
```
d = fdesign.arbmagnphase
d = fdesign.arbmagnphase(specification)
d = fdesign.arbmagnphase(specification,specvalue1,specvalue2,
    ...)
d = fdesign.arbmagnphase(specvalue1,specvalue2,specvalue3)
d = fdesign.arbmagnphase(...,fs)
```

Description   `d = fdesign.arbmagnphase` constructs an arbitrary magnitude filter specification object `d`.

`d = fdesign.arbmagnphase(specification)` initializes the Specification property for specifications object `d` to the string in `specification`. The input argument `specification` must be one of the strings shown in the following table. Specification strings are not case sensitive.

Specification String	Description of Resulting Filter
n,f,h	Single band design (default). FIR and IIR (n is the order for both numerator and denominator).
n,b,f,h	FIR multiband design where b defines the number of bands.
nb,na,f,h	IIR single band design.

The following table describes the arguments in the strings.

Argument	Description
b	Number of bands in the multiband filter.
f	Frequency vector. Frequency values specified in f indicate locations where you provide specific filter response amplitudes. When you provide f you must also provide h which contains the response values.

Argument	Description
h	Complex frequency response values.
n	Filter order for FIR filters and the numerator and denominator orders for IIR filters (when not specified by nb and na).
nb	Numerator order for IIR filters.
na	Denominator order for IIR filter designs.

By default, this method assumes that all frequency specifications are supplied in normalized frequency.

Specifying f and h

f and h are the input arguments you use to define the filter response desired. Each frequency value you specify in f must have a corresponding response value in h. This example creates a filter with two passbands (b = 4) and shows how f and h are related. This example is for illustration only. It is not an actual filter.

Define the frequency vector f as [0 0.1 0.2 0.4 0.5 0.6 0.9 1.0]

Define the response vector h as [0 0.5 0.5 0.1 0.1 0.8 0.8 0]

These specifications connect f and h as shown in the following table.

f (Normalized Frequency)	h (Response Desired at f)
0	0
0.1	0.5
0.2	0.5
0.4	0.1
0.5	0.1
0.6	0.8

f (Normalized Frequency)	h (Response Desired at f)
0.9	0.8
1.0	0.0

A response with two passbands—one roughly between 0.1 and 0.2 and the second between 0.6 and 0.9—results from the mapping between f and h. Plotting f and h yields the following figure that resembles a filter with two passbands.
The second example in Examples shows this plot in more detail with a complex filter response for h. In the example, h uses complex values for the response.

Different specification types often have different design methods available. Use `designmethods(d)` to get a list of design methods available for a given specification string and specifications object.

`d = fdesign.arbmagnphase(specification,specvalue1,specvalue2,...)` initializes the filter specification object with `specvalue1`, `specvalue2`, and so on. Use `get(d,'description')` for descriptions of the various specifications `specvalue1`, `specvalue2`, ...`specn`.

`d = fdesign.arbmagnphase(specvalue1,specvalue2,specvalue3)` uses the default specification string `n,f,h`, setting the filter order, filter frequency vector, and the complex frequency response vector to the values `specvalue1`, `specvalue2`, and `specvalue3`.

`d = fdesign.arbmagnphase(...,fs)` specifies the sampling frequency in Hz. All other frequency specifications are also assumed to be in Hz when you specify `fs`.

Examples   Use `fdesign.arbmagnphase` to model a complex analog filter:

```
d=fdesign.arbmagnphase('n,f,h',100); % N=100, f and h set to defaults.
design(d,'freqsamp');
```

For a more complex example, design a bandpass filter with low group delay by specifying the desired delay and using f and h to define the filter bands.

```
n = 50;     % Group delay of a linear phase filter would be 25.
gd = 12;    % Set the desired group delay for the filter.
f1=linspace(0,.25,30); % Define the first stopband frequencies.
f2=linspace(.3,.56,40);% Define the passband frequencies.
f3=linspace(.62,1,30); % Define the second stopband frequencies.
h1 = zeros(size(f1)); % Specify the filter response at the freqs in f1.
h2 = exp(-1j*pi*gd*f2); % Specify the filter response at the freqs in f2.
h3 = zeros(size(f3)); % Specify the response at the freqs in f3.
d=fdesign.arbmagnphase('n,b,f,h',50,3,f1,h1,f2,h2,f3,h3);
D = design(d,'equiripple');
fvtool(D,'Analysis','freq');
```

fdesign.arbmagnphase
See Also   fdesign | design | designmethods | setspecs

Purpose   Audio weighting filter specification object

Syntax   *HAwf* = fdesign.audioweighting
                HAwf = fdesign.audioweighting(*spec*)
                HAwf = fdesign.audioweighting(*spec*,*specvalue1*,*specvalue2*)
                HAwf = fdesign.audioweighting(*specvalue1*,*specvalue2*)
                HAwf = fdesign.audioweighting(...,Fs)

Description Supported audio weighting filter types are: A weighting, C weighting,
                C-message, ITU-T 0.41, and ITU-R 468–4 weighting.

                HAwf = fdesign.audioweighting constructs an audio weighting filter
                specification object *HAwf* with a weighting type of A and a filter class
                of 1. Use the design method to instantiate a dfilt object based on
                the specifications in *HAwf*. Use designmethods to find valid filter
                design methods. Because the standards for audio weighting filters
                are in Hz, normalized frequency specifications are not supported for
                fdesign.audioweighting objects. The default sampling frequency for
                A weighting, C weighting, C-message, and ITU-T 0.41 filters is 48 kHz.
                The default sampling frequency for the ITU-R 468–4 filter is 80 kHz.
                If you invoke the normalizefreq method, a warning is issued when
                you instantiate the dfilt object and the default sampling frequencies
                in Hz are used.

                HAwf = fdesign.audioweighting(*spec*) returns an audio weighting
                filter specification object using default values for the specification string
                in *spec*. The following are valid entries for *spec*. The entries are not
                case sensitive.

                • 'WT,Class' (default *spec*)

                  The 'WT,Class' specification is valid for A weighting and C
                  weighting filters of class 1 or 2.

                  The weighting type is specified by the string: 'A' or 'C'. The class
                  is the scalar 1 or 2.

                  The default values for 'WT,Class' are 'A',1.

                • 'WT'

The `'WT'` specification is valid for C-message (default), ITU-T 0.41, and ITU-R 468–4 weighting filters.

The weighting type is specified by the string: `'Cmessage'`, `'ITUT041'`, or `'ITUR4684'`.

HAwf = fdesign.audioweighting(*spec*,*specvalue1*,*specvalue2*) constructs an audio weighting filter specification object *HAwf* and sets its specifications at construction time.

HAwf = fdesign.audioweighting(*specvalue1*,*specvalue2*) constructs an audio weighting filter specification object *HAwf* with the specification `'WT,Class'` using the values you provide. The valid weighting types are `'A'` or `'C'`.

HAwf = fdesign.audioweighting(...,Fs) specifies the sampling frequency in Hz. The sampling frequency is a scalar trailing all other input arguments.

Input Arguments

Parameter Name/Value Pairs

WT

Weighting type

The weighting type defines the frequency response of the filter. The valid weighting types are: A weighting, C weighting, C-message, ITU-T 0.41, and ITU-R 468–4 weighting. The weighting types are described in "Definitions" on page 7-513.

Class

Filter Class

Filter class is only applicable for A weighting and C weighting filters. The filter class describes the frequency-dependent tolerances specified in the relevant standards [1], [2]. There are two possible class values: 1 and 2. Class 1 weighting filters have stricter tolerances than class 2 filters. The filter class value does not affect the design. The class value is only used to provide a specification mask in fvtool for the analysis of the filter design.

Default: 1

Definitions

A weighting

The specifications for the A weighting filter are found in ANSI standard S1.42-2001. The A weighting filter is based on the 40–phon Fletcher-Munson equal loudness contour [3]. One phon is equal to one dB sound pressure level (SPL) at one kHz. The Fletcher-Munson equal loudness contours are designed to account for frequency and level dependent differences in the perceived loudness of tonal stimuli. The 40–phon contour reflects the fact that the human auditory system is more sensitive to frequencies around 1–2 kHz than lower and higher frequencies. The filter roll off is more pronounced at lower frequencies and more modest at higher frequencies. While A weighting is based on the equal loudness contour for low-level (40–phon) tonal stimuli, it is commonly used in the United States for assessing potential health risks associated with noise exposure to narrowband and broadband stimuli at high levels.

C weighting

The specifications for the C weighting filter are found in ANSI standard S1.42-2001. The C weighting filter approximates the 100–phon Fletcher-Munson equal loudness contour for tonal stimuli. The C weighting magnitude response is essentially flat with 3–dB frequencies at 31.5 Hz and 8000 Hz. While C weighting is not as common as A weighting, sound level meters frequently have a C weighting filter option.

C-message

The specifications for the C–message weighting filter are found in Bell System Technical Reference, PUB 41009. C-message weighting filters are designed for measuring the impact of noise on telecommunications circuits used in speech transmission [6]. C-message weighting filters are commonly used in North America, while the ITU-T 0.41 filter is more commonly used outside of North America.

ITU-R 468–4

The specifications for the ITU-R 486–4 weighting filter are found in the International Telecommunication Union Recommendation ITU-R BS.468-4. ITU-R 486–4 is an equal loudness contour weighting filter. Unlike the A weighting filter, the ITU-R 468–4 filter describes subjective loudness judgements for broadband stimuli [4]. A common criticism of the A weighting filter is that it underestimates the loudness judgement of real-world stimuli particularly in the frequency band from about 1–9 kHz. A comparison of A weighting and ITU-R 468–4 weighting curves shows that the ITU-R 468–4 curve applies more gain between 1 and 10 kHz with a peak difference of approximately 12 dB around 6–7 kHz.

ITU-T 0.41

The specifications for the ITU-T 0.41 filter are found in the ITU-T Recommendation 0.41. ITU-T 0.41 weighting filters are designed for measuring the impact of noise on telecommunications circuits used in speech transmission [5]. ITU-T 0.41 weighting filters are commonly used outside of North America, while the C-message weighting filter is more common in North America.

Examples

Compare class 1 A weighting and ITU-R 468–4 filters between 0.1 and 12 kHz:

```
HawfA = fdesign.audioweighting('WT,Class','A',1,44.1e3);
% Sampling frequency is 44.1 kHz
HawfITUR = fdesign.audioweighting('WT','ITUR4684',44.1e3);
Afilter = design(HawfA);
ITURfilter = design(HawfITUR);
hfvt = fvtool([Afilter ITURfilter]);
axis([0.1 12 -80 20]);
legend(hfvt,'A-weighting','ITU-R 468-4');
```
Compare C-message and ITU-T 0.41 filters:

```
hCmessage = fdesign.audioweighting('WT','Cmessage',24e3);
hITUT = fdesign.audioweighting('WT','ITUT041',24e3);
dCmessage = design(hCmessage);
dITUT = design(hITUT);
hfvt = fvtool([dCmessage dITUT]);
legend(hfvt,'C-Message Weighting','ITU-T 0.41 Weighting');
axis([0.1 10 -50 5]);
```
Construct an ITU-R 468–4 filter using all available design methods:

```
HAwf = fdesign.audioweighting('WT','ITUR4684');
ValidDesigns = designmethods(HAwf);
% returns iirlpnorm,equiripple,freqsamp in cell array
D = design(HAwf,'all'); % returns all designs
hfvt = fvtool(D);
legend(hfvt,'Least P-norm IIR','FIR Equiripple',...,
'FIR Frequency Sampling')
```

How To
- Audio Weighting Filters Example
- "Design a Filter in Fdesign — Process Overview"

Purpose   Bandpass filter specification object

Syntax
```
D = fdesign.bandpass
D = fdesign.bandpass(SPEC)
D = fdesign.bandpass(spec,specvalue1,specvalue2,...)
D = fdesign.bandpass(specvalue1,specvalue2,specvalue3,
specvalue4,...specvalue4,specvalue5,specvalue6)
D = fdesign.bandpass(...,Fs)
D = fdesign.bandpass(...,MAGUNITS)
```

Description   D = fdesign.bandpass constructs a bandpass filter specification object D, applying default values for the properties Fstop1, Fpass1, Fpass2, Fstop2, Astop1, Apass, and Astop2 — one possible set of values you use to specify a bandpass filter.

D = fdesign.bandpass(SPEC) constructs object D and sets its Specification property to SPEC. Entries in the SPEC string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for SPEC are shown below and used to define the bandpass filter. The strings are not case sensitive.

Note Specifications strings marked with an asterisk require the DSP System Toolbox software.

- 'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2' (default spec)

- 'N,F3dB1,F3dB2'

- "N,F3dB1,F3dB2,Ap' *

- 'N,F3dB1,F3dB2,Ast' *

- 'N,F3dB1,F3dB2,Ast1,Ap,Ast2' *

- 'N,F3dB1,F3dB2,BWp *

- 'N,F3dB1,F3dB2,BWst' *

- 'N,Fc1,Fc2'

- `'N,Fc1,Fc2,Ast1,Ap,Ast2'`

- `'N,Fp1,Fp2,Ap'`

- `'N,Fp1,Fp2,Ast1,Ap,Ast2'`

- `'N,Fst1,Fp1,Fp2,Fst2'`

- `'N,Fst1,Fp1,Fp2,Fst2,C'` *

- `'N,Fst1,Fp1,Fp2,Fst2,Ap'` *

- `'N,Fst1,Fst2,Ast'`

- `'Nb,Na,Fst1,Fp1,Fp2,Fst2'` *

The string entries are defined as follows:

- `Ap` — amount of ripple allowed in the pass band. Also called Apass.

- `Ast1` — attenuation in the first stop band in decibels (the default units). Also called Astop1.

- `Ast2` — attenuation in the second stop band in decibels (the default units). Also called Astop2.

- `BWp` — bandwidth of the filter passband. Specified in normalized frequency units.

- `BWst` — bandwidth of the filter stopband. Specified in normalized frequency units.

- `C` — Constrained band flag. This enables you to specify passband ripple or stopband attenuation for fixed-order designs in one or two of the three bands.

  In the specification string `'N,Fst1,Fp1,Fp2,Fst2,C'`, you cannot specify constraints in both stopbands and the passband simultaneously. You can specify constraints in any one or two bands.

- `F3dB1` — cutoff frequency for the point 3 dB point below the passband value for the first cutoff. Specified in normalized frequency units. (IIR filters)

- F3dB2 — cutoff frequency for the point 3 dB point below the passband value for the second cutoff. Specified in normalized frequency units. (IIR filters)

- Fc1 — cutoff frequency for the point 6 dB point below the passband value for the first cutoff. Specified in normalized frequency units. (FIR filters)

- Fc2 — cutoff frequency for the point 6 dB point below the passband value for the second cutoff. Specified in normalized frequency units. (FIR filters)

- Fp1 — frequency at the edge of the start of the pass band. Specified in normalized frequency units. Also called Fpass1.

- Fp2 — frequency at the edge of the end of the pass band. Specified in normalized frequency units. Also called Fpass2.

- Fst1 — frequency at the edge of the start of the first stop band. Specified in normalized frequency units. Also called Fstop1.

- Fst2 — frequency at the edge of the start of the second stop band. Specified in normalized frequency units. Also called Fstop2.

- N — filter order for FIR filters. Or both the numerator and denominator orders for IIR filters when na and nb are not provided.

- Na — denominator order for IIR filters

- Nb — numerator order for IIR filters

Graphically, the filter specifications look similar to those shown in the following figure.

fdesign.bandpass
Regions between specification values like `Fst1` and `Fp1` are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a bandpass filter specification object change depending on the `Specification` string. Use `designmethods` to determine which design methods apply to an object and the `Specification` property value.

Use `designopts` to determine the design options for a given design method. Enter `help(D,METHOD)` at the MATLAB command line to obtain detailed help on the design options for a given design method, `METHOD`.

`D = fdesign.bandpass(spec,specvalue1,specvalue2,...)` constructs an object `D` and sets its specifications at construction time.

`D = fdesign.bandpass(specvalue1,specvalue2,specvalue3, specvalue4,...specvalue4,specvalue5,specvalue6)` constructs `D` with the default `Specification` property string, using the values you provide as input arguments for `specvalue1,specvalue2,specvalue3,specvalue4,specvalue4,specvalue5, specvalue6` and `specvalue7`.

`D = fdesign.bandpass(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

D = fdesign.bandpass(...,MAGUNITS) specifies the units for any magnitude specification you provide in the input arguments. MAGUNITS can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

When you omit the MAGUNITS argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples   Filter a discrete-time signal with a bandpass filter. The signal is a sum of three discrete-time sinusoids, π/8, π/2, and 3π/4 radians/sample.

```
n = 0:159;
x = cos(pi/8*n)+cos(pi/2*n)+sin(3*pi/4*n);
```

Design an FIR equiripple bandpass filter to remove the lowest and highest discrete-time sinusoids.

```
d = fdesign.bandpass('Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2',1/4,3/8,5/8,6/8,
Hd = design(d,'equiripple');
```

Apply the filter to the discrete-time signal.

```
y = filter(Hd,x);
freq = 0:(2*pi)/length(x):pi;
xdft = fft(x);
ydft = fft(y);
plot(freq,abs(xdft(1:length(x)/2+1)));
hold on;
plot(freq,abs(ydft(1:length(x)/2+1)),'r','linewidth',2);
legend('Original Signal','Bandpass Signal');
```

fdesign.bandpass

Design an IIR Butterworth filter of order 10 with 3–dB frequencies of 1 and 1.2 kHz. The sampling frequency is 10 kHz

```
d = fdesign.bandpass('N,F3dB1,F3dB2',10,1e3,1.2e3,1e4);
Hd = design(d,'butter');
fvtool(Hd)
```

This example requires the DSP System Toolbox software.

Design a constrained-band FIR equiripple filter of order 100 with a passband of [1, 1.4] kHz. Both stopband attenuation values are constrained to 60 dB. The sampling frequency is 10 kHz.

```
d = fdesign.bandpass('N,Fst1,Fp1,Fp2,Fst2,C',100,800,1e3,1.4e3,1.6e3,1e4)
d.Stopband1Constrained = true; d.Astop1 = 60;
d.Stopband2Constrained = true; d.Astop2 = 60;
Hd = design(d,'equiripple');
fvtool(Hd);
measure(Hd)
```

The passband ripple is slightly over 2 dB. Because the design constrains both stopbands, you cannot constrain the passband ripple.

Purpose Bandstop filter specification object

Syntax
```
D = fdesign.bandstop
D = fdesign.bandstop(SPEC)
D = fdesign.bandstop(SPEC,specvalue1,specvalue2,...)
D = fdesign.bandstop(specvalue1,specvalue2,specvalue3,specvalue4,...
specvalue5,specvalue6,specvalue7)
D = fdesign.bandstop(...,Fs)
D = fdesign.bandstop(...,MAGUNITS)
```

Description D = fdesign.bandstop constructs a bandstop filter specification object D, applying default values for the properties Fpass1, Fstop1, Fstop2, Fpass2, Apass1, Astop1 and Apass2.

D = fdesign.bandstop(SPEC) constructs object D and sets the Specification property to SPEC. Entries in the SPEC string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for SPEC are shown below. The strings are not case sensitive.

Note Specifications strings marked with an asterisk require the DSP System Toolbox software.

- `'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2'` (default spec)

- `'N,F3dB1,F3dB2'`

- `'N,F3dB1,F3dB2,Ap'` *

- `'N,F3dB1,F3dB2,Ap,Ast'` *

- `'N,F3dB1,F3dB2,Ast'` *

- `'N,F3dB1,F3dB2,BWp'` *

- `'N,F3dB1,F3dB2,BWst'` *

- `'N,Fc1,Fc2'`

- `'N,Fc1,Fc2,Ap1,Ast,Ap2'`

- `'N,Fp1,Fp2,Ap'`

- `'N,Fp1,Fp2,Ap,Ast'`

- `'N,Fp1,Fst1,Fst2,Fp2'`

- `'N,Fp1,Fst1,Fst2,Fp2,C'` *

- `'N,Fp1,Fst1,Fst2,Fp2,Ap'` *

- `'N,Fst1,Fst2,Ast'`

- `'Nb,Na,Fp1,Fst1,Fst2,Fp2'` *

The string entries are defined as follows:

- `Ap` — amount of ripple allowed in the passband in decibels (the default units). Also called Apass.

- `Ap1` — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass1.

- `Ap2` — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass2.

- `Ast` — attenuation in the first stopband in decibels (the default units). Also called Astop1.

- `BWp` — bandwidth of the filter passband. Specified in normalized frequency units.

- `BWst` — bandwidth of the filter stopband. Specified in normalized frequency units.

- `C` — Constrained band flag. This enables you to specify passband ripple or stopband attenuation for fixed-order designs in one or two of the three bands.

  In the specification string `'N,Fp1,Fst1,Fst2,Fp2,C'`, you cannot specify constraints simultaneously in both passbands and the stopband. You can specify constraints in any one or two bands.

- F3dB1 — cutoff frequency for the point 3 dB point below the passband value for the first cutoff.

- F3dB2 — cutoff frequency for the point 3 dB point below the passband value for the second cutoff.

- Fc1 — cutoff frequency for the point 6 dB point below the passband value for the first cutoff. (FIR filters)

- Fc2 — cutoff frequency for the point 6 dB point below the passband value for the second cutoff. (FIR filters)

- Fp1 — frequency at the start of the pass band. Also called Fpass1.

- Fp2 — frequency at the end of the pass band. Also called Fpass2.

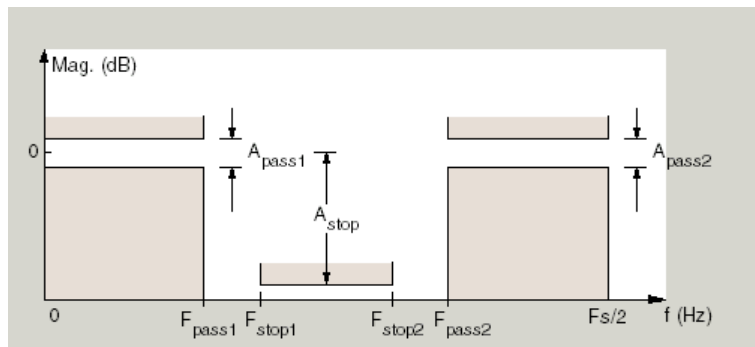
- Fst1 — frequency at the end of the first stop band. Also called Fstop1.

- Fst2 — frequency at the start of the second stop band. Also called Fstop2.

- N — filter order.

- Na — denominator order for IIR filters.

- Nb — numerator order for IIR filters.

Graphically, the filter specifications look similar to those shown in the following figure.


fdesign.bandstop

Regions between specification values like `Fp1` and `Fst1` are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a bandstop filter specification object change depending on the `Specification` string. Use `designmethods` to determine which design methods apply to an object and the `Specification` property value.

Use `designopts` to determine the design options for a given design method. Enter `help(D,METHOD)` at the MATLAB command line to obtain detailed help on the design options for a given design method, `METHOD`.

`D = fdesign.bandstop(SPEC,specvalue1,specvalue2,...)` constructs an object D and sets its specifications at construction time.

`D = fdesign.bandstop(specvalue1,specvalue2,specvalue3,specvalue4,...specvalue5,specvalue6,specvalue7)` constructs an object D with the default `Specification` property string , using the values you provide in `specvalue1,specvalue2,specvalue3,specvalue4,specvalue5,` `specvalue6` and `specvalue7`.

`D = fdesign.bandstop(...,Fs)` adds the argument Fs, specified in Hz to define the sampling frequency. If you specify the sampling frequency as a trailing scalar, all frequencies in the specifications are in Hz as well.

`D = fdesign.bandstop(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. MAGUNITS can be one of

- `'linear'` — specify the magnitude in linear units

- `'dB'` — specify the magnitude in dB (decibels)

- `'squared'` — specify the magnitude in power units

When you omit the MAGUNITS argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples   Construct a bandstop filter to reject the discrete frequency band between
3π/8 and 5π/8 radians/sample. Apply the filter to a discrete-time signal
consisting of the superposition of three discrete-time sinusoids.

Design an FIR equiripple filter and view the magnitude response.

```
d = fdesign.bandstop('Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2',2/8,3/8,5/8,6/8,
Hd = design(d,'equiripple');
fvtool(Hd)
```

Construct the discrete-time signal to filter.

```
n = 0:99;
x = cos(pi/5*n)+sin(pi/2*n)+cos(4*pi/5*n);
y = filter(Hd,x);
xdft = fft(x);
ydft = fft(y);
freq = 0:(2*pi)/length(x):pi;
plot(freq,abs(xdft(1:length(x)/2+1)));
hold on;
plot(freq,abs(ydft(1:length(y)/2+1)),'r','linewidth',2);
xlabel('Radians/Sample'); ylabel('Magnitude');
legend('Original Signal','Bandstop Signal');
```

Create a Butterworth bandstop filter for data sampled at 10 kHz. The
stopband is [1,1.5] kHz. The order of the filter is 20.

```
d = fdesign.bandstop('N,F3dB1,F3dB2',20,1e3,1.5e3,1e4);
Hd = design(d,'butter');
fvtool(Hd);
```

Zoom in on the magnitude response plot to verify that the 3-dB down
points are located at 1 and 1.5 kHz.

The following example requires the DSP System Toolbox license.

Design a constrained-band FIR equiripple filter of order 100 for data sampled at 10 kHz. You can specify constraints on at most two of the three bands: two passbands and one stopband. In this example, you choose to constrain the passband ripple to be 0.5 dB in each passband. Design the filter, visualize the magnitude response and measure the filter's design.

```
d = fdesign.bandstop('N,Fp1,Fst1,Fst2,Fp2,C',100,800,1e3,1.5e3,1.7e3,1e4)
d.Passband1Constrained = true; d.Apass1 = 0.5;
d.Passband2Constrained = true; d.Apass2 = 0.5;
Hd = design(d,'equiripple');
fvtool(Hd);
measure(Hd)
```

With this order filter and passband ripple constraints, you achieve approximately 50 dB of stopband attentuation.

See Also   fdesign, fdesign.bandpass, fdesign.highpass, fdesign.lowpass

Purpose   CIC compensator filter specification object

Syntax
```
d= fdesign.ciccomp
d= fdesign.ciccomp(d,nsections,rcic)
d= fdesign.ciccomp(...,spec)
h = fdesign.ciccomp(...,spec,specvalue1,specvalue2,...)
```

Description   `d= fdesign.ciccomp` constructs a CIC compensator specifications object `d`, applying default values for the properties Fpass, Fstop, Apass, and Astop. In this syntax, the filter has two sections and the differential delay is 1.

Using `fdesign.ciccomp` with a design method creates a `dfilt` object, a single-rate discrete-time filter.

`d= fdesign.ciccomp(d,nsections,rcic)` constructs a CIC compensator specifications object with the filter differential delay set to `d`, the number of sections in the filter set to `nsections`, and the CIC rate change factor set to `rcic`. The default values of these parameters are: the differential delay equal to 1, the number of sections equal to 2, and the CIC rate change factor equal to 1.

If the CIC rate change factor is equal to 1, the filter passband response is an inverse sinc that is an approximation to the true inverse passband response of the CIC filter.

If you specify a CIC rate change factor not equal to 1, the filter passband response is an inverse Dirichlet sinc that matches exactly the true inverse passband response of the CIC filter.

`d= fdesign.ciccomp(...,spec)` constructs a CIC Compensator specifications object and sets its `Specification` property to *spec*. Entries in the spec string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for *spec* are shown in the list below. The strings are not case sensitive.

- `'fp,fst,ap,ast'` (default spec)

- `'n,fc,ap,ast'`

- `'n,fp,ap,ast'`

- `'n,fp,fst'`

- `'n,fst,ap,ast'`

The string entries are defined as follows:

- `ap` — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass.

- `ast` — attenuation in the stop band in decibels (the default units). Also called Astop.

- `fc` — cutoff frequency for the point 6 dB point below the passband value. Specified in normalized frequency units.

- `fp` — frequency at the end of the pass band. Specified in normalized frequency units. Also called Fpass.

- `fst` — frequency at the start of the stop band. Specified in normalized frequency units. Also called Fstop.

- `n` — filter order.

In graphic form, the filter specifications look like this:
Regions between specification values like `fp` and `fst` are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a CIC compensator specifications object change depending on the `Specification` string.

Use `designmethods` to determine which design method applies to an object and its specification string.

`h = fdesign.ciccomp(...,spec,specvalue1,specvalue2,...)` constructs an object and sets the specifications in the order they are specified in the `spec` input when you construct the object.

Designing CIC Compensators

Typically, when they develop filters, designers want flat passbands and transition regions that are as narrow as possible. CIC filters present a $(\sin x/x)$ profile in the passband and relatively wide transitions.

To compensate for this fall off in the passband, and to try to reduce the width of the transition region, you can use a CIC compensator filter that demonstrates an $(x/\sin x)$ profile in the passband. `fdesign.ciccomp` is specifically tailored to designing CIC compensators.

Here is a plot of a CIC filter and a compensator for that filter. The example that produces these filters follows the plot.

Magnitude Response (dB)
Given a CIC filter, how do you design a compensator for that filter? CIC compensators share three defining properties with the CIC filter — differential delay, d; number of sections, numberofsections; and the usable passband frequency, Fpass.

By taking the number of sections, passband, and differential delay from your CIC filter and using them in the definition of the CIC compensator, the resulting compensator filter effectively corrects for the passband droop of the CIC filter, and narrows the transition region.

As a demonstration of this concept, this example creates a CIC decimator and its compensator.

```
fs = 96e3;   % Input sampling frequency.
fpass = 4e3; % Frequency band of interest.
m = 6;   % Decimation factor.
hcic = design(fdesign.decimator(m,'cic',1,fpass,60,fs));
```

```
hd = cascade(dfilt.scalar(1/gain(hcic)),hcic);
hd(2) = design(fdesign.ciccomp(hcic.differentialdelay, ...
            hcic.numberofsections,fpass,4.5e3,.1,60,fs/m));
fvtool(hd(1),hd(2),...
cascade(hd(1),hd(2)),'Fs',[96e3 96e3/m 96e3])
```

You see the results in the preceding plot.

Examples   Designed to compensate for the rolloff inherent in CIC filters, CIC
compensators can improve the performance of your CIC design.
This example designs a compensator d with five sections and a
differential delay equal to one. The plot displayed after the code
shows the increasing gain in the passband that is characteristic of
CIC compensators, to overcome the droop in the CIC filter passband.
Ideally, cascading the CIC compensator with the CIC filter results in a
lowpass filter with flat passband response and narrow transition region.

```
h = fdesign.ciccomp;
set(h, 'NumberOfSections', 5, 'DifferentialDelay', 1);
hd = equiripple(h);
fvtool(hd);
```

Magnitude Response (dB)
This compensator would work for a decimator or interpolator that had differential delay of 1 and 5 sections.

See Also   `fdesign.decimator` | `fdesign.interpolator`

Purpose   IIR comb filter specification object

Syntax
```
d=fdesign.comb
d=fdesign.comb(combtype)
d=fdesign(combtype,specstring)
d=fdesign(combtype,specstring,specvalue1,specvalue2,...)
d=fdesign.comb(...,Fs)
```

Description   fdesign.comb specifies a peaking or notching comb filter. Comb filters amplify or attenuate a set of harmonically related frequencies.

d=fdesign.comb creates a notching comb filter specification object and applies default values for the filter order (N=10) and quality factor (Q=16).

d=fdesign.comb(combtype) creates a comb filter specification object of the specified type and applies default values for the filter order and quality factor. The valid entries for combtype are shown in the following table. The entries are not case-sensitive.

Argument	Description
notch	creates a comb filter that attenuates a set of harmonically related frequencies.
peak	creates a comb filter that amplifies a set of harmonically related frequencies.

d=fdesign(combtype,*specstring*) creates a comb filter specification object of type combtype and sets its Specification property to *specstring* with default values. The entries in *specstring* determine the number of peaks or notches in the comb filter as well as their bandwidth and slope. Valid entries for *specstring* are shown below. The entries are not case-sensitive.

- 'N,Q' (default)

- ''N,BW'

- `'L,BW,GWB,Nsh'`

The following table describes the arguments in *specstring*.

Argument	Description
BW	Bandwidth of the notch or peak. By default the bandwidth is calculated at the point −3 dB down from the center frequency of the peak or notch. For example, setting BW=0.01 specifies that the −3 dB point will be +/- 0.005 (in normalized frequency) from the center of the notch or peak.
GWB	Gain at which the bandwidth is measured. This allows the user to specify the bandwidth of the notch or peak at a gain different from the −3 dB default.
L	Upsampling factor for a shelving filter of order Nsh. L determines the number of peaks or notches, which are equally spaced over the normalized frequency interval [-1,1].
N	Filter order. Specifies a filter with N+1 numerator and denominator coefficients.The filter will have N peaks or notches equally spaced over the interval [−1,1] .

Argument	Description
Nsh	Shelving filter order. Nsh represents a positive integer that determines the sharpness of the peaks or notches. The greater the value of the shelving filter order, the steeper the slope of the peak or notch. This results in a filter of order L*Nsh.
Q	Peak or notch quality factor. Q represents the ratio of the lowest center frequency peak or notch (not including DC) to the bandwidth calculated at the −3 dB point.

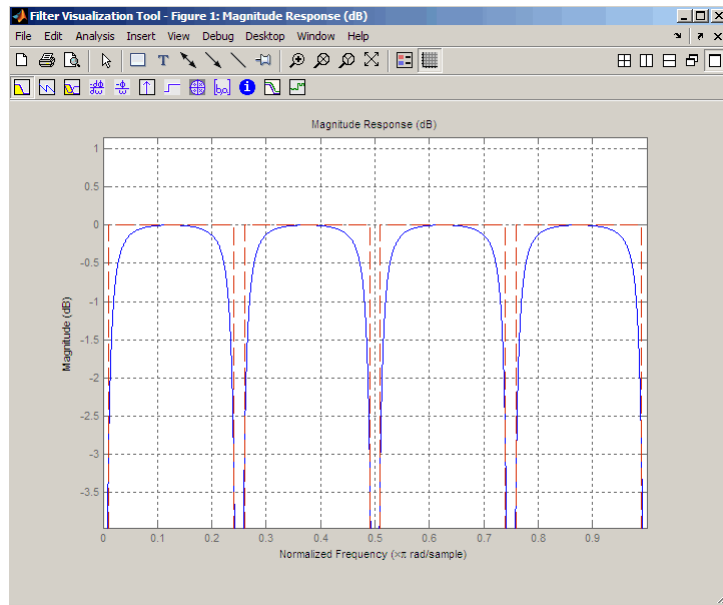
d=fdesign(combtype,*specstring*,specvalue1,specvalue2,...) creates an IIR comb filter specification object of type combtype and sets its Specification property to the values in specvalue1,specvalue2,...

d=fdesign.comb(...,Fs) creates an IIR comb filter specification object using the sampling frequency, Fs, of the signal to be filtered. The function assumes that Fs is in Hertz and must be specified as a scalar trailing all other provided values.

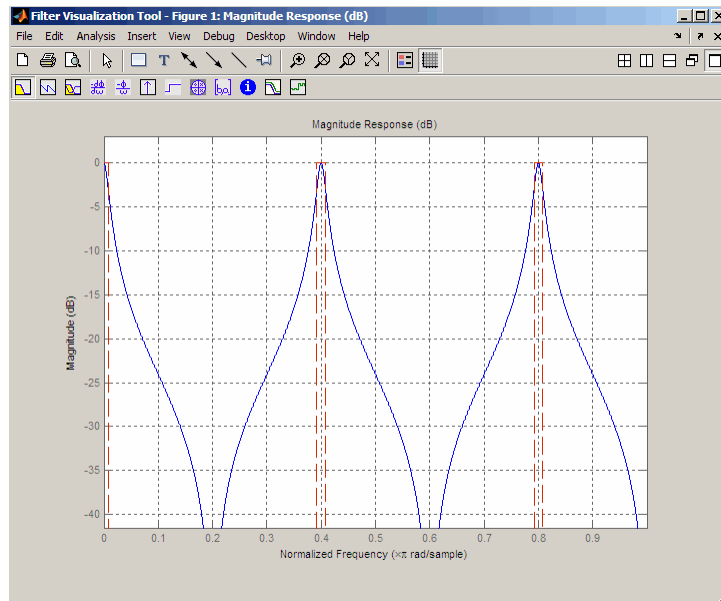
Examples These examples demonstrate how to create IIR comb filter specification objects. First, create a default specification object.

```
d=fdesign.comb;
```

In the next example, create a notching filter of order 8 with a bandwidth of 0.02 (normalized frequency) referenced to the −3 dB point.

```
d  = fdesign.comb('notch','N,BW',8,0.02);
Hd = design(d);
fvtool(Hd)
```


Next, create a peaking comb filter with 5 peaks and a quality factor of 25.

```
d = fdesign.comb('peak','N,Q',5,25);
Hd = design(d);
fvtool(Hd)
```


In the next example, create a notching filter to remove interference at 60 Hz and its harmonics. The following code creates a filter with 10 notches and a notch bandwidth of 5 Hz referenced to the -4dB level. The filter has a shelving filter order of 4 and a sampling frequency of 600 Hz. Because the notches are equidistantly spaced in the interval [-300, 300] Hz, they occur at multiples of 60 Hz.

```
d = fdesign.comb('notch','L,BW,GBW,Nsh',10,5,-4,4,600);
Hd=design(d);
fvtool(Hd)
```
Purpose   Decimator filter specification object

Syntax
```
D = fdesign.decimator(M)
D = fdesign.decimator(M,RESPONSE)
D = fdesign.decimator(M,PULSESHAPINGRESPONSE,SPS)
D = fdesign.decimator(M,CICRESPONSE,D)
D = fdesign.decimator(M,RESPONSE,SPEC)
D = fdesign.decimator(...,SPEC,specvalue1,specvalue2,...)
D = fdesign.decimator(...,Fs)
D = fdesign.decimator(...,MAGUNITS)
```

Description   `D = fdesign.decimator(M)` constructs a decimator filter specification object D with the DecimationFactor property equal to the positive integer M and the Response property set to `'Nyquist'`. The default values for the transition width and stopband attenuation in the Nyquist design are 0.1π radians/sample and 80 dB. If M is unspecified, M defaults to 2.

`D = fdesign.decimator(M,RESPONSE)` constructs a decimator specification object with the decimation factor M and the `'Response'` property.

`D = fdesign.decimator(M,PULSESHAPINGRESPONSE,SPS)` constructs a pulse-shaping decimator specification object with the decimation factor M and `'Response'` property equal to one of the supported pulse-shaping filters: `'Gaussian'`, `'Raised Cosine'`, or `'Square Root Raised Cosine'`. SPS is the samples per symbol. The samples per symbol, SPS, must precede any specification string.

`D = fdesign.decimator(M,CICRESPONSE,D)` constructs a CIC or CIC compensator decimator specification object with the decimation factor, M, `'Response'` property equal to `'CIC'` or `'CICCOMP'`, and D equal to the differential delay. The differential delay, D, must precede any specification string.

Because you are designing multirate filters, the specification strings available are not the same as the specifications for designing single-rate filters. The decimation factor M is not included in the specification strings. Different filter responses support different specifications. The

following table lists the supported response types and specification strings. The strings are not case sensitive.

Design String	Valid Specification Strings
'Arbitrary Magnitude'	See `fdesign.arbmag` for a description of the specification string entries. • `'N,F,A'` (default string) • `'N,B,F,A'`
'Arbitrary Magnitude and Phase'	See `fdesign.arbmagnphase` for a description of the specification string entries. • `'N,F,H'` (default string) • `'N,B,F,H'`
'Bandpass'	See `fdesign.bandpass` for a description of the specification string entries. • `'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2'` (default string) • `'N,Fc1,Fc2'` • `'N,Fst1,Fp1,Fp2,Fst2'`
'Bandstop'	See `fdesign.bandstop` for a description of the specification string entries.
'CIC'	`'Fp,Ast'` — Only valid specification. `Fp` is the passband frequency and `Ast` is the stopband attenuation in decibels. To specify a CIC decimator, include the differential delay after `'CIC'` and before the filter specification string: `'Fp,Ast'`. For example: `d = fdesign.decimator(2,'cic',4,'Fp,Ast',0.4,40);`

Design String	Valid Specification Strings
`'CIC Compensator'`	See `fdesign.ciccomp` for a description of the specification string entries. • `'Fp,Fst,Ap,Ast'` (default string) • `'N,Fc,Ap,Ast'` • `'N,Fp,Ap,Ast'` • `'N,Fp,Fst'` • `'N,Fst,Ap,Ast'` To specify a CIC compensator decimator, include the differential delay after `'CICCOMP'` and before the filter specification string.. For example: `d = fdesign.decimator(2,'ciccomp',4);`
`'Differentiator'`	`'N'` — filter order
`'Gaussian'`	`'Nsym,BT` — Nsym is the filter order in symbols and BT is the bandwidth-symbol time product. The specification string must be preceded by an integer-valued `SamplesPerSymbol`.
`'Halfband`	See `fdesign.halfband` for a description of the specification string entries. • `'TW,Ast'` (default string) • `'N,TW'` • `` `N' `` • `'N,Ast'` If you use the quasi-linear IIR design method, `iirlinphase`, with a halfband specification, the interpolation factor must be 2.

Design String	Valid Specification Strings
'Highpass'	See fdesign.highpass for a description of the specification string entries. • 'Fst,Fp,Ast,Ap' (default string) • 'N,F3db' • 'N,Fc' • 'N,Fc,Ast,Ap' • 'N,Fp,Ast,Ap' • 'N,Fst,Ast,Ap' • 'N,Fst,Fp' • 'N,Fst,Ast,Ap' • 'N,Fst,Fp,Ast'
'Hilbert'	See fdesign.hilbert for a description of the specification string entries. • 'N,TW' (default string) • 'TW,Ap'
'Inverse-sinc Lowpass'	See fdesign.isinclp for a description of the specification string entries. • 'Fp,Fst,Ap,Ast' (default string)) • 'N,Fc,Ap,Ast' • 'N,Fp,Fst' • 'N,Fst,Ap,Ast'

Design String	Valid Specification Strings
`'Inverse-sinc Highpass'`	See `fdesign.isinchp` for a description of the specification string entries. • `'Fst,Fp,Ast,Ap'` (default string)) • `'N,Fc,Ast,Ap'` • `'N,Fst,Fp'` • `'N,Fst,Ast,Ap'`
`'Lowpass'`	See `fdesign.lowpass` for a description of the specification string entries. • `'Fp,Fst,Ap,Ast'` (default string) • `'N,F3dB'` • `'N,Fc'` • `'N,Fc,Ap,Ast'` • `'N,Fp,Ap,Ast'` • `'N,Fp,Fst'` • `'N,Fp,Fst,Ap'` • `'N,Fp,Fst,Ast'` • `'N,Fst,Ap,Ast'`

Design String	Valid Specification Strings
`'Nyquist'`	See `fdesign.nyquist` for a description of the specification string entries. For all Nyquist specifications, you must specify the *L*th band. This typically corresponds to the `DecimationFactor`. • `'TW,Ast'` (default string) • `'N'` • `'N,Ast'` • `'N,Ast'`
`'Raised Cosine'`	See `fdesign.pulseshaping` for a description of the specification string entries. • `'Ast,Beta'` (default string) • `'Nsym,Beta'` • `'N,Beta'` The specification string must be preceded by an integer-valued `SamplesPerSymbol`.
`'Square Root Raised Cosine'`	See `fdesign.pulseshaping` for a description of the specification string entries. • `'Ast,Beta'` (default string) • `'Nsym,Beta'` • `'N,Beta'` The specification string must be preceded by an integer-valued `SamplesPerSymbol`.

`D = fdesign.decimator(M,RESPONSE,SPEC)` constructs object `D` and sets the `Specification` property to `SPEC` for the response type, `RESPONSE`. Entries in the `SPEC` string represent various filter response features,

such as the filter order, that govern the filter design. Valid entries for SPEC depend on the RESPONSE type.

Because you are designing multirate filters, the specification strings available are not the same as the specifications for designing single-rate filters with such response types as fdesign.lowpass. The strings are not case sensitive.

The decimation factor M is not in the specification strings.

D = fdesign.decimator(...,SPEC,specvalue1,specvalue2,...) constructs an object D and sets its specifications at construction time.

D = fdesign.decimator(...,Fs) provides the sampling frequency of the signal to be filtered. Fs must be specified as a scalar trailing the other numerical values provided. Fs is assumed to be in Hz as are all other frequency values provided.

D = fdesign.decimator(...,MAGUNITS) specifies the units for any magnitude specification you provide in the input arguments. MAGUNITS can be one of

- 'linear' — specify the magnitude in linear units.

- 'dB' — specify the magnitude in dB (decibels).

- 'squared' — specify the magnitude in power units.

When you omit the MAGUNITS argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples   These examples show how to construct decimating filter specification objects. First, create a default specifications object without using input arguments except for the decimation factor m.

```
d = fdesign.decimator(2,'Nyquist',2,0.1,80) % Set tw=0.1, and ast=80.
```

Now create an object by passing a specification type string 'fst1,fp1,fp2,fst2,ast1,ap,ast2' and a design — the resulting object uses default values for the filter specifications. You must provide

the design input argument, bandpass in this example, when you include a specification.

```
d=fdesign.decimator(8,'bandpass',...
'fst1,fp1,fp2,fst2,ast1,ap,ast2');
```

Create another decimating filter specification object, passing the specification values to the object rather than accepting the default values for fp,fst,ap,ast.

```
d=fdesign.decimator(3,'lowpass',.45,0.55,.1,60);
```

Now pass the filter specifications that correspond to the specifications — n,fc,ap,ast.

```
d=fdesign.decimator(3,'ciccomp',1,2,'n,fc,ap,ast',...
20,0.45,.05,50);
```

Now design a decimator using the equiripple design method.

```
hm = equiripple(d);
```

Pass a new specification type for the filter, specifying the filter order. Note that the inputs must include the differential delay dd with the CIC input argument to design a CIC specification object.

```
m = 5;
dd = 2;
d = fdesign.decimator(m,'cic',dd,'fp,ast',0.55,55);
```

In this example, you specify a sampling frequency as the last input argument. Here is it 1000 Hz. Design an equiripple filter and plot the magnitude response:

```
d=fdesign.decimator(8,'bandpass','fst1,fp1,fp2,fst2,ast1,ap,ast2',...
100,150,250,300,50,.05,50,1000);
fvtool(design(d,'equiripple'))
```

fdesign.differentiator

Purpose   Differentiator filter specification object

Syntax   D = fdesign.differentiator
                   D = fdesign.differentiator(SPEC)
                   D = fdesign.differentiator(SPEC,specvalue1,specvalue2, ...)
                   D = fdesign.differentiator(specvalue1)
                   D = fdesign.differentiator(...,Fs)
                   D = fdesign.differentiator(...,MAGUNITS)

Description   D = fdesign.differentiator constructs a default differentiator filter
                   designer D with the filter order set to 31.

                   D = fdesign.differentiator(SPEC) initializes the filter designer
                   Specification property to SPEC. You provide one of the following
                   strings as input to replace SPEC. The string you provide is not case
                   sensitive.

                   Note Specifications strings marked with an asterisk require the DSP
                   System Toolbox software.

                   - 'N' — Full band differentiator (default)

                   - 'N,Fp,Fst' — Partial band differentiator

                   - 'N,Fp,Fst,Ap' — Partial band differentiator *

                   - 'N,Fp,Fst,Ast' — Partial band differentiator *

                   - 'Ap' — Minimum order full band differentiator *

                   - 'Fp,Fst,Ap,Ast' — Minimum order partial band differentiator *

                   The string entries are defined as follows:

                   - Ap — amount of ripple allowed in the pass band in decibels (the
                     default units). Also called Apass.

                   - Ast — attenuation in the stop band in decibels (the default units).
                     Also called Astop.

- Fp — frequency at the start of the pass band. Specified in normalized frequency units. Also called Fpass.

- Fst — frequency at the end of the stop band. Specified in normalized frequency units. Also called Fstop.

- N — filter order.

By default, fdesign.differentiator assumes that all frequency specifications are provided in normalized frequency units. Also, decibels is the default for all magnitude specifications.

Use designopts to determine the design options for a given design method. Enter help(D,METHOD) at the MATLAB command line to obtain detailed help on the design options for a given design method, METHOD.

D = fdesign.differentiator(SPEC,specvalue1,specvalue2, ...) initializes the filter designer specifications in SPEC with specvalue1, specvalue2, and so on. To get a description of the specifications specvalue1, specvalue2, and more, enter

```
get(d,'description')
```

at the Command prompt.

D = fdesign.differentiator(specvalue1) assumes the default specification string N, setting the filter order to the value you provide.

D = fdesign.differentiator(...,Fs) adds the argument Fs, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

D = fdesign.differentiator(...,MAGUNITS) specifies the units for any magnitude specification you provide in the input arguments. MAGUNITS can be one of

- 'linear' — specify the magnitude in linear units

- 'dB' — specify the magnitude in dB (decibels)

- 'squared' — specify the magnitude in power units

fdesign.differentiator

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

Use an FIR equiripple differentiator to transform frequency modulation into amplitude modulation, which can be detected using an envelope detector.

Modulate a message signal consisting of a 20-Hz sine wave with a 1 kHz carrier frequency. The sampling frequency is 10 kHz .

```
t = linspace(0,1,1e4);
x = cos(2*pi*20*t);
Fc = 1e3;
Fs = 1e4;
y = modulate(x,Fc,Fs,'fm');
```

Design the equiripple FIR differentiator of order 31.

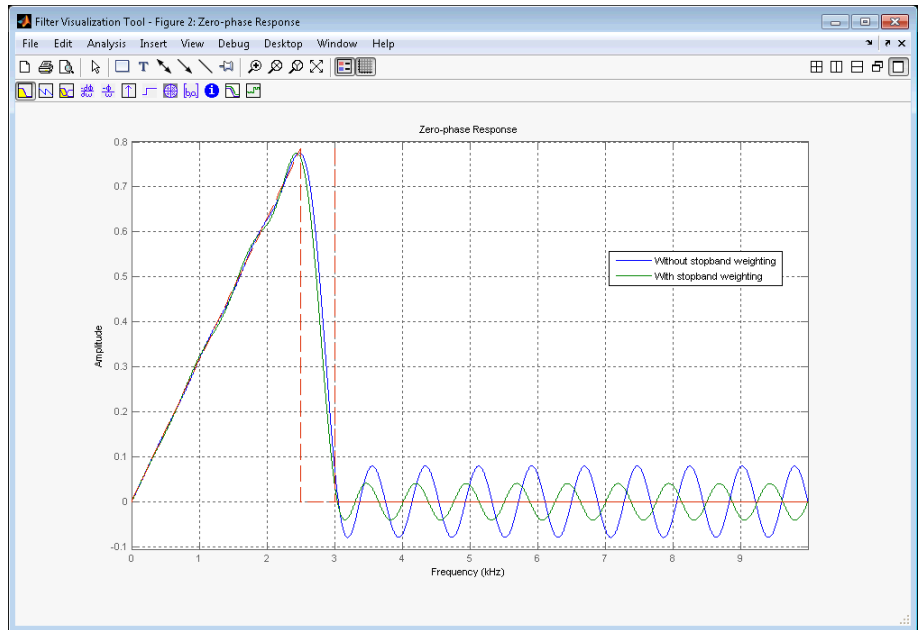
```
d = fdesign.differentiator(31,1e4);
Hd = design(d,'equiripple');
```

Filter the modulated signal and take the Hilbert transform to obtain the envelope.

```
y1 = filter(Hd,y);
y1 = hilbert(y1);
% Plot the envelope
plot(t.*1000,abs(y1));
xlabel('Milliseconds'); ylabel('Magnitude');
grid on;
title('Envelope of the Demodulated Signal');
```
From the preceding figure, you see that the envelope completes two cycles every 100 milliseconds. The envelope is oscillating at 20 Hz, which corresponds to the frequency of the message signal.

Design an FIR differentiator using least squares and plot the zero phase response.

```
d = fdesign.differentiator(33); % Filter order is 33.
hd = design(d,'firls');
fvtool(hd,'magnitudedisplay','zero-phase',...
'frequencyrange','[-pi, pi)')
```
Design a narrow band differentiator. Differentiate the first 25 percent of the frequencies in the Nyquist range and filter the higher frequencies.

```
Fs=20000; %sampling frequency
d = fdesign.differentiator('N,Fp,Fst',54,2500,3000,Fs);
Hd= design(d,'equiripple');
% Weight the stopband to increase attenuation
Hd1 = design(d,'equiripple','Wstop',4);
hfvt = fvtool(Hd,Hd1,'magnitudedisplay','zero-phase',...
'frequencyrange','[O, Fs/2)');
legend(hfvt,'Without stopband weighting',...
'With stopband weighting');
```


See Also   design | fdesign

fdesign.fracdelay

Purpose   Fractional delay filter specification object

Syntax
```
d = fdesign.fracdelay(delta)
d = fdesign.fracdelay(delta,'N')
d = fdesign.fracdelay(delta,'N',n)
d = fdesign.fracdelay(delta,n)
d = fdesign.fracdelay(...,fs)
```

Description   `d = fdesign.fracdelay(delta)` constructs a default fractional delay filter designer `d` with the filter order set to 3 and the delay value set to `delta`. The fractional delay `delta` must be between 0 and 1 samples.

`d = fdesign.fracdelay(delta,'N')` initializes the filter designer specification string to `N`, where `N` specifies the fractional delay filter order and defaults to filter order of 3.

Use `designmethods(d)` to get a list of the design methods available for a specification string.

`d = fdesign.fracdelay(delta,'N',n)` initializes the filter designer to specification string `N` and sets the filter order to `n`.

`d = fdesign.fracdelay(delta,n)` assumes the default specification `N`, filter order, and sets the filter order to the value you provide in input `n`.

`d = fdesign.fracdelay(...,fs)` adds the argument `fs`, specified in units of Hertz (Hz) to define the sampling frequency. In this case, specify the fractional delay `delta` to be between 0 and 1/`fs`.

Examples   Design a second-order fractional delay filter of 0.2 samples using the Lagrange method. Implement the filter using a Farrow fractional delay (`fd`) structure.

```
d = fdesign.fracdelay(0.2,'N',2);
hd = design(d,'lagrange','filterstructure','farrowfd');
fvtool(hd,'analysis','grpdelay')
```

Design a cubic fractional delay filter with a sampling frequency of 8 kHz and fractional delay of 50 microseconds using the Lagrange method.

```
d = fdesign.fracdelay(50e-6,'N',3,8000);
Hd = design(d, 'lagrange', 'FilterStructure', 'farrowfd');
```

See Also   design | designopts | fdesign | setspecs

fdesign.halfband

Purpose　Halfband filter specification object

Syntax
```
d = fdesign.halfband
d = fdesign.halfband('type',type)
d = fdesign.halfband(spec)
d = fdesign.halfband(spec,specvalue1,specvalue2,...)
d = fdesign.halfband(specvalue1,specvalue2)
d = fdesign.halfband(...,fs)
d = fdesign.halfband(...,magunits)
```

Description　`d = fdesign.halfband` constructs a halfband filter specification object `d`, applying default values for the properties `tw` and `ast`.

Using `fdesign.halfband` with a design method generates a `dfilt` object.

`d = fdesign.halfband('type',type)` initializes the filter designer 'Type' property with `type`. "type" must be either `lowpass` or `highpass` and is not case sensitive.

`d = fdesign.halfband(spec)` constructs object `d` and sets its 'Specification' to *spec*. Entries in the `spec` string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for *spec* are shown below. The strings are not case sensitive.

- tw,ast (default `spec`)
- n,tw
- n
- n,ast

The string entries are defined as follows:

- ast — attenuation in the stop band in decibels (the default units).
- n — filter order.
- tw — width of the transition region between the pass and stop bands. Specified in normalized frequency units.

By default, all frequency specifications are assumed to be in normalized frequency units. Moreover, all magnitude specifications are assumed to be in dB. Different specification types may have different design methods available.

The filter design methods that apply to a halfband filter specification object change depending on the `Specification` string. Use `designmethods` to determine which design method applies to an object and its specification string. Different filter design methods also have options that you can specify. Use `designopts` with the design method string to see the available options. For example:

```
f=fdesign.halfband('N,TW');
designmethods(f)
```

`d = fdesign.halfband(spec,specvalue1,specvalue2,...)` constructs an object `d` and sets its specifications at construction time.

`d = fdesign.halfband(specvalue1,specvalue2)` constructs an object `d` assuming the default `Specification` property string `tw,ast`, using the values you provide for the input arguments `specvalue1` and `specvalue2` for `tw` and `ast`.

`d = fdesign.halfband(...,fs)` adds the argument `fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.halfband(...,magunits)` specifies the units for any magnitude specification you provide in the input arguments. `magunits` can be one of

- `linear` — specify the magnitude in linear units

- `dB` — specify the magnitude in dB (decibels)

- `squared` — specify the magnitude in power units

When you omit the `magunits` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

fdesign.halfband

Examples

Create a default halfband filter specifications object:

```
d=fdesign.halfband;
```

Create another halfband filter object, passing the specification values to the object rather than accepting the default values for n and ast.

```
 d = fdesign.halfband('n,ast', 42, 80);
```

For another example, pass the filter values that correspond to the default Specification — n,ast.

```
d = fdesign.halfband(.01, 80);
```

This example designs an equiripple FIR filter, starting by passing a new specification type and specification values to fdesign.halfband.

```
 hs = fdesign.halfband('n,ast',80,70);
hd =design(hs,'equiripple'); % Opens FVTool automatically.
```

In this example, pass the specifications for the filter, and then design a least-squares FIR filter from the object, using firls as the design method.

```
 hs = fdesign.halfband('n,tw', 42, .04);
% designmethods(hs)
hd=design(hs,'firls');
```

Create two equiripple halfband filters with and without a nonnegative zero phase response:

```
f=fdesign.halfband('N,TW',12,0.2);
% Equiripple halfband filter with nonnegative zero phase response
Hd1=design(f,'equiripple','ZeroPhase',true);
% Equiripple halfband filter with zero phase false
% 'zerophase',false is the default
Hd2=design(f,'equiripple','ZeroPhase',false);
%Obtain real-valued amplitudes (not magnitudes)
[Hr_zerophase,W]=zerophase(Hd1);
```

```
[Hr,W]=zerophase(Hd2);
% Plot and compare response
plot(W,Hr_zerophase,'k','linewidth',2);
xlabel('Radians/sample'); ylabel('Amplitude');
hold on;
plot(W,Hr,'r');
axis tight; grid on;
legend('with ''ZeroPhase'', true','with ''ZeroPhase'' false');
```

Note that the amplitude of the zero phase response (black line) is nonnegative for all frequencies.
The 'ZeroPhase' option is valid only for equiripple halfband designs with the 'N,TW' specification. You cannot specify 'MinPhase' and 'ZeroPhase' to be simultaneously 'true'.

See Also   fdesign | fdesign.decimator | design | fdesign.interpolator | fdesign.nyquist | setspecs | zerophase

fdesign.highpass

Purpose Highpass filter specification object

Syntax
```
D = fdesign.highpass
D = fdesign.highpass(SPEC)
D = fdesign.highpass(SPEC,specvalue1,specvalue2,...)
D = fdesign.highpass(specvalue1,specvalue2,specvalue3,
specvalue4)
D = fdesign.highpass(...,Fs)
D = fdesign.highpass(...,MAGUNITS)
```

Description D = fdesign.highpass constructs a highpass filter specification object D, applying default values for the specification string, 'Fst,Fp,Ast,Ap'.

D = fdesign.highpass(SPEC) constructs object D and sets the Specification property to SPEC. Entries in the SPEC string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for SPEC are shown below. The strings are not case sensitive.

Note Specifications strings marked with an asterisk require the DSP System Toolbox software.

- 'Fst,Fp,Ast,Ap' (default spec)
- 'N,F3db'
- 'N,F3db,Ap' *
- 'N,F3db,Ast' *
- 'N,F3db,Ast,Ap' *
- 'N,F3db,Fp *
- 'N,Fc'
- 'N,Fc,Ast,Ap'
- 'N,Fp,Ap'

- `'N,Fp,Ast,Ap'`

- `'N,Fst,Ast'`

- `'N,Fst,Ast,Ap'`

- `'N,Fst,F3db'` *

- `'N,Fst,Fp'`

- `'N,Fst,Fp,Ap'` *

- `'N,Fst,Fp,Ast'` *

- `'Nb,Na,Fst,Fp'` *

The string entries are defined as follows:

- `Ap` — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass.

- `Ast` — attenuation in the stop band in decibels (the default units). Also called Astop.

- `F3db` — cutoff frequency for the point 3 dB point below the passband value. Specified in normalized frequency units.

- `Fc` — cutoff frequency for the point 6 dB point below the passband value. Specified in normalized frequency units.

- `Fp` — frequency at the start of the pass band. Specified in normalized frequency units. Also called Fpass.

- `Fst` — frequency at the end of the stop band. Specified in normalized frequency units. Also called Fstop.

- `N` — filter order.

- `Na` and `Nb` are the order of the denominator and numerator.

Graphically, the filter specifications look similar to those shown in the following figure.

Regions between specification values like `Fst` and `Fp` are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a highpass filter specification object change depending on the `Specification` string. Use `designmethods` to determine which design method applies to an object and its specification string.

Use `designopts` to determine which design options are valid for a given design method. For detailed information on design options for a given design method, `METHOD`, enter `help(D,METHOD)` at the MATLAB command line.

`D = fdesign.highpass(SPEC,specvalue1,specvalue2,...)` constructs an object d and sets its specification values at construction time.

`D = fdesign.highpass(specvalue1,specvalue2,specvalue3, specvalue4)` constructs an object `D` with the default `Specification` property and the values you enter for `specvalue1,specvalue2,...`.

`D = fdesign.highpass(...,Fs)` provides the sampling frequency for the filter specification object. `Fs` is in Hz and must be specified as a scalar trailing the other numerical values provided. If you specify a sampling frequency, all other frequency specifications are in Hz.

`D = fdesign.highpass(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units

- `'dB'` — specify the magnitude in dB (decibels)

- `'squared'` — specify the magnitude in power units

When you omit the MAGUNITS argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples   Higpass filter a discrete-time signal consisting of two sine waves.

Create a highpass filter specification object. Specify the passband frequency to be 0.25π radians/sample and the stopband frequency to be 0.15π radians/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB.

```
d = fdesign.highpass('Fst,Fp,Ast,Ap',0.15,0.25,60,1);
```

Query the valid design methods for your filter specification object, d.

```
designmethods(d)
```

Create an FIR equiripple filter and view the filter magnitude response with fvtool.

```
Hd = design(d,'equiripple');
fvtool(Hd);
```

Create a signal consisting of the sum of two discrete-time sinusoids with frequencies of $\pi/8$ and $\pi/4$ radians/sample and amplitudes of 1 and 0.25 respectively. Filter the discrete-time signal with the FIR equiripple filter object, Hd

```
n = 0:159;
x = cos((pi/8)*n)+0.25*sin((pi/4)*n);
y = filter(Hd,x);
Domega = (2*pi)/160;
freq = 0:(2*pi)/160:pi;
```

```
xdft = fft(x);
ydft = fft(y);
plot(freq,abs(xdft(1:length(x)/2+1)));
hold on;
plot(freq,abs(ydft(1:length(y)/2+1)),'r','linewidth',2);
legend('Original Signal','Lowpass Signal', ...
'Location','NorthEast');
ylabel('Magnitude'); xlabel('Radians/Sample');
```

Create a filter of order 10 with a 6-dB frequency of 9.6 kHz and a sampling frequency of 48 kHz.

```
d=fdesign.highpass('N,Fc',10,9600,48000);
designmethods(d)
% only valid design method is FIR window method
Hd = design(d);
% Display filter magnitude response
fvtool(Hd);
```

If you have the DSP System Toolbox software, you can specify the shape of the stopband and the rate at which the stopband decays.

Create two FIR equiripple filters with different linear stopband slopes. Specify the passband frequency to be 0.3π radians/sample and the stopband frequency to be 0.35π radians/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB. Design one filter with a 20 dB/rad/sample stopband slope and another filter with 40 dB/rad/sample.

```
D = fdesign.highpass('Fst,Fp,Ast,Ap',0.3,0.35,60,1);
Hd1 = design(D,'equiripple','StopBandShape','linear','StopBandDecay',20);
Hd2 = design(D,'equiripple','StopBandShape','linear','StopBandDecay',40);
hfvt = fvtool([Hd1 Hd2]);
legend(hfvt,'20 dB/rad/sample','40 dB/rad/sample');
```

fdesign.hilbert

Purpose   Hilbert filter specification object

Syntax
```
d = fdesign.hilbert
d = fdesign.hilbert(specvalue1,specvalue2)
d = fdesign.hilbert(spec)
d = fdesign.hilbert(spec,specvalue1,specvalue2)
d = fdesign.hilbert(...,Fs)
d = fdesign.hilbert(...,MAGUNITS)
```

Description   d = fdesign.hilbert constructs a default Hilbert filter designer d with N, the filter order, set to 30 and TW, the transition width set to 0.1π radians/sample.

d = fdesign.hilbert(specvalue1,specvalue2) constructs a Hilbert filter designer d assuming the default specification string 'N,TW'. You input specvalue1 and specvalue2 for N and TW.

d = fdesign.hilbert(spec) initializes the filter designer Specification property to spec. You provide one of the following strings as input to replace spec. The specification strings are not case sensitive.

Note Specifications strings marked with an asterisk require the DSP System Toolbox software.

- 'N,TW' default spec string.

- 'TW,Ap' *

The string entries are defined as follows:

- Ap — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass.

- N — filter order.

- TW — width of the transition region between the pass and stop bands.

By default, `fdesign.hilbert` assumes that all frequency specifications are provided in normalized frequency units. Also, decibels is the default for all magnitude specifications.

Different specification strings may have different design methods available. Use `designmethods(d)` to get a list of the design methods available for a given specification string.

`d = fdesign.hilbert(`*spec*`,specvalue1,specvalue2)` initializes the filter designer specifications in spec with specvalue1, specvalue2, and so on. To get a description of the specifications specvalue1 and specvalue2, enter

`get(d,'`**description**`')`

at the Command prompt.

`d = fdesign.hilbert(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.hilbert(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples   Design a Hilbert transformer of order 30 with a transition width of 0.2π radians/sample. Plot the zero phase response from [-π,π) radians/sample and the impulse response.

```
d = fdesign.hilbert('N,TW',30,0.2);
```

```
% Show available design methods
designmethods(d)
% Use least square minimization to obtain linear-phase FIR filter
Hd = design(d,'equiripple');
% Display zero phase response from [-pi,pi)
fvtool(Hd,'magnitudedisplay','zero-phase',...
'frequencyrange','[-pi, pi)')
```

The impulse response of this even order filter is antisymmetric (type III).

```
fvtool(Hd,'analysis','impulse')
```

Impulse Response
Apply the filter to a discrete-time sinusoid with a frequency of π/2 radians/sample.

```
n = 0:99;
x = cos(pi/2*n);
y = filter(Hd,x);
% Correct for the filter delay
Delay = floor(length(Hd.Numerator)/2);
y = y(Delay+1:end);
```

Plot a the filter input and output and validate the approximate π/2 phase shift obtained with the Hilbert transformer.

```
stem(x(1:end-Delay),'markerfacecolor',[0 0 1]);
hold on;
stem(y,'Color',[1 0 0],'markerfacecolor',[1 0 0]);
axis([10 20 -1.5 1.5]); grid on;
xlabel('Samples'); ylabel('Amplitude');
legend('Input','Output','Location','NorthWest')
```
Because the frequency of the discrete-time sinusoid is π/2 radians/sample, a one sample shift corresponds to a phase shift of π/2.

Form the analytic signal and demonstrate that the frequency content of the analytic signal is zero for negative frequencies and approximately twice the spectrum of the input for positive frequencies.

```
x1 = x(1:end-Delay);
% Form the analytic signal
xa = x1+1j*y;
freq = -pi:(2*pi)/length(x1):pi-(2*pi)/length(x);
plot(freq,abs(fftshift(fft(x1))));
hold on;
plot(freq,abs(fftshift(fft(xa))),'r'); grid on;
xlabel('Radians/Sample'); ylabel('Magnitude');
legend('Input DFT','Analytic Signal DFT','Location','NorthWest');
```
Design a minimum-order Hilbert transformer that has a sampling frequency of 1 kHz. Specify the passband ripple to be 1 dB.

```
d = fdesign.hilbert('TW,Ap',1,0.1,1e3);
hd = design(d,'equiripple');
fvtool(hd,'magnitudedisplay','zero-phase', ...
'frequencyrange','[-Fs/2, Fs/2)');
```
See Also   design | fdesign | setspecs

fdesign.interpolator

Purpose	Interpolator filter specification
Syntax	D = fdesign.interpolator(L)
	D = fdesign.interpolator(L,RESPONSE)
	D = fdesign.interpolator(L,PULSESHAPINGRESPONSE,SPS)
	D = fdesign.interpolator(L,CICRESPONSE,D)
	D = fdesign.interpolator(L,RESPONSE,spec)
	D = fdesign.interpolator(...,spec,specvalue1,specvalue2,...)
	D = fdesign.interpolator(...,Fs)
	d = fdesign.interpolator(...,MAGUNITS)

Description   D = fdesign.interpolator(L) constructs an interpolator filter
specification object D with the InterpolationFactor property equal to
the positive integer L and the Response property set to 'Nyquist'. The
default values for the transition width and stopband attenuation in the
Nyquist design are 0.1π radians/sample and 80 dB. If L is unspecified,
L defaults to 2.

D = fdesign.interpolator(L,RESPONSE) constructs a interpolator
specification object with the interpolation factor L and the 'Response'
property set to one of the supported types.

D = fdesign.interpolator(L,PULSESHAPINGRESPONSE,SPS) constructs
a pulse-shaping interpolator specification object with the interpolation
factor L and 'Response' property equal to one of the supported
pulse-shaping filters: 'Gaussian', 'Raised Cosine', or 'Square Root
Raised Cosine'. SPS is the samples per symbol. The samples per
symbol, SPS, must precede any specification string.

D = fdesign.interpolator(L,CICRESPONSE,D) constructs a CIC or
CIC compensator interpolator specification object with the interpolation
factor, L, and 'Response' property equal to 'CIC' or 'CICCOMP'. D
is the differential delay. The differential delay, D, must precede any
specification string.

D = fdesign.interpolator(L,RESPONSE,spec) constructs object D and
sets its Specification property to spec. Entries in the spec string
represent various filter response features, such as the filter order, that

govern the filter design. Valid entries for spec depend on the design type of the specifications object.

When you add the spec input argument, you must also add the RESPONSE input argument.

Because you are designing multirate filters, the specification strings available are not the same as the specifications for designing single-rate filters with design methods such as fdesign.lowpass. The strings are not case sensitive.

The interpolation factor L is not in the specification strings. The different filter responses support different specifications. The following table lists the supported response types and specification strings.

Design String	Valid Specification Strings
'Arbitrary Magnitude'	See fdesign.arbmag for a description of the specification string entries. • 'N,F,A' (default string) • 'N,B,F,A'
'Arbitrary Magnitude and Phase'	See fdesign.arbmagnphase for a description of the specification string entries. • 'N,F,H' (default string) • 'N,B,F,H'
'Bandpass'	See fdesign.bandpass for a description of the specification string entries. • 'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2' (default string) • 'N,Fc1,Fc2' • 'N,Fst1,Fp1,Fp2,Fst2'
'Bandstop'	See fdesign.bandstop for a description of the specification string entries. • 'N,Fc1,Fc2' • 'N,Fp1,Fst1,Fst2,Fp2' • 'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2' (default string)

Design String	Valid Specification Strings
`'CIC'`	`'Fp,Ast'` — Only valid specification. `Fp` is the passband frequency and `Ast` is the stopband attenuation in decibels.
	To specify a CIC interpolator, include the differential delay after `'CIC'` and before the filter specification string: `'Fp,Ast'`. For example: `d = fdesign.interpolator(2,'cic',4,'Fp,Ast',0.4,40);`
`'CIC Compensator'`	See `fdesign.ciccomp` for a description of the specification string entries.
	• `'Fp,Fst,Ap,Ast'` (default string)
	• `'N,Fc,Ap,Ast'`
	• `'N,Fp,Ap,Ast'`
	• `'N,Fp,Fst'`
	• `'N,Fst,Ap,Ast'`
	To specify a CIC compensator interpolator, include the differential delay after `'CICCOMP'` and before the filter specification string.. For example: `d = fdesign.interpolator(2,'ciccomp',4);`
`'Differentiator'`	`'N'` — filter order
`'Gaussian'`	`'Nsym,BT` — `Nsym` is the filter order in symbols and `BT` is the bandwidth-symbol time product.
	The specification string must be preceded by an integer-valued `SamplesPerSymbol`.

Design String	Valid Specification Strings
'Halfband	See fdesign.halfband for a description of the specification string entries. • 'TW,Ast' (default string) • 'N,TW' • `N' • 'N,Ast' If you use the quasi-linear IIR design method, iirlinphase, with a halfband specification, the interpolation factor must be 2.
'Highpass'	See fdesign.highpass for a description of the specification string entries. • 'Fst,Fp,Ast,Ap' (default string) • 'N,F3db' • 'N,Fc' • 'N,Fc,Ast,Ap' • 'N,Fp,Ast,Ap' • 'N,Fst,Ast,Ap' • 'N,Fst,Fp' • 'N,Fst,Ast,Ap' • 'N,Fst,Fp,Ast'
'Hilbert'	See fdesign.hilbert for a description of the specification string entries. • 'N,TW' (default string) • 'TW,Ap'

Design String	Valid Specification Strings
`'Inverse-sinc Lowpass'`	See `fdesign.isinclp` for a description of the specification string entries. • `'Fp,Fst,Ap,Ast'` (default string)) • `'N,Fc,Ap,Ast'` • `'N,Fp,Fst'` • `'N,Fst,Ap,Ast'`
`'Inverse-sinc Highpass'`	See `fdesign.isinchp` for a description of the specification string entries. • `'Fst,Fp,Ast,Ap'` (default string)) • `'N,Fc,Ast,Ap'` • `'N,Fst,Fp'` • `'N,Fst,Ast,Ap'`
`'Lowpass'`	See `fdesign.lowpass` for a description of the specification string entries. • `'Fp,Fst,Ap,Ast'` (default string) • `'N,F3dB'` • `'N,Fc'` • `'N,Fc,Ap,Ast'` • `'N,Fp,Ap,Ast'` • `'N,Fp,Fst'` • `'N,Fp,Fst,Ap'` • `'N,Fp,Fst,Ast'` • `'N,Fst,Ap,Ast'`

Design String	Valid Specification Strings
'Nyquist'	See fdesign.nyquist for a description of the specification string entries. For all Nyquist specifications, you must specify the *L*th band. This typically corresponds to the interpolation factor so that the nonzero samples of the upsampler output are preserved. • 'TW,Ast' (default string) • 'N' • 'N,Ast' • 'N,Ast'
'Raised Cosine'	See fdesign.pulseshaping for a description of the specification string entries. • 'Ast,Beta' (default string) • 'Nsym,Beta' • 'N,Beta' The specification string must be preceded by an integer-valued SamplesPerSymbol.
'Square Root Raised Cosine'	See fdesign.pulseshaping for a description of the specification string entries. • 'Ast,Beta' (default string) • 'Nsym,Beta' • 'N,Beta' The specification string must be preceded by an integer-valued SamplesPerSymbol.

D = fdesign.interpolator(...,spec,specvalue1,specvalue2,...) constructs an object D and sets its specifications at construction time.

D = fdesign.interpolator(...,Fs) adds the argument Fs, specified in Hz, to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

d = fdesign.interpolator(...,MAGUNITS) specifies the units for any magnitude specification you provide in the input arguments. MAGUNITS can be one of

• 'linear' — specify the magnitude in linear units.

• 'dB' — specify the magnitude in dB (decibels).

• 'squared' — specify the magnitude in power units.

When you omit the MAGUNITS argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples   These examples show how to construct interpolating filter specification objects. First, create a default specifications object without using input arguments except for the interpolation factor l.

```
l = 2;
d = fdesign.interpolator(2);
```

Now create an object by passing a specification string 'fst1,fp1,fp2,fst2,ast1,ap,ast2' and a design — the resulting object uses default values for all of the filter specifications. You must provide the design input argument when you include a specification.

```
d=fdesign.interpolator(8,'bandpass','fst1,fp1,fp2,fst2,ast1,ap,ast2');
```

Create another interpolating filter object, passing the specification values to the object rather than accepting the default values for, in this case, fp,fst,ap,ast.

```
d=fdesign.interpolator(3,'lowpass',.45,0.55,.1,60);
```

Now pass the filter specifications that correspond to the specifications — n,fc,ap,ast.

```
d=fdesign.interpolator(3,'ciccomp',1,2,'n,fc,ap,ast',...
20,0.45,.05,50);
```

With the specifications object in your workspace, design an interpolator using the equiripple design method.

```
hm = design(d,'equiripple');
```

Pass a new specification type for the filter, specifying the filter order.

```
d = fdesign.interpolator(5,'CIC',1,'fp,ast',0.55,55);
```

With the specifications object in your workspace, design an interpolator using the multisection design method.

```
hm = design(d,'multisection');
```

In this example, you specify a sampling frequency as the right most input argument. Here, it is set to 1000 Hz.

```
d=fdesign.interpolator(8,'bandpass','fst1,fp1,fp2,fst2,ast1,ap,ast2',
    0.25,0.35,.55,.65,50,.05,1e3);
```

In this, the last example, use the linear option for the filter specification object and specify the stopband ripple attenuation in linear form.

```
d = fdesign.interpolator(4,'lowpass','n,fst,ap,ast',15,0.55,.05,...
    1e3,'linear'); % 1e3 = 60dB.
```

Now design a CIC interpolator for a signal sampled at 19200 Hz. Specify the differential delay of 2 and set the attenuation of information beyond 50 Hz to be at least 80 dB.

The filter object sampling frequency is (l x fs) where fs is the sampling frequency of the input signal.

```
dd  = 2;    % Differential delay.
fp  = 50;   % Passband of interest.
ast = 80;   % Minimum attenuation of alias components in passband.
fs  = 600;  % Sampling frequency for input signal.
l   = 32;   % Interpolation factor.
d   = fdesign.interpolator(l,'cic',dd,'fp,ast',fp,ast,l*fs);
hm = design(d);  %Use the default design method.
```

This next example results in a minimum-order CIC compensator that interpolates by 4 and compensates for the droop in the passband for the CIC filter hm from the previous example.

```
nsecs = hm.numberofsections;
d = fdesign.interpolator(4,'ciccomp',dd,nsecs,...
50,100,0.1,80,fs);
hmc = design(d,'equiripple');
hmc.arithmetic = 'fixed';
```

hmc is designed to compensate for hm. To see the effect of the compensating CIC filter, use FVTool to analyze both filters individually and include the compound filter response by cascading hm and hmc.

```
hfvt = fvtool(hmc,hm,cascade(hmc,hm),'fs',[fs,l*fs,l*fs],...
'showreference','off');
legend(hfvt,'CIC Compensator','CIC Interpolator',...
'Overall Response');
```

FVTool returns with this plot.
For the third example, use `fdesign.interpolator` to design a minimum-order Nyquist interpolator that uses a Kaiser window. For comparison, design a multistage interpolator as well and compare the responses.

```
l   = 15;   % Set the interpolation factor and the Nyquist band.
tw  = 0.05; % Specify the normalized transition width.
ast = 40;   % Set the minimum stopband attenuation in dB.
d   = fdesign.interpolator(l,'nyquist',l,tw,ast);
hm  = design(d,'kaiserwin');
hm2 = design(d,'multistage'); % Design the multistage interpolator.
hfvt = fvtool(hm,hm2);
legend(hfvt,'Kaiser Window','Multistage')
```

FVTool shows both responses.
Design a lowpass interpolator for an interpolation factor of 8. Compare the single-stage equiripple design to a multistage design with the same interpolation factor.

```
l = 8; % Interpolation factor.
d = fdesign.interpolator(l,'lowpass');
hm(1) = design(d,'equiripple');
% Use halfband filters whenever possible.
hm(2) = design(d,'multistage','usehalfbands',true);
hfvt = fvtool(hm);
legend(hfvt,'Single-Stage Equiripple','Multistage')
```
See Also   fdesign | fdesign.arbmag | fdesign.arbmagnphase |
fdesign.interpolator | fdesign.rsrc | setspecs

fdesign.isinchp

Purpose   Inverse sinc highpass filter specification

Syntax
```
D = fdesign.isinchp
D = fdesign.isinchp(SPEC)
D = fdesign.isinchp(SPEC,specvalue1,specvalue2,...)
D = fdesign.isinchp(specvalue1,specvalue2,specvalue3,
   specvalue4)
D = fdesign.isinchp(...,Fs)
D = fdesign.isinchp(...,MAGUNITS)
```

Description   `D = fdesign.isinchp` constructs an inverse sinc highpass filter specification object `D`, applying default values for the default specification string `'Fst,Fp,Ast,Ap'`.

`D = fdesign.isinchp(SPEC)` constructs object `D` and sets the `Specification` property to SPEC. Entries in the SPEC string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for SPEC are shown below. The strings are not case sensitive.

- `'Fst,Fp,Ast,Ap'` (default spec)

- `'N,Fc,Ast,Ap'`

- `'N,Fst,Fp'`

- `'N,Fp,Ast,Ap'`

- `'N,Fst,Ast,Ap'`

The string entries are defined as follows:

- `Ast` — attenuation in the stopband in decibels (the default units). Also called Astop.

- `Ap` — amount of ripple allowed in the passband in decibels (the default units). Also called Apass.

- `Fp` — frequency at the start of the passband. Specified in normalized frequency units. Also called Fpass.

- Fst — frequency at the end of the stopband. Specified in normalized frequency units. Also called Fstop.

- N — filter order.

The filter design methods that apply to an inverse sinc highpass filter specification object change depending on the value of the Specification property. Use designmethods to determine which design method applies to a specific Specification.

Use designopts to see the available design options for a specific design method. Enter help(D,METHOD) at the MATLAB command line to obtain detailed information on the design options for a given design method, METHOD.

D = fdesign.isinchp(SPEC,specvalue1,specvalue2,...) constructs an object D and sets the specifications at construction time.

D = fdesign.isinchp(specvalue1,specvalue2,specvalue3,specvalue4) constructs an object D assuming the default Specification property string 'Fst,Fp,Ast,Ap', using the values you provide in specvalue1,specvalue2, specvalue3, and specvalue4.

D = fdesign.isinchp(...,Fs) adds the argument Fs, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

D = fdesign.isinchp(...,MAGUNITS) specifies the units for any magnitude specification you provide in the input arguments. MAGUNITS can be one of

- 'linear' — specify the magnitude in linear units

- 'dB' — specify the magnitude in dB (decibels)

- 'squared' — specify the magnitude in power units

When you omit the MAGUNITS argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

fdesign.isinchp

The design method of fdesign.isinchp implements a filter with a passband magnitude response equal to:

$$H(\omega) = sinc(C(1-\omega))^{-P}$$

You can control the values of the sinc frequency factor, *C*, and the sinc power, *P*, using the 'SincFrequencyFactor' and 'SincPower' options in the design method. 'SincFrequencyFactor' and 'SincPower' default to 0.5 and 1 respectively.

Examples   Design a minimum order inverse sinc highpass filter and shape the stopband to have a slope of 20 dB/radian/sample.

```
d = fdesign.isinchp('Fst,Fp,Ast,Ap',.4,.5,40,0.01);
Hd = design(d);
% Shape the stopband to have a linear slope of 20 dB/rad/sample
Hd1 = design(d,'StopbandShape','linear','StopbandDecay',20);
fvtool(Hd,Hd1);
```
Design a 50th order inverse sinc highpass filter. Set the sinc frequency factor to 0.25, and the sinc power to 16 to achieve a magnitude response in the passband of the form $H(\omega) = \text{sinc}(0.25*(1-\omega))^{(-16)}$.

```
d = fdesign.isinchp('N,Fst,Fp',50,.4,.5);
Hd = design(d,'SincFrequencyFactor',0.25,'SincPower',16);
fvtool(Hd);
```
See Also   design | designmethods | fdesign | fdesign.ciccomp |
fdesign.highpass | fdesign.isinclp | fdesign.nyquist

Purpose   Inverse sinc lowpass filter specification

Syntax
```
d = fdesign.isinclp
d = fdesign.isinclp(spec)
d = fdesign.isinclp(spec,specvalue1,specvalue2,...)
d = fdesign.isinclp(specvalue1,specvalue2,specvalue3,
    specvalue4)
d = fdesign.isinclp(...,Fs)
d = fdesign.isinclp(...,MAGUNITS)
```

Description   d = fdesign.isinclp constructs an inverse sinc lowpass filter
specification object d, applying default values for the default
specification string, 'Fp,Fst,Ap,Ast'.

d = fdesign.isinclp(*spec*) constructs object d and sets its
'Specification' to *spec*. Entries in the spec string represent various
filter response features, such as the filter order, that govern the filter
design. Valid entries for *spec* are shown below. The strings are not
case sensitive.

- 'Fp,Fst,Ap,Ast' (default spec)

- 'N,Fc,Ap,Ast'

- 'N,Fp,Ap,Ast'

- 'N,Fp,Fst'

- 'N,Fst,Ap,Ast'

The string entries are defined as follows:

- Ast — attenuation in the stopband in decibels (the default units).
  Also called Astop.

- Ap — amount of ripple allowed in the passband in decibels (the
  default units). Also called Apass.

- Fp — frequency at the start of the passband. Specified in normalized
  frequency units. Also called Fpass.

- `Fst` — frequency at the end of the stopband. Specified in normalized frequency units. Also called Fstop.

- `N` — filter order.

The filter design methods that apply to an inverse sinc lowpass filter specification object change depending on the `Specification` string. Use `designmethods` to determine which design method applies to an object and its specification string.

`d = fdesign.isinclp(spec,specvalue1,specvalue2,...)` constructs an object `d` and sets its specifications at construction time.

`d = fdesign.isinclp(specvalue1,specvalue2,specvalue3,specvalue4)` constructs an object `d` assuming the default `Specification` property string `'Fp,Fst,Ap,Ast'`, using the values you provide in `specvalue1,specvalue2, specvalue3,` and `specvalue4`.

`d = fdesign.isinclp(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.isinclp(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units

- `'dB'` — specify the magnitude in dB (decibels)

- `'squared'` — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

The design method of `fdesign.isinclp` implements a filter with a passband magnitude response equal to:

$$H(\omega) = sinc(C\omega)^{-P}$$

You can control the values of the sinc frequency factor, *C*, and the sinc power, *P*, using the `'SincFrequencyFactor'` and `'SincPower'` options in the design method. `'SincFrequencyFactor'` and `'SincPower'` default to 0.5 and 1 respectively.

Examples   Pass the specifications for the default specification — `'Fp,Fst,Ap,Ast'` — as input arguments to the specifications object.

```
d = fdesign.isinclp(.4,.5,.01,40);
hd = design(d,'equiripple');
fvtool(hd);
```

Design a 50th order inverse sinc lowpass filter. Set the sinc frequency factor to 0.25 and the sinc power to 16 to achieve a magnitude response in the passband of the form `H(w) = sinc(0.25*w)^(-16)` .

```
d = fdesign.isinclp('N,Fp,Fst',50,.4,.5);
Hd = design(d,'SincFrequencyFactor',0.25,'SincPower',16);
fvtool(Hd, 'MagnitudeDisplay', 'Magnitude');
```

fdesign.isinclp

fdesign.nyquist

Purpose   Lowpass filter specification

Syntax   D = fdesign.lowpass
                 D = fdesign.lowpass(SPEC)
                 D = fdesign.lowpass(SPEC,specvalue1,specvalue2,...)
                 D = fdesign.lowpass(specvalue1,specvalue2,specvalue3,
                     specvalue4)
                 D = fdesign.lowpass(...,Fs)
                 D = fdesign.lowpass(...,MAGUNITS)

Description   D = fdesign.lowpass constructs a lowpass filter specification
                 object D, applying default values for the default specification string
                 'Fp,Fst,Ap,Ast'.

                 D = fdesign.lowpass(SPEC) constructs object D and sets the
                 Specification property to the string in SPEC. Entries in the SPEC
                 string represent various filter response features, such as the filter
                 order, that govern the filter design. Valid entries for SPEC are shown
                 below. The strings are not case sensitive.

                 Note Specifications strings marked with an asterisk require the DSP
                 System Toolbox software.

                 • 'Fp,Fst,Ap,Ast' (default spec)

                 • 'N,F3db'

                 • 'N,F3db,Ap' *

                 • 'N,F3db,Ap,Ast' *

                 • 'N,F3db,Ast' *

                 • 'N,F3db,Fst' *

                 • 'N,Fc'

                 • "N,Fc,Ap,Ast'

- `'N,Fp,Ap'`
- `'N,Fp,Ap,Ast'`
- `'N,Fp,Fst,Ap'` *
- `'N,Fp,F3db'` *
- `'N,Fp,Fst'`
- `'N,Fp,Fst,Ast'` *
- `'N,Fst,Ap,Ast'` *
- `'N,Fst,Ast'`
- `'Nb,Na,Fp,Fst'` *

The string entries are defined as follows:

- `Ap` — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass.

- `Ast` — attenuation in the stop band in decibels (the default units). Also called Astop.

- `F3db` — cutoff frequency for the point 3 dB point below the passband value. Specified in normalized frequency units.

- `Fc` — cutoff frequency for the point 6 dB point below the passband value. Specified in normalized frequency units.

- `Fp` — frequency at the start of the pass band. Specified in normalized frequency units. Also called Fpass.

- `Fst` — frequency at the end of the stop band. Specified in normalized frequency units. Also called Fstop.

- `N` — filter order.

- `Na` and `Nb` are the order of the denominator and numerator.

Graphically, the filter specifications look similar to those shown in the following figure.

Regions between specification values like `Fp` and `Fst` are transition regions where the filter response is not explicitly defined.

`D = fdesign.lowpass(SPEC,specvalue1,specvalue2,...)` constructs an object `D` and sets the specification values at construction time using `specvalue1`, `specvalue2`, and so on for all of the specification variables in `SPEC`.

`D = fdesign.lowpass(specvalue1,specvalue2,specvalue3,specvalue4)` constructs an object `D` with values for the default `Specification` property string `'Fp,Fst,Ap,Ast'` using the specifications you provide as input arguments `specvalue1,specvalue2,specvalue3,specvalue4`.

`D = fdesign.lowpass(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`D = fdesign.lowpass(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units

- `'dB'` — specify the magnitude in dB (decibels)

- `'squared'` — specify the magnitude in power units

fdesign.lowpass

When you omit the `MAGNUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples   Lowpass filter a discrete-time signal consisting of two sine waves.

Create a lowpass filter specification object. Specify the passband frequency to be 0.15π radians/sample and the stopband frequency to be 0.25π radians/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB.

```
d=fdesign.lowpass('Fp,Fst,Ap,Ast',0.15,0.25,1,60);
```

Query the valid design methods for your filter specification object, `d`.

```
designmethods(d)
```

Create an FIR equiripple filter and view the filter magnitude response with `fvtool`.

```
Hd = design(d,'equiripple');
fvtool(Hd);
```

Create a signal consisting of the sum of two discrete-time sinusoids with frequencies of $\pi/8$ and $\pi/4$ radians/sample and amplitudes of 1 and 0.25 respectively. Filter the discrete-time signal with the FIR equiripple filter object, `Hd`.

```
n = 0:159;
x = 0.25*cos((pi/8)*n)+sin((pi/4)*n);
y = filter(Hd,x);
Domega = (2*pi)/160;
freq = 0:(2*pi)/160:pi;
xdft = fft(x);
ydft = fft(y);
plot(freq,abs(xdft(1:length(x)/2+1)));
hold on;
plot(freq,abs(ydft(1:length(y)/2+1)),'r','linewidth',2);
```

```
legend('Original Signal','Highpass Signal', ...
'Location','NorthEast');
ylabel('Magnitude'); xlabel('Radians/Sample');
```

Create a filter of order 10 with a 6-dB frequency of 9.6 kHz and a sampling frequency of 48 kHz.

```
d=fdesign.lowpass('N,Fc',10,9600,48000);
designmethods(d)
% only valid design method is FIR window method
Hd = design(d);
% Display filter magnitude response
fvtool(Hd);
```

Zoom in on the magnitude response to verify that the -6 dB point is at 9.6 kHz.

If you have the DSP System Toolbox software, you can specify the shape of the stopband and the rate at which the stopband decays. The following example requires the DSP System Toolbox.

Create an FIR equiripple filter with a passband frequency of 0.2π radians/sample, a stopband frequency of 0.25π radians/sample, a passband ripple of 1 dB, and a stopband attenuation of 60 dB. Design the filter with a 20 dB/rad/sample linear stopband.

```
D = fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.25,1,60);
Hd = design(D,'equiripple','StopBandShape','linear','StopBandDecay',20
fvtool(Hd);
```

See Also   design | designmethods | fdesign

fdesign.notch

Purpose   Notch filter specification

Syntax
```
d = fdesign.notch(specstring, value1, value2, ...)
d = fdesign.notch(n,f0,q)
d = fdesign.notch(...,Fs)
d = fdesign.notch(...,MAGUNITS)
```

Description   `d = fdesign.notch(specstring, value1, value2, ...)` constructs a notch filter specification object `d`, with a specification string set to `specstring` and values provided for all members of the `specstring`. The possible specification strings, which are not case sensitive, are listed as follows:

- 'N,F0,Q' (default)

- 'N,F0,Q,Ap'

- 'N,F0,Q,Ast'

- 'N,F0,Q,Ap,Ast'

- 'N,F0,BW'

- 'N,F0,BW,Ap'

- 'N,F0,BW,Ast'

- 'N,F0,BW,Ap,Ast'

where the variables are defined as follows:

- N - Filter Order (must be even)

- F0 - Center Frequency

- Q - Quality Factor

- BW - 3-dB Bandwidth

- Ap - Passband Ripple (decibels)

- Ast - Stopband Attenuation (decibels)

Different specification strings, resulting in different specification objects, may have different design methods available. Use the function

designmethods to get a list of design methods available for a given specification. For example:

```
d  = fdesign.notch('N,F0,Q,Ap',6,0.5,10,1);
% designmethods(d) returns
% Design Methods for class fdesign.notch (N,F0,Q,Ap):
% cheby1
```

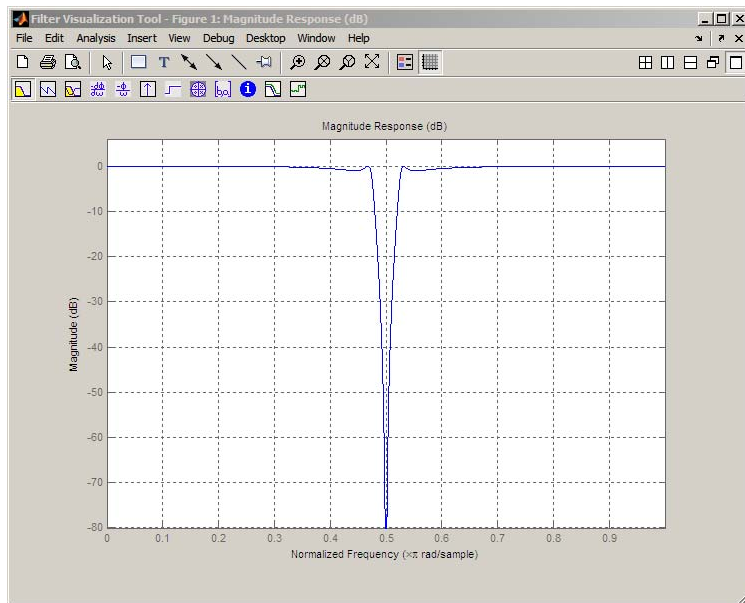
d = fdesign.notch(n,f0,q) constructs a notch filter specification object using the default specstring ('N,F0,Q') and setting the corresponding values to n, f0, and q.

By default, all frequency specifications are assumed to be in normalized frequency units. All magnitude specifications are assumed to be in decibels.

d = fdesign.notch(...,Fs) constructs a notch filter specification object while providing the sampling frequency of the signal to be filtered. Fs must be specified as a scalar trailing the other values provided. If you specify an Fs, it is assumed to be in Hz, as are all the other frequency values provided.

d = fdesign.notch(...,MAGUNITS) constructs a notch filter specification while providing the units for any magnitude specification given. MAGUNITS can be one of the following: 'linear', 'dB', or 'squared'. If this argument is omitted, 'dB' is assumed. The magnitude specifications are always converted and stored in decibels regardless of how they were specified. If Fs is provided, MAGUNITS must follow Fs in the input argument list.

Examples   Design a notching filter with a passband ripple of 1 dB.

```
d  = fdesign.notch('N,F0,Q,Ap',6,0.5,10,1);
Hd = design(d);
fvtool(Hd)
```


See Also   `fdesign | fdesign.peak`

Purpose   Nyquist filter specification

Syntax   d = fdesign.nyquist
                     d = fdesign.nyquist(l,*spec*)
                     d = fdesign.nyquist(l,*spec*,specvalue1,specvalue2,...)
                     d = fdesign.nyquist(l,specvalue1,specvalue2)
                     d = fdesign.nyquist(...,fs)
                     d = fdesign.nyquist(...,magunits)

Description   d = fdesign.nyquist constructs a Nyquist or L-band filter specification
                     object d, applying default values for the properties tw and ast. By
                     default, the filter object designs a minimum-order half-band (L=2)
                     Nyquist filter.

                     Using fdesign.nyquist with a design method generates a dfilt object.

                     d = fdesign.nyquist(l,*spec*) constructs object d and sets its
                     Specification property to *spec*. Use l to specify the desired value for
                     L. L = 2 designs a half-band FIR filter, L = 3 a third-band FIR filter,
                     and so on. When you use a Nyquist filter as an interpolator, l or L is the
                     interpolation factor. The first input argument must be l when you are
                     not using the default syntax d = fdesign.nyquist.

                     Entries in the spec string represent various filter response features,
                     such as the filter order, that govern the filter design. Valid entries for
                     spec are shown below. The strings are not case sensitive.

                     - tw,ast (default spec)

                     - n,tw

                     - n

                     - n,ast

                     The string entries are defined as follows:

                     - ast — attenuation in the stop band in decibels (the default units).

                     - n — filter order.

- tw — width of the transition region between the pass and stop bands. Specified in normalized frequency units.

The filter design methods that apply to a Nyquist filter specification object change depending on the Specification string. Use designmethods to determine which design method applies to an object and its specification string. Different filter design methods also have options that you can specify. Use designopts with the design method string to see the available options. For example:

```
f=fdesign.nyquist(4,'N,TW');
designmethods(f)
```

d = fdesign.nyquist(l,*spec*,specvalue1,specvalue2,...) constructs an object d and sets its specification to *spec*, and the specification values to specvalue1, specvalue2, and so on at construction time.

d = fdesign.nyquist(l,specvalue1,specvalue2) constructs an object d with the values you provide in l, specvalue1,specvalue2 as the values for l, tw and ast.

d = fdesign.nyquist(...,fs) adds the argument fs, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

d = fdesign.nyquist(...,magunits) specifies the units for any magnitude specification you provide in the input arguments. magunits can be one of

- linear — specify the magnitude in linear units
- dB — specify the magnitude in dB (decibels)
- squared — specify the magnitude in power units

When you omit the magunits argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Limitations of the Nyquist fdesign Object

Using Nyquist filter specification objects with the `equiripple` design method imposes a few limitations on the resulting filter, caused by the `equiripple` design algorithm.

- When you request a minimum-order design from `equiripple` with your Nyquist object, the design algorithm might not converge and can fail with a filter convergence error.

- When you specify the order of your desired filter, and use the `equiripple` design method, the design might not converge.

- Generally, the following specifications, alone or in combination with one another, can cause filter convergence problems with Nyquist objects and the `equiripple` design method.

  - very high order

  - small transition width

  - very large stopband attenuation

Note that halfband filters (filters where band = 2) do not exhibit convergence problems.

When convergence issues arise, either in the cases mentioned or in others, you might be able to design your filter with the `kaiserwin` method.

In addition, if you use Nyquist objects to design decimators or interpolators (where the interpolation or decimation factor is not a prime number), using multistage filter designs might be your best approach.

Examples   These examples show how to construct a Nyquist filter specification object. First, create a default specifications object without using input arguments.

```
d=fdesign.nyquist
```

Now create an object by passing a specification type string 'n,ast' — the resulting object uses default values for n and ast.

```
d=fdesign.nyquist(2,'n,ast')
```

Create another Nyquist filter object, passing the specification values to the object rather than accepting the default values for n and ast.

```
d=fdesign.nyquist(3,'n,ast',42,80)
```

Finally, pass the filter specifications that correspond to the default Specification — tw,ast. When you pass only the values, fdesign.nyquist assumes the default Specification string.

```
d = fdesign.nyquist(4,.01,80)
```

Now design a Nyquist filter using the kaiserwin design method.

```
hd = design(d,'kaiserwin')
```

Create two equiripple Nyquist 4th–band filters with and without a nonnegative zero phase response:

```
f=fdesign.nyquist(4,'N,TW',12,0.2);
% Equiripple Nyquist 4th-band filter with
% nonnegative zero phase response
Hd1=design(f,'equiripple','zerophase',true);
% Equiripple Nyquist 4th-band filter with 'ZeroPhase' set to false
% 'zerophase',false is the default
Hd2=design(f,'equiripple','zerophase',false);
%Obtain real-valued amplitudes (not magnitudes)
[Hr_zerophase,W]=zerophase(Hd1);
[Hr,W]=zerophase(Hd2);
% Plot and compare response
plot(W,Hr_zerophase,'k','linewidth',2);
xlabel('Radians/sample'); ylabel('Amplitude');
hold on;
plot(W,Hr,'r');
axis tight; grid on;
```

```
legend('with ''ZeroPhase'', true','with ''ZeroPhase'' false');
```

Note that the amplitude of the zero phase response (black line) is nonnegative for all frequencies.
The 'ZeroPhase' option is valid only for equiripple Nyquist designs with the 'N,TW' specification. You cannot specify 'MinPhase' and 'ZeroPhase' to be simultaneously 'true'.

fdesign.octave

Purpose　　Octave filter specification

Syntax　　
```
d = fdesign.octave(l)
d = fdesign.octave(l, MASK)
d = fdesign.octave(l, MASK, spec)
d = fdesign.octave(..., Fs)
```

Description　　`d = fdesign.octave(l)` constructs an octave filter specification object `d`, with `l` bands per octave. The default value for `l` is 1.

`d = fdesign.octave(l, MASK)` constructs an octave filter specification object `d` with `l` bands per octave and `MASK` specification for the FVTool. The available values for mask are:

- `'class 0'`

- `'class 1'`

- `'class 2'`

`d = fdesign.octave(l, MASK, spec)` constructs an octave filter specification object `d` with `l` bands per octave, `MASK` specification for the FVTool, and the `spec` specification string. The specification strings available are:

- `'N, F0'`
(not case sensitive), where:

- `N` is the filter order

- `F0` is the center frequency.

The center frequency is typically specified in normalized frequency units, unless a sampling frequency in Hz is included in the specification: `d = fdesign.octave(..., Fs)`. In this case, all frequencies must be specified in Hz, with the center frequency falling between 20 Hz and 20 kHz (the audio range).

Examples　　Design an sixth order, octave-band class 0 filter with a center frequency of 1000 Hz and, a sampling frequency of 44.1 kHz.

```
d = fdesign.octave(1,'Class 0','N,F0',6,1000,44100);
Hd = design(d);
fvtool(Hd)
```

The following figure shows the magnitude response plot of the filter. The logarithmic scale for frequency is automatically set by FVTool for the octave filters.
See Also   fdesign

fdesign.parameq

Purpose	Parametric equalizer filter specification
Syntax	d = fdesign.parameq(spec, specvalue1, specvalue2, ...) d = fdesign.parameq(... fs)
Description	d = fdesign.parameq(spec, specvalue1, specvalue2, ...) constructs a parametric equalizer filter design object, where spec is a non-case sensitive specification string. The choices for spec are as follows:

- 'FO, BW, BWp, Gref, GO, GBW, Gp' (minimum order default)

- 'FO, BW, BWst, Gref, GO, GBW, Gst'

- 'FO, BW, BWp, Gref, GO, GBW, Gp, Gst'

- 'N, FO, BW, Gref, GO, GBW'

- 'N, FO, BW, Gref, GO, GBW, Gp'

- 'N, FO, Fc, Qa, GO'

- 'N, FO, Fc, S, GO'

- 'N, FO ,BW, Gref, GO, GBW, Gst'

- 'N, FO, BW, Gref, GO, GBW, Gp, Gst'

- 'N, Flow, Fhigh, Gref, GO, GBW'

- 'N, Flow, Fhigh, Gref, GO, GBW, Gp'

- 'N, Flow, Fhigh, Gref, GO, GBW, Gst'

- 'N, Flow, Fhigh, Gref, GO, GBW, Gp, Gst'

where the parameters are defined as follows:

- BW — Bandwidth

- BWp — Passband Bandwidth

- BWst — Stopband Bandwidth

- Gref — Reference Gain (decibels)

- G0 — Center Frequency Gain (decibels)

- GBW — Gain at which Bandwidth (BW) is measured (decibels)

- Gp — Passband Gain (decibels)

- Gst — Stopband Gain (decibels)

- N — Filter Order

- F0 — Center Frequency

- Fc— Cutoff frequency

- Fhigh - Higher Frequency at Gain GBW

- Flow - Lower Frequency at Gain GBW

- Qa-Quality Factor

- S-Slope Parameter for Shelving Filters

Regardless of the specification string chosen, there are some conditions that apply to the specification parameters. These are as follows:

- Specifications for parametric equalizers must be given in decibels

- To boost the input signal, set `G0 > Gref`; to cut, set `Gref > G0`

- For boost: `G0 > Gp > GBW > Gst > Gref`; For cut: `G0 < Gp < GBW < Gst < Gref`

- Bandwidth must satisfy: `BWst > BW > BWp`

`d = fdesign.parameq(...  fs)` adds the input sampling frequency. Fs must be specified as a scalar trailing the other numerical values provided, and is assumed to be in Hz.

Examples   Design a Chebyshev Type II parametric equalizer filter that cuts by 12 dB:

```
d = fdesign.parameq('N,Flow,Fhigh,Gref,G0,GBW,Gst',...
     4,.3,.5,0,-12,-10,-1);
Hd = design(d,'cheby2');
fvtool(Hd)
```
Design a 4th order audio lowpass (F0 = 0) shelving filter with cutoff frequency of Fc = 0.25, quality factor Qa =10, and boost gain of G0 = 8 dB:

```
d = fdesign.parameq('N,F0,Fc,Qa,G0',4,0,0.25,10,8);
Hd = design(d);
fvtool(Hd)
```
Design 4th-order highpass shelving filters with S=1.5 and S=3:

```
N=4;
FO = 1;
Fc = .4; % Cutoff Frequency
GO = 10;
S = 1.5;
S2=3;
f = fdesign.parameq('N,FO,Fc,S,GO',N,FO,Fc,S,GO);
h1 = design(f);
f.S=3;
h2=design(f);
hfvt=fvtool([h1 h2]);
set(hfvt,'Filters',[h1 h2]);
legend(hfvt,'S=1.5','S=3');
```

How To   • Parametric Equalizer Design

fdesign.peak

Purpose   Peak filter specification

Syntax
```
d = fdesign.peak(specstring, value1, value2, ...)
d = fdesign.peak(n,f0,q)
d = fdesign.peak(...,Fs)
d = fdesign.peak(...,MAGUNITS)
```

Description   `d = fdesign.peak(specstring, value1, value2, ...)` constructs a peaking filter specification object `d`, with a specification string set to `specstring` and values provided for all members of the `specstring`. The possible specification strings, which are not case sensitive, are listed as follows:

- 'N,F0,Q' (default)
- 'N,F0,Q,Ap'
- 'N,F0,Q,Ast'
- 'N,F0,Q,Ap,Ast'
- 'N,F0,BW'
- 'N,F0,BW,Ap'
- 'N,F0,BW,Ast'
- 'N,F0,BW,Ap,Ast'

where the variables are defined as follows:

- N - Filter Order (must be even)
- F0 - Center Frequency
- Q - Quality Factor
- BW - 3-dB Bandwidth
- Ap - Passband Ripple (decibels)
- Ast - Stopband Attenuation (decibels)

Different specification strings, resulting in different specification objects, may have different design methods available. Use the function

7-619

designmethods to get a list of design methods available for a given specification. For example:

```
>> d  = fdesign.peak('N,F0,Q,Ap',6,0.5,10,1);
>> designmethods(d)

Design Methods for class fdesign.peak (N,F0,Q,Ap):

cheby1
```

d = fdesign.peak(n,f0,q) constructs a peaking filter specification object using the default specstring ('N,F0,Q') and setting the corresponding values to n, f0, and q.

By default, all frequency specifications are assumed to be in normalized frequency units. All magnitude specifications are assumed to be in decibels.

d = fdesign.peak(...,Fs) constructs a peak filter specification object while providing the sampling frequency of the signal to be filtered. Fs must be specified as a scalar trailing the other values provided. If you specify an Fs, it is assumed to be in Hz, as all the other frequency values provided.

d = fdesign.peak(...,MAGUNITS) constructs a notch filter specification while providing the units for any magnitude specification given. MAGUNITS can be one of the following: 'linear', 'dB', or 'squared'. If this argument is omitted, 'dB' is assumed. The magnitude specifications are always converted and stored in decibels regardless of how they were specified. If Fs is provided, MAGUNITS must follow Fs in the input argument list.

Examples   Design a Chebyshev Type II peaking filter with a stopband attenuation of 80 dB:

```
d = fdesign.peak('N,F0,BW,Ast',8,.65,.02,80);
Hd = design(d,'cheby2');
```

```
fvtool(Hd)
```

This design produces a filter with the magnitude response shown in the following figure.
See Also   fdesign | fdesign.notch | fdesign.parameq

fdesign.polysrc

Purpose
Construct polynomial sample-rate converter (POLYSRC) filter designer

Syntax
```
d = fdesign.polysrc(l,m)
d = fdesign.polysrc(l,m,'Fractional Delay','Np',Np)
d = fdesign.polysrc(...,Fs)
```

Description
d = fdesign.polysrc(l,m) constructs a polynomial sample-rate converter filter designer D with an interpolation factor L and a decimation factor M. L defaults to 3. M defaults to 2. L and M can be arbitrary positive numbers.

d = fdesign.polysrc(l,m,'Fractional Delay','Np',Np) initializes the filter designer specification with Np and sets the polynomial order to the value Np. If omitted Np defaults to 3.

d = fdesign.polysrc(...,Fs) specifies the sampling frequency (in Hz).

Examples
This example shows how to design sample-rate converter that uses a 3rd order Lagrange interpolation filter to convert from 44.1kHz to 48kHz:

```
[L,M] = rat(48/44.1);
f = fdesign.polysrc(L,M,'Fractional Delay','Np',3);
Hm = design(f,'lagrange');
% Original sampling frequency
Fs = 44.1e3;
% 9408 samples, 0.213 seconds long
n = 0:9407;
% Original signal, sinusoid at 1kHz
x  = sin(2*pi*1e3/Fs*n);
% 10241 samples, still 0.213 seconds
y = filter(Hm,x);
% Plot original sampled at 44.1kHz
stem(n(1:45)/Fs,x(1:45))
hold on
% Plot fractionally interpolated signal (48kHz) in red
stem((n(3:51)-2)/(Fs*L/M),y(3:51),'r','filled')
xlabel('Time (sec)');ylabel('Signal value')
legend('44.1 kHz sample rate','48 kHz sample rate')
```

This code generates the following figure.
For more information about Farrow SRCs, see the "Efficient Sample Rate Conversion between Arbitrary Factors" example, efficientsrcdemo.

See Also   fdesign

fdesign.pulseshaping

Purpose   Pulse-shaping filter specification object

Syntax
```
D = fdesign.pulseshaping
D = fdesign.pulseshaping(sps)
D = fdesign.pulseshaping(sps,shape)
d = fdesign.pulseshaping(sps,shape,spec,value1,value2,...)
d = fdesign.pulseshaping(...,fs)
d = fdesign.pulseshaping(...,magunits)
```

Description   D = fdesign.pulseshaping constructs a specification object D, which can be used to design a minimum-order raised cosine filter object with a default stop band attenuation of 60dB and a rolloff factor of 0.25.

D = fdesign.pulseshaping(sps) constructs a minimum-order raised cosine filter specification object d with a positive integer-valued oversampling factor, SamplesPerSymbol .

D = fdesign.pulseshaping(sps,shape) constructs d where shape specifies the PulseShape property. Valid entries for shape are:

- 'Raised Cosine'

- 'Square Root Raised Cosine'

- 'Gaussian'

d = fdesign.pulseshaping(sps,shape,spec,value1,value2,...) constructs d where spec defines the Specification properties. The string entries for spec specify various properties of the filter, including the order and frequency response. Valid entries for spec depend upon the shape property. For 'Raised Cosine' and 'Square Root Raised Cosine' filters, the valid entries for spec are:

- 'Ast,Beta' (minimum order; default)

- 'Nsym,Beta'

- 'N,Beta'

The string entries are defined as follows:

- `Ast` —stopband attenuation (in dB). The default stopband attenuation for a raised cosine filter is 60 dB. The default stopband attenuation for a square root raised cosine filter is 30 dB. If `Ast` is specified, the minimum-order filter is returned.

- `Beta` —rolloff factor expressed as a real-valued scalar ranging from 0 to 1. Smaller rolloff factors result in steeper transitions between the passband and stopband of the filter.

- `Nsym` —filter order in symbols. The length of the impulse response is given by `Nsym*SamplesPerSymbol+1`. The product `Nsym*SamplesPerSymbol` must be even.

- `N` —filter order (must be even). The length of the impulse response is `N+1`.

If the `shape` property is specified as `'Gaussian'`, the valid entries for `spec` are:

- `'Nsym,BT'` (default)

The string entries are defined as follows:

- `Nsym`—filter order in symbols. `Nsym` defaults to 6. The length of the filter impulse response is `Nsym*SamplesPerSymbol+1`. The product `Nsym*SamplesPerSymbol` must be even.

- `BT` —the 3–dB bandwidth-symbol time product. `BT` is a positive real-valued scalar, which defaults to 0.3. Larger values of `BT` produce a narrower pulse width in time with poorer concentration of energy in the frequency domain.

`d = fdesign.pulseshaping(...,fs)` specifies the sampling frequency of the signal to be filtered. `fs` must be specified as a scalar trailing the other numerical values provided. For this case, `fs` is assumed to be in Hz and is used for analysis and visualization.

`d = fdesign.pulseshaping(...,magunits)` specifies the units for any magnitude specification you provide in the input arguments. Valid entries for `magunits` are:

- `linear` — specify the magnitude in linear units

fdesign.pulseshaping

- dB — specify the magnitude in dB (decibels)

- squared — specify the magnitude in power units

When you omit the magunits argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

After creating the specification object d, you can use the design function to create a filter object such as h in the following example:

```
d = fdesign.pulseshaping(8,'Raised Cosine','Nsym,Beta',6,0.25);
h = design(d);
```

Normally, the Specification property of the specification object also determines which design methods you can use when you create the filter object. Currently, regardless of the Specification property, the design function uses the window design method with all fdesign.pulseshaping specification objects. The window method creates an FIR filter with a windowed impulse response.

Examples

Pulse-shaping can be used to change the waveform of transmitted pulses so the signal bandwidth matches that of the communication channel. This helps to reduce distortion and intersymbol interference (ISI).

This example shows how to design a minimum-order raised cosine filter that provides a stop band attenuation of 60 dB, rolloff factor of 0.50, and 8 samples per symbol.

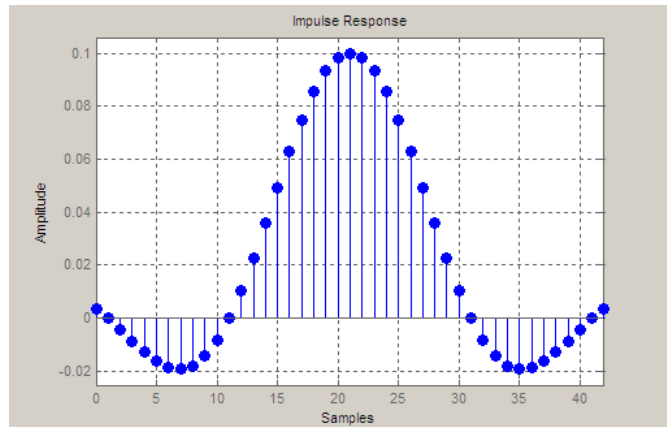
```
h  = fdesign.pulseshaping(8,'Raised Cosine','Ast,Beta',60,0.50);
   Hd = design(h);
   fvtool(Hd)
```

This code generates the following figure.
This example shows how to design a raised cosine filter that spans 8 symbol durations (i.e., of order 8 symbols), has a rolloff factor of 0.50, and oversampling factor of 10.

```
h  = fdesign.pulseshaping(10,'Raised Cosine','Nsym,Beta',8,0.50);
    Hd = design(h);
    fvtool(Hd, 'impulse')
```
fdesign.pulseshaping

This example shows how to design a square root raised cosine filter of order 42, rolloff factor of 0.25, and 10 samples per symbol.

```
h  = fdesign.pulseshaping(10,'Square Root Raised Cosine','N,Beta',42);
  Hd = design(h);
  fvtool(Hd, 'impulse')
```



The following example demonstrates how to create a Gaussian pulse-shaping filter with an oversampling factor (sps) of 10, a bandwidth-time symbol product of 0.2, and 8 symbol periods. The sampling frequency is specified as 10 kHz.
fdesign.rsrc

Purpose Rational-factor sample-rate converter specification

Syntax
```
D = fdesign.rsrc(L,M)
D = fdesign.rsrc(L,M,RESPONSE)
D = fdesign.rsrc(L,M,PULSESHAPINGRESPONSE,SPS)
D = fdesign.rsrc(L,M,CICRESPONSE,D)
D = fdesign.rsrc(L,M,RESPONSE,SPEC)
D = fdesign.rsrc(L,M,SPEC,specvalue1,specvalue2,...)
D = fdesign.rsrc(...,Fs)
D = fdesign.rsrc(...,MAGUNITS)
```

Description D = fdesign.rsrc(L,M) constructs a rational-factor sample-rate filter specification object D with the InterpolationFactor property equal to the positive integer L, the DecimationFactor property equal to the positive integer M and the Response property set to 'Nyquist'. The default values for the transition width and stopband attenuation in the Nyquist design are 0.1π radians/sample and 80 dB. If L is unspecified, L defaults to 3. If M is unspecified, M defaults to 2.

D = fdesign.rsrc(L,M,RESPONSE) constructs an rational-factor sample-rate converter with the interpolation factor L, decimation factor M, and the response you specify in RESPONSE.

D = fdesign.rsrc(L,M,PULSESHAPINGRESPONSE,SPS) constructs a pulse-shaping rational-factor sample-rate convertor filter specification object with the 'RESPONSE' property equal to one of the supported pulseshaping filters: 'Gaussian', 'Raised Cosine', or 'Square Root Raised Cosine'. SPS is the samples per symbol. The samples per symbol, SPS, must precede any specification string.

D = fdesign.rsrc(L,M,CICRESPONSE,D) constructs a CIC or CIC compensator rational-factor sample-rate convertor filter specification object with the 'RESPONSE' property equal to 'CIC' or 'CICCOMP'. D is the differential delay. The differential delay, D, must precede any specification string.

Because you are designing multirate filters, the specification strings available are not the same as the specifications for designing single-rate filters. The interpolation and decimation factors are not included in

the specification strings. Different filter responses support different specifications. The following table lists the supported response types and specification strings. The strings are not case sensitive.

Design String	Valid Specification Strings
`'Arbitrary Magnitude'`	See `fdesign.arbmag` for a description of the specification string entries. • `'N,F,A'` (default string) • `'N,B,F,A'`
`'Arbitrary Magnitude and Phase'`	See `fdesign.arbmagnphase` for a description of the specification string entries. • `'N,F,H'` (default string) • `'N,B,F,H'`
`'Bandpass'`	See `fdesign.bandpass` for a description of the specification string entries. • `'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2'` (default string) • `'N,Fc1,Fc2'` • `'N,Fst1,Fp1,Fp2,Fst2'`
`'Bandstop'`	See `fdesign.bandstop` for a description of the specification string entries.
`'CIC'`	`'Fp,Fst,Ap,Ast'` — Only valid specification. `Fp` is the passband frequency, `Fst` is the stopband frequency, `Ap` is the passband ripple, and `Ast` is the stopband attenuation in decibels. To specify a CIC rational-factor sample-rate convertor, include the differential delay after `'CIC'` and before the filter specification string: `'Fp,Ast'`. For example: `d = fdesign.rsrc(2,2,'cic',4);`

Design String	Valid Specification Strings
`'CIC Compensator'`	See `fdesign.ciccomp` for a description of the specification string entries. • `'Fp,Fst,Ap,Ast'` (default string) • `'N,Fc,Ap,Ast'` • `'N,Fp,Ap,Ast'` • `'N,Fp,Fst'` • `'N,Fst,Ap,Ast'` To specify a CIC compensator rational-factor sample-rate convertor, include the differential delay after `'CICCOMP'` and before the filter specification string. For example: `d = fdesign.rsrc(2,2,'ciccomp',4);`
`'Differentiator'`	`'N'` — filter order
`'Gaussian'`	`'Nsym,BT` — `Nsym` is the filter order in symbols and `BT` is the bandwidth-symbol time product. The specification string must be preceded by an integer-valued `SamplesPerSymbol`.
`'Halfband`	See `fdesign.halfband` for a description of the specification string entries. • `'TW,Ast'` (default string) • `'N,TW'` • `` `N' `` • `'N,Ast'` If you use the quasi-linear IIR design method, `iirlinphase`, with a halfband specification, the interpolation factor must be 2.

Design String	Valid Specification Strings
`'Highpass'`	See `fdesign.highpass` for a description of the specification string entries. • `'Fst,Fp,Ast,Ap'` (default string) • `'N,F3db'` • `'N,Fc'` • `'N,Fc,Ast,Ap'` • `'N,Fp,Ast,Ap'` • `'N,Fst,Ast,Ap'` • `'N,Fst,Fp'` • `'N,Fst,Ast,Ap'` • `'N,Fst,Fp,Ast'`
`'Hilbert'`	See `fdesign.hilbert` for a description of the specification string entries. • `'N,TW'` (default string) • `'TW,Ap'`
`'Inverse-sinc Lowpass'`	See `fdesign.isinclp` for a description of the specification string entries. • `'Fp,Fst,Ap,Ast'` (default string)) • `'N,Fc,Ap,Ast'` • `'N,Fp,Fst'` • `'N,Fst,Ap,Ast'`

Design String	Valid Specification Strings
`'Inverse-sinc Highpass'`	See `fdesign.isinchp` for a description of the specification string entries. • `'Fst,Fp,Ast,Ap'` (default string)) • `'N,Fc,Ast,Ap'` • `'N,Fst,Fp'` • `'N,Fst,Ast,Ap'`
`'Lowpass'`	See `fdesign.lowpass` for a description of the specification string entries. • `'Fp,Fst,Ap,Ast'` (default string) • `'N,F3dB'` • `'N,Fc'` • `'N,Fc,Ap,Ast'` • `'N,Fp,Ap,Ast'` • `'N,Fp,Fst'` • `'N,Fp,Fst,Ap'` • `'N,Fp,Fst,Ast'` • `'N,Fst,Ap,Ast'`

Design String	Valid Specification Strings
`'Nyquist'`	See `fdesign.nyquist` for a description of the specification string entries. For all Nyquist specifications, you must specify the *L*th band. This typically corresponds to the interpolation factor so that the nonzero samples of the upsampler output are preserved. • `'TW,Ast'` (default string) • `'N'` • `'N,Ast'` • `'N,Ast'`
`'Raised Cosine'`	See `fdesign.pulseshaping` for a description of the specification string entries. • `'Ast,Beta'` (default string) • `'Nsym,Beta'` • `'N,Beta'` The specification string must be preceded by an integer-valued `SamplesPerSymbol`.
`'Square Root Raised Cosine'`	See `fdesign.pulseshaping` for a description of the specification string entries. • `'Ast,Beta'` (default string) • `'Nsym,Beta'` • `'N,Beta'` The specification string must be preceded by an integer-valued `SamplesPerSymbol`.

`D = fdesign.rsrc(L,M,RESPONSE,SPEC)` constructs object `D` and sets its `Specification` property to `SPEC`. Entries in the `SPEC` string represent various filter response features, such as the filter order, that govern

the filter design. Valid entries for SPEC depend on the design type of the specifications object.

When you add the SPEC input argument, you must also add the RESPONSE input argument.

D = fdesign.rsrc(L,M,SPEC,specvalue1,specvalue2,...) constructs an object D and sets its specifications at construction time.

D = fdesign.rsrc(...,Fs) provides the sampling frequency of the signal to be filtered. Fs must be specified as a scalar trailing the other numerical values provided. Fs is assumed to be in Hz as are all other frequency values provided.

D = fdesign.rsrc(...,MAGUNITS) specifies the units for any magnitude specification you provide in the input arguments. MAGUNITS can be one of

- 'linear' — specify the magnitude in linear units.

- 'dB' — specify the magnitude in dB (decibels).

- 'squared' — specify the magnitude in power units.

When you omit the MAGUNITS argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples   Design a rational-factor sample-rate converter. Set the rational sample-rate change to 5/3. Use the default Nyquist design with a transition width of 0.05π radians/sample and stopband attenuation of 40 dB. The *L*th band factor in the Nyquist design is equal to the interpolation factor.

```
d = fdesign.rsrc(5,3,'nyquist',5,.05,40);
hm = design(d,'kaiserwin'); %design with Kaiser window
```

Design a rational-factor sample-rate converter. Set the rational sample-rate change to 5/3. Use a Nyquist design with the 'N,TW'

specification string. Set the order equal to 12 and the transition width to 0.1π radians/sample. The *L*th band factor in the Nyquist design is equal to the interpolation factor.

```
d = fdesign.rsrc(5,3,'nyquist',5,'N,TW',12,0.1);
```

Design a rational-factor sample-rate converter. Assume the data are sampled at 10 kHz. Set the rational sample-rate change to 3/2. Use a Nyquist design with the 'N,TW' specification string. Set the order equal to 12 and the transition width to 100 Hz. The *L*th band factor in the Nyquist design is equal to the interpolation factor.

```
d = fdesign.rsrc(3,2,'nyquist',3,'N,TW',12,100,1e4);
hd = design(d,'equiripple');
```

fftcoeffs

Purpose	Frequency-domain coefficients

Syntax
```
c = fftcoeffs(hd)
c = fftcoeffs(ha)
```

Description   c = fftcoeffs(hd) return the frequency-domain coefficients used when filtering with the dfilt.fftfir object. c contains the coefficients

c = fftcoeffs(ha) return the frequency-domain coefficients used when filtering with adaptfilt objects.

fftcoeffs applies to the following adaptive filter algorithms:

- adaptfilt.fdaf

- adaptfilt.pbfdaf

- adaptfilt.pbufdaf

- adaptfilt.ufdaf

Examples   This example demonstrates returning the FFT coefficients from the discrete-time filter hd.

```
b = [0.05 0.9 0.05];
len = 50;
hd = dfilt.fftfir(b,len);
c=fftcoeffs(hd);
```

Similarly, you can use fftcoeffs with the adaptive filters algorithms listed above. Start by constructing an adaptive filter ha.

```
d  = 16;                  % Number of samples of delay.
b = exp(1j*pi/4)*[-0.7 1]; % Numerator coefficients of channel.
a = [1 -0.7];             % Denominator coefficients of channel.
ntr= 1000;                % Number of iterations.
s  = sign(randn(1,ntr+d)) +...
1j*sign(randn(1,ntr+d));     % Baseband QPSK signal.
n = 0.1*(randn(1,ntr+d) + 1j*randn(1,ntr+d));  % Noise signal.
r = filter(b,a,s)+n;      % Received signal.
```

```
x   = r(1+d:ntr+d);          % Input signal (received signal).
s   = s(1:ntr);              % Desired signal (delayed QPSK signal).
del = 1;                     % Initial FFT input powers.
mu  = 0.1;                   % Step size.
lam = 0.9;                   % Averaging factor.
blocksize   = 8;                        % Block size.
ha = adaptfilt.pbufdaf(32,mu,1,del,lam,blocksize);
```

Here are the coefficients before you filter a signal.

```
c=fftcoeffs(ha);
% all coefficients are zero
NumNonzero =nnz(c);
```

Filtering a signal y produces complex nonzero coefficients that you use
fftcoeffs to see.

```
[y,e] = filter(ha,x,s);
c=fftcoeffs(ha);
```

                   adaptfilt.ufdaf

filter

Purpose   Filter data with filter object

Syntax   **Fixed-Point Filter Syntaxes**
                `y = filter(hd,x)`
                `y = filter(hd,x,dim)`

                Adaptive Filter Syntax
                `y = filter(ha,x,d)`
                `[y,e] = filter(ha,x,d)`

                Multirate Filter Syntax
                `y = filter(hm,x)`
                `y = filter(hm,x,dim)`

Description   This reference page contains three sections that describe the syntaxes
                 for the filter objects:

- "Fixed-Point Filter Syntaxes" on page 7-640

- "Adaptive Filter Syntaxes" on page 7-641

- "Multirate Filter Syntaxes" on page 7-642

Fixed-Point Filter Syntaxes

`y = filter(hd,x)` filters a vector of real or complex input data x
through a fixed-point filter hd, producing filtered output data y. The
vectors x and y have the same length. filter stores the final conditions
for the filter in the States property of hd — hd.states.

When you set the property PersistentMemory to false (the default
setting), the initial conditions for the filter are set to zero before filtering
starts. To use nonzero initial conditions for hd, set PersistentMemory
to true. Then set hd.states to a vector of nstates(hd) elements, one
element for each state to set. If you specify a scalar for hd.states,
filter expands the scalar to a vector of the proper length for the states.
All elements of the expanded vector have the value of the scalar.

If x is a matrix, `y = filter(hd,x)` filters along each column of x to
produce a matrix y of independent channels. If x is a multidimensional

array, `y = filter(hd,x)` filters x along the first nonsingleton dimension of x.

To use nonzero initial conditions when you are filtering a matrix x, set the filter states to a matrix of initial condition values. Set the initial conditions by setting the `States` property for the filter (`hd.states`) to a matrix of `nstates(hd)` rows and `size(x,2)` columns.

`y = filter(hd,x,dim)` applies the filter hd to the input data located along the specific dimension of x specified by dim.

When you are filtering multichannel data, dim lets you specify which dimension of the input matrix to filter along — whether a row represents a channel or a column represents a channel. When you provide the dim input argument, the filter operates along the dimension specified by dim. When your input data x is a vector or matrix and dim is 1, each column of x is treated as a one input channel. When dim is 2, the filter treats each row of the input x as a channel.

To filter multichannel data in a loop environment, you must use the dim input argument to set the proper processing dimension.

You specify the initial conditions for each channel individually, when needed, by setting `hm.states` to a matrix of `nstates(hd)` rows (one row containing the states for one channel of input data) and `size(x,2)` columns (one column containing the filter states for each channel).

Adaptive Filter Syntaxes

`y = filter(ha,x,d)` filters a vector of real or complex input data x through an adaptive filter object ha, producing the estimated desired response data y from the process of adapting the filter. The vectors x and y have the same length. Use d for the desired signal. Note that d and x must be the same length signal chains.

`[y,e] = filter(ha,x,d)` produces the estimated desired response data y and the prediction error e (refer to previous syntax for more information).

filter

Multirate Filter Syntaxes

`y = filter(hd,x)` filters a vector of real or complex input data `x` through a fixed-point filter `hd`, producing filtered output data `y`. The vectors `x` and `y` have the same length. filter stores the final conditions for the filter in the `States` property of `hd` — `hd.states`.

`y = filter(hm,x,dim)` applies the filter `hd` to the input data located along the specific dimension of `x` specified by `dim`.

When you are filtering multichannel data, `dim` lets you specify which dimension of the input matrix to filter along — whether a row represents a channel or a column represents a channel. When you provide the `dim` input argument, the filter operates along the dimension specified by `dim`. When your input data `x` is a vector or matrix and `dim` is 1, each column of `x` is treated as a one input channel. When `dim` is 2, the filter treats each row of the input `x` as a channel.

To filter multichannel data in a loop environment, you must use the `dim` input argument to set the processing dimension.

You specify the initial conditions for each channel individually, when needed, by setting `hm.states` to a matrix of `nstates(hm)` rows (one row containing the states for one channel of input data) and `size(x,2)` columns (one column containing the filter states for each channel).

The number of data samples in your input data set `x` does not need to be a multiple of the rate change factor `r` for the object. When the rate change factor is not an even divisor of the number of input samples `x`, `filter` processes the samples as shown in the following figure, where the rate change factor is 3 and the number of input samples is 23. Decimators always take the first input sample to generate the first output sample. After that, the next output sample comes after each `r` number of input samples.

Given 23 Input Data Samples

You Get 7 Output Data Samples
After Decimation By 3

2 Processed Samples
That Did Not Generate
An Output Sample
Examples   Filter a signal using a filter with various initial conditions (IC) or no
initial conditions.

```
x = randn(100,1);    % Original signal.
b = fir1(50,.4);     % 50th-order linear-phase FIR filter.
hd = dfilt.dffir(b);    % Direct-form FIR implementation.

% Do not set specific initial conditions.

y1 = filter(hd,x);   % 'PersistentMemory'='false'(default).
zf = hd.states;      % Final conditions.
```

Now use nonzero initial conditions by setting ICs after before you filter.

```
hd.persistentmemory = true;
hd.states = 1;       % Uses scalar expansion.
y2 = filter(hd,x);
stem([y1 y2])        % Different sequences at beginning.
```

Looking at the stem plot shows that the sequences are different at the
beginning of the filter process.
Here is one way to use `filter` with streaming data.

```
reset(hd);           % Clear filter history.
y3 = filter(hd,x);   % Filter entire signal in one block.
```

As an experiment, repeat the process, filtering the data as sections, rather than in streaming form.

```
reset(hd);              % Clear filter history.
yloop = zeros(20,5);    % Preallocate output array.
xblock = reshape(x,[20 5]);
for i=1:5,
   yloop(:,i) = filter(hd,xblock(:,i));
end
```

Use a stem plot to see the comparison between streaming and block-by-block filtering.

```
stem([y3 yloop(:)]);
```

Filtering the signal section-by-section is equivalent to filtering the entire signal at once.

To show the similarity between filtering with discrete-time and with multirate filters, this example demonstrates multirate filtering.

```
Fs = 44.1e3;             % Original sampling frequency: 44.1kHz.
n = [0:10239].';         % 10240 samples, 0.232 second long signal.
x  = sin(2*pi*1e3/Fs*n); % Original signal, sinusoid at 1kHz.
m = 2;                   % Decimation factor.
hm = mfilt.firdecim(m);  % Use the default filter.
```

First, filter without setting initial conditions.

```
y1 = filter(hm,x);        % PersistentMemory is false (default).
zf = hm.states;           % Final conditions.
```

This time, set nonzero initial conditions before filtering the data.

```
hm.persistentmemory = true;
hm.states = 1;          % Uses scalar expansion to set ICs.
y2 = filter(hm,x);
stem([y1(1:60) y2(1:60)]) % Show the filtering results.
```

Note the different sequences at the start of filtering.

Finally, try filtering streaming data.

```
reset(hm);             % Clear the filter history.
y3 = filter(hm,x);     % Filter entire signal in one block.
```

As with the discrete-time filter, filtering the signal section by section is equivalent to filtering the entire signal at once.

```
reset(hm);              % Clear filter history again.
yloop = zeros(1024,5);  % Preallocate output array.
xblock = reshape(x,[2048 5]);
for i=1:5,
   yloop(:,i) = filter(hm,xblock(:,i));
end
stem([y3 yloop(:)]);
```

Algorithms   Quantized Filters

The `filter` command implements fixed- or floating-point arithmetic on the quantized filter structure you specify.

The algorithm applied by `filter` when you use a discrete-time filter object on an input signal depends on the response you chose for the filter, such as lowpass or Nyquist or bandstop. To learn more about each filter algorithm, refer to the literature reference provided on the appropriate discrete-time filter reference page.

> **Note** dfilt/filter does not normalize the filter coefficients automatically. Function filter supplied by MATLAB does normalize the coefficients.

Adaptive Filters

The algorithm used by filter when you apply an adaptive filter object to a signal depends on the algorithm you chose for your adaptive filter. To learn more about each adaptive filter algorithm, refer to the literature reference provided on the appropriate adaptfilt.*algorithm* reference page.

Multirate Filters

The algorithm applied by filter when you apply a multirate filter objects to signals depends on the algorithm you chose for the filter — the form of the multirate filter, such as decimator or interpolator. To learn more about each filter algorithm, refer to the literature reference provided on the appropriate multirate filter reference page.

filterbuilder

Purpose   GUI-based filter design

Syntax   `filterbuilder(h)`
                  `filterbuilder('`*response*`')`

Description   `filterbuilder` starts a GUI-based tool for building filters. It relies
                  on the `fdesign` object-object oriented filter design paradigm, and is
                  intended to reduce development time during the filter design process.
                  `filterbuilder` uses a specification-centered approach to find the best
                  algorithm for the desired response.

Note You must have the Signal Processing Toolbox installed to use
`fdesign` and `filterbuilder`. Some of the features described below
may be unavailable if your installation does not additionally include the
DSP System Toolbox. You can verify the presence of both toolboxes by
typing `ver` at the command prompt.

The `filterbuilder` GUI contains many features not available in
FDATool. For more information on how to use `filterbuilder`, see
"Filterbuilder Design Process".

To use `filterbuilder`, enter `filterbuilder` at the MATLAB command
line using one of three approaches:

- Simply enter `filterbuilder`. MATLAB opens a dialog for you to
  select a filter response type. After you select a filter response type,
  `filterbuilder` launches the appropriate filter design dialog box.

- Enter `filterbuilder(h)`, where h is an existing filter object. For
  example, if h is a bandpass filter, `filterbuilder(h)` opens the
  bandpass filter design dialog box. (The h object must have been
  created using `filterbuilder` or must be a `dfilt` ,`mfilt`, or filter
  System object created using fdesign.)

Note You must have the DSP System Toolbox software to create and import filter System objects.

- Enter filterbuilder('*response*'), replacing *response* with a response string from the following table. MATLAB opens a filter design dialog that corresponds to the response string.

Note You must have the DSP System Toolbox software to implement a number of the filter designs listed in the following table. If you only have the Signal Processing Toolbox software, you can design a limited set of the following filter-response types.

Response String	Description of Resulting Filter Design	Filter Object
arbgrpdelay	Arbitrary group delay filter design	fdesign.arbgrpdelay
arbmag	Arbitrary magnitude filter design	fdesign.arbmag
arbmagnphase	Arbitrary response filter (magnitude and phase)	fdesign.arbmagnphase
audioweighting	Audio weighting filter	fdesign.audioweighting
bandpass or bp	Bandpass filter	fdesign.bandpass
bandstop or bs	Bandstop filter	fdesign.bandstop
cic	CIC filter	fdesign.decimator(M,'cic',... or
ciccomp	CIC compensator	fdesign.ciccomp r(L,'cic',
comb	Comb filter	fdesign.comb

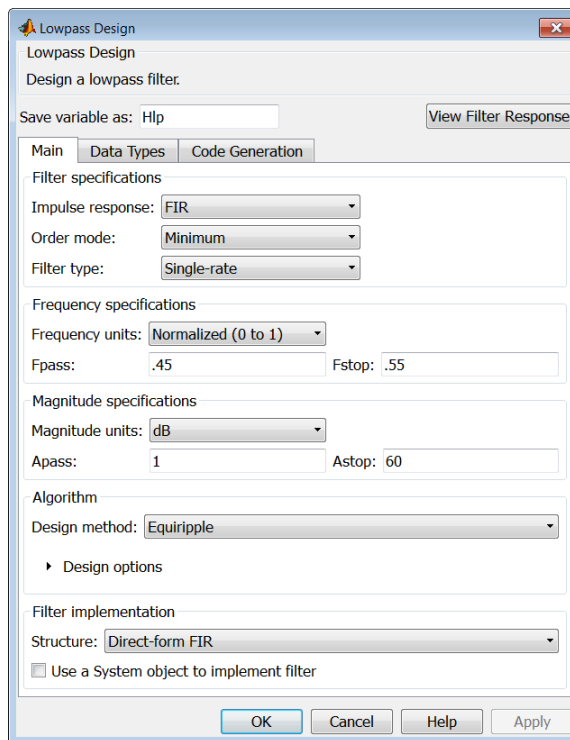
and
fdesign.interpolator

Response String	Description of Resulting Filter Design	Filter Object
diff	Differentiator filter	`fdesign.differentiator`
fracdelay	Fractional delay filter	`fdesign.fracdelay`
halfband or `hb`	Halfband filter	`fdesign.halfband`
highpass or `hp`	Highpass filter	`fdesign.highpass`
hilb	Hilbert filter	`fdesign.hilbert`
isinc, isinclp, or isinchp	Inverse sinc lowpass or highpass filter	`fdesign.isinclp` and `fdesign.isinchp`
lowpass or `lp`	Lowpass filter (default)	`fdesign.lowpass`
notch	Notch filter	`fdesign.notch`
nyquist	Nyquist filter	`fdesign.nyquist`
octave	Octave filter	`fdesign.octave`
parameq	Parametric equalizer filter	`fdesign.parameq`
peak	Peak filter	`fdesign.peak`
pulseshaping	Pulse-shaping filter	`fdesign.pulseshaping`

Note Because they do not change the filter structure, the magnitude specifications and design method are tunable when using `filterbuilder`.

Filterbuilder Design Panes

Main Design Pane

The main pane of filterbuilder varies depending on the filter response type, but the basic structure is the same. The following figure shows the basic layout of the dialog box.


As you choose the response for the filter, the available options and design parameters displayed in the dialog box change. This display allows you to focus only on parameters that make sense in the context of your filter design.

Every filter design dialog box includes the options displayed at the top of the dialog box, shown in the following figure.

- **Save variable as** — When you click **Apply** to apply your changes or **OK** to close this dialog box, filterbuilder saves the current filter to your MATLAB workspace as a filter object with the name you enter.

- **View Filter Response** — Displays the magnitude response for the current filter specifications and design method by opening the Filter Visualization Tool (fvtool).

Note The filterbuilder dialog box includes an **Apply** option. Each time you click **Apply**, filterbuilder writes the modified filter to your MATLAB workspace. This modified filter has the variable name you assign in **Save variable as**. To apply changes without overwriting the variable in you workspace, change the variable name in **Save variable as** before you click **Apply**.

There are three tabs in the Filterbuilder dialog box, containing three panes: **Main**, **Data Types**, and **Code Generation**. The first pane changes according to the filter being designed. The last two panes are the same for all filters. These panes are discussed in the following sections.

Data Types Pane

The second tab in the Filterbuilder dialog box is shown in the following figure.
The **Arithmetic** drop down box allows the choice of `Double precision`, `Single precision`, or `Fixed point`. Some of these options may be unavailable depending on the filter parameters. The following table describes these options.

Arithmetic List Entry	Effect on the Filter
`Double precision`	All filtering operations and coefficients use double-precision, floating-point representations and math. When you use `filterbuilder` to

Arithmetic List Entry	Effect on the Filter
	create a filter, `double precision` is the default value for the Arithmetic property.
`Single precision`	All filtering operations and coefficients use single-precision floating-point representations and math.
`Fixed point`	This string applies selected default values, typically used on many digital processors, for the properties in the fixed-point filter. These properties include coefficient word lengths, fraction lengths, and various operating modes. This setting allows signed fixed data types only. Fixed-point filter design with `filterbuilder` is available only when you install Fixed-Point Toolbox software along with DSP System Toolbox software.

The following figure shows the **Data Types** pane after you select `Fixed point` for **Arithmetic** and set **Filter internals** to `Specify precision`. This figure shows the **Data Types** pane for the case where the **Use a System object to implement filter** check box is not selected in the **Main** pane.

Input signal

Specify the format the filter applies to data to be filtered. For all cases, `filterbuilder` implements filters that use binary point scaling and signed input. You set the word length and fraction length as needed.

Coefficients

Choose how you specify the word length and the fraction length of the filter numerator and denominator coefficients:

- `Specify word length` enables you to enter the word length of the coefficients in bits. In this mode, `filterbuilder` automatically sets the fraction length of the coefficients to the binary-point only scaling that provides the best possible precision for the value and word length of the coefficients.

- `Binary point scaling` enables you to enter the word length and the fraction length of the coefficients in bits. If applicable, enter separate fraction lengths for the numerator and denominator coefficients.

- The filter coefficients do not obey the **Rounding mode** and **Overflow mode** parameters that are available when you select `Specify precision` from the Filter internals list. Coefficients are always saturated and rounded to `Nearest`.

Section Input

Choose how you specify the word length and the fraction length of the fixed-point data type going into each section of an SOS filter. This parameter is visible only when the selected filter structure is IIR and SOS.

- `Binary point scaling` enables you to enter the word and fraction lengths of the section input in bits.

- `Specify word length` enables you to enter the word lengths in bits.

Section Output

Choose how you specify the word length and the fraction length of the fixed-point data type coming out of each section of an SOS

filter. This parameter is visible only when the selected filter structure is IIR and SOS.

- `Binary point scaling` enables you to enter the word and fraction lengths of the section output in bits.

- `Specify word length` enables you to enter the output word lengths in bits.

State

Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. Use this parameter to specify how to designate the state word and fraction lengths. This parameter is not visible for direct form and direct form I filter structures because `filterbuilder` deduces the state directly from the input format. States always use signed representation:

- `Binary point scaling` enables you to enter the word length and the fraction length of the accumulator in bits.

- `Specify precision` enables you to enter the word length and fraction length in bits (if available).

Product

Determines how the filter handles the output of product operations. Choose from the following options:

- `Full precision` — Maintain full precision in the result.

- `Keep LSB` — Keep the least significant bit in the result when you need to shorten the data words.

- `Specify Precision` — Enables you to set the precision (the fraction length) used by the output from the multiplies.

Filter internals

Specify how the fixed-point filter performs arithmetic operations within the filter. The affected filter portions are filter products, sums, states, and output. Select one of these options:

- Full precision — Specifies that the filter maintains full precision in all calculations for products, output, and in the accumulator.

- Specify precision — Set the word and fraction lengths applied to the results of product operations, the filter output, and the accumulator. Selecting this option enables the word and fraction length controls.

Signed

Selecting this option directs the filter to use signed representations for the filter coefficients.

Word length

Sets the word length for the associated filter parameter in bits.

Fraction length

Sets the fraction length for the associate filter parameter in bits.

Accum

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths.

Determines how the accumulator outputs stored values. Choose from the following options:

- Full precision — Maintain full precision in the accumulator.

- Keep MSB — Keep the most significant bit in the accumulator.

- Keep LSB — Keep the least significant bit in the accumulator when you need to shorten the data words.

- Specify Precision — Enables you to set the precision (the fraction length) used by the accumulator.

Output

Sets the mode the filter uses to scale the output data after filtering. You have the following choices:

- Avoid Overflow — Set the output data fraction length to avoid causing the data to overflow. Avoid overflow is considered

the conservative setting because it is independent of the input data values and range.

- `Best Precision` — Set the output data fraction length to maximize the precision in the output data.

- `Specify Precision` — Set the fraction length used by the filtered data.

Fixed-point operational parameters

Parameters in this group control how the filter rounds fixed-point values and how it treats values that overflow.

Rounding mode

Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).

- `ceil` - Round toward positive infinity.

- `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.

- `zero/fix` - Round toward zero.

- `floor` - Round toward negative infinity.

- `nearest` - Round toward nearest. Ties round toward positive infinity.

- `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.

The choice you make affects everything except coefficient values and input data which always round. In most cases, products do not overflow—they maintain full precision.

Overflow mode

Sets the mode the filter uses to respond to overflow conditions in fixed-point arithmetic. Choose from the following options:

- Saturate — Limit the output to the largest positive or negative representable value.

- Wrap — Set overflowing values to the nearest representable value using modular arithmetic.

The choice you make affects everything except coefficient values and input data which always round. In most cases, products do not overflow—they maintain full precision.

Cast before sum

Specifies whether to cast numeric data to the appropriate accumulator format before performing sum operations. Selecting **Cast before sum** ensures that the results of the affected sum operations match most closely the results found on most digital signal processors. Performing the cast operation before the summation adds one or two additional quantization operations that can add error sources to your filter results.

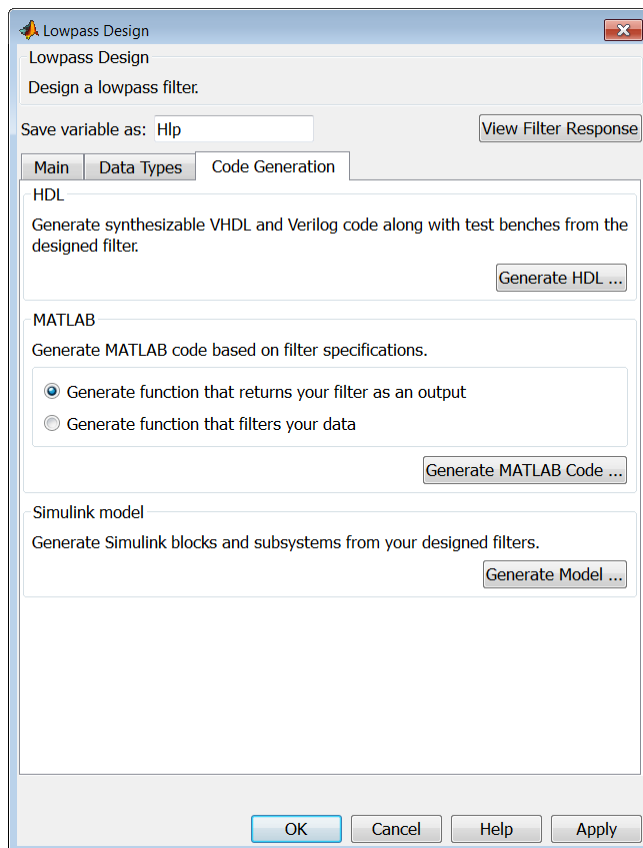
If you clear **Cast before sum**, the filter prevents the addends from being cast to the sum format before the addition operation. Choose this setting to get the most accurate results from summations without considering the hardware your filter might use. The input format referenced by **Cast before sum** depends on the filter structure you are using.

The effect of clearing or selecting **Cast before sum** is as follows:

- Cleared — Configures filter summation operations to retain the addends in the format carried from the previous operation.

- Selected — Configures filter summation operations to convert the input format of the addends to match the summation output format before performing the summation operation. Usually, selecting **Cast before sum** generates results from the summation that more closely match those found from digital signal processors.

Code Generation Pane

The code generation pane contains options for various implementations of the completed filter design. Depending on your installation, you can generate MATLAB, VHDL, and Verilog code from the designed filter. You can also choose to create or update a Simulink model from the designed filter. The following section explains these options.


filterbuilder

HDL

For more information on this option, see "Opening the Filter Design HDL Coder™ GUI From the filterbuilder GUI".

MATLAB

Generate MATLAB code based on filter specifications

- **Generate function that returns your filter as an output**

  Selecting this option generates a function that designs either a DFILT/MFILT object or a system object (depending on whether you have selected the **Use a System object to implement the filter** check box) using fdesign. The function call returns a filter object.

- **Generate function that filters your data**

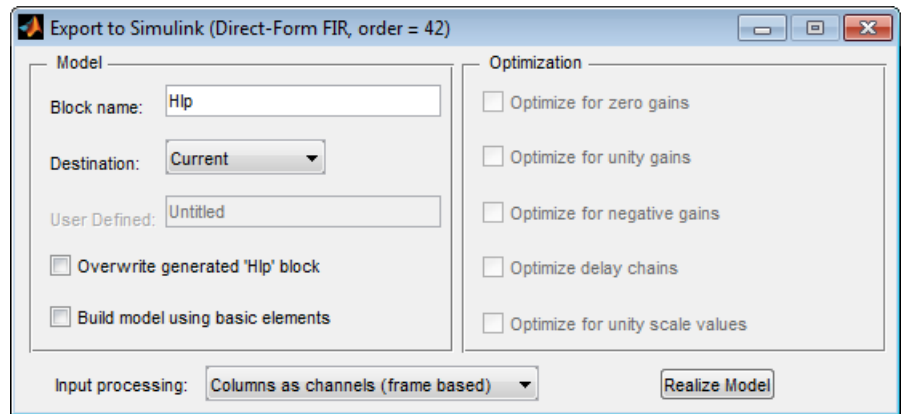
  Selecting this option generates a function that takes data as input, and outputs data filtered with the designed filter.

  Clicking on the **Generate MATLAB code** button, brings up a Save File dialog. Specify the file name and location, and save. The filter is now contained in an editable file.

Simulink Model

Generate Simulink blocks and subsystems from your designed filters

When the **Use a System object to implement filter** check box is selected in the **Main** pane, you are able to generate Simulink models as long as the **Arithmetic** is not set to Fixed point in the **Data Types** pane. If the **Arithmetic** is set to Fixed point, the **Generate Model** button in the **Simulink model** panel will be disabled.

Clicking on the **Generate Model** button brings up the **Export to Simulink** dialog box, as shown in the following figure.


You can set the following parameters in this dialog box:

- **Block Name** — The name for the new subsystem block, set to **Filter** by default.

- **Destination** — **Current** saves the generated model to the current Simulink model; **New** creates a new model to contain the generated block; **User Defined** creates a new model or subsystem to the user-specified location enumerated in the **User Defined** text box.

- **Overwrite generated 'Filter' block** — When this check box is selected, DSP System Toolbox software overwrites an existing block with the name specified in **Block Name**; when cleared, creates a new block with the same name.

- **Build model using basic elements** — When this check box is selected, DSP System Toolbox software builds the model using only basic blocks.

- **Optimize for zero gains** — When this check box is selected, DSP System Toolbox software removes all zero gain blocks from the model.

- **Optimize for unity gains** — When this check box is selected, DSP System Toolbox software replaces all unity gains with direct connections.

- **Optimize for negative gains** — When this check box is selected, DSP System Toolbox software removes all negative unity gain blocks, and changes sign at the nearest summation block.

- **Optimize delay chains** — When this check box is selected, DSP System Toolbox software replaces delay chains made up of *n* unit delays with a single delay by *n*.

- **Optimize for unity scale values** — When this check box is selected, DSP System Toolbox software removes all scale value multiplications by 1 from the filter structure.

- **Input processing** — Specify how the generated filter block or subsystem block processes the input. Depending on the type of filter you are designing, one or both of the following options may be available:

  - `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.

  - `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

  For more information about sample- and frame-based processing, see "Sample- and Frame-Based Concepts".

- **Realize Model** — DSP System Toolbox software builds the model with the set parameters.

Filter Responses

Select your filter response from the `filterbuilder` **Response Selection** main menu.

If you have the DSP System Toolbox software, the following **Response Selection** menu appears.
Select your desired filter response from the menu and design your filter.

The following sections describe the options available for each response type.

Arbitrary Response Filter Design Dialog Box — Main Pane

Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Impulse response

This dialog only applies if you have the DSP System Toolbox software. Select either FIR or IIR from the drop down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly. Arbitrary group delay designs are only available if **Impulse response** is IIR. Without the DSP System Toolbox, the only available arbitrary response filter design is FIR.

Order mode

This dialog only applies if you have the DSP System Toolbox software. Choose Minimum or Specify. Choosing Specify enables the **Order** dialog.

Order

This dialog only applies when **Order mode** is Specify. For an FIR design, specify the filter order. For an IIR design, you can specify an equal order for the numerator and denominator, or you can specify different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box. Because the Signal Processing Toolbox only supports FIR arbitrary-magnitude filters, you do not have the option to specify a denominator order.

Denominator order

Select the check box and enter the denominator order. This option is enabled only if IIR is selected for **Impulse response**.

Filter type

This dialog only applies if you have the DSP System Toolbox software and is only available for FIR filters. Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods

and structures that are available to implement your filter. By default, `filterbuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.

- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2 for `Decimator` and 3 for `Sample-rate converter`.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Response Specification

Number of Bands

Select the number of bands in the filter. Multiband design is available for both FIR and IIR filters.

Specify response as:

Specify the response as `Amplitudes`, `Magnitudes and phase`, `Frequency response`, or `Group delay`. `Amplitudes` is the only option if you do not have the DSP System Toolbox software. `Group delay` is only available for IIR designs.

Frequency units

Specify frequency units as either `Normalized`, `Hz`, `kHz`, `MHz`, or `GHz`.

Input Fs

Enter the input sampling frequency in the units specified in the **Frequency units** drop-down box. This option is enabled when **Frequency units** is set to an option in hertz.

Band Properties

These properties are modified automatically depending on the response chosen in the **Specify response as** drop-down box. Two or three columns are presented for input. The first column is always Frequencies. The other columns are either Amplitudes, Magnitudes, Phases, or Frequency Response. Enter the corresponding vectors of values for each column.

- **Frequencies** and **Amplitudes** — These columns are presented for input if you select Amplitudes in the **Specify response as** drop-down box.

- **Frequencies**, **Magnitudes**, and **Phases** — These columns are presented for input if the response chosen in the **Specify response as** drop-down box is Magnitudes and phases.

- **Frequencies** and **Frequency response** — These columns are presented for input if the response chosen in the **Specify response as** drop-down box is Frequency response.

Algorithm

The options for each design are specific for each design method. In the arbitrary response design, the available options also depend on the **Response specifications**. This section does not present all of the available options for all designs and design methods.

Design Method

Select the design method for the filter. Different methods are enabled depending on the defining parameters entered in the previous sections.

Design Options

- **Window** — Valid when the **Design method** is `Frequency Sampling`. Replace the square brackets with the name of a `window` function or function handle. For example, `'hamming'` or `@hamming`. If the window function takes parameters other than the length, use a cell array. For example, {`` `kaiser' ``,`3.5`} or {`@chebwin,60`}.

- **Density factor** — Valid when the **Design method** is `equiripple`. Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

  Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

  The default changes to 20 for an IIR arbitrary group delay design.

- **Phase constraint** — Valid when the **Design method** is `equiripple`, you have the DSP System Toolbox installed, and **Specify response as** is set to `Amplitudes`. Choose one of `Linear`, `Minimum`, or `Maximum`.

- **Weights** — Uses the weights in **Weights** to weight the error for a single-band design. If you have multiple frequency bands, the **Weights** design option changes to **B1 Weights**, **B2 Weights** to designate the separate bands. Use **Bi Weights** to specify weights for the i-th band. The **Bi Weights** design option is only available when you specify the i-th band as an unconstrained.

- **Bi forced frequency point** — This option is only available in a multi-band constrained equiripple design when **Specify response as** is `Amplitudes`. **Bi forced frequency point** is

the frequency point in the i-th band at which the response is forced to be zero. The index **i** corresponds to the frequency bands in **Band properties**. For example, if you specify two bands in **Band properties**, you have **B1 forced frequency point** and **B2 forced frequency point**.

- **Norm** — Valid only for IIR arbitrary group delay designs. **Norm** is the norm used in the optimization. The default value is 128, which essentially equals the L-infinity norm. The norm must be even.

- **Max pole radius** — Valid only for IIR arbitrary group delay designs. Constrains the maximum pole radius. The default is 0.999999. Reducing the **Max pole radius** can produce a transfer function more resistant to quantization.

- **Init norm** — Valid only for IIR arbitrary group delay designs. The initial norm used in the optimization. The default initial norm is 2.

- **Init numerator** — Specifies an initial estimate of the filter numerator coefficients.

- **Init denominator** — Specifies an initial estimate of the filter denominator coefficients. This may be useful in difficult optimization problems. In allpass filters, you only have to specify either the denominator or numerator coefficients. If you specify the denominator coefficients, you can obtain the numerator coefficients.

Filter implementation

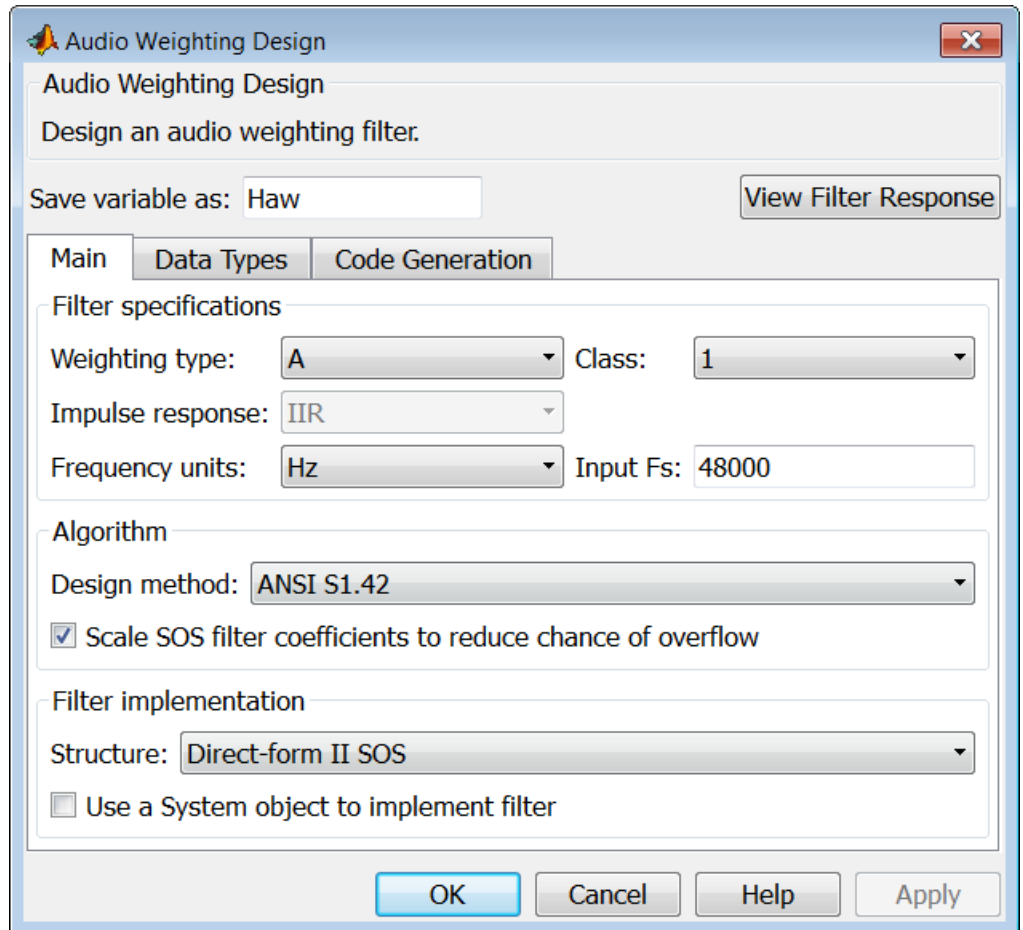
Structure

Select the structure for the filter. The available filter structures depend on the parameters you select for your filter.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned

off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Audio Weighting Filter Design Dialog Box — Main Pane


Filter specifications

- **Weighting type** — The weighting type defines the frequency response of the filter. The valid weighting types are: A, C , C-message, ITU-T 0.41, and ITU-R 468–4 weighting. See `fdesign.audioweighting` for definitions of the weighting types.

- **Class** — Filter class is only applicable for A weighting and C weighting filters. The filter class describes the frequency-dependent tolerances specified in the relevant standards. There are two possible class values: 1 and 2. Class 1 weighting filters have stricter tolerances than class 2 filters. The filter class value does not affect the design. The class value is only used to provide a specification mask in `fvtool` for the analysis of the filter design.

- **Impulse response** — Impulse response type as one of `IIR` or `FIR`. For A, C , C-message, and ITU-R 468–4 filter, IIR is the only option. For a ITU-T 0.41 weighting filter, FIR is the only option.

- **Frequency units** — Choose `Hz`, `kHz`, `MHz`, or `GHz`. Normalized frequency designs are not supported for audio weighting filters.

- **Input Fs** — The sampling frequency in **Frequency units**. For example, if **Frequency units** is set to `kHz`, setting **Input Fs** to 40 is equivalent to a 40 kHz sampling frequency.

Algorithm

- **Design method** — Valid design methods depend on the weighting type. For type A and C weighting filters, the only valid design type is `ANSI S1.42`. This is an IIR design method that follows ANSI standard S1.42–2001. For a C message filter, the only valid design method is `Bell 41009`, which is an IIR design method following the Bell System Technical Reference PUB 41009. For a ITU-R 468–4 weighting filter, you can design an IIR or FIR filter. If you choose an IIR design, the design method is `IIR least p-norm`. If you choose an FIR design, the design method choices are: `Equirriple` or `Frequency Sampling`. For an ITU-T 0.41 weighting filter, the available FIR design methods are `equirriple` or `Frequency Sampling`

- **Scale SOS filter coefficients to reduce chance of overflow** — Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Filter implementation

- **Structure** — For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. For audio weighting IIR filter designs, you can choose direct form I or II biquad (SOS). You can also choose to implement these structures in transposed form.

  For FIR designs, you can choose direct form, direct-form transposed, direct-form symmetric, direct-form asymmetric structures, or an overlap and add structure.

- **Use a System object to implement filter** — Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Bandpass Filter Design Dialog Box — Main Pane

Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select Minimum (the default) or Specify from the drop-down box. Selecting Specify enables the **Order** option so you can enter the filter order.

If you have the DSP System Toolbox software installed, you can specify IIR filters with different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

Filter type — This dialog only applies if you have the DSP System Toolbox software.

Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterbuilder specifies single-rate filters.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.

- Selecting Sample-rate converter activates both factors.

Order

> Enter the filter order. This option is enabled only if you select
> `Specify` for **Order mode**.

Decimation Factor

> Enter the decimation factor. This option is enabled only if the
> **Filter type** is set to `Decimator` or `Sample-rate converter`. The
> default factor value is 2.

Interpolation Factor

> Enter the decimation factor. This option is enabled only if the
> **Filter type** is set to `Interpolator` or `Sample-rate converter`.
> The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response
curve. Graphically, the filter specifications look similar to those shown
in the following figure.

In the figure, regions between specification values such as Fstop1 and
Fpass1 represent transition regions where the filter response is not
explicitly defined.

Frequency constraints

Select the filter features to use to define the frequency response characteristics. This dialog applies only when **Order mode** is **Specify**.

- `Passband and stopband edges` — Define the filter by specifying the frequencies for the edges for the stop- and passbands.

- `Passband edges` — Define the filter by specifying frequencies for the edges of the passband.

- `Stopband edges` — Define the filter by specifying frequencies for the edges of the stopbands.

- `3dB points` — Define the filter response by specifying the locations of the 3 dB points (IIR filters). The 3-dB point is the frequency for the point 3 dB below the passband value.

- `3dB points and passband width` — Define the filter by specifying frequencies for the 3-dB points in the filter response and the width of the passband. (IIR filters)

- `3dB points and stopband widths` — Define the filter by specifying frequencies for the 3-dB points in the filter response and the width of the stopband. (IIR filters)

- `6dB points` — Define the filter response by specifying the locations of the 6-dB points. The 6-dB point is the frequency for the point 6dB below the passband value. (FIR filters)

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0 1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in hertz, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fstop1

Enter the frequency at the edge of the end of the first stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fpass1

Enter the frequency at the edge of the start of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fpass2

Enter the frequency at the edge of the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop2

Enter the frequency at the edge of the start of the second stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude constraints

Specify as Unconstrained or Constrained bands. You must have the DSP System Toolbox software to select Constrained bands. Selecting Constrained bands enables dialogs for both stopbands and the passband: **Astop1**, **Astop2**, and **Apass**. You cannot specify constraints for all three bands simultaneously.

Setting **Magnitude constraints** to `Constrained bands` enables the **Wstop** and **Wpass** options under **Design options**.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.

- `dB` — Specify the magnitude in dB (decibels). This is the default setting.

- `Squared` — Specify the magnitude in squared units.

Astop1

Enter the filter attenuation in the first stopband in the units you choose for **Magnitude units**, either linear or decibels.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop2

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow
> Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

> Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).
>
> Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

> Valid when the **Design method** is `equiripple` and you have the DSP System Toolbox installed. Choose one of `Linear`, `Minimum`, or `Maximum`.

Minimum order

> This option only applies when you have the DSP System Toolbox software and **Order mode** is `Minimum`.
>
> Select `Any` (default), `Even`, or `Odd`. Selecting `Even` or `Odd` forces the minimum-order design to be an even or odd order.

Wstop1

Weight for the first stopband.

Wpass

Passband weight.

Wstop2

Weight for the second stopband.

Max pole radius

Valid only for IIR designs. Constrains the maximum pole radius. The default is 1. Reducing the max pole radius can produce a transfer function more resistant to quantization.

Init norm

Valid only for IIR designs. The initial norm used in the optimization. The default initial norm is 2.

Init numerator

Specifies an initial estimate of the filter numerator coefficients. This may be useful in difficult optimization problems.

Init denominator

Specifies an initial estimate of the filter denominator coefficients. This may be useful in difficult optimization problems.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Bandstop Filter Design Dialog Box — Main Pane

7-683

filterbuilder

Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option so you can enter the filter order.

If you have the DSP System Toolbox software installed, you can specify IIR filters with different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

Filter type

Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterbuilder specifies single-rate filters.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.

- Selecting Sample-rate converter activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

Frequency constraints
> Select the filter features to use to define the frequency response characteristics. This dialog applies only when **Order mode** is **Specify**.
>
> - `Passband and stopband edges` — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
>
> - `Passband edges` — Define the filter by specifying frequencies for the edges of the passband.
>
> - `Stopband edges` — Define the filter by specifying frequencies for the edges of the stopbands.
>
> - `3dB points` — Define the filter response by specifying the locations of the 3 dB points (IIR filters). The 3 dB point is the frequency for the point 3 dB point below the passband value.
>
> - `3dB points and passband width` — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the passband (IIR filters).
>
> - `3dB points and stopband widths` — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the stopband (IIR filters).
>
> - `6dB points` — Define the filter response by specifying the locations of the 6-dB points (FIR filters). The 6-dB point is the frequency for the point 6 dB point below the passband value.

Frequency units
> Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0 1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Output Fs

When you design an interpolator, Fs represents the sampling frequency at the filter output rather than the filter input. This option is available only when you set **Filter type** is `interpolator`.

Fpass1

Enter the frequency at the edge of the end of the first passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fstop1

Enter the frequency at the edge of the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop2

Enter the frequency at the edge of the end of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fpass2

Enter the frequency at the edge of the start of the second passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude constraints

Specify as `Unconstrained` or `Constrained bands`. You must have the DSP System Toolbox software to select `Constrained bands`. Selecting `Constrained bands` enables dialogs for both passbands and the stopband: **Apass1**, **Apass2**, and **Astop**. You cannot specify constraints for all three bands simultaneously.

Setting **Magnitude constraints** to `Constrained bands` enables the **Wstop** and **Wpass** options under **Design options**.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.

- `dB` — Specify the magnitude in decibels (default).

- `Squared` — Specify the magnitude in squared units.

Apass1

Enter the filter ripple allowed in the first passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels

Apass2

Enter the filter ripple allowed in the second passband in the units you choose for **Magnitude units**, either linear or decibels

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the

specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow
Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor
Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint
Valid when the **Design method** is equiripple and you have the DSP System Toolbox installed. Choose one of Linear, Minimum, or Maximum.

Minimum order

This option only applies when you have the DSP System Toolbox software and **Order mode** is `Minimum`.

Select `Any` (default), `Even`, or `Odd`. Selecting `Even` or `Odd` forces the minimum-order design to be an even or odd order.

Wpass1

Weight for the first passband.

Wstop

Stopband weight.

Wpass2

Weight for the second passband.

Match exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select `passband` or `stopband` .

Max pole radius

Valid only for IIR designs. Constrains the maximum pole radius. The default is 1. Reducing the max pole radius can produce a transfer function more resistant to quantization.

Init norm

Valid only for IIR designs. The initial norm used in the optimization. The default initial norm is 2.

Init numerator

Specifies an initial estimate of the filter numerator coefficients. This may be useful in difficult optimization problems.

Init denominator

Specifies an initial estimate of the filter denominator coefficients. This may be useful in difficult optimization problems.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Filter specifications

Parameters in this group enable you to specify your CIC filter format, such as the filter type and the differential delay.

Filter type

> Select whether your filter will be a `decimator` or an `interpolator`. Your choice determines the type of filter and the design methods and structures that are available to implement your filter. Selecting `decimator` or `interpolator` activates the **Factor** option. When you design an interpolator, you enable the **Output Fs** parameter.
>
> When you design either a decimator or interpolator, the resulting filter is a CIC filter that decimates or interpolates your input signal.

Differential Delay

> Specify the differential delay of your CIC filter as an integer value greater than or equal to 1. The default value is 1. The differential delay changes the shape, number, and location of nulls in the filter response. Increasing the differential delay increases the sharpness of the nulls and the response between the nulls. In practice, differential delay values of 1 or 2 are the most common.

Factor

> Specify the decimation or interpolation factor for your filter as an integer value greater than or equal to 1. The default value is 2.

Frequency specifications

Frequency units

> Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0 1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Output Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.

- dB — Specify the magnitude in decibels (default).

- Squared — Specify the magnitude in squared units.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Filter implementation

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

CIC Compensator Filter Design Dialog Box — Main Pane

Filter specifications

Parameters in this group enable you to specify your filter format, such as the filter order mode and the filter type.

Order mode

Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterbuilder specifies single-rate filters.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.

- Selecting Sample-rate converter activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if Specify was selected for **Order mode**.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default factor value is 2.

Number of CIC sections

Specify the number of sections in the CIC filter for which you are designing this compensator. Select the number of sections from the drop-down list or enter the number.

Differential Delay

Specify the differential delay of your target CIC filter. The default value is 1. Most CIC filters use 1 or 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve.

Frequency specifications

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0 1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Output Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.

- dB — Specify the magnitude in decibels (default).

- Squared — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels

Algorithm

The parameters in this group allow you to specify the design method and structure that filterbuilder uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The

default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Minimum phase

To design a filter that is minimum phase, select **Minimum phase**. Clearing the **Minimum phase** option removes the phase constraint—the resulting design is not minimum phase.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select Any, Even, or Odd from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

> **Note** Generally, **Minimum order** designs are not available for IIR filters.

Match exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select `passband` or `stopband` or `both` from the drop-down list.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.

- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.

- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.

- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. `filterbuilder` applies that slope to the stopband.

- When you set **Stopband shape** to `1/f`, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay.

filterbuilder applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Comb Filter Design Dialog Box—Main Pane

Filter specifications

Parameters in this group enable you to specify the type of comb filter and the number of peaks or notches.

Comb Type

Select Notch or Peak from the drop-down list. Notch creates a comb filter that attenuates a set of harmonically related frequencies. Peak creates a comb filter that amplifies a set of harmonically related frequencies.

Order mode

Select Order or Number of Peaks/Notches from the drop-down menu.

Select Order to enter the desired filter order in the

dialog box. The comb filter has notches or peaks at increments of 2/Order in normalized frequency units.

Select Number of Peaks or Number of Notches to specify the number of peaks or notches and the Shelving filter order

Shelving filter order

The Shelving filter order is a positive integer that determines the sharpness of the peaks or notches. Larger values result in sharper peaks or notches.

Frequency specifications

Parameters in this group enable you to specify the frequency constraints and frequency units.

Frequency specifications

Select Quality factor or Bandwidth.

Quality factor is the ratio of the center frequency of the peak or notch to the bandwidth calculated at the –3 dB point.

Bandwidth specifies the bandwidth of the peak or notch. By default the bandwidth is measured at the –3 dB point. For example, setting the bandwidth equal to 0.1 results in 3 dB frequencies at normalized frequencies 0.05 above and below the center frequency of the peak or notch.

Frequency Units

Specify the frequency units. The default is normalized frequency. Choosing an option in Hz enables the **Input Fs** dialog box.

Magnitude specifications

Specify the units for the magnitude specification and the gain at which the bandwidth is measured. This menu is disabled if you specify a filter order. Select one of the following magnitude units from the drop down list:

- dB — Specify the magnitude in decibels (default).

- Squared — Specify the magnitude in squared units.

Bandwidth gain — Specify the gain at which the bandwidth is measured. The default is –3 dB.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

Design Method
> The IIR Butterworth design is the only option for peaking or notching comb filters.

Filter implementation

Structure
> For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

Use a System object to implement filter
> Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off.

Differentiator Filter Design Dialog Box — Main Pane

Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order. Graphically, the filter specifications look similar to those shown in the following figure.
In the figure, regions between specification values such as **Fpass** (f_1) and **Fstop** (f_3) represent transition regions where the filter response is not explicitly defined.

Order mode

Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterbuilder specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.

- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve.

Frequency constraints

This option is only available when you specify the order of the filter design. Supported options are `Unconstrained` and `Passband edge` and `stopband edge`.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0 1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the

frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude constraints

This option is only available when you specify the order of your filter design. The options for **Magnitude constraints** depend on the value of the **Frequency constraints**. If the value of **Frequency constraints** is Unconstrained, **Magnitude constraints** must be Unconstrained. If the value of **Frequency constraints** is Passband edge and stopband edge, **Magnitude constraints** can be Unconstrained, Passband ripple, or Stopband attenuation.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.

- dB — Specify the magnitude in decibels (default).

- Squared — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop2

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that filterbuilder uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Wpass

Passband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to `Passband edge and stopband edge` and the **Design method** is `Equiripple`.

Wstop

Stopband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to `Passband edge and stopband edge` and the **Design method** is `Equiripple`.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned

off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Fractional Delay Filter Design Dialog Box — Main Pane
Frequency specifications

Parameters in this group enable you to specify your filter format, such as the fractional delay and the filter order.

Order

If you choose Specify for **Order mode**, enter your filter
order in this field, or select the order from the drop-down
list.filterbuilder designs a filter with the order you specify.

Fractional delay

Specify a value between 0 and 1 samples for the filter fractional
delay. The default value is 0.5 samples.

Frequency units

Use this parameter to specify whether your frequency settings are
normalized or in absolute frequency. Select Normalized (0 1)
to enter frequencies in normalized form. This behavior is the
default. To enter frequencies in absolute values, select one of the
frequency units from the drop-down list—Hz, kHz, MHz, or GHz.
Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**,
defines the sampling frequency at the filter input. When you
provide an input sampling frequency, all frequencies in the
specifications are in the selected units as well. This parameter is
available when you select one of the frequency options from the
Frequency units list.

Halfband Filter Design Dialog Box — Main Pane

Filter specifications

Parameters in this group enable you to specify your filter type and order.

Impulse response

> Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

> **Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

> Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

> Select Single-rate, Decimator, or Interpolator. By default, filterbuilder specifies single-rate filters.

> When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that decimates or interpolates your input by a factor of two.

Order

> Enter the filter order. This option is enabled only if Specify was selected for **Order mode**.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications for a halfband lowpass filter look similar to those shown in the following figure.

In the figure, the transition region lies between the end of the passband and the start of the stopband. The width is defined explicitly by the value of **Transition width**.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0 1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Transition width
> Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units
> Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.
>
> - Linear — Specify the magnitude in linear units.
> - dB — Specify the magnitude in decibels (default).

Astop
> Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that filterbuilder uses to implement your filter.

Design Method
> Lists the design methods available for the frequency and magnitude specifications you entered. For FIR halfband filters, the available design options are Equiripple and Kaiser window. For IIR halfband filters, the available design options are Butterworth, Elliptic, and IIR quasi-linear phase.

Design Options

The following design options are available for FIR halfband filters when the user specifies an equiripple design:

Minimum phase

To design a filter that is minimum phase, select **Minimum phase**. Clearing the **Minimum phase** option removes the phase constraint—the resulting design is not minimum phase.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- Flat — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.

- Linear — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.

- 1/f — Specifies that the stopband attenuation changes exponentially as the frequency increases, where f is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to Flat, **Stopband decay** has no affect on the stopband.

- When you set **Stopband shape** to Linear, enter the slope of the stopband in units of dB/rad/s. filterbuilder applies that slope to the stopband.

- When you set **Stopband shape** to 1/f, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay. filterbuilder applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter implementation

Structure
> For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

Use a System object to implement filter
> Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Highpass Filter Design Dialog Box — Main Pane

Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option so you can enter the filter order.

If your **Impulse response** is IIR, you can specify an equal order for the numerator and denominator, or different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

Filter type

This option is only available if you have the DSP System Toolbox software. Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterbuilder specifies single-rate filters.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.

- Selecting Sample-rate converter activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a highpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure, the region between specification values Fstop and Fpass represents the transition region where the filter response is not explicitly defined.

Frequency constraints

Select the filter features to use to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- `Stopband edge and passband edge` — Define the filter by specifying the frequencies for the edges for the stopband and passband.

- `Passband edge` — Define the filter by specifying the frequency for the edge of the passband.

- `Stopband edge` — Define the filter by specifying the frequency for the edges of the stopband.

- `Stopband edge and 3dB point` — Define the filter by specifying the stopband edge frequency and the 3-dB down point (IIR designs).

- `3dB point and passband edge` — Define the filter by specifying the 3-dB down point and passband edge frequency (IIR designs).

- `3dB point` — Define the filter by specifying the frequency for the 3-dB point (IIR designs or maxflat FIR).

- `6dB point` — Define the filter by specifying the frequency for the 6-dB point in the filter response (FIR designs).

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0 1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the

specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fpass

Enter the frequency at the of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.

- dB — Specify the magnitude in decibels (default).

- Squared — Specify the magnitude in squared units.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

Design Method

>   Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow

>   Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

>   Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).
>
>   Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a

reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

This option only applies when you have the DSP System Toolbox software and when the **Design method** is `equiripple`. Select one of `Linear`, `Minimum`, or `Maximum`.

Minimum order — This option only applies when you have the DSP System Toolbox software and the **Order mode** is `Minimum`.

Select `Any` (default), `Even`, or `Odd`. Selecting `Even` or `Odd` forces the minimum-order design to be an even or odd order.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband when you select `Passband` or `Stopband`.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.

- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.

- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.

- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. `filterbuilder` applies that slope to the stopband.

- When you set **Stopband shape** to `1/f`, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay. `filterbuilder` applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Wpass
> Passband weight. This option only applies when **Impulse response** is FIR and **Order mode** is `Specify`.

Wstop
> Stopband weight. This option only applies when **Impulse response** is FIR and **Order mode** is `Specify`.

Filter implementation

Structure
> For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter
> Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Hilbert Filter Design Dialog Box — Main Pane

7-729

Impulse response
> Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

> ---
> **Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.
> ---

Order mode
> This option is only available if you have the DSP System Toolbox software. Select either Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type
> This option is only available if you have the DSP System Toolbox software. Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterbuilder specifies single-rate filters.

> • Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.

> • Selecting Sample-rate converter activates both factors.

> When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order
> Enter the filter order. This option is enabled only if Specify was selected for **Order mode**.
Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure, the regions between 0 and f_1 and between f_2 and 1 represent the transition regions where the filter response is explicitly defined by the transition width.

filterbuilder

Frequency units

> Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0 1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

> Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Transition width

> Specify the width of the transitions at the ends of the passband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

> Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.
>
> - `Linear` — Specify the magnitude in linear units.
>
> - `dB` — Specify the magnitude in decibels (default)
>
> - `Squared` — Specify the magnitude in squared units.

Apass

> Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

Design Method

> Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow

> Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

> Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).
>
> Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a

reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

FIR Type

This option is only available in a minimum-order design. Specify whether to design a type 3 or a type 4 FIR filter. The filter type is defined as follows:

- Type 3 — FIR filter with even order antisymmetric coefficients

- Type 4 — FIR filter with odd order antisymmetric coefficients
Select 3 or 4 from the drop-down list.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Inverse Sinc Filter Design Dialog Box — Main Pane

Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Order mode

    Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

Response type

    Select Lowpass or Highpass to design an inverse sinc lowpass or highpass filter.

Filter type

    Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterbuilder specifies single-rate filters.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.

- Selecting Sample-rate converter activates both factors.

    When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

    Enter the filter order. This option is enabled only if Specify was selected for **Order mode**.

Decimation Factor

    Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default factor value is 2.

Interpolation Factor

    Enter the decimation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

Regions between specification values such as Fpass and Fstop represent transition regions where the filter response is not explicitly defined.

Frequency constraints

This option is only available when you specify the filter order. The following options are available:

- Passband and stopband edges — Define the filter by specifying the frequencies for the edges for the stop- and passbands.

- Passband edge — Define the filter by specifying frequencies for the edges of the passband.

- Stopband edge — Define the filter by specifying frequencies for the edges of the stopbands.

- 6dB point — The 6-dB point is the frequency for the point 6 dB point below the passband value.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select Normalized (0 1) to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.

- dB — Specify the magnitude in decibels (default)

- Squared — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that filterbuilder uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Available options are `Linear`, `Minimum`, and `Maximum`.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options;

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.

- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.

- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.

- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. `filterbuilder` applies that slope to the stopband.

- When you set **Stopband shape** to `1/f`, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay. `filterbuilder` applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Sinc frequency factor

A frequency dilation factor. The sinc frequency factor, C, parameterizes the passband magnitude response for a lowpass design through $H(\omega) = \text{sinc}(C\omega)^{(-P)}$ and for a highpass design through $H(\omega) = \text{sinc}(C(1-\omega))^{(-P)}$.

Sinc power

Negative power of passband magnitude response. The sinc power, P, parameterizes the passband magnitude response for a lowpass design through $H(\omega) = \text{sinc}(C\omega)^{(-P)}$ and for a highpass design through $H(\omega) = \text{sinc}(C(1-\omega))^{(-P)}$.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Lowpass Filter Design Dialog Box — Main Pane

Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

If your **Impulse response** is IIR, you can specify an equal order for the numerator and denominator, or different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

Filter type

This option is only available if you have the DSP System Toolbox. Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterbuilder specifies single-rate filters.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.

- Selecting Sample-rate converter activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if Specify was selected for **Order mode**.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to the one shown in the following figure.

In the figure, regions between specification values such as F_{pass} and F_{stop} represent transition regions where the filter response is not explicitly defined.

Frequency constraints

Select the filter features to use to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- `Passband and stopband edge` — Define the filter by specifying the frequencies for the edge of the stopband and passband.

- `Passband edge` — Define the filter by specifying the frequency for the edge of the passband.

- `Stopband edge` — Define the filter by specifying the frequency for the edges of the stopband.

- `Passband edge and 3dB point` — Define the filter by specifying the passband edge frequency and the 3-dB down point (IIR designs).

- `3dB point and stopband edge` — Define the filter by specifying the 3-dB down point and stopband edge frequency (IIR designs).

- `3dB point` — Define the filter by specifying the frequency for the 3-dB point (IIR designs or maxflat FIR).

- `6dB point` — Define the filter by specifying the frequency for the 6-dB point in the filter response (FIR designs).

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0 1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is

available when you select one of the frequency options from the **Frequency units** list.

Fpass

Enter the frequency at the of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.

- dB — Specify the magnitude in decibels (default)

- Squared — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that filterbuilder uses to implement your filter.

Design Method

> Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow

> Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

> Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).
>
> Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint
> This option only applies when you have the DSP System Toolbox software and when the **Design method** is `equiripple`. Select one of `Linear`, `Minimum`, or `Maximum`.

Minimum order — This option only applies when you have the DSP System Toolbox software and the **Order mode** is `Minimum`.
> Select `Any` (default), `Even`, or `Odd`. Selecting `Even` or `Odd` forces the minimum-order design to be an even or odd order.

Match Exactly
> Specifies that the resulting filter design matches either the passband or stopband when you select `Passband` or `Stopband`.

Stopband Shape
> Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:
>
> - `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
>
> - `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
>
> - `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay
> When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:
>
> - When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
>
> - When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. `filterbuilder` applies that slope to the stopband.

- When you set **Stopband shape** to `1/f`, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay. `filterbuilder` applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Wpass

Passband weight. This option only applies when **Impulse response** is `FIR` and **Order mode** is `Specify`.

Wstop

Stopband weight. This option only applies when **Impulse response** is `FIR` and **Order mode** is `Specify`.

Filter implementation

Structure

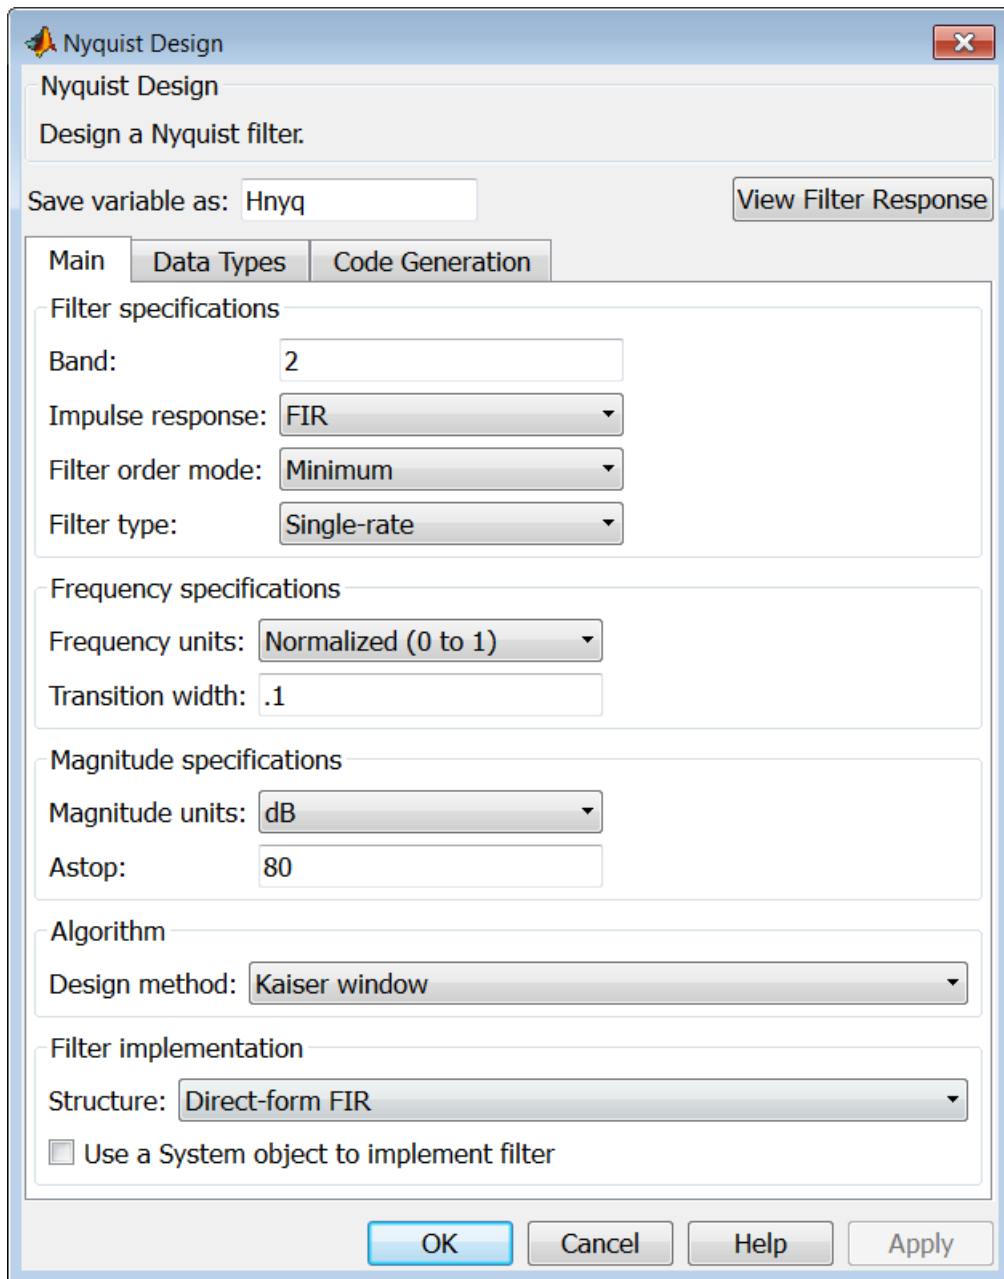
For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Notch

See "Peak/Notch Filter Design Dialog Box — Main Pane" on page 7-767.

Nyquist Filter Design Dialog Box — Main Pane


Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Band

> Specifies the location of the center of the transition region between the passband and the stopband. The center of the transition region, bw, is calculated using the value for Band:
>
> bw = Fs/(2*Band).

Impulse response

> Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.
>
> ---
>
> **Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.
>
> ---

Order mode

> Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

> Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterbuilder specifies single-rate filters.
>
> - Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
>
> - Selecting Sample-rate converter activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.
Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure, BW is the width of the transition region and **Band** determines the location of the center of the region.

Frequency constraints

Select the filter features to use to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- `Passband and stopband edges` — Define the filter by specifying the frequencies for the edges for the stopbands and passbands.

- `Passband edges` — Define the filter by specifying frequencies for the edges of the passband.

- `Stopband edges` — Define the filter by specifying frequencies for the edges of the stopbands.

- `3 dB points` — Define the filter response by specifying the locations of the 3 dB points. The 3 dB point is the frequency for the point 3 dB point below the passband value.

- `3 dB points and passband width` — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the passband.

- `3 dB points and stopband widths` — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the stopband.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0 1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Transition width

Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default)
- Squared — Specify the magnitude in squared units.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that filterbuilder uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Minimum phase

> To design a filter that is minimum phase, select **Minimum phase**. Clearing the **Minimum phase** option removes the phase constraint—the resulting design is not minimum phase.

Minimum order

> When you select this parameter, the design method determines and designs the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select Any, Even, or Odd from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

> ---
> **Note** Generally, **Minimum order** designs are not available for IIR filters.
> ---

Match Exactly

> Specifies that the resulting filter design matches either the passband or stopband or both bands when you select passband or stopband or both from the drop-down list.

Stopband Shape

> Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

> - Flat — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.

> - Linear — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.

> - 1/f — Specifies that the stopband attenuation changes exponentially as the frequency increases, where f is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.

- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. `filterbuilder` applies that slope to the stopband.

- When you set **Stopband shape** to `1/f`, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay. `filterbuilder` applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Octave Filter Design Dialog Box — Main Pane

Filter specifications

Order

Specify filter order. Possible values are: `4, 6, 8, 10`.

Bands per octave

Specify the number of bands per octave. Possible values are: `1, 3, 6, 12, 24`.

Frequency units

Specify frequency units as `Hz` or `kHz`.

Input Fs

Specify the input sampling frequency in the frequency units specified previously.

Center Frequency

Select from the drop-down list of available center frequency values.

Algorithm

Design Method

Butterworth is the design method used for this type of filter.

Scale SOS filter coefficients to reduce chance of overflow

Select the check box to scale the filter coefficients.

Filter implementation

Structure

Specify filter structure. Choose from:

- Direct-form I SOS

- Direct-form II SOS

- Direct-form I transposed SOS

- Direct-form II transposed SOS

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default, the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Parametric Equalizer Filter Design Dialog Box — Main Pane

filterbuilder

Filter specifications

Order mode

Select Minimum to design a minimum order filter that meets the design specifications, or Specify to enter a specific filter order. The order mode also affects the possible frequency constraints, which in turn limit the gain specifications. For example, if you specify a Minimum order filter, the available frequency constraints are:

- Center frequency, bandwidth, passband width

- Center frequency, bandwidth, stopband width

If you select Specify, the available frequency constraints are:

- Center frequency, bandwidth

- Center frequency, quality factor

- Shelf type, cutoff frequency, quality factor

- Shelf type, cutoff frequency, shelf slope parameter

- Low frequency, high frequency

Order

This parameter is enabled only if the **Order mode** is set to Specify. Enter the filter order in this text box.

Frequency specifications

Depending on the filter order, the possible frequency constraints change. Once you choose the frequency constraints, the input boxes in this area change to reflect the selection.

Frequency constraints

Select the specification to represent the frequency constraints. The following options are available:

- Center frequency, bandwidth, passband width (available for minimum order only)

- `Center frequency, bandwidth, stopband width` (available for minimum order only)

- `Center frequency, bandwidth` (available for a specified order only)

- `Center frequency, quality factor` (available for a specified order only)

- `Shelf type, cutoff frequency, quality factor` (available for a specified order only)

- `Shelf type, cutoff frequency, shelf slope parameter` (available for a specified order only)

- `Low frequency, high frequency` (available for a specified order only)

Frequency units

Select the frequency units from the available drop down list (`Normalized, Hz, kHz, MHz, GHz`). If `Normalized` is selected, then the **Input Fs** box is disabled for input.

Input Fs

Enter the input sampling frequency. This input box is disabled for input if `Normalized` is selected in the **Frequency units** input box.

Center frequency

Enter the center frequency in the units specified by the value in **Frequency units**.

Bandwidth

The bandwidth determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Bandwidth gain** in the **Gain specifications** section. By default, the **Bandwidth gain** defaults to `db(sqrt(.5))`, or −3 dB relative to the center frequency. The **Bandwidth** property only applies when the **Frequency constraints** are: `Center frequency, bandwidth, passband width`, `Center frequency, bandwidth, stopband width`, or `Center frequency, bandwidth`.

Passband width

> The passband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Passband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is `Center frequency, bandwidth, passband width`.

Stopband width

> The stopband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Stopband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is `Center frequency, bandwidth, stopband width`.

Low frequency

> Enter the low frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is `Low frequency, high frequency`. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

High frequency

> Enter the high frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is `Low frequency, high frequency`. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

Gain specifications

Depending on the filter order and frequency constraints, the possible gain constraints change. Also, once you choose the gain constraints the input boxes in this area change to reflect the selection.

Gain constraints

> Select the specification array to represent gain constraints, and remember that not all of these options are available for all configurations. The following is a list of all available options:

- Reference, center frequency, bandwidth, passband

- Reference, center frequency, bandwidth, stopband

- Reference, center frequency, bandwidth,passband, stopband

- Reference, center frequency, bandwidth

Gain units

Specify the gain units either dB or squared. These units are used for all gain specifications in the dialog box.

Reference gain

The reference gain determines the level to which the filter magnitude attenuates in **Gain units**. The reference gain is a *floor* gain for the filter magnitude response. For example, you may use the reference gain together with the **Center frequency gain** to leave certain frequencies unattenuated (reference gain of 0 dB) while boosting other frequencies.

Bandwidth gain

Specifies the gain in **Gain units** at which the bandwidth is defined. This property applies only when the **Frequency constraints** specification contains a bandwidth parameter, or is Low frequency, high frequency.

Center frequency gain

Specify the center frequency in **Gain units**

Passband gain

The passband gain determines the level in **Gain units** at which the passband is defined. The passband is determined either by the **Passband width** value, or the **Low frequency** and **High frequency** values in the **Frequency specifications** section.

Stopband gain

The stopband gain is the level in **Gain units** at which the stopband is defined. This property applies only when the **Order mode** is minimum and the **Frequency constaints** are Center frequency, bandwidth, stopband width.

Boost/cut gain

> The boost/cut gain applies only when the designing a shelving filter. Shelving filters include the `Shelf type` parameter in the **Frequency constraints** specification. The gain in the passband of the shelving filter is increased by **Boost/cut gain** dB from a *floor* gain of 0 dB.

Algorithm

Design method

> Select the design method from the drop-down list. Different IIR design methods are available depending on the filter constraints you specify.

Scale SOS filter coefficients to reduce chance of overflow

> Select the check box to scale the filter coefficients.

Filter implementation

Structure

> Select filter structure. The possible choices are:
>
> - Direct-form I SOS
>
> - Direct-form II SOS
>
> - Direct-form I transposed SOS
>
> - Direct-form II transposed SOS

Use a System object to implement filter

> Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Peak/Notch Filter Design Dialog Box — Main Pane

filterbuilder

Filter specifications

In this area you can specify whether you want to design a peaking filter or a notching filter, as well as the order of the filter.

Response
> Select Peak or Notch from the drop-down box.

Order
> Enter the filter order. The order must be even.

Frequency specifications

This group of parameters allows you to specify frequency constraints and units.

Frequency Constraints
> Select the frequency constraints for filter specification. There are two choices as follows:
>
> - Center frequency and quality factor
> - Center frequency and bandwidth

Frequency units
> The frequency units are normalized by default. If you specify units other than normalized, filterbuilder assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: Normalized (0 to 1), Hz, kHz, MHz, GHz.

Input Fs
> This input box is enabled if **Frequency units** other than Normalized (0 to 1) are specified. Enter the input sampling frequency.

Center frequency
> Enter the center frequency in the units you specified in **Frequency units**.

Quality Factor

This input box is enabled only when Center frequency and quality factor is chosen for the **Frequency Constraints**. Enter the quality factor.

Bandwidth

This input box is enabled only when Center frequency and bandwidth is chosen for the **Frequency Constraints**. Enter the bandwidth.

Magnitude specifications

This group of parameters allows you to specify the magnitude constraints, as well as their values and units.

Magnitude Constraints

Depending on the choice of constraints, the other input boxes are enabled or disabled. Select from four magnitude constraints available:

- Unconstrained

- Passband ripple

- Stopband attenuation

- Passband ripple and stopband attenuation

Magnitude units

Select the magnitude units: either dB or squared.

Apass

This input box is enabled if the magnitude constraints selected are Passband ripple or Passband ripple and stopband attenuation. Enter the passband ripple.

Astop

This input box is enabled if the magnitude constraints selected are Stopband attenuation or Passband ripple and stopband attenuation. Enter the stopband attenuation.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

Design Method
> Lists all design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter the methods available to design filters changes as well.

Scale SOS filter coefficients to reduce chance of overflow
> Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Filter implementation

Structure
> Lists all available filter structures for the filter specifications and design method you select. The typical options are:
>
> - Direct-form I SOS
>
> - Direct-form II SOS
>
> - Direct-form I transposed SOS
>
> - Direct-form II transposed SOS

Use a System object to implement filter
> Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Pulse-shaping Filter Design Dialog Box—Main Pane

Filter specifications

Parameters in this group enable you to specify the shape and length of the filter.

Pulse shape

Select the shape of the impulse response from the following options:

- `Raised Cosine`

- `Square Root Raised Cosine`

- `Gaussian`

Order mode

This specification is only available for raised cosine and square root raised cosine filters. For these filters, select one of the following options:

- `Minimum`— This option will result in the minimum-length filter satisfying the user-specified **Frequency specifications**.

- `Specify order`—This option allows the user to construct a raised cosine or square root cosine filter of a specified order by entering an even number in the **Order** input box. The length of the impulse response will be `Order+1` .

- `Specify symbols`—This option enables the user to specify the length of the impulse response in an alternative manner. If `Specify symbols` is chosen, the **Order** input box changes to the **Number of symbols** input box.

Samples per symbol

Specify the oversampling factor. Increasing the oversampling factor guards against aliasing and improves the FIR filter approximation to the ideal frequency response. If **Order** is specified in **Number of symbols**, the filter length will be **Number of symbols*Samples per symbol**+1. The product **Number of symbols*Samples per symbol** must be an even number.

If a Gaussian filter is specified, the filter length must be specified in **Number of symbols** and **Samples per symbol**. The product **Number of symbols*Samples per symbol** must be an even number. The filter length will be **Number of symbols*Samples per symbol**+1.

Filter Type

This option is only available if you have the DSP System Toolbox software. Choose `Single rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. If you select `Decimator` or `Interpolator`, the decimation and interpolation factors default to the value of the **Samples per symbol**. If you select `Sample-rate converter`, the interpolation factor defaults to **Samples per symbol** and the decimation factor defaults to 3.

Frequency specifications

Parameters in this group enable you to specify the frequency response of the filter. For raised cosine and square root raised cosine filters, the frequency specifications include:

Rolloff factor

The rolloff factor takes values in the range [0,1]. The smaller the rolloff factor, the steeper the transition in the stopband.

Frequency units

The frequency units are normalized by default. If you specify units other than normalized, `filterbuilder` assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: `Normalized (0 to 1)`, `Hz`, `kHz`, `MHz`, `GHz`

For a Gaussian pulse shape, the available frequency specifications are:

Bandwidth-time product

This option allows the user to specify the width of the Gaussian filter. Note that this is independent of the length of the filter. The bandwidth-time product (BT) must be a positive real number.

Smaller values of the bandwidth-time product result in larger pulse widths in time and steeper stopband transitions in the frequency response.

Frequency units

The frequency units are normalized by default. If you specify units other than normalized, `filterbuilder` assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: `Normalized (0 to 1)`, `Hz`, `kHz`, `MHz`, `GHz`

Magnitude specifications

If the **Order mode** is specified as `Minimum`, the **Magnitude units** may be selected from:

- `dB`—Specify the magnitude in decibels (default).

- `Linear`—Specify the magnitude in linear units.

Algorithm

The only **Design method** available for FIR pulse-shaping filters is the `Window` method.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Purpose   Store CIC filter states

Description   `filtstates.cic` objects hold the states information for CIC filters. Once you create a CIC filter, the states for the filter are stored in `filtstates.cic` objects, and you can access them and change them as you would any property of the filter. This arrangement parallels that of the `filtstates` object that IIR direct-form I filters use (refer to `filtstates` for more information).

Each `States` property in the CIC filter comprises two properties — `Numerator` and `Comb` — that hold `filtstates.cic` objects. Within the `filtstates.cic` objects are the numerator-related and comb-related filter states. The states are column vectors, where each column represents the states for one section of the filter. For example, a CIC filter with four decimator sections and four interpolator sections has `filtstates.cic` objects that contain four columns of states each.

Examples   To show you the `filtstates.cic` object, create a CIC decimator and filter a signal:

```
fs = 44.1e3;             % Original sampling frequency: 44.1kHz.
n = 0:10239;             % 10240 samples, 0.232 second long signal.
x  = sin(2*pi*1e3/fs*n); % Original signal, sinusoid at 1kHz.
hm=mfilt.cicdecim(5,2,4);
y=filter(hm,x);
```

`hm` has nonzero states now.

You can use `int` to see the states as 32-bit integers.

```
s=hm.states;
int(s.Integrator)
```

See Also   `mfilt` | `mfilt.cicdecim` | `mfilt.cicinterp` | `filtstates`

fircband

Purpose　　　　Constrained-band equiripple FIR filter

Syntax　　　　```
b = fircband(n,f,a,w,c)
b = fircband(n,f,a,s)
b = fircband(...,'1')
b = fircband(...,'minphase')
b = fircband(..., 'check')
b = fircband(...,{lgrid})
[b,err] = fircband(...)
[b,err,res] = fircband(...)
```

**Description**　　`fircband` is a minimax filter design algorithm that you use to design the following types of real FIR filters:

- Types 1-4 linear phase

  - Type 1 is even order, symmetric

  - Type 2 is odd order, symmetric

  - Type 3 is even order, antisymmetric

  - Type 4 is odd order, antisymmetric

- Minimum phase

- Maximum phase

- Minimum order (even or odd), extra ripple

- Maximal ripple

- Constrained ripple

- Single-point band (notching and peaking)

- Forced gain

- Arbitrary shape frequency response curve filters

`b = fircband(n,f,a,w,c)` designs filters having constrained error magnitudes (ripples). `c` is a cell array of strings of the same length as `w`. The entries of `c` must be either 'c' to indicate that the corresponding element in `w` is a constraint (the ripple for that band cannot exceed that

value) or 'w' indicating that the corresponding entry in w is a weight. There must be at least one unconstrained band — c must contain at least one w entry. For instance, Example 1 below uses a weight of one in the passband, and constrains the stopband ripple not to exceed 0.2 (about 14 dB).

A hint about using constrained values: if your constrained filter does not touch the constraints, increase the error weighting you apply to the unconstrained bands.

Notice that, when you work with constrained stopbands, you enter the stopband constraint according to the standard conversion formula for power — the resulting filter attenuation or constraint equals 20*log(*constraint*) where *constraint* is the value you enter in the function. For example, to set 20 dB of attenuation, use a value for the constraint equal to 0.1. This applies to constrained stopbands only.

b = fircband(n,f,a,s) is used to design filters with special properties at certain frequency points. s is a cell array of strings and must be the same length as f and a. Entries of s must be one of:

- 'n' — normal frequency point.

- 's' — single-point band. The frequency band is given by a single point. You must specify the corresponding gain at this frequency point in a.

- 'f' — forced frequency point. Forces the gain at the specified frequency band to be the value specified.

- 'i' — indeterminate frequency point. Use this argument when bands abut one another (no transition region).

b = fircband(...,'1') designs a type 1 filter (even-order symmetric). You could also specify type 2 (odd-order symmetric), type 3 (even-order antisymmetric), or type 4 (odd-order antisymmetric) filters. Note there are restrictions on a at f = 0 or f = 1 for types 2, 3, and 4.

b = fircband(...,'minphase') designs a minimum-phase FIR filter. There is also 'maxphase'.

b = fircband(..., '**check**') produces a warning when there are potential transition-region anomalies in the filter response.

b = fircband(...,{lgrid}), where {lgrid} is a scalar cell array containing an integer, controls the density of the frequency grid.

[b,err] = fircband(...) returns the unweighted approximation error magnitudes. err has one element for each independent approximation error.

[b,err,res] = fircband(...) returns a structure res of optional results computed by fircband, and contains the following fields:

| Structure Field | Contents |
| --- | --- |
| res.fgrid | Vector containing the frequency grid used in the filter design optimization |
| res.des | Desired response on fgrid |
| res.wt | Weights on fgrid |
| res.h | Actual frequency response on the frequency grid |
| res.error | Error at each point (desired response - actual response) on the frequency grid |
| res.iextr | Vector of indices into fgrid of external frequencies |
| res.fextr | Vector of extremely frequencies |
| res.order | Filter order |
| res.edgecheck | Transition-region anomaly check. One element per band edge. Element values have the following meanings: 1 = OK , 0 = probable transition-region anomaly , -1 = edge not checked. Computed when you specify the 'check' input option in the function syntax. |

| Structure Field | Contents |
|---|---|
| res.iterations | Number of Remez iterations for the optimization |
| res.evals | Number of function evaluations for the optimization |

**Examples**  Two examples of designing filters with constrained bands.

### Example 1

design a 12th-order lowpass filter with a constraint on the filter response.

```
b = fircband(12,[0 0.4 0.5 1], [1 1 0 0], ...
[1 0.2], {'w' 'c'});
```

Using fvtool to display the result b shows you the response of the filter you designed.

Magnitude Response (dB)

Example 2

design two filters of different order with the stopband constrained to 60 dB. Use excess order (80) in the second filter to improve the passband ripple.

```
b1=fircband(60,[0 .2 .25 1],[1 1 0 0],...
[1 .001],{'w','c'});
b2=fircband(80,[0 .2 .25 1],[1 1 0 0],...
[1 .001],{'w','c'});
hfvt = fvtool(b1,1,b2,1);
legend(hfvt,'Filter Order 60','Filter Order 80');
```

To set the stopband constraint to 60 dB, enter 0.001, since $20*\log(0.001) = -60$, or 60 dB of signal attenuation.

See Also   firceqrip | firgr | firls | firpm

fireqint

Purpose
Equiripple FIR interpolators

Syntax
```
b = fireqint(n,l,alpha)
b = fireqint(n,l,alpha,w)
b = fireqint('minorder',l,alpha,r)
b = fireqint({'minorder',initord},l,alpha,r)
```

Description
`b = fireqint(n,l,alpha)` designs an FIR equiripple filter useful for interpolating input signals. `n` is the filter order and it must be an integer. `l`, also an integer, is the interpolation factor. `alpha` is the bandlimitedness factor, identical to the same feature in `intfilt`.

`alpha` is inversely proportional to the transition bandwidth of the filter. It also affects the bandwith of the don't-care regions in the stopband. Specifying `alpha` allows you to control how much of the Nyquist interval your input signal occupies. This can be beneficial for signals to be interpolated because it allows you to increase the transition band width without affecting the interpolation, resulting in better stopband attenuation for a given `l`. If you set `alpha` to 1, `fireqint` assumes that your signal occupies the entire Nyquist interval. Setting `alpha` to a value less than one allows for don't-care regions in the stopband. For example, if your input occupies half the Nyquist interval, you could set `alpha` to 0.5.

The signal to be interpolated is assumed to have zero (or negligible) power in the frequency band between ($alpha*\pi$) and π. `alpha` must therefore be a positive scalar between 0 and 1. `fireqint` treat such bands as don't-care regions for assessing filter design.

`b = fireqint(n,l,alpha,w)` allows you to specify a vector of weights in `w`. The number of weights required in `w` is given by `1 + floor(l/2)`. The weights in `w` are applied to the passband ripple and stopband attenuations. Using weights (values between 0 and 1) enables you to specify different attenuations in different parts of the stopband, as well as providing the ability to adjust the compromise between passband ripple and stopband attenuation.

`b = fireqint('minorder',l,alpha,r)` allows you to design a minimum-order filter that meets the design specifications. `r` is a vector

of maximum deviations or ripples from the ideal filter magnitude response. When you use the input argument **minorder**, you must provide the vector r. The number of elements required in r is given by $1 + \texttt{floor(l/2)}$.

b = fireqint({'**minorder**',initord},l,alpha,r) adds the argument initord so you can provide an initial estimate of the filter order. Any positive integer is valid here. Again, you must provide r, the vector of maximum deviations or ripples, from the ideal filter magnitude response.

Examples   Design a minimum order interpolation filter for l = 6 and alpha = 0.8. A vector of ripples must be supplied with the input argument **minorder**.

```
b = fireqint('minorder',6,.8,[0.01 .1 .05 .02]);
hm = mfilt.firinterp(6,b); % Create a polyphase interpolator filter
zerophase(hm);
```

Here is the resulting plot of the zerophase response for hm.

For hm, the minimum order filter with the requested design specifications, here is the filter information.

```
hm =
FilterStructure: 'Direct-Form FIR Polyphase Interpolator'
        Arithmetic: 'double'
         Numerator: [1x70 double]
InterpolationFactor: 6
  PersistentMemory: false
```

Purpose   Constrained equiripple FIR filter

Syntax
```
B = firceqrip(n,Fo,DEV)
B = firceqrip(...,'slope',r)
B = firceqrip(...,'passedge')
B = firceqrip(...,'stopedge')
B = firceqrip(...,'high')
B = firceqrip(...,'min')
B = firceqrip(...,'invsinc',C)
B = firceqrip(...,'invdiric',C)
```

Description   `B = firceqrip(n,Fo,DEV)` designs an order n filter (filter length equal n + 1) lowpass FIR filter with linear phase.

`firceqrip` produces the same equiripple lowpass filters that `firpm` produces using the Parks-McClellan algorithm. The difference is how you specify the filter characteristics for the function.

The input argument `Fo` specifies the frequency at the upper edge of the passband in normalized frequency (0<Fo<1). The two-element vector `dev` specifies the peak or maximum error allowed in the passband and stopbands. Enter `[d1 d2]` for `dev` where `d1` sets the passband error and `d2` sets the stopband error.

`B = firceqrip(...,'slope',r)` uses the input keyword `'slope'` and input argument `r` to design a filter with a nonequiripple stopband. `r` is specified as a positive constant and determines the slope of the stopband attenuation in dB/normalized frequency. Greater values of `r` result in increased stopband attenuation in dB/normalized frequency.

`B = firceqrip(...,'passedge')` designs a filter where `Fo` specifies the frequency at which the passband starts to rolloff.

`B = firceqrip(...,'stopedge')` designs a filter where `Fo` specifies the frequency at which the stopband begins.

`B = firceqrip(...,'high')` designs a high pass FIR filter instead of a lowpass filter.

`B = firceqrip(...,'min')` designs a minimum-phase filter.

B = firceqrip(...,'invsinc',C) designs a lowpass filter whose magnitude response has the shape of an inverse sinc function. This may be used to compensate for sinc-like responses in the frequency domain such as the effect of the zero-order hold in a D/A converter. The amount of compensation in the passband is controlled by C, which is specified as a scalar or two-element vector. The elements of C are specified as follows:

- If C is supplied as a real-valued scalar or the first element of a two-element vector, firceqrip constructs a filter with a magnitude response of 1/sinc(C*pi*F) where F is the normalized frequency.

- If C is supplied as a two-element vector, the inverse-sinc shaped magnitude response is raised to the positive power C(2). If we set P=C(2), firceqrip constructs a filter with a magnitude response 1/sinc(C*pi*F)^P.

If this FIR filter is used with a cascaded integrator-comb (CIC) filter, setting C(2) equal to the number of stages compensates for the multiplicative effect of the successive sinc-like responses of the CIC filters.

Note Since the value of the inverse sinc function becomes unbounded at C=1/F, the value of C should be greater the reciprocal of the passband edge frequency. This can be expressed as Fo<1/C. For users familar with CIC decimators, C is equal to 1/2 the product of the differential delay and decimation factor.

B = firceqrip(...,'invdiric',C) designs a lowpass filter with a passband that has the shape of an inverse Dirichlet sinc function. The frequency response of the inverse Dirichlet sinc function is given by

$$\{rC(\frac{\sin(f/2r)}{\sin(Cf/2)}\}^p$$

where *C*, *r*, and *p* are scalars. The input C can be a scalar or vector containing 2 or 3 elements. If C is a scalar, p and r equal 1. If C is a two-element vector, the first element is C and the second element is p, [C p]. If C is a three-element vector, the third element is r, [C p r].

Examples   To introduce a few of the variations on FIR filters that you design with firceqrip, these five examples cover both the default syntax b = firceqrip(n,wo,del) and some of the optional input arguments. For each example, the input arguments n, wo, and del remain the same.

Example 1

Design an order = 30 FIR filter.

```
b = firceqrip(30,0.4,[0.05 0.03]); fvtool(h)
```

When the plot appears in the Filter Visualization Tool window, select **Analysis > Overlay Analysis > Phase Response**. Then select **View > Full View**. This displays the following plot.

Example 2

Design an order = 30 FIR filter with the stopedge keyword to define the response at the edge of the filter stopband.

```
b = firceqrip(30,0.4,[0.05 0.03],'stopedge'); fvtool(h)
```

Example 3

Design an order = 30 FIR filter with the slope keyword and r = 20.

```
b = firceqrip(30,0.4,[0.05 0.03],'slope',20,'stopedge'); fvtool(h)
```

Example 4

Design an order = 30 FIR filter defining the stopband and specifying that the resulting filter is minimum phase with the **min** keyword.

```
b = firceqrip(30,0.4,[0.05 0.03],'stopedge','min'); fvtool(h)
```

Comparing this filter to the filter in Example 1, the cutoff frequency wo = 0.4 now applies to the edge of the stopband rather than the point at which the frequency response magnitude is 0.5.

Viewing the zero-pole plot shown here reveals this is a minimum phase FIR filter — the zeros lie on or inside the unit circle, z = 1.

Pole/Zero Plot

Example 5

Design an order = 30 FIR filter with the invsinc keyword to shape the filter passband with an inverse sinc function.

```
b = firceqrip(30,0.4,[0.05 0.03],'invsinc',[2 1.5]); fvtool(h)
```

With the inverse sinc function being applied defined as $1/\text{sinc}(2\text{*w})^{1.5}$, the figure shows the reshaping of the passband that results from using the **invsinc** keyword option, and entering c as the two-element vector [2 1.5].

Inverse-Dirichlet-Sinc–Shaped Passband

Design two order 30 constrained equiripple FIR filters with inverse-Dirichlet-sinc-shaped passbands. The cutoff frequency in both designs is π/4 radians/sample. Set C=1 in one design C=2 in the second design. The maximum passband and stopband ripple is 0.05. Set p=1 in one design and p=2 in the second design.

Design the filters.

```
b1 = firceqrip(30,0.25,[0.05 0.05],'invdiric',[1 1]);
b2 = firceqrip(30,0.25,[0.05 0.05],'invdiric',[2 2]);
```

Obtain the filter frequency responses using freqz. Plot the magnitude responses.

```
[h1,~] = freqz(b1,1);
[h2,w] = freqz(b2,1);
plot(w,abs(h1)); hold on;
plot(w,abs(h2),'r');
axis([0 pi 0 1.5]);
xlabel('Radians/sample');
```

```
ylabel('Magnitude');
legend('C=1 p=1','C=2 p=2');
```

Inspect the stopband ripple in the design with C=1 and p=1. The constrained design sets the maximum ripple to be 0.05. Zoom in on the stopband from the cutoff frequency of π/4 radians/sample to 3π/4 radians/sample.

```
figure;
plot(w,abs(h1));
set(gca,'xlim',[pi/4 3*pi/4]);
grid on;
```

fircls

Purpose   FIR Constrained Least Squares filter

Syntax
```
hd = design(d,'fircls')
hd = design(d,'fircls','FilterStructure',value)
hd = design(d,'fircls','PassbandOffset',value)
hd = design(d,'fircls','zerophase',value)
```

Description `hd = design(d,'fircls')` designs a FIR Constrained Least Squares (CLS) filter, `hd`, from a filter specifications object, `d`.

`hd = design(d,'fircls','FilterStructure',value)` where `value` is one of the following filter structures:

- `'dffir'`, a discrete-time, direct-form FIR filter (the default value)

- `'dffirt'`, a discrete-time, direct-form FIR transposed filter

- `'dfsymfir'`, a discrete-time, direct-form symmetric FIR filter

- `'fftfir'`, a discrete-time, overlap-add, FIR filter

`hd = design(d,'fircls','PassbandOffset',value)` where `value` sets the passband band gain in dB. The `PassbandOffset` and `Ap` values affect the upper and lower approximation bound in the passband as follows:

- Lower bound = (`PassbandOffset`-Ap/2)

- Upper bound = (`PassbandOffset`+A/2)

For bandstop filters, the `PassbandOffset` is a vector of length two that specifies the first and second passband gains. The `PassbandOffset` value defaults to 0 for lowpass, highpass and bandpass filters. The `PassbandOffset` value defaults to [0 0] for bandstop filters.

`hd = design(d,'fircls','zerophase',value)` where `value` is either `'true'` ('1') or `'false'` ('0') . If `zerophase` is true, the lower approximation bound in the stopband is forced to zero (i.e., the filter has a zero phase response). Zerophase is false (0) by default.

To determine the available design options, use designopts with the
specification object and the design method as input arguments as
shown.

```
designopts(d,'fircls')
```

For complete help about using fircls, refer to the command line help
system. For example, to get specific information about using fircls
with d, the specification object, enter the following at the MATLAB
prompt.

```
help(d,'fircls')
```

Examples

The following example designs a constrained least-squares FIR lowpass
filter.

```
h  = fdesign.lowpass('n,fc,ap,ast', 50, 0.3, 2, 30);
Hd = design(h, 'fircls');
fvtool(Hd)
```

The following example constructs a constrained least-squares FIR
bandpass filter.

```
d = fdesign.bandpass('N,Fc1,Fc2,Ast1,Ap,Ast2',...
```

```
30,0.4,0.6,60,1,60);
Hd = design(d, 'fircls');
fvtool(Hd)
```

Purpose	Parks-McClellan FIR filter

Syntax
```
b = firgr(n,f,a,w)
b = firgr(n,f,a,'hilbert')
b = firgr(m,f,a,r),
b = firgr({m,ni},f,a,r)
b = firgr(n,f,a,w,e)
b = firgr(n,f,a,s)
b = firgr(n,f,a,s,w,e)
b = firgr(...,'1')
b = firgr(...,'minphase')
b = firgr(..., 'check')
b = firgr(...,{lgrid}),
[b,err] = firgr(...)
[b,err,res] = firgr(...)
b = firgr(n,f,fresp,w)
b = firgr(n,f,{fresp,p1,p2,...},w)
b = firgr(n,f,a,w)
```

Description   firgr is a minimax filter design algorithm you use to design the following types of real FIR filters:

- Types 1-4 linear phase:

  - Type 1 is even order, symmetric

  - Type 2 is odd order, symmetric

  - Type 3 is even order, antisymmetric

  - Type 4 is odd order, antisymmetric

- Minimum phase

- Maximum phase

- Minimum order (even or odd)

- Extra ripple

- Maximal ripple

- Constrained ripple

- Single-point band (notching and peaking)

- Forced gain

- Arbitrary shape frequency response curve filters

`b = firgr(n,f,a,w)` returns a length n+1 linear phase FIR filter which has the best approximation to the desired frequency response described by `f` and `a` in the minimax sense. `w` is a vector of weights, one per band. When you omit `w`, all bands are weighted equally. For more information on the input arguments, refer to `firpm` in *Signal Processing Toolbox User's Guide*.

`b = firgr(n,f,a,'hilbert')` and `b = firgr(n,f,a,'differentiator')` design FIR Hilbert transformers and differentiators. For more information on designing these filters, refer to `firpm` in *Signal Processing Toolbox User's Guide*.

`b = firgr(m,f,a,r)`, where m is one of 'minorder', 'mineven' or 'minodd', designs filters repeatedly until the minimum order filter, as specified in `m`, that meets the specifications is found. `r` is a vector containing the peak ripple per frequency band. You must specify `r`. When you specify 'mineven' or 'minodd', the minimum even or odd order filter is found.

`b = firgr({m,ni},f,a,r)` where m is one of 'minorder', 'mineven' or 'minodd', uses `ni` as the initial estimate of the filter order. `ni` is optional for common filter designs, but it must be specified for designs in which `firpmord` cannot be used, such as while designing differentiators or Hilbert transformers.

`b = firgr(n,f,a,w,e)` specifies independent approximation errors for different bands. Use this syntax to design extra ripple or maximal ripple filters. These filters have interesting properties such as having the minimum transition width. `e` is a cell array of strings specifying the approximation errors to use. Its length must equal the number of bands. Entries of `e` must be in the form 'e#' where # indicates which approximation error to use for the corresponding band. For example, when `e = {'e1','e2','e1'}`, the first and third bands use the same

approximation error `'e1'` and the second band uses a different one `'e2'`. Note that when all bands use the same approximation error, such as `{'e1','e1','e1',...}`, it is equivalent to omitting e, as in `b = firgr(n,f,a,w)`.

`b = firgr(n,f,a,s)` is used to design filters with special properties at certain frequency points. `s` is a cell array of strings and must be the same length as `f` and `a`. Entries of `s` must be one of:

- `'n'` — normal frequency point.

- `'s'` — single-point band. The frequency "band" is given by a single point. The corresponding gain at this frequency point must be specified in `a`.

- `'f'` — forced frequency point. Forces the gain at the specified frequency band to be the value specified.

- `'i'` — indeterminate frequency point. Use this argument when adjacent bands abut one another (no transition region).

For example, the following command designs a bandstop filter with zero-valued single-point stop bands (notches) at 0.25 and 0.55.

```
b = firgr(42,[0 0.2 0.25 0.3 0.5 0.55 0.6 1],...
[1 1 0 1 1 0 1 1],{'n' 'n' 's' 'n' 'n' 's' 'n' 'n'})
```

`b = firgr(82,[0 0.055 0.06 0.1 0.15 1],[0 0 0 0 1 1],...{'n' 'i' 'f' 'n' 'n' 'n'})` designs a highpass filter with the gain at 0.06 forced to be zero. The band edge at 0.055 is indeterminate since the first two bands actually touch. The other band edges are normal.

`b = firgr(n,f,a,s,w,e)` specifies weights and independent approximation errors for filters with special properties. The weights and properties are included in vectors `w` and `e`. Sometimes, you may need to use independent approximation errors to get designs with forced values to converge. For example,

```
b = firgr(82,[0 0.055 0.06 0.1 0.15 1], [0 0 0 0 1 1],...
{'n' 'i' 'f' 'n' 'n' 'n'}, [10 1 1] ,{'e1' 'e2' 'e3'});
```

`b = firgr(...,'1')` designs a type 1 filter (even-order symmetric). You can specify type 2 (odd-order symmetric), type 3 (even-order antisymmetric), and type 4 (odd-order antisymmetric) filters as well. Note that restrictions apply to a at f = 0 or f = 1 for FIR filter types 2, 3, and 4.

`b = firgr(...,'minphase')` designs a minimum-phase FIR filter. You can use the argument `'maxphase'` to design a maximum phase FIR filter.

`b = firgr(..., 'check')` returns a warning when there are potential transition-region anomalies.

`b = firgr(...,{lgrid})`, where {lgrid} is a scalar cell array. The value of the scalar controls the density of the frequency grid by setting the number of samples used along the frequency axis.

`[b,err] = firgr(...)` returns the unweighted approximation error magnitudes. `err` contains one element for each independent approximation error returned by the function.

`[b,err,res] = firgr(...)` returns the structure `res` comprising optional results computed by `firgr`. `res` contains the following fields.

Structure Field	Contents
res.fgrid	Vector containing the frequency grid used in the filter design optimization
res.des	Desired response on fgrid
res.wt	Weights on fgrid
res.h	Actual frequency response on the frequency grid
res.error	Error at each point (desired response - actual response) on the frequency grid
res.iextr	Vector of indices into fgrid of external frequencies
res.fextr	Vector of external frequencies

Structure Field	Contents
res.order	Filter order
res.edgecheck	Transition-region anomaly check. One element per band edge. Element values have the following meanings: 1 = OK, 0 = probable transition-region anomaly, -1 = edge not checked. Computed when you specify the 'check' input option in the function syntax.
res.iterations	Number of s iterations for the optimization
res.evals	Number of function evaluations for the optimization

firgr is also a "function function," allowing you to write a function that defines the desired frequency response.

b = firgr(n,f,fresp,w) returns a length N + 1 FIR filter which has the best approximation to the desired frequency response as returned by the user-defined function fresp. Use the following firgr syntax to call fresp:

[dh,dw] = fresp(n,f,gf,w)

where:

- fresp is the string variable that identifies the function that you use to define your desired filter frequency response.

- n is the filter order.

- f is the vector of frequency band edges which must appear monotonically between 0 and 1, where 1 is one-half of the sampling frequency. The frequency bands span f(k) to f(k+1) for k odd. The intervals f(k+1) to f(k+2) for k odd are "transition bands" or "don't care" regions during optimization.

firgr

- gf is a vector of grid points that have been chosen over each specified frequency band by firgr, and determines the frequencies at which firgr evaluates the response function.

- w is a vector of real, positive weights, one per band, for use during optimization. w is optional in the call to firgr. If you do not specify w, it is set to unity weighting before being passed to fresp.

- dh and dw are the desired frequency response and optimization weight vectors, evaluated at each frequency in grid gf.

firgr includes a predefined frequency response function named 'firpmfrf2'. You can write your own based on the simpler 'firpmfrf'. See the help for private/firpmfrf for more information.

b = firgr(n,f,{*fresp*,p1,p2,...},w) specifies optional arguments p1, p2,..., pn to be passed to the response function fresp.

b = firgr(n,f,a,w) is a synonym for b = firgr(n,f,{'firpmfrf2',a},w), where a is a vector containing your specified response amplitudes at each band edge in f. By default, firgr designs symmetric (even) FIR filters. 'firpmfrf2' is the predefined frequency response function. If you do not specify your own frequency response function (the fresp string variable), firgr uses 'firpmfrf2'.

b = firgr(...,'h') and b = firgr(...,'d') design antisymmetric (odd) filters. When you omit the 'h' or 'd' arguments from the firgr command syntax, each frequency response function fresp can tell firgr to design either an even or odd filter. Use the command syntax sym = *fresp*('defaults',{n,f,[],w,p1,p2,...}).

firgr expects fresp to return sym = 'even' or sym = 'odd'. If fresp does not support this call, firgr assumes even symmetry.

For more information about the input arguments to firgr, refer to firpm.

Examples These examples demonstrate some filters you might design using firgr.

Example 1

design an FIR filter with two single-band notches at 0.25 and 0.55

```
b1 = firgr(42,[0 0.2 0.25 0.3 0.5 0.55 0.6 1],[1 1 0 1 1 0 1 1],...
{'n' 'n' 's' 'n' 'n' 's' 'n' 'n'});
```

Example 2

design a highpass filter whose gain at 0.06 is forced to be zero. The gain at 0.055 is indeterminate since it should abut the band.

```
b2 = firgr(82,[0 0.055 0.06 0.1 0.15 1],[0 0 0 0 1 1],...
{'n' 'i' 'f' 'n' 'n' 'n'});
```

Example 3

design a second highpass filter with forced values and independent approximation errors.

```
b3 = firgr(82,[0 0.055 0.06 0.1 0.15 1], [0 0 0 0 1 1], ...
{'n' 'i' 'f' 'n' 'n' 'n'}, [10 1 1] ,{'e1' 'e2' 'e3'});
```

Use the filter visualization tool to view the results of the filters created in these examples.

```
fvtool(b1,1,b2,1,b3,1)
```

Here is the figure from FVTool.

Magnitude Response (dB)

Purpose   Halfband FIR filter

Syntax   b = firhalfband(n,fp)
                   b = firhalfband(n,win)
                   b = firhalfband(n,dev,'**dev**')
                   b = firhalfband('**minorder**',fp,dev)
                   b = firhalfband('**minorder**',fp,dev,'**kaiser**')
                   b = firhalfband(...,'**high**')
                   b = firhalfband(...,'**minphase**')

Description   b = firhalfband(n,fp) designs a lowpass halfband FIR filter of order
                   n with an equiripple characteristic. n must be an even integer. fp
                   determines the passband edge frequency, and it must satisfy $0 < fp <$
                   $1/2$, where $1/2$ corresponds to $\pi/2$ rad/sample.

                   b = firhalfband(n,win) designs a lowpass Nth-order filter using the
                   truncated, windowed-impulse response method instead of the equiripple
                   method. win is an n+1 length vector. The ideal impulse response is
                   truncated to length n + 1, and then multiplied point-by-point with the
                   window specified in win.

                   b = firhalfband(n,dev,'**dev**') designs an Nth-order lowpass
                   halfband filter with an equiripple characteristic. Input argument dev
                   sets the value for the maximum passband and stopband ripple allowed.

                   b = firhalfband('**minorder**',fp,dev) designs a lowpass
                   minimum-order filter, with passband edge fp. The peak ripple is
                   constrained by the scalar dev. This design uses the equiripple method.

                   b = firhalfband('**minorder**',fp,dev,'**kaiser**') designs a lowpass
                   minimum-order filter, with passband edge fp. The peak ripple is
                   constrained by the scalar dev. This design uses the Kaiser window
                   method.

                   b = firhalfband(...,'**high**') returns a highpass halfband FIR filter.

                   b = firhalfband(...,'**minphase**') designs a minimum-phase FIR
                   filter such that the filter is a spectral factor of a halfband filter
                   (recall that h = conv(b,fliplr(b)) is a halfband filter). This can
                   be useful for designing perfect reconstruction, two-channel FIR filter

banks. The **minphase** option for `firhalfband` is not available for the window-based halfband filter designs — `b = firhalfband(n,win)` and `b = firhalfband('`**minorder** `',fp,dev,'`**kaiser**`')`.

In the minimum phase cases, the filter order must be odd.

Examples

This example designs a minimum order halfband filter with specified maximum ripple:

```
b = firhalfband('minorder',.45,0.0001);
h = dfilt.dfsymfir(b);
impz(b) % Impulse response is zero for every other sample
```

The next example designs a halfband filter with specified maximum ripple of 0.0001 dB in the pass and stop bands.

```
b = firhalfband(98,0.0001,'dev');
h = mfilt.firdecim(2,b); % Create a polyphase decimator
freqz(h); % 80 dB attenuation in the stopband
```

firlp2lp

Purpose	Convert FIR Type I lowpass to FIR Type 1 lowpass with inverse bandwidth
Syntax	`g = firlp2lp(b)`
Description	`g = firlp2lp(b)` transforms the Type I lowpass FIR filter `b` with zero-phase response Hr(w) to a Type I lowpass FIR filter `g` with zero-phase response [1 - Hr(π-w)].
	When `b` is a narrowband filter, `g` will be a wideband filter and vice versa. The passband and stopband ripples of `g` will be equal to the stopband and passband ripples of `b`.
Examples	Overlay the original narrowband lowpass and the resulting wideband lowpass

```
b = firgr(36,[0 .2 .25 1],[1 1 0 0],[1 5]);
zerophase(b);
hold on
h = firlp2lp(b);
zerophase(h);
```

References	Saramaki, T, Finite Impulse Response Filter Design, *Handbook for Digital Signal Processing*. S.K. Mitra and J.F. Kaiser Eds. Wiley-Interscience, N.Y., 1993, Chapter 4.
See Also	`firlp2hp` | `zerophase`

Purpose	Convert FIR lowpass filter to Type I FIR highpass filter
Syntax	`g = firlp2hp(b)`
	`g = firlp2hp(b,'narrow')`
	`g = firlp2hp(b,'wide')`

Description   `g = firlp2hp(b)` transforms the lowpass FIR filter `b` into a Type I highpass FIR filter `g` with zero-phase response Hr(π-w). Filter `b` can be any FIR filter, including a nonlinear-phase filter.

The passband and stopband ripples of `g` will be equal to the passband and stopband ripples of `b`.

`g = firlp2hp(b,'narrow')` transforms the lowpass FIR filter `b` into a Type I narrow band highpass FIR filter `g` with zero-phase response Hr(π-w). `b` can be any FIR filter, including a nonlinear-phase filter.

`g = firlp2hp(b,'wide')` transforms the Type I lowpass FIR filter `b` with zero-phase response Hr(w) into a Type I wide band highpass FIR filter `g` with zero-phase response 1 - Hr(w). Note the restriction that b must be a Type I linear-phase filter.

For this case, the passband and stopband ripples of `g` will be equal to the stopband and passband ripples of `b`.

Examples   Overlay the original narrowband lowpass (the prototype filter) and the post-conversion narrowband highpass and wideband highpass filters to compare and assess the conversion. The following plot shows the results.

```
b = firgr(36,[0 .2 .25 1],[1 1 0 0],[1 3]);
h = firlp2hp(b);
hfvt = fvtool(b,1,h,1);
legend(hfvt,'Prototype Lowpass','Narrowband Highpass');
```

Purpose   Least P-norm optimal FIR filter

Syntax   b = firlpnorm(n,f,edges,a)
                    b = firlpnorm(n,f,edges,a,w)
                    b = firlpnorm(n,f,edges,a,w,p)
                    b = firlpnorm(n,f,edges,a,w,p,dens)
                    b = firlpnorm(n,f,edges,a,w,p,dens,initnum)
                    b = firlpnorm(...,'minphase')
                    [b,err] = firlpnorm(...)

Description   b = firlpnorm(n,f,edges,a) returns a filter of numerator order n
                    which represents the best approximation to the frequency response
                    described by f and a in the least-Pth norm sense. P is set to 128 by
                    default, which essentially equivalent to the infinity norm. Vector edges
                    specifies the band-edge frequencies for multiband designs. firlpnorm
                    uses an unconstrained quasi-Newton algorithm to design the specified
                    filter.

                    f and a must have the same number of elements, which can exceed the
                    number of elements in edges. This lets you specify filters with any gain
                    contour within each band. However, the frequencies in edges must also
                    be in vector f. Always use freqz to check the resulting filter.

                    Note firlpnorm uses a nonlinear optimization routine that may not
                    converge in some filter design cases. Furthermore the algorithm is not
                    well-suited for certain large-order (order > 100) filter designs.

                    ---

                    b = firlpnorm(n,f,edges,a,w) uses the weights in w to weight the
                    error. w has one entry per frequency point (the same length as f and
                    a) which tells firlpnorm how much emphasis to put on minimizing
                    the error in the vicinity of each frequency point relative to the other
                    points. For example,

                    b = firlpnorm(20,[0 .15 .4 .5 1],[0 .4 .5 1],...
                    [1 1.6 1 0 0],[1 1 1 10 10])

firlpnorm

designs a lowpass filter with a peak of 1.6 within the passband, and with emphasis placed on minimizing the error in the stopband.

`b = firlpnorm(n,f,edges,a,w,p)` where `p` is a two-element vector `[pmin pmax]` lets you specify the minimum and maximum values of `p` used in the least-pth algorithm. Default is `[2 128]` which essentially yields the L-infinity, or Chebyshev, norm. `pmin` and `pmax` should be even numbers. The design algorithm starts optimizing the filter with `pmin` and moves toward an optimal filter in the `pmax` sense. When `p` is the string '**inspect**', `firlpnorm` does not optimize the resulting filter. You might use this feature to inspect the initial zero placement.

`b = firlpnorm(n,f,edges,a,w,p,dens)` specifies the grid density `dens` used in the optimization. The number of grid points is `[dens*(n+1)]`. The default is 20. You can specify `dens` as a single-element cell array. The grid is equally spaced.

`b = firlpnorm(n,f,edges,a,w,p,dens,initnum)` lets you determine the initial estimate of the filter numerator coefficients in vector `initnum`. This can prove helpful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initnum`.

`b = firlpnorm(...,'minphase')` where string 'minphase' is the last argument in the argument list generates a minimum-phase FIR filter. By default, `firlpnorm` design mixed-phase filters. Specifying input option 'minphase' causes `firlpnorm` to use a different optimization method to design the minimum-phase filter. As a result of the different optimization used, the minimum-phase filter can yield slightly different results.

`[b,err] = firlpnorm(...)` returns the least-pth approximation error `err`.

Examples   To demonstrate `firlpnorm`, here are two examples — the first designs a lowpass filter and the second a highpass, minimum-phase filter.

```
% Lowpass filter with a peak of 1.4 in the passband.
b = firlpnorm(22,[0 .15 .4 .5 1],[0 .4 .5 1],[1 1.4 1 0 0],...
```

```
[1 1 1 2 2]);
fvtool(b)
```

From the figure you see the resulting filter is lowpass, with the desired 1.4 peak in the passband (notice the 1.4 specified in vector a).

Now for the minimum-phase filter.

```
% Highpass minimum-phase filter optimized for the 4-norm.
b = firlpnorm(44,[0 .4 .45 1],[0 .4 .45 1],[0 0 1 1],[5 1 1 1],...
[2 4],'minphase');
fvtool(b)
```

As shown in the next figure, this is a minimum-phase, highpass filter.

firlpnorm

The next zero-pole plot shows the minimum phase nature more clearly.

Zero–Pole Plot of Minimum Phase FIR Filter

Purpose　　　Least-square linear-phase FIR filter design

Syntax　　　```
b = firls(n,f,a)
b = firls(n,f,a,w)
b = firls(n,f,a,ftype)
b = firls(n,f,a,w,ftype)
```
Description　　　`b = firls(n,f,a)` returns row vector `b` containing the n+1 coefficients of the order n FIR filter. This filter has frequency-amplitude characteristics approximately matching those given by vectors, `f` and `a`.

`b = firls(n,f,a,w)` uses the weights in vector `w`, to weigh the error.

`b = firls(n,f,a,ftype)` specifies a filter type where `ftype` is:

- `'hilbert'`

- `'differentiator'`

`b = firls(n,f,a,w,ftype)` uses the weights in vector `w` to weigh the error. It also specifies a filter type where `ftype` is:

- `'hilbert'`

- `'differentiator'`

Input Arguments

n - Filter order

(default) | integer scalar

Order of the filter, specified as an integer scalar. For odd orders, the frequency response at the Nyquist frequency is necessarily 0. For this reason, `firls` always uses an even filter order for configurations with a passband at the Nyquist frequency. If you specify an odd-valued n, `firls` increments it by 1.

Example: 8

Data Types
int8 | int16 | int32 | int64
Complex Number Support: No

f - Pairs of frequency points
vector of numeric values

Pairs of frequency points, specified as a vector of values ranging between 0 and 1, where 1 corresponds to the Nyquist frequency. The frequencies must be in increasing order, and duplicate frequency points are allowed. You can use duplicate frequency points to design filters exactly like those returned by the fir1 and fir2 functions with a rectangular (rectwin) window.

f and a are the same length. This length must be an even number.

Example: [0 0.3 0.4 1]

Data Types
double | single
Complex Number Support: No

a - Amplitude values
vector of numeric values

Amplitude values of the function at each frequency point, specified as a vector of the same length as f. This length must be an even number.

The desired amplitude at frequencies between pairs of points (*f*(*k*), *f*(*k*+1)) for *k* odd, is the line segment connecting the points (*f*(*k*), *a*(*k*)) and (*f*(*k*+1), *a*(*k*+1)).

The desired amplitude at frequencies between pairs of points (*f*(*k*), *f*(*k*+1)) for *k* even is unspecified. These are transition or "don't care" regions.

Example: [1 1 0 0]

Data Types
double | single
Complex Number Support: No

w - Weights
vector of numeric values

Weights to weigh the fit for each frequency band, specified as a vector of length half the length of f and a, so there is exactly one weight per band. w indicates how much emphasis to put on minimizing the integral squared error in each band, relative to the other bands.

Example: [0.5 1]

Data Types
double | single
Complex Number Support: No

ftype - Filter type
'hilbert' and 'differentiator'

Filter type, specified as either `hilbert' or `differentiator'.

Example: 'hilbert'

Data Types
char

Output Arguments

b - Filter coefficients
vector of numeric values

Filter coefficients, returned as a numeric vector of n+1 values, where n is the filter order.

b = firls(n,f,a) designs a linear-phase filter of type I (n odd) and type II (n) . The output coefficients, or "taps," in b obey the relation:

$$b(k) = b(n+2-k), k = 1, \ldots , n + 1$$

b = firls(n,f,a,'hilbert') designs a linear-phase filter with odd symmetry (type III and type IV). The output coefficients, or "taps," in b obey the relation:

firls

$$b(k) = -b(n+2\text{-}k), \ k = 1, \ ... \ , \ n + 1$$

`b = firls(n,f,a,'differentiator')` designs type III and type IV filters, using a special weighting technique. For nonzero amplitude bands, the integrated squared error has a weight of $(1/f)^2$. This weighting causes the error at low frequencies to be much smaller than at high frequencies. For FIR differentiators, which have an amplitude characteristic proportional to frequency, the filters minimize the relative integrated squared error. This value is the integral of the square of the ratio of the error to the desired amplitude.

Examples

Design a Lowpass Filter with Transition Band

The following illustrates how to design a lowpass filter of order 225 with transition band.

Create the frequency and amplitude vectors, `f` and `a`.

```
f = [0 0.25 0.3 1]
a = [1 1 0 0]
```

Use `firls` to obtain the `n+1` coefficients of the order `n` lowpass FIR filter.

```
b = firls(255,f,a);
```

Design an Antisymmetric Filter with Piecewise Linear Passbands

The following shows how to design a 24th-order anti-symmetric filter with piecewise linear passbands, and plot the desired and actual amplitude responses.

Create the frequency and amplitude vectors, `f` and `a`.

```
f = [0 0.3 0.4 0.6 0.7 0.9];
a = [0 1 0 0 0.5 0.5];
```

Use `firls` to obtain the 25 coefficients of the filter.

```
b = firls(24,f,a,'hilbert');
```

Plot the ideal amplitude response along with the transition regions.

```
plot(f.*pi,a,'o','markerfacecolor',[1 0 0]);
hold on;
plot(f.*pi,a,'r--','linewidth',2);
```

Use freqz to obtain the frequency response of the designed filter and
plot the magnitude response of the filter.

```
[H,F] = freqz(b,1);
plot(F,abs(H));
set(gca,'xlim',[O pi])
legend('Filter Specification','Transition Regions','Magnitude Response
```

firls
Algorithms firls designs a linear-phase FIR filter. This filter minimizes the weighted, integrated squared error between an ideal piecewise linear function and the magnitude response of the filter over a set of desired frequency bands.

Reference [1] describes the theoretical approach behind firls. The function solves a system of linear equations involving an inner product matrix of size roughly n/2 using the MATLAB \ operator.

This function designs type I, II, III, and IV linear-phase filters. Type I and II are the defaults for n even and odd respectively. The `'hilbert'` and `'differentiator'` flags produce type III (n even) and IV (n odd) filters. The various filter types have different symmetries and constraints on their frequency responses (see [2] for details).

Linear Phase Filter Type	Filter Order	Symmetry of Coefficients	Response H(f), f = 0	Response H(f), f = 1 (Nyquist)
Type I	Even	b(k) = b(n+2-k), k=1,..., n+1	No restriction	No restriction
Type II	Even	b(k) = b(n+2-k), k=1,..., n+1	No restriction	$H(1) = 0$
Type III	Odd	b(k) = –b(n+2-k), k=1,..., n+1	$H(0) = 0$	$H(1) = 0$
Type IV	Odd	b(k) = –b(n+2-k), k=1,..., n+1	$H(0) = 0$	No restriction

Definitions

Diagnostics

Error and warning messages

One of the following diagnostic messages is displayed when an incorrect argument is used:

```
F must be even length.
F and A must be equal lengths.
Requires symmetry to be 'hilbert' or 'differentiator'.
Requires one weight per band.
Frequencies in F must be nondecreasing.
Frequencies in F must be in range [0,1].
```

A more serious warning message is

```
Warning: Matrix is close to singular or badly scaled.
```

This tends to happen when the product of the filter length and transition width grows large. In this case, the filter coefficients b might not represent the desired filter. You can check the filter by looking at its frequency response.

Purpose	Minimum-phase FIR spectral factor
Syntax	`h = firminphase(b)` `h = firminphase(b,nz)`

Description

`h = firminphase(b)` computes the minimum-phase FIR spectral factor `h` of a linear-phase FIR filter `b`. Filter `b` must be real, have even order, and have nonnegative zero-phase response.

`h = firminphase(b,nz)` specifies the number of zeros, `nz`, of `b` that lie on the unit circle. You must specify `nz` as an even number to compute the minimum-phase spectral factor because every root on the unit circle must have even multiplicity. Including `nz` can help `firminphase` calculate the required FIR spectral factor. Zeros with multiplicity greater than two on the unit circle cause problems in the spectral factor determination.

Note You can find the maximum-phase spectral factor, g, by reversing h, such that $g = fliplr(h)$, and $b = conv(h, g)$.

Examples

This example designs a constrained least squares filter with a nonnegative zero-phase response, and then uses `firminphase` to compute the minimum-phase spectral factor.

```
f  = [0 0.4 0.8 1];
a  = [0 1 0];
up = [0.02 1.02  0.01];
lo = [0 0.98 0]; % The zeros insure nonnegative zero-phase resp.
n  = 32;
b  = fircls(n,f,a,up,lo);
h  = firminphase(b);
```

Saramaki, T, Finite Impulse Response Filter Design, *Handbook for Digital Signal Processing*Mitra, S.K. and J.F. Kaiser Eds. Wiley-Interscience, N.Y., 1993, Chapter 4.

firminphase

See Also   firgr | fircls | zerophase

Purpose   Lowpass Nyquist (Lth-band) FIR filter

Syntax
```
b = firnyquist(n,l,r)
b = firnyquist('minorder',l,r,dev)
b = firnyquist(n,l,r,decay)
b = firnyquist(n,l,r,'nonnegative')
b = firnyquist(n,l,r,'minphase')
```

Description   `b = firnyquist(n,l,r)` designs an Nth order, Lth band, Nyquist FIR filter with a rolloff factor `r` and an equiripple characteristic.

The rolloff factor `r` is related to the normalized transition width `tw` by $tw = 2\pi(r/l)$ (rad/sample). The order, n, must be even. `l` must be an integer greater than one. If `l` is not specified, it defaults to `4`. `r` must satisfy `0< r < 1`. If `r` is not specified, it defaults to `0.5`.

`b = firnyquist('minorder',l,r,dev)` designs a minimum-order, Lth band Nyquist FIR filter with a rolloff factor `r` using the Kaiser window. The peak ripple is constrained by the scalar `dev`.

`b = firnyquist(n,l,r,decay)` designs an Nth order (n), Lth band (l), Nyquist FIR filter where the scalar `decay`, specifies the rate of decay in the stopband. `decay` must be nonnegative. If you omit or leave it empty, `decay` defaults to `0` which yields an equiripple stopband. A nonequiripple stopband (decay $\neq 0$) may be desirable for decimation purposes.

`b = firnyquist(n,l,r,'nonnegative')` returns an FIR filter with nonnegative zero-phase response. This filter can be spectrally factored into minimum-phase and maximum-phase "square-root" filters. This allows you to use the spectral factors in applications such as matched-filtering.

`b = firnyquist(n,l,r,'minphase')` returns the minimum-phase spectral factor `bmin` of order n. `bmin` meets the condition `b=conv(bmin,bmax)` so that b is an Lth band FIR Nyquist filter of order 2n with filter rolloff factor `r`. Obtain `bmax`, the maximum phase spectral factor by reversing the coefficients of `bmin`. For example, `bmax = bmin(end:-1:1)`.

firnyquist

Examples   **Example 1**

This example designs a minimum phase factor of a Nyquist filter.

```
bmin = firnyquist(47,10,.45,'minphase');
b = firnyquist(2*47,10,.45,'nonnegative');
[h,w,s] = freqz(b); hmin = freqz(bmin);
fvtool(b,1,bmin,1);
```

Example 2

This example compares filters with different decay rates.

```
b1 = firnyquist(72,8,.3,0); % Equiripple
b2 = firnyquist(72,8,.3,15);
b3 = firnyquist(72,8,.3,25);
fvtool(b1,1,b2,1,b3,1);
```

References   T. Saramaki, Finite Impulse Response Filter Design, *Handbook for Digital Signal Processing*, Mitra, S.K. and J.F. Kaiser Eds. Wiley-Interscience, N.Y., 1993, Chapter 4.

See Also   firhalfband | firgr | firls | firminphase | firrcos | firls

Purpose   Two-channel FIR filter bank for perfect reconstruction

Syntax
```
[h0,h1,g0,g1] = firpr2chfb(n,fp)
[h0,h1,g0,g1] = firpr2chfb(n,dev,'dev')
[h0,h1,g0,g1] = firpr2chfb('minorder',fp,dev)
```

Description   `[h0,h1,g0,g1] = firpr2chfb(n,fp)` designs four FIR filters for the analysis sections (`h0` and `h1`) and synthesis section is (`g0` and `g1`) of a two-channel perfect reconstruction filter bank. The design corresponds to the orthogonal filter banks also known as power-symmetric filter banks.

`n` is the order of all four filters. It must be an odd integer. `fp` is the passband-edge for the lowpass filters `h0` and `g0`. The passband-edge argument `fp` must be less than 0.5. `h1` and `g1` are highpass filters with the passband-edge given by (1-`fp`).

`[h0,h1,g0,g1] = firpr2chfb(n,dev,'dev')` designs the four filters such that the maximum stopband ripple of `h0` is given by the scalar `dev`. Specify `dev` in linear units, not decibels. The stopband-ripple of `h1` is also be given by `dev`, while the maximum stopband-ripple for both `g0` and `g1` is (2*`dev`).

`[h0,h1,g0,g1] = firpr2chfb('minorder',fp,dev)` designs the four filters such that `h0` meets the passband-edge specification `fp` and the stopband-ripple `dev` using minimum order filters to meet the specification.

Examples   Design a filter bank with filters of order `n` equal to 99 and passband edges of 0.45 and 0.55.

```
n = 99;
[h0,h1,g0,g1] = firpr2chfb(n,.45);
fvtool(h0,1,h1,1,g0,1,g1,1);
```

Here are the filters, showing clearly the passband edges.
Use the following stem plots to verify perfect reconstruction using the
filter bank created by `firpr2chfb`.

```
stem(1/2*conv(g0,h0)+1/2*conv(g1,h1))
n=0:n;
stem(1/2*conv((-1).^n.*h0,g0)+1/2*conv((-1).^n.*h1,g1))
stem(1/2*conv((-1).^n.*g0,h0)+1/2*conv((-1).^n.*g1,h1))
stem(1/2*conv((-1).^n.*g0,(-1).^n.*h0)+...
1/2*conv((-1).^n.*g1,(-1).^n.*h1))
stem(conv((-1).^n.*h1,h0)-conv((-1).^n.*h0,h1))
```

Purpose   Type of linear phase FIR filter

Syntax   t = firtype(hd)
               t = firtype(hm)
               t = firtype(hs)

Description t = firtype(hd) determines the type (1 through 4) of a discrete-time
                FIR filter object hd, returning the type number in t. Filter hd must be
                real and have linear phase.

                t = firtype(hm) determines the type (1 through 4) of the multirate
                filter object hm. The filter must be real and have linear phase. When hm
                has multiple sections, all sections must be real FIR filters with linear
                phase. In this case, t is a cell array containing the filter type of each
                section.

                t = firtype(hs) determines the type (1 through 4) of the filter System
                object hs. The filter must be real and have linear phase.

Input   **hd**
Arguments
                Discrete-time dfilt filter object.

                hm

                Multirate mfilt filter object.

                hs

                Filter System object. The function supports the following filter
                structures.

                - dsp.FIRFilter

                - dsp.BiquadFilter

                - dsp.FIRInterpolator

                - dsp.CICInterpolator

                - dsp.FIRDecimator

firtype

- dsp.CICDecimator
- dsp.FIRRateConverter

Output Arguments

t

Filter type. t is either 1, 2, 3, or 4. These types are defined as follows:

- Type 1 — Even-order symmetric coefficients
- Type 2 — Odd-order symmetric coefficients
- Type 3 — Even-order antisymmetric coefficients
- Type 4 — Odd-order antisymmetric coefficients

Examples

Determine the type of the default interpolator for L=4.

```
l = 4;
hm = mfilt.firinterp(l);
firtype(hm)
ans =

     1
```

Purpose   Frequency response estimate via filtering

Syntax   ```
[h,w] = freqrespest(H,L)
[h,w] = freqrespest(H,L,param1,value1,param2,value2,...)
[h,w] = freqrespest(H,L,opts)
freqrespest(H,...)
```

**Description**      `[h,w] = freqrespest(H,L)` estimates the frequency response of a
`dfilt` object or a filter System object. A set of input data is filtered
and then forming the ratio between output data and input data. The
test input data comprises sinusoids with uniformly distributed random
frequencies.

Use this technique for comparing the performance of fixed-point
filters to that of another filter type. You can, for example, compare
fixed—point frequency response estimate to that of a similar filter
that uses quantized coefficients, but applies floating-point arithmetic
internally. Such comparison determines whether the fixed-point filter
performance closely matches the floating-point, quantized coefficients
version of the filter.

`L` is the number of trials to use to compute the estimate. If you do
not specify this value, `L` defaults to 10. More trials generates a more
accurate estimate of the response, but require more time to compute
the estimate.

`h` is the estimate of the complex frequency response. `w` contains the
vector of frequencies at which `h` is estimated.

`[h,w] = freqrespest(H,L,param1,value1,param2,value2,...)`
accepts H as either a `dfilt` object or a filter System object. This
approach uses parameter value (PV) pairs as input arguments to specify
optional parameters for the test. These parameters are the valid PV
pairs. Enter the parameter names as string input arguments in single
quotation marks. The following table provides valid parameters for
`[h, w]`.

| Parameter Name | Default Value | Description |
|---|---|---|
| NFFT | 512 | Number of FFT points to use. |
| NormalizedFrequency | true | Indicate whether to use normalized frequency or linear frequency. Values are true (use normalized frequency), or false (use linear frequency). When you specify false, you must supply the sampling frequency Fs. |
| Fs | normalized | Specify the sampling frequency when NormalizedFrequency is false. No default value. You must set NormalizedFrequency to false before setting a value for Fs. |
| SpectrumRange | half | Specify the spectrum range to be used as whole or half (default). |
| CenterDC | false | Specify whether to set the center of the spectrum to the DC value in the output plot. If you select true, both the negative and positive values appear in the plot. If you select false, DC appears at the origin of the axes. |
| Arithmetic (only for filter System objects) | ARITH | Analyze the filter System object, based on the arithmetic specified in the ARITH input. ARITH can be set to double, single, or fixed. The analysis tool assumes a double-precision |

| Parameter Name | Default Value | Description |
|---|---|---|
| | | filter when the arithmetic input is not specified and the filter System object is in an unlocked state. |

If H is a filter System object, freqrespest requires knowledge of the input data type. Analysis cannot be performed if the input data type is not available. If you do not specify the Arithmetic parameter, i.e., use the syntax [h,w] = freqrespest(H) , then the following rules apply for this method:

- The System object state is Unlocked — freqrespest performs double precision analysis.

- The System object state is Locked — freqrespest performs analysis based on the locked input data type.

When you do specify the Arithmetic parameter, i.e., use the syntax [h,w] = freqrespest(H,'Arithmetic', ARITH)), review the following rules for this method. Which rule applies depends on the value you set for the Arithmetic parameter.

| Value | System Object State | Rule |
|---|---|---|
| ARITH = 'double' | Unlocked | freqrespest performs double-precision analysis. |
| | Locked | freqrespest performs double-precision analysis. |

| Value | System Object State | Rule |
|---|---|---|
| ARITH = `single' | Unlocked | freqrespest performs single-precision analysis. |
| | Locked | freqrespest performs single-precision analysis. |
| ARITH = `fixed' | Unlocked | freqrespest produces an error because the fixed-point input data type is unknown. |
| | Locked | If the input data type is double or single, then freqrespest produces an error because the fixed-point input data type is unknown. |
| | | When the input data is of fixed-point type, freqrespest performs analysis based on the locked input data type. |

freqrespest supports only the following filter System objects:

- dsp.FIRFilter
- dsp.IIRFilter
- dsp.AllpoleFilter

• `dsp.BiquadFilter`

Regardless of whether H is a `dfilt` object or a filter System object, `[h,w] = freqrespest(H,L,opts)` uses an object, `opts`, to specify the optional input parameters. This specification is not done directly by specifying PV pairs as input arguments. Create `opts` with

```
opts = freqrespopts(H);
```

Because `opts` is an object, you use `set` to change the parameter values in `opts` before you use it with `freqrespest`. For example, you could specify a new sample rate with

```
set(opts,'fs',48e3); % Same as opts.fs=48e3
```

Regardless of whether H is a `dfilt` object or a filter System object, `freqrespest(H,...)` with no output argument launches FVTool.

`freqrespest` can also compute the frequency response of double-precision floating filters. Such filters cannot be converted to transfer-function form without introducing significant round off errors which affect the `freqz` frequency response computation. Examples of these kinds of filters include state-space or lattice filters, especially if they are high-order filters.

Examples
These examples demonstrate some uses for `freqrespest`.

Example 1

Start by estimating the frequency response of a fixed-point FIR filter that has filter internals set to `full precision`.

```
hd = design(fdesign.lowpass(.4,.5,1,60),'equiripple');
hd.arithmetic = 'fixed';
[h,w] = freqrespest(hd); % This should be about the same as freqz.
```

Continuing with filter hd, change the value of the `filterinternals` property to `specifyprecision` and then specify the word lengths and precision (the fraction lengths) applied to the output from internal addition and multiplication operations. After you set the word and

fraction lengths, use `freqrespest` to compute the frequency response estimate for the fixed-point filter.

```
hd.filterinternals = 'specifyprecision';
hd.outputwordlength=16;
hd.outputfraclength=15;
hd.productwordlength=16;
hd.productfraclength=15;
hd.accumwordlength=16;
hd.accumfraclength=15;
[h,w] = freqrespest(hd,2);
[h2,w2] = freqz(hd,512);
plot(w/pi,20*log10(abs([h,h2])))
legend('Frequency response estimated by filtering',...
'Freq. response computed by quantizing coefficients only');
xlabel('Normalized Frequency (\times\pi rad/sample)')
ylabel('Magnitude (dB)')
```

Example 2

freqrespest works with state-space filters as well. This example estimates the frequency response of a state-space filter.

```
fs = 315000;
wp = [320 3800]/(fs/2);
ws = [50 19000]/(fs/2);
rp=0.15; rs=60;
[n,wn]=cheb1ord(wp,ws,rp,rs);
[a,b,c,d] = cheby1(n,rp,wn);
hd = dfilt.statespace(a,b,c,d);
% Compare the following to freqz(hd,8192)
freqrespest(hd,1,'nfft',8192);
```

freqrespest

Purpose   Options for filter frequency response analysis

Syntax   opts = freqrespopts(H)

Description   opts = freqrespopts(H) uses the settings in the dfilt object or the
filter System object, H, to create an object, opts. This object contains
parameters and values for estimating the filter frequency response.
You pass opts as an input argument to freqrespest to specify values
for the input parameters.

freqrespopts allows you to use the same settings for freqrespest
with multiple filters without specifying all of the parameters as input
arguments to freqrespest.

freqrespopts supports only the following filter System objects:

- dsp.FIRFilter
- dsp.IIRFilter
- dsp.AllpoleFilter
- dsp.BiquadFilter

Examples   This example shows freqrespopts in use for setting options for
freqrespest. hd and hd2 are bandpass filters that use different design
methods. The opts object makes it easier to set the same conditions for
the frequency response estimate in freqrespest.

```
d=fdesign.bandpass('fst1,fp1,fp2,fst2,ast1,ap,ast2',...
0.25,0.3,0.45,0.5,60,0.1,60);

hd=design(d,'butter');
hd.arithmetic='fixed';
hd2=design(d,'cheby2')
hd2.arithmetic='fixed';
opts=freqrespopts(hd)

opts =
```

```
                         NFFT: 512
        NormalizedFrequency: true
                           Fs: 'Normalized'
               SpectrumRange: 'Half'
                     CenterDC: false

opts.NFFT=256; % Same as set(opts,'nfft',256).
opts.NormalizedFrequency=false;
opts.fs=1.5e3;
opts.CenterDC=true

opts =

                         NFFT: 256
        NormalizedFrequency: false
                           Fs: 1500
               SpectrumRange: 'Whole'
                     CenterDC: true
```

With opts configured as needed, use it as an input argument for
freqrespest.

```
[h2,w2]=freqrespest(hd2,20,opts);
[h1,w1]=freqrespest(hd,20,opts);
```

See Also freqrespest | noisepsd | noisepsdopts | norm | scale

Purpose   Real or complex frequency-sampled FIR filter from specification object

Syntax   hd = design(d,'freqsamp')
                   hd = design(...,'filterstructure',structure)
                   hd = design(...,'window',window)

Description   hd = design(d,'freqsamp') designs a frequency-sampled filter
                   specified by the filter specifications object d.

                   hd = design(...,'filterstructure',structure) returns a filter with
                   the filter structure you specify by the structure input argument.
                   structure is dffir by default and can be any one of the following filter
                   structures.

Structure String	Description of Resulting Filter Structure
dffir	Direct-form FIR filter
dffirt	Transposed direct-form FIR filter
dfsymfir	Symmetrical direct-form FIR filter
dfasymfir	Asymmetrical direct-form FIR filter
fftfir	Fast Fourier transform FIR filter

hd = design(...,'window',window) designs filters using the window
specified by the string in window. Provide the input argument window as

- A string for the window type. For example, use 'bartlett', or
  'hamming'. See window for the full list of windows available or refer
  to window in the *Signal Processing Toolbox User's Guide*.

- A function handle that references the window function. When the
  window function requires more than one input, use a cell array to
  hold the required arguments. The first example shows a cell array
  input argument.

- The window vector itself.

Examples   These examples design FIR filters that have arbitrary magnitude responses. In the first filter, the response has three distinct sections and the resulting filter is real.

The second example creates a complex filter.

```
b1 = 0:0.01:0.18;
b2 = [.2 .38 .4 .55 .562 .585 .6 .78];
b3 = [0.79:0.01:1];
a1 = .5+sin(2*pi*7.5*b1)/4;    % Sinusoidal response section.
a2 = [.5 2.3 1 1 -.2 -.2 1 1]; % Piecewise linear response section.
a3 = .2+18*(1-b3).^2;          % Quadratic response section.
f = [b1 b2 b3];
a = [a1 a2 a3];
n = 300;
d = fdesign.arbmag('n,f,a',n,f,a); % First specifications object.
hd = design(d,'freqsamp','window',{@kaiser,.5}); % Filter.
fvtool(hd)
```

The plot from FVTool shows the response for hd.

Magnitude Response (dB)

Now design the arbitrary-magnitude complex FIR filter. Recall that vector f contains frequency locations and vector a contains the desired filter response values at the locations specified in f.

```
f = [-1 -.93443 -.86885 -.80328 -.7377 -.67213 -.60656 -.54098 ...
-.47541,-.40984 -.34426 -.27869 -.21311 -.14754 -.081967 ...
-.016393 .04918 .11475,.18033 .2459 .31148 .37705 .44262 ...
 .5082 .57377 .63934 .70492 .77049,.83607 .90164 1];
a = [.0095848 .021972 .047249 .099869 .23119 .57569 .94032 ...
.98084 .99707,.99565 .9958 .99899 .99402 .99978 .99995 .99733 ...
.99731 .96979 .94936,.8196 .28502 .065469 .0044517 .018164 ...
.023305 .02397 .023141 .021341,.019364 .017379 .016061];
n = 48;
d = fdesign.arbmag('n,f,a',n,f,a); % Second spec. object.
hdc = design(d,'freqsamp','window','rectwin'); % Filter.
fvtool(hdc)
```

FVTool shows you the response for `hdc` from -1 to 1 in normalized frequency. `design(d,...)` returns a complex filter for `hdc` because the frequency vector includes negative frequency values.

Magnitude Response (dB)

Purpose   Frequency response of filter

Syntax
```
[h,w] = freqz(hfilt)
[h,w] = freqz(hfilt,n)
freqz(hfilt)
[h,w] = freqz(hs)
[h,w] = freqz(hs,n)
[h,w] = freqz(hs,Name,Value)
freqz(hs)
```

Description   freqz returns the frequency response based on the current filter
coefficients. This section describes common freqz operation with
adaptive filters, discrete-time filters, multirate filters, and filter System
objects. For more input options, refer to freqz in Signal Processing
Toolbox documentation.

[h,w] = freqz(hfilt) returns the frequency response h and the
corresponding frequencies w at which the filter response of hfilt is
computed. The frequency response is evaluated at 8192 points equally
spaced around the upper half of the unit circle.

[h,w] = freqz(hfilt,n) returns the frequency response h and
corresponding frequencies w for the filter or vector of filters hfilt. The
frequency response is evaluated at n points equally spaced around the
upper half of the unit circle. freqz uses the transfer function associated
with the filter to calculate the frequency response of the filter with the
current coefficient values.

freqz(hfilt) uses FVTool to plot the magnitude and unwrapped phase
of the frequency response of the filter hfilt. If hfilt is a vector of
filters, freqz plots the magnitude response and phase for each filter in
the vector.

[h,w] = freqz(hs) returns a frequency response for the filter System
object hs using 8192 samples.

[h,w] = freqz(hs,n) returns a frequency response for the filter
System object hs using n samples.

freqz

[h,w] = freqz(hs,Name,Value) returns a frequency response
with additional options specified by one or more Name,Value pair
arguments.

freqz(hs) uses FVTool to plot the magnitude and unwrapped phase of
the frequency response of the filter System object hs.

Input Arguments

hfilt

hfilt is either:

- An adaptive adaptfilt, discrete-time dfilt, or multirate mfilt
  filter object

- A vector of adaptive, discrete-time, or multirate filter objects

hs

Filter System object. The function supports the following filter
structures.

- dsp.FIRFilter

- dsp.BiquadFilter

- dsp.FIRInterpolator

- dsp.CICInterpolator

- dsp.FIRDecimator

- dsp.CICDecimator

- dsp.FIRRateConverter

n

Number of samples. For an FIR filter where n is a power of two, the
computation is done faster using FFTs.

  Default: 8192

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Arithmetic
`double' | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

System Object State	Coefficient Data Type	Rule
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

h

Complex, n-element frequency response vector. If hfilt is a vector of filters, h is a complex, length(hfilt)-by-n matrix of frequency response vectors corresponding to each filter in hfilt. If n is not specified, the function uses a default value of 8192.

For adaptive filters, h is the instantaneous frequency response.

w

Frequency vector of length n, in radians/sample. w consists of n points equally spaced around the upper half of the unit circle (from 0 to π radians/sample). If n is not specified, the function uses a default value of 8192.

Tips   There are several ways of analyzing the frequency response of filters. freqz accounts for quantization effects in the filter coefficients, but does not account for quantization effects in filtering arithmetic. To account for the quantization effects in filtering arithmetic, refer to function noisepsd.

Algorithms   freqz calculates the frequency response for a filter from the filter transfer function $Hq(z)$. The complex-valued frequency response is calculated by evaluating $Hq(e^{j\omega})$ at discrete values of w specified by the syntax you use. The integer input argument n determines the number of equally-spaced points around the upper half of the unit circle at which freqz evaluates the frequency response. The frequency ranges from 0 to π radians per sample when you do not supply a sampling frequency as an input argument. When you supply the scalar sampling frequency fs as an input argument to freqz, the frequency ranges from 0 to fs/2 Hz.

Examples   Plot the estimated frequency response of a filter. This example uses discrete-time filters, but hd can be any adaptfilt object, dfilt object, mfilt object, or filter System object. First plot the results for one filter.

```
b = fir1(80,0.5,kaiser(81,8));
hd = dfilt.dffir(b);
freqz(hd);
```

If you have more than one filter, you can plot them on the same figure using a vector of filters.

```
b = fir1(40,0.5,kaiser(41,6));
hd2 = dfilt.dffir(b);
h = [hd hd2];
freqz(h);
```

See Also   adaptfilt | dfilt | mfilt | fvtool

gain

Purpose	CIC filter gain

Syntax

```
gain(hm)
gain(hm,j)
gain(hs)
```

Description   gain(hm) returns the gain of hm, the CIC decimation or interpolation filter.

When hm is a decimator, gain returns the gain for the overall CIC decimator.

When hm is an interpolator, the CIC interpolator inserts zeros into the input data stream, reducing the filter overall gain by $1/R$, where R is the interpolation factor, to account for the added zero valued samples. Therefore, the gain of a CIC interpolator is $(RM)^N/R$, where N is the number of filter sections and M is the filter differential delay. gain(hm) returns this value. The next example presents this case.

gain(hm,j) returns the gain of the jth section of a CIC interpolation filter. When you omit j, gain assumes that j is 2*N, where N is the number of sections, and returns the gain of the last section of the filter. This syntax does not apply when hm is a decimator.

gain(hs) returns the gain of the filter System object hs. The function supports the dsp.CICDecimator and dsp.CICInterpolator filter structures.

Examples   To compare the performance of two interpolators, one a CIC filter and the other an FIR filter, use gain to adjust the CIC filter output amplitude to match the FIR filter output amplitude. Start by creating an input data set—a sinusoidal signal x.

```
fs = 1000;          % Input sampling frequency.
t = 0:1/fs:1.5;     % Signal length = 1501 samples.
x = sin(2*pi*10*t); % Amplitude = 1 sinusoid.

l = 4; % Interpolation factor for FIR filter.
d = fdesign.interpolator(l);
```

```
hm = design(d,'multistage');
ym = filter(hm,x);

r = 4; % Interpolation factor for the CIC filter.
d = fdesign.interpolator(r,'cic');
hcic = design(d,'multisection');
ycic = filter(hcic,x);
gaincic = gain(hcic);
subplot(211);
plot(1:length(ym),[ym; double(ycic)]);
subplot(212)
plot(1:length(ym),[ym; double(ycic)/gain(hcic)]);
```

After correcting for the gain induced by the CIC interpolator, the figure shows the filters provide nearly identical interpolation.

See Also   scale

grpdelay

Purpose   Filter group delay

Syntax
```
[gd,w]=grpdelay(hfilt)
[gd,w]=grpdelay(hfilt,n)
grpdelay(hfilt)
[gd,w] = grpdelay(hs)
[gd,w] = grpdelay(hs,n)
[gd,w] = grpdelay(hs,Name,Value)
grpdelay(hs)
```

Description   grpdelay returns the group delay based on the current filter coefficients. This section describes common grpdelay operation with adaptive filters, discrete-time filters, multirate filters, and filter System objects. For more input options, refer to grpdelay in Signal Processing Toolbox documentation.

[gd,w]=grpdelay(hfilt) returns the phase response phi of the filter hfilt and the corresponding frequencies w at which the function evaluates the group delay. Group delay is

$$-\frac{d}{dw}(angle(w))$$

The group delay is evaluated at 8192 points equally spaced around the upper half of the unit circle.

[gd,w]=grpdelay(hfilt,n) returns the group delay phi of the filter hfilt and the corresponding frequencies w at which the function evaluates the group delay. The group delay is evaluated at n points equally spaced around the upper half of the unit circle.

grpdelay(hfilt) displays the group delay of hfilt in the Filter Visualization Tool (FVTool).

[gd,w] = grpdelay(hs) returns the group delay for the filter System object hs using 8192 samples.

[gd,w] = grpdelay(hs,n) returns the group delay for the filter System object hs using n samples.

[gd,w] = grpdelay(hs,Name,Value) returns the group delay with additional options specified by one or more Name,Value pair arguments.

grpdelay(hs) uses FVTool to plot the group delay of the filter System object hs.

Input Arguments

hfilt

hfilt is either:

- An adaptive adaptfilt, discrete-time dfilt, or multirate mfilt filter object

- A vector of adaptive, discrete-time, or multirate filter objects

hs

Filter System object. The function supports the following filter structures.

- dsp.FIRFilter

- dsp.BiquadFilter

- dsp.FIRInterpolator

- dsp.CICInterpolator

- dsp.FIRDecimator

- dsp.CICDecimator

- dsp.FIRRateConverter

n

Number of samples. For an FIR filter where n is a power of two, the computation is done faster using FFTs.

Default: 8192

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments, where Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Arithmetic

`double' | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

System Object State	Coefficient Data Type	Rule
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

gd

Complex, n-element group-delay vector. If hfilt is a vector of filters, gd is a complex, length(hfilt)-by-n matrix of group-delay vectors whose columns correspond to each filter in hfilt. If n is not specified, the function uses a default value of 8192.

For adaptive filters, gd is the instantaneous group delay.

w

Frequency vector of length n, in radians/sample. w consists of n points equally spaced around the upper half of the unit circle (from 0 to π radians/sample). If hfilt is a vector of filters, w is a complex, length(hfilt)-by-n matrix of group-delay vectors whose columns correspond to each filter in hfilt. If n is not specified, the function uses a default value of 8192.

Purpose   Help for design method with filter specification

Syntax   help(d,'*designmethod*')

Description help(d,'*designmethod*') displays help in the Command Window for
                the design algorithm designmethod for the current specifications of the
                filter specification object d. The string you enter for designmethod must
                be one of the strings returned by designmethods for d, the design object.

Examples   Get specific help for designing lowpass Butterworth filters. The first
                lowpass filter uses the default specification string 'Fp,Fst,Ap,Ast' and
                returns help text specific to the specification string.

```
d = fdesign.lowpass;
designmethods(d)

Design Methods for class fdesign.lowpass (Fp,Fst,Ap,Ast):

butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage

help(d,'butter')

DESIGN Design a Butterworth IIR filter.
HD = DESIGN(D, 'butter') designs a Butterworth filter specified
by the FDESIGN object D.

HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns a filter
with the structure STRUCTURE.  STRUCTURE is 'df2sos' by default
and can be any of the following.
```

```
'df1sos'
'df2sos'
'df1tsos'
'df2tsos'

HD = DESIGN(..., 'MatchExactly', MATCH) designs a Butterworth
filter and matches the frequency and magnitude specification for
the band MATCH exactly. The other band will exceed the
specification.  MATCH can be 'stopband' or 'passband' and is
'stopband' by default.

% Example #1 - Compare passband and stopband MatchExactly.
h    = fdesign.lowpass('Fp,Fst,Ap,Ast', .1, .3, 1, 60);
Hd   = design(h, 'butter', 'MatchExactly', 'passband');
Hd(2) = design(h, 'butter', 'MatchExactly', 'stopband');

% Compare the passband edges in FVTool.
fvtool(Hd);
axis([.09 .11 -2 0]);
```

Note the discussion of the `MatchExactly` input option. When you use a design object that uses a different specification string, such as 'N,F3dB', the help content for the `butter` design method changes.

In this case, the `MatchExactly` option does not appear in the help because it is not an available input argument for the specification string 'N,F3dB'.

```
d=fdesign.lowpass('N,F3dB')

d =
                 Response: 'Lowpass'
            Specification: 'N,F3dB'
              Description: {'Filter Order';'3dB Frequency'}
      NormalizedFrequency: true
              FilterOrder: 10
                     F3dB: 0.5
```

```
designmethods(d)

Design Methods for class fdesign.lowpass (N,F3dB):

butter

help(d,'butter

DESIGN Design a Butterworth IIR filter.

HD = DESIGN(D, 'butter') designs a Butterworth filter
specified by the FDESIGN object D.

HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns a
filter with the structure STRUCTURE. STRUCTURE is 'df2sos'
by default and can be any of the following.

'df1sos'

'df2sos'

'df1tsos'

'df2tsos'

% Example #1 - Design a lowpass Butterworth filter in the
DF2TSOS structure.

h = fdesign.lowpass('N,F3dB');

Hd = design(h, 'butter', 'FilterStructure', 'df2tsos');
```

ifir

Purpose	Interpolated FIR filter from filter specification

Syntax	`hd = ifir(d)`
	`hd = design(d,'ifir',designoption,value,designoption,...`
	`value,...)`

Description   `hd = ifir(d)` designs an FIR filter from design object `d`, using the interpolated FIR method. `ifir` returns `hd` as a cascade of two filters that act together to meet the specifications in `d`. The resulting filter is particularly efficient, having a low number of multipliers. However, if `ifir` determines that a single-stage filter would be more efficient than the default two-stage design, it returns `hd` as a single-stage filter. `ifir` only creates linear phase filters. Generally, `ifir` uses an advanced optimization algorithm to create highly efficient FIR filters.

`ifir` returns `hd` as either a single-rate `dfilt` object or a multirate `mfilt` object (when you have DSP System Toolbox software installed), based on the specifications you provide in `d`, the filter specification object.

specifications supplied in the object `h`.

`hd = design(d,'ifir',designoption,value,designoption,...`
`value,...)` returns an interpolated FIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

`designopts(d,'method')`

For complete help about using `ifir`, refer to the command line help system. For example, to get specific information about using `ifir` with `d`, the specification object, enter the following at the MATLAB prompt.

`help(d,'ifir')`

Note For help about how you use `ifir` to design filters without using design objects, enter

```
help ifir
```

at the MATLAB prompt.

Examples   Use `fdesign.lowpass` and `fdesign.highpass` to design a lowpass filter and a wideband highpass filter. After designing the filters, use FVTool to plot the response curves for both.

```
fpass = 0.2;
fstop = 0.24;
d1 = fdesign.lowpass(fpass, fstop);
hd1 = design(d1,'ifir');
fstop = 0.2;
fpass = 0.25;
astop = 40;
apass = 1;
d2 = fdesign.highpass(fstop,fpass,astop,apass);
hd2 = design(d2,'ifir');
fvtool(hd1,hd2)
```

See Also   fdesign | firgr | fir1 | firls | firpm

Purpose   Transform IIR complex bandpass filter to IIR complex bandpass filter
                     with different characteristics

Syntax   [Num,Den,AllpassNum,AllpassDen] = iirbpc2bpc(B,A,Wo,Wt)

Description   [Num,Den,AllpassNum,AllpassDen] = iirbpc2bpc(B,A,Wo,Wt)
                     returns the numerator and denominator vectors, Num and Den
                     respectively, of the target filter transformed from the complex bandpass
                     prototype by applying a first-order complex bandpass to complex
                     bandpass frequency transformation.

                     It also returns the numerator, AllpassNum, and the denominator,
                     AllpassDen, of the allpass mapping filter. The prototype lowpass
                     filter is given with the numerator specified by B and the denominator
                     specified by A.

                     This transformation effectively places two features of an original
                     filter, located at frequencies W_{o1} and W_{o2}, at the required target
                     frequency locations, W_{t1}, and W_{t2} respectively. It is assumed that W_{t2}
                     is greater than W_{t1}. In most of the cases the features selected for the
                     transformation are the band edges of the filter passbands. In general
                     it is possible to select any feature; e.g., the stopband edge, the DC, the
                     deep minimum in the stopband, or other ones.

                     Relative positions of other features of an original filter do not change in
                     the target filter. This means that it is possible to select two features of
                     an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still
                     precede F_2 after the transformation. However, the distance between F_1
                     and F_2 will not be the same before and after the transformation.

                     This transformation can also be used for transforming other types of
                     filters; e.g., complex notch filters or resonators can be repositioned at
                     two distinct desired frequencies at any place around the unit circle;
                     e.g., in the adaptive system.

Examples   Design a prototype real IIR halfband filter using a standard elliptic
                     approach:

                     [b, a] = ellip(3, 0.1, 30, 0.409);

Create a complex passband from 0.25 to 0.75:

```
[b, a] = iirlp2bpc (b, a, 0.5, [0.25,0.75]);
[num, den] = iirbpc2bpc(b, a, [0.25, 0.75], [-0.5, 0.5]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Using FVTool to plot the filters shows you the comparison, presented in this figure.

Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
Wo	Frequency values to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
Num	Numerator of the target filter
Den	Denominator of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

See Also   iirftransf | allpassbpc2bpc | zpkbpc2bpc

iircomb

Purpose   IIR comb notch or peak filter

Syntax
```
[num,den] = iircomb(n,bw)
[num,den] = iircomb(n,bw,ab)
[num,den] = iircomb(...,'type')
```

Description   `[num,den] = iircomb(n,bw)` returns a digital notching filter with order `n` and with the width of the filter notch at -3 dB set to `bw`, the filter bandwidth. The filter order must be a positive integer. `n` also defines the number of notches in the filter across the frequency range from 0 to 2π — the number of notches equals `n+1`.

For the notching filter, the transfer function takes the form

$$H(z) = b\frac{1 - z^{-n}}{1 - \alpha z^{-n}}$$

where α and b are the positive scalars and n is the filter order or the number of notches in the filter minus 1.

The quality factor (Q factor) `q` for the filter is related to the filter bandwidth by $q = \omega_0/bw$ where ω_0 is the frequency to remove from the signal.

`[num,den] = iircomb(n,bw,ab)` returns a digital notching filter whose bandwidth, `bw`, is specified at a level of `-ab` decibels. Including the optional input argument `ab` lets you specify the magnitude response bandwidth at a level that is not the default -3 dB point, such as -6 dB or 0 dB.

`[num,den] = iircomb(...,'type')` returns a digital filter of the specified type. The input argument `type` can be either

- `'notch'` to design an IIR notch filter. Notch filters attenuate the response at the specified frequencies. This is the default type. When you omit the `type` input argument, `iircomb` returns a notch filter.

- `'peak'` to design an IIR peaking filter. Peaking filters boost the signal at the specified frequencies.

The transfer function for peaking filters is

$$H(z) = b \frac{1 - z^{-n}}{1 + az^{-n}}$$

Examples   Design and plot an IIR notch filter with 11 notches (equal to filter order plus 1) that removes a 60 Hz tone (f0) from a signal at 600 Hz (fs). For this example, set the Q factor for the filter to 35 and use it to specify the filter bandwidth.

```
fs = 600; fo = 60;  q = 35; bw = (fo/(fs/2))/q;
[b,a] = iircomb(fs/fo,bw,'notch'); % Note type flag 'notch'
fvtool(b,a);
```

Using the Filter Visualization Tool (FVTool) generates the following plot showing the filter notches. Note the notches are evenly spaced and one falls at exactly 60 Hz.

See Also   firgr | iirnotch | iirpeak

Purpose   IIR frequency transformation of filter

Syntax   `[OutNum,OutDen] = iirftransf(OrigNum,OrigDen,FTFNum,FTFDen)`

Description   `[OutNum,OutDen] = iirftransf(OrigNum,OrigDen,FTFNum,FTFDen)`
returns the numerator and denominator vectors, `OutNum` and `OutDen`,
of the target filter, which is the result of transforming the prototype
filter specified by the numerator, `OrigNum`, and denominator, `OrigDen`,
with the mapping filter given by the numerator, `FTFNum`, and the
denominator, `FTFDen`. If the allpass mapping filter is not specified, then
the function returns an original filter.

Examples   Design a prototype real IIR halfband filter using a standard elliptic
approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
[AlpNum, AlpDen] = allpasslp2lp(0.5, 0.25);
[num, den] = iirftransf(b, a, AlpNum, AlpDen);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Here's the comparison between the filters.

iirftransf

Arguments

Variable	Description
OrigNum	Numerator of the prototype lowpass filter
OrigDen	Denominator of the prototype lowpass filter
FTFNum	Numerator of the mapping filter
FTFDen	Denominator of the mapping filter
OutNum	Numerator of the target filter
OutDen	Denominator of the target filter

See Also   zpkftransf

Purpose   Optimal IIR filter with prescribed group-delay

Syntax   ```
[num,den] = iirgrpdelay(n,f,edges,a)
[num,den] = iirgrpdelay(n,f,edges,a,w)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden,
    tau)
[num,den,tau] = iirgrpdelay(n,f,edges,a,w)
```
Description `[num,den] = iirgrpdelay(n,f,edges,a)` returns an allpass IIR filter of order n (n must be even) which is the best approximation to the relative group-delay response described by f and a in the least-pth sense. f is a vector of frequencies between 0 and 1 and a is specified in samples. The vector edges specifies the band-edge frequencies for multi-band designs. iirgrpdelay uses a constrained Newton-type algorithm. Always check your resulting filter using grpdelay or freqz.

`[num,den] = iirgrpdelay(n,f,edges,a,w)` uses the weights in w to weight the error. w has one entry per frequency point and must be the same length as f and a). Entries in w tell iirgrpdelay how much emphasis to put on minimizing the error in the vicinity of each specified frequency point relative to the other points.

f and a must have the same number of elements. f and a can contains more elements than the vector edges contains. This lets you use f and a to specify a filter that has any group-delay contour within each band.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius)` returns a filter having a maximum pole radius equal to radius, where 0<radius<1. radius defaults to 0.999999. Filters whose pole radius you constrain to be less than 1.0 can better retain transfer function accuracy after quantization.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p)`, where p is a two-element vector [pmin pmax], lets you determine the minimum and maximum values of p used in the least-pth algorithm. p defaults to [2

128] which yields filters very similar to the L-infinity, or Chebyshev, norm. `pmin` and `pmax` should be even. If p is the string `'inspect'`, no optimization occurs. You might use this feature to inspect the initial pole/zero placement.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens)` specifies the grid density `dens` used in the optimization process. The number of grid points is `(dens*(n+1))`. The default is 20. `dens` can be specified as a single-element cell array. The grid is not equally spaced.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden)` allows you to specify the initial estimate of the denominator coefficients in vector `initden`. This can be useful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initden`.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden,tau)` allows the initial estimate of the group delay offset to be specified by the value of `tau`, in samples.

`[num,den,tau] = iirgrpdelay(n,f,edges,a,w)` returns the resulting group delay offset. In all cases, the resulting filter has a group delay that approximates [a + tau]. Allpass filters can have only positive group delay and a non-zero value of tau accounts for any additional group delay that is needed to meet the shape of the contour specified by (f,a). The default for tau is max(a).

Hint: If the zeros or poles cluster together, your filter order may be too low or the pole radius may be too small (overly constrained). Try increasing `n` or `radius`.

For group-delay equalization of an IIR filter, compute `a` by subtracting the filter's group delay from its maximum group delay. For example,

```
[be,ae] = ellip(4,1,40,0.2);
f = 0:0.001:0.2;
g = grpdelay(be,ae,f,2);   % Equalize only the passband.
a = max(g)-g;
```

```
[num,den]=iirgrpdelay(8, f, [O 0.2], a);
```

iirlinphase

Purpose	Quasi-linear phase IIR filter from halfband filter specification
Syntax	`hd = design(d,'iirlinphase')` `hd = design(...,'`**`filterstructure`**`',structure)`
Description	`hd = design(d,'iirlinphase')` designs a quasi-linear phase filter `hd` specified by the filter specification object `d`.
	`hd = design(...,'`**`filterstructure`**`',structure)` returns a filter with the structure specified by `structure`. By default, the filter structure is df2sos (direct-form II with second-order sections). You can substitute one of the following strings for `structure` to specify the structure of `hd`.

Structure String	Filter Structure
df1sos	Direct-form I IIR filter with second-order sections
df2sos	Direct-form II IIR filter with second-order sections
df1tsos	Transposed direct-form I IIR filter with second-order sections
df2tsos	Transposed direct-form II IIR filter with second-order sections

Examples

Design a quasi-linear phase, minimum-order halfband IIR filter with transition width of 0.36 and stopband attenuation of at least 80 dB.

```
tw = 0.36;
ast = 80;
d = fdesign.halfband('tw,ast',tw,ast); % Transition width,
                                       % stopband attenuation.
hd = design(d,'iirlinphase');
fvtool(hd)
```

Notice the characteristic halfband nature of the ripple in the stopband. If you measure the resulting filter, you see it meets the specifications.

measure(hd)
See Also fdesign.halfband

iirlp2bp

Purpose   Transform IIR lowpass filter to IIR bandpass filter

Syntax   ```
[Num,Den,AllpassNum,AllpassDen] = iirlp2bp(B,A,Wo,Wt)
[G,AllpassNum,AllpassDen] = iirlp2bp(Hd,Wo,Wt)
```

where `Hd` is a `dfilt` object

**Description**  `[Num,Den,AllpassNum,AllpassDen] = iirlp2bp(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a second-order real lowpass to real bandpass frequency mapping.

It also returns the numerator, `AllpassNum`, and the denominator `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency -$W_o$, at the required target frequency location, $W_{t1}$, and the second feature, originally at +$W_o$, at the new location, $W_{t2}$. It is assumed that $W_{t2}$ is greater than $W_{t1}$. This transformation implements the "DC Mobility," meaning that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of $W_t$s.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, $F_1$ and $F_2$, with $F_1$ preceding $F_2$. Feature $F_1$ will still precede $F_2$ after the transformation. However, the distance between $F_1$ and $F_2$ will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature: the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Real lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies.

[G,AllpassNum,AllpassDen] = iirlp2bp(Hd,Wo,Wt) returns transformed dfilt object G with a real bandpass magnitude response. The coefficients AllpassNum and AllpassDen represent the allpass mapping filter for mapping the prototype filter frequency Wo and target frequencies vector Wt. Note that in this syntax Hd is a dfilt object with a lowpass magnitude response.

**Examples**     Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b,a] = ellip(3, 0.1, 30, 0.409);
```

Create the real bandpass filter by placing the cutoff frequencies of the prototype filter at the band edge frequencies W_{t1}=0.25 and W_{t2}=0.75:

```
[num,den] = iirlp2bp(b,a,0.5,[0.25,0.75]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b,a,num,den);
```

You can compare the results in this figure to verify the transformation.

Magnitude Response (dB)

Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
Num	Numerator of the target filter
Den	Denominator of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

iirlp2bpc

Purpose   IIR lowpass to complex bandpass transformation

Syntax   `[Num,Den,AllpassNum,AllpassDen] = iirlp2bpc(B,A,Wo,Wt)`
                   `[G,AllpassNum,AllpassDen] = iirlp2bpc(Hd,Wo,Wt)`

                   where `Hd` is a `dfilt` object

Description   `[Num,Den,AllpassNum,AllpassDen] = iirlp2bpc(B,A,Wo,Wt)`
                   returns the numerator and denominator vectors, `Num` and `Den`
                   respectively, of the target filter transformed from the real lowpass
                   prototype by applying a first-order real lowpass to complex bandpass
                   frequency transformation.

                   It also returns the numerator, `AllpassNum`, and the denominator,
                   `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter
                   is given with a numerator specified by `B` and a denominator specified
                   by `A`.

                   This transformation effectively places one feature of an original filter,
                   located at frequency $-W_o$, at the required target frequency location, W_{t1},
                   and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is
                   assumed that W_{t2} is greater than W_{t1}.

                   Relative positions of other features of an original filter do not change in
                   the target filter. This means that it is possible to select two features of
                   an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still
                   precede F_2 after the transformation. However, the distance between F_1
                   and F_2 will not be the same before and after the transformation.

                   Choice of the feature subject to the lowpass to bandpass transformation
                   is not restricted only to the cutoff frequency of an original lowpass filter.
                   In general it is possible to select any feature; e.g., the stopband edge,
                   the DC, the deep minimum in the stopband, or other ones.

                   Lowpass to bandpass transformation can also be used for transforming
                   other types of filters; for example real notch filters or resonators can be
                   doubled and positioned at two distinct desired frequencies at any place
                   around the unit circle forming a pair of complex notches/resonators.
                   This transformation can be used for designing bandpass filters for radio
                   receivers from the high-quality prototype lowpass filter.

[G,AllpassNum,AllpassDen] = iirlp2bpc(Hd,Wo,Wt) returns transformed dfilt object G with a bandpass magnitude response. The coefficients AllpassNum and AllpassDen represent the allpass mapping filter for mapping the prototype filter frequency Wo and the target frequencies vector Wt. Note that in this syntax Hd is a dfilt object with a lowpass magnitude response.

Examples   Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Move the cutoffs of the prototype filter to the new locations W_{t1}=0.25 and W_{t2}=0.75 creating a complex bandpass filter:

```
[num, den] = iirlp2bpc(b, a, 0.5, [0.25, 0.75]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Plotting the prototype and target filters together in FVTool lets you compare the filters.

Magnitude Response (dB)

Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
Num	Numerator of the target filter

Variable	Description
Den	Denominator of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

iirlp2bs

Purpose   Transform IIR lowpass filter to IIR bandstop filter

Syntax   `[Num,Den,AllpassNum,AllpassDen] = iirlp2bs(B,A,Wo,Wt)`
                 `[G,AllpassNum,AllpassDen] = iirlp2bs(Hd,Wo,Wt)`

                 where `Hd` is a `dfilt` object

Description `[Num,Den,AllpassNum,AllpassDen] = iirlp2bs(B,A,Wo,Wt)` returns
                 the numerator and denominator vectors, `Num` and `Den` respectively, of the
                 target filter transformed from the real lowpass prototype by applying a
                 second-order real lowpass to real bandstop frequency mapping.

                 It also returns the numerator, `AllpassNum`, and the denominator,
                 `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter
                 is given with a numerator specified by `B` and a denominator specified
                 by `A`.

                 This transformation effectively places one feature of an original filter,
                 located at frequency $-W_o$, at the required target frequency location, W_{t1},
                 and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is
                 assumed that W_{t2} is greater than W_{t1}. This transformation implements
                 the "Nyquist Mobility," which means that the DC feature stays at DC,
                 but the Nyquist feature moves to a location dependent on the selection
                 of W_o and W_ts.

                 Relative positions of other features of an original filter change in the
                 target filter. This means that it is possible to select two features
                 of an original filter, F_1 and F_2, with F_1 preceding F_2. After the
                 transformation feature F_2 will precede F_1 in the target filter. However,
                 the distance between F_1 and F_2 will not be the same before and after
                 the transformation.

                 Choice of the feature subject to the lowpass to bandstop transformation
                 is not restricted only to the cutoff frequency of an original lowpass filter.
                 In general it is possible to select any feature; e.g., the stopband edge,
                 the DC, the deep minimum in the stopband, or other ones.

                 `[G,AllpassNum,AllpassDen] = iirlp2bs(Hd,Wo,Wt)` returns
                 transformed `dfilt` object `G` with a bandstop magnitude response. The
                 coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping

filter for mapping the prototype filter frequency Wo and the target frequencies vector Wt. Note that in this syntax Hd is a dfilt object with a lowpass magnitude response.

Examples   Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Create the real bandstop filter by placing the cutoff frequencies of the prototype filter at the band edge frequencies W_{t1}=0.25 and W_{t2}=0.75:

```
[num, den] = iirlp2bs(b, a, 0.5, [0.25, 0.75]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

iirlp2bs

With both filters plotted in the figure, you see clearly the results of the transformation.

Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
Num	Numerator of the target filter
Den	Denominator of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

iirlp2bsc

Purpose　　Transform IIR lowpass filter to IIR complex bandstop filter

Syntax　　`[Num,Den,AllpassNum,AllpassDen] = iirlp2bsc(B,A,Wo,Wt)`
`[G,AllpassNum,AllpassDen] = iirlp2bsc(Hd,Wo,Wt)`

where `Hd` is a `dfilt` object

Description　　`[Num,Den,AllpassNum,AllpassDen] = iirlp2bsc(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to complex bandstop frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and the denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. Additionally the transformation swaps passbands with stopbands in the target filter.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/resonators. This transformation can be used for designing bandstop filters for band

attenuation or frequency equalizers, from the high-quality prototype lowpass filter.

[G,AllpassNum,AllpassDen] = iirlp2bsc(Hd,Wo,Wt) returns transformed dfilt object G with a bandstop magnitude response. The coefficients AllpassNum and AllpassDen represent the allpass mapping filter for mapping the prototype filter frequency Wo and the target frequencies vector Wt. Note that in this syntax Hd is a dfilt object with a lowpass magnitude response.

Examples Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Move the cutoffs of the prototype filter to the new locations W_{t1}=0.25 and W_{t2}=0.75 creating a complex bandstop filter:

```
[num, den] = iirlp2bsc(b, a, 0.5, [0.25, 0.75]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

The last command in the example plots both filters in the same window so you can compare the results.

Magnitude Response (dB)

Arguments	**Variable**	**Description**
	B	Numerator of the prototype lowpass filter
	A	Denominator of the prototype lowpass filter
	Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
	Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

Variable	Description
Num	Numerator of the target filter
Den	Denominator of the target filter

iirlp2hp

Purpose	Transform lowpass IIR filter to highpass filter

Syntax

```
[num,den] = iirlp2hp(b,a,wc,wd)
[G,AllpassNum,AllpassDen] = iirlp2hp(Hd,Wo,Wt)
```

where Hd is a dfilt object

Description

[num,den] = iirlp2hp(b,a,wc,wd) with input arguments b and a, the numerator and denominator coefficients (zeros and poles) for a lowpass IIR filter, iirlp2bp transforms the magnitude response from lowpass to highpass. num and den return the coefficients for the transformed highpass filter. For wc, enter a selected frequency from your lowpass filter. You use the chosen frequency to define the magnitude response value you want in the highpass filter. Enter one frequency for the highpass filter — the value that defines the location of the transformed point — in wd. Note that all frequencies are normalized between zero and one. Notice also that the filter order does not change when you transform to a highpass filter.

When you select wc and designate wd, the transformation algorithm sets the magnitude response at the wd values of your bandstop filter to be the same as the magnitude response of your lowpass filter at wc. Filter performance between the values in wd is not specified, except that the stopband retains the ripple nature of your original lowpass filter and the magnitude response in the stopband is equal to the peak response of your lowpass filter. To accurately specify the filter magnitude response across the stopband of your bandpass filter, use a frequency value from within the stopband of your lowpass filter as wc. Then your bandstop filter response is the same magnitude and ripple as your lowpass filter stopband magnitude and ripple.

The fact that the transformation retains the shape of the original filter is what makes this function useful. If you have a lowpass filter whose characteristics, such as rolloff or passband ripple, particularly meet your needs, the transformation function lets you create a new filter with the same characteristic performance features, but in a highpass version. Without designing the highpass filter from the beginning.

In some cases transforming your filter may cause numerical problems, resulting in incorrect conversion to the highpass filter. Use fvtool to verify the response of your converted filter.

[G,AllpassNum,AllpassDen] = iirlp2hp(Hd,Wo,Wt) returns transformed dfilt object G with a highpass magnitude response. The coefficients AllpassNum and AllpassDen represent the allpass mapping filter for mapping the prototype filter frequency Wo and the target frequencies vector Wt. Note that in this syntax Hd is a dfilt object with a lowpass magnitude response.

Examples   This example transforms an IIR filter from lowpass to high pass by moving the magnitude response at one frequency in the source filter to a new location in the transformed filter. To generate a highpass filter whose passband flattens out at 0.4, select the frequency in the lowpass filter where the passband starts to rolloff (wc = 0.0175) and move it to the new location at wd = 0.4.

```
[b,a] = iirlpnorm(10,6,[0 0.0175 0.02 0.0215 0.025 1],...
[0 0.0175 0.02 0.0215 0.025 1],[1 1 0 0 0 0],...
[1 1 1 1 10 10]);
wc = 0.0175;
wd = 0.4;
[num,den] = iirlp2hp(b,a,wc,wd);
fvtool(b,a,num,den);
```

iirlp2hp

In the figure showing the magnitude responses for the two filters, the transition band for the highpass filter is essentially the mirror image of the transition for the lowpass filter from 0.0175 to 0.025, stretched out over a wider frequency range. In the passbands, the filter share common ripple characteristics and magnitude.

Purpose   Transform lowpass IIR filter to different lowpass filter

Syntax   ```
[num,den] = iirlp2hp(b,a,wc,wd)
[G,AllpassNum,AllpassDen] = iirlp2lp(Hd,Wo,Wt)
```
where `Hd` is a `dfilt` object

Description `[num,den] = iirlp2hp(b,a,wc,wd)` with input arguments `b` and `a`, the numerator and denominator coefficients (zeros and poles) for a lowpass IIR filter, `iirlp2bp` transforms the magnitude response from lowpass to highpass. `num` and `den` return the coefficients for the transformed highpass filter. For `wc`, enter a selected frequency from your lowpass filter. You use the chosen frequency to define the magnitude response value you want in the highpass filter. Enter one frequency for the highpass filter — the value that defines the location of the transformed point — in `wd`. Note that all frequencies are normalized between zero and one. Notice also that the filter order does not change when you transform to a highpass filter.

When you select `wc` and designate `wd`, the transformation algorithm sets the magnitude response at the `wd` values of your bandstop filter to be the same as the magnitude response of your lowpass filter at `wc`. Filter performance between the values in `wd` is not specified, except that the stopband retains the ripple nature of your original lowpass filter and the magnitude response in the stopband is equal to the peak response of your lowpass filter. To accurately specify the filter magnitude response across the stopband of your bandpass filter, use a frequency value from within the stopband of your lowpass filter as `wc`. Then your bandstop filter response is the same magnitude and ripple as your lowpass filter stopband magnitude and ripple.

The fact that the transformation retains the shape of the original filter is what makes this function useful. If you have a lowpass filter whose characteristics, such as rolloff or passband ripple, particularly meet your needs, the transformation function lets you create a new filter with the same characteristic performance features, but in a highpass version. Without designing the highpass filter from the beginning.

In some cases transforming your filter may cause numerical problems, resulting in incorrect conversion to the highpass filter. Use `fvtool` to verify the response of your converted filter.

`[G,AllpassNum,AllpassDen] = iirlp2lp(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with a lowpass magnitude response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

Examples   This example transforms an IIR filter from lowpass to high pass by moving the magnitude response at one frequency in the source filter to a new location in the transformed filter. To generate a lowpass filter whose passband extends out to 0.2, select the frequency in the lowpass filter where the passband starts to rolloff (`wc = 0.0175`) and move it to the new location at `wd = 0.2`.

```
[b,a] = iirlpnorm(10,6,[0 0.0175 0.02 0.0215 0.025 1],...
[0 0.0175 0.02 0.0215 0.025 1],[1 1 0 0 0 0],...
[1 1 1 1 10 10]);
wc = 0.0175;
wd = 0.2;
[num,den] = iirlp2lp(b,a,wc,wd);
fvtool(b,a,num,den);
```

Moving the edge of the passband from 0.0175 to 0.2 results in a new lowpass filter whose peak response in-band is the same as the original filter: same ripple, same absolute magnitude.
The rolloff is slightly less steep and the stopband profiles are the same for both filters; the new filter stopband is a "stretched" version of the original, as is the passband of the new filter.

iirlp2mb

Purpose

Transform IIR lowpass filter to IIR M-band filter

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2mb(B,A,Wo,Wt)
[Num,Den,AllpassNum,AllpassDen]=iirlp2mb(B,A,Wo,Wt,Pass)
[G,AllpassNum,AllpassDen] = iirlp2mb(Hd,Wo,Wt)
[G,AllpassNum,AllpassDen] = iirlp2mb(...,Pass)
```

Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2mb(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying an Mth-order real lowpass to real multiple bandpass frequency mapping. By default the DC feature is kept at its original location.

`[Num,Den,AllpassNum,AllpassDen]=iirlp2mb(B,A,Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility." In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is movable.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency W_o, at the required target frequency locations, $W_{t1},...,W_{tM}$.

Relative positions of other features of an original filter do not change in the target filter. It is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

`[G,AllpassNum,AllpassDen] = iirlp2mb(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with an IIR real M-band filter frequency response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

`[G,AllpassNum,AllpassDen] = iirlp2mb(...,Pass)` returns transformed `dfilt` object `G` with an IIR real M-band filter frequency response. This syntax allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility." In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is allowed to move.

The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

Examples   Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Example 1

Create the real multiband filter with two passbands:

```
[num1, den1] = iirlp2mb(b, a, 0.5, [2 4 6 8]/10);
[num2, den2] = iirlp2mb(b, a, 0.5, [2 4 6 8]/10, 'pass');
```

The second code snippet uses the `pass` option to select the Nyquist mobility option. In this case the resulting filter is the same.

Example 2

Create the real multiband filter with two stopbands:

```
[num3, den3] = iirlp2mb(b, a, 0.5, [2 4 6 8]/10, 'stop');
```

Verify the result by comparing the prototype filter with target filters:

```
fvtool(b, a, num1, den1, num2, den2, num3, den3);
```

Combining all of the filters, prototypes and targets, on one figure makes comparing them straightforward. Passbands for the filters in example 1 appear separately in the figure, although they overlap to a degree that makes them hard to identify — they have identical coefficients.

| Magnitude Response (dB) |

Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
Pass	Choice (`'pass'`/`'stop'`) of passband/stopband at DC, `'pass'` being the default
Num	Numerator of the target filter

iirlp2mb

Variable	Description
Den	Denominator of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Purpose   Transform IIR lowpass filter to IIR complex M-band filter

Syntax   [Num,Den,AllpassNum,AllpassDen] = iirlp2mbc(B,A,Wo,Wc)
                   [G,AllpassNum,AllpassDen] = iirlp2mbc(Hd,Wo,Wt)

                   where Hd is a `dfilt` object

Description   [Num,Den,AllpassNum,AllpassDen] = iirlp2mbc(B,A,Wo,Wc)
                   returns the numerator and denominator vectors, Num and Den
                   respectively, of the target filter transformed from the real lowpass
                   prototype by applying an Mth-order real lowpass to complex
                   multibandpass frequency transformation.

                   It also returns the numerator, AllpassNum, and the denominator,
                   AllpassDen, of the allpass mapping filter. The prototype lowpass filter
                   is given with a numerator specified by B and a denominator specified
                   by A.

                   This transformation effectively places one feature of an original filter,
                   located at frequency W_o, at the required target frequency locations,
                   $W_{t1},...,W_{tM}$.

                   Relative positions of other features of an original filter do not change in
                   the target filter. This means that it is possible to select two features of
                   an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still
                   precede F_2 after the transformation. However, the distance between F_1
                   and F_2 will not be the same before and after the transformation.

                   Choice of the feature subject to this transformation is not restricted
                   to the cutoff frequency of an original lowpass filter. In general it is
                   possible to select any feature; e.g., the stopband edge, the DC, the deep
                   minimum in the stopband, or other ones.

                   This transformation can also be used for transforming other types of
                   filters; e.g., notch filters or resonators can be easily replicated at a
                   number of required frequency locations. A good application would be
                   an adaptive tone cancellation circuit reacting to the changing number
                   and location of tones.

[G,AllpassNum,AllpassDen] = iirlp2mbc(Hd,Wo,Wt) returns transformed `dfilt` object G with an IIR complex M-band filter frequency response. The coefficients AllpassNum and AllpassDen represent the allpass mapping filter for mapping the prototype filter frequency Wo and the target frequencies vector Wt. Note that in this syntax Hd is a `dfilt` object with a lowpass magnitude response.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Now create a complex multiband filter with two passbands:

```
[num1, den1] = iirlp2mbc(b, a, 0.5, [2 4 6 8]/10);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num1, den1);
```

Magnitude Response (dB)
You see in the figure that `iirlp2mbc` replicates the desired feature at 0.5 in the lowpass filter at four locations in the multiband filter.

Arguments

Variable	Description
B	Numerator of the prototype lowpass filter.
A	Denominator of the prototype lowpass filter.
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wc	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
Num	Numerator of the target filter.

iirlp2mbc

Variable	Description
Den	Denominator of the target filter.
AllpassNum	Numerator of the mapping filter.
AllpassDen	Denominator of the mapping filter.

See Also   iirftransf | allpasslp2mbc | zpklp2mbc

Purpose   Transform IIR lowpass filter to IIR complex N-point filter

Syntax   [Num,Den,AllpassNum,AllpassDen] = iirlp2xc(B,A,Wo,Wt)
                   [G,AllpassNum,AllpassDen] = iirlp2xc(Hd,Wo,Wt)

                   where Hd is a dfilt object

Description   [Num,Den,AllpassNum,AllpassDen] = iirlp2xc(B,A,Wo,Wt) returns
                   the numerator and denominator vectors, Num and Den respectively, of the
                   target filter transformed from the real lowpass prototype by applying an
                   Nth-order real lowpass to complex multipoint frequency transformation.

                   It also returns the numerator, AllpassNum, and the denominator,
                   AllpassDen, of the allpass mapping filter. The prototype lowpass filter
                   is given with a numerator specified by B and a denominator specified
                   by A.

                   Parameter N also specifies the number of replicas of the prototype
                   filter created around the unit circle after the transformation. This
                   transformation effectively places N features of an original filter, located
                   at frequencies W_{o1},...,W_{oN}, at the required target frequency locations,
                   W_{t1},...,W_{tM}.

                   Relative positions of other features of an original filter are the same
                   in the target filter for the Nyquist mobility and are reversed for the
                   DC mobility. For the Nyquist mobility this means that it is possible to
                   select two features of an original filter, F_1 and F_2, with F_1 preceding F_2.
                   Feature F_1 will still precede F_2 after the transformation. However,
                   the distance between F_1 and F_2 will not be the same before and after
                   the transformation. For DC mobility feature F_2 will precede F_1 after
                   the transformation.

                   Choice of the feature subject to this transformation is not restricted to
                   the cutoff frequency of an original lowpass filter. In general it is possible
                   to select any feature; e.g., a stopband edge, DC, the deep minimum in
                   the stopband, or other ones. The only condition is that the features
                   must be selected in such a way that when creating N bands around the
                   unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

`[G,AllpassNum,AllpassDen] = iirlp2xc(Hd,Wo,Wt)` returns transformed `dfilt` object G with an IIR complex N-point filter frequency response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency Wo and the target frequencies vector Wt. Note that in this syntax Hd is a `dfilt` object with a lowpass magnitude response.

Examples   Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Create the complex bandpass filter from the real lowpass filter:

```
[num, den] = iirlp2xc(b, a, [-0.5 0.5], [-0.25 0.25]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Reviewing the coefficients and the figure produced by the example shows that the target filter has complex coefficients and is indeed a bandpass filter as expected.

Arguments

Variable	Description
B	Numerator of the prototype lowpass filter.
A	Denominator of the prototype lowpass filter.
Wo	Frequency values to be transformed from the prototype filter. They should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
Num	Numerator of the target filter.

iirlp2xc

Variable	Description
Den	Denominator of the target filter.
AllpassNum	Numerator of the mapping filter.
AllpassDen	Denominator of the mapping filter.

See Also   iirftransf | allpasslp2xc | zpklp2xc

Purpose　　　Transform IIR lowpass filter to IIR real N-point filter

Syntax　　　　```
[Num,Den,AllpassNum,AllpassDen] = iirlp2xn(B,A,Wo,Wt)
[Num,Den,AllpassNum,AllpassDen] = iirlp2xn(B,A,Wo,Wt,Pass)
[G,AllpassNum,AllpassDen] = iirlp2bpc(Hd,Wo,Wt),
where Hd is a dfilt object
[G,AllpassNum,AllpassDen] = iirlp2bpc(...,Pass)
```

**Description**　　[Num,Den,AllpassNum,AllpassDen] = iirlp2xn(B,A,Wo,Wt) returns
the numerator and denominator vectors, Num and Den respectively,
of the target filter transformed from the real lowpass prototype by
applying an Nth-order real lowpass to real multipoint frequency
transformation, where N is the number of features being mapped. By
default the DC feature is kept at its original location.

[Num,Den,AllpassNum,AllpassDen]= iirlp2xn(B,A,Wo,Wt,Pass)
allows you to specify an additional parameter, Pass, which chooses
between using the "DC Mobility" and the "Nyquist Mobility." In the
first case the Nyquist feature stays at its original location and the DC
feature is free to move. In the second case the DC feature is kept at an
original frequency and the Nyquist feature is allowed to move.

It also returns the numerator, AllpassNum, and the denominator,
AllpassDen, of the allpass mapping filter. The prototype lowpass
filter is given with the numerator specified by B and the denominator
specified by A.

Parameter N also specifies the number of replicas of the prototype
filter created around the unit circle after the transformation. This
transformation effectively places N features of an original filter, located
at frequencies $W_{o1},...,W_{oN}$, at the required target frequency locations,
$W_{t1},...,W_{tM}$.

Relative positions of other features of an original filter are the same
in the target filter for the Nyquist mobility and are reversed for the
DC mobility. For the Nyquist mobility this means that it is possible to
select two features of an original filter, $F_1$ and $F_2$, with $F_1$ preceding $F_2$.
Feature $F_1$ will still precede $F_2$ after the transformation. However,
the distance between $F_1$ and $F_2$ will not be the same before and after

the transformation. For DC mobility feature $F_2$ will precede $F_1$ after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating `N` bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

`[G,AllpassNum,AllpassDen] = iirlp2xn(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with an IIR real N-point filter frequency response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

`[G,AllpassNum,AllpassDen] = iirlp2xn(...,Pass)` returns transformed `dfilt` object `G` with an IIR real N-point filter frequency response. This syntax allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility." In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is allowed to move.

The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

**Examples**    Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Move the cutoffs of the prototype filter to the new locations W_{t1}=0.25 and W_{t2}=0.75 creating a real bandpass filter:

```
[num, den] = iirlp2xn(b, a, [-0.5 0.5], [0.25 0.75], ...
pass');
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

iirlp2xn has created the desired bandpass filter with the cutoff locations specified in the command.

Magnitude Response in dB

Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
Wo	Frequency values to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
Pass	Choice ('pass'/'stop') of passband/stopband at DC, 'pass' being the default
Num	Numerator of the target filter

Variable	Description
Den	Denominator of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

iirlpnorm

Purpose　　　　Least P-norm optimal IIR filter

Syntax　　　　　```
[num,den] = iirlpnorm(n,d,f,edges,a)
[num,den] = iirlpnorm(n,d,f,edges,a,w)
[num,den] = iirlpnorm(n,d,f,edges,a,w,p)
[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens)
[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens,initnum,initden)
```

Description　　`[num,den] = iirlpnorm(n,d,f,edges,a)` returns a filter having
a numerator order `n` and denominator order `d` which is the best
approximation to the desired frequency response described by `f` and
`a` in the least-pth sense. The vector `edges` specifies the band-edge
frequencies for multi-band designs. An unconstrained quasi-Newton
algorithm is employed and any poles or zeros that lie outside of the
unit circle are reflected back inside. `n` and `d` should be chosen so that
the zeros and poles are used effectively. See the "Hints" on page 7-917
section. Always use `freqz` to check the resulting filter.

`[num,den] = iirlpnorm(n,d,f,edges,a,w)` uses the weights in `w`
to weight the error. `w` has one entry per frequency point (the same
length as `f` and `a`) which tells `iirlpnorm` how much emphasis to put
on minimizing the error in the vicinity of each frequency point relative
to the other points. `f` and `a` must have the same number of elements,
which may exceed the number of elements in `edges`. This allows for
the specification of filters having any gain contour within each band.
The frequencies specified in `edges` must also appear in the vector `f`.
For example,

```
[num,den] = iirlpnorm(5,12,[0 .15 .4 .5 1],[0 .4 .5 1],...
[1 1.6 1 0 0],[1 1 1 10 10])
```

is a lowpass filter with a peak of 1.6 within the passband.

`[num,den] = iirlpnorm(n,d,f,edges,a,w,p)` where `p` is a
two-element vector `[pmin pmax]` allows for the specification of the
minimum and maximum values of `p` used in the least-pth algorithm.
Default is [2 128] which essentially yields the L-infinity, or Chebyshev,
norm. Pmin and pmax should be even. If `p` is the string `'inspect'`, no

optimization will occur. This can be used to inspect the initial pole/zero placement.

`[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens)` specifies the grid density `dens` used in the optimization. The number of grid points is `(dens*(n+d+1))`. The default is 20. `dens` can be specified as a single-element cell array. The grid is not equally spaced.

`[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens,initnum,initden)` allows for the specification of the initial estimate of the filter numerator and denominator coefficients in vectors `initnum` and `initden`. This may be useful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initnum` and `initden`.

Hints
- This is a weighted least-pth optimization.

- Check the radii and locations of the poles and zeros for your filter. If the zeros are on the unit circle and the poles are well inside the unit circle, try increasing the order of the numerator or reducing the error weighting in the stopband.

- Similarly, if several poles have a large radii and the zeros are well inside of the unit circle, try increasing the order of the denominator or reducing the error weighting in the passband.

iirlpnormc

Purpose　　　Constrained least Pth-norm optimal IIR filter

Syntax　　　　`[num,den] = iirlpnormc(n,d,f,edges,a)`
`[num,den] = iirlpnormc(n,d,f,edges,a,w)`
`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius)`
`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p)`
`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p,dens)`
`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p,dens,...`
`initnum,initden)`
`[num,den,err] = iirlpnormc(...)`
`[num,den,err,sos,g] = iirlpnormc(...)`

Description　　`[num,den] = iirlpnormc(n,d,f,edges,a)` returns a filter having
numerator order `n` and denominator order `d` which is the best
approximation to the desired frequency response described by `f` and
`a` in the least-pth sense. The vector `edges` specifies the band-edge
frequencies for multi-band designs. A constrained Newton-type
algorithm is employed. `n` and `d` should be chosen so that the zeros and
poles are used effectively. See the Hints section. Always check the
resulting filter using `fvtool`.

`[num,den] = iirlpnormc(n,d,f,edges,a,w)` uses the weights in `w`
to weight the error. `w` has one entry per frequency point (the same
length as `f` and `a`) which tells `iirlpnormc` how much emphasis to put
on minimizing the error in the vicinity of each frequency point relative
to the other points. `f` and `a` must have the same number of elements,
which can exceed the number of elements in `edges`. This allows for
the specification of filters having any gain contour within each band.
The frequencies specified in `edges` must also appear in the vector `f`.
For example,

`[num,den] = iirlpnormc(5,5,[0 .15 .4 .5 1],[0 .4 .5 1],...`
`[1 1.6 1 0 0],[1 1 1 10 10])`

designs a lowpass filter with a peak of 1.6 within the passband.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius)` returns a filter
having a maximum pole radius of `radius` where 0<`radius`<1. `radius`

defaults to 0.999999. Filters that have a reduced pole radius may retain better transfer function accuracy after you quantize them.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p)` where `p` is a two-element vector [`pmin pmax`] allows for the specification of the minimum and maximum values of `p` used in the least-pth algorithm. Default is [2 128] which essentially yields the L-infinity, or Chebyshev, norm. `pmin` and `pmax` should be even. If `p` is the string `'inspect'`, no optimization will occur. This can be used to inspect the initial pole/zero placement.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p,dens)` specifies the grid density `dens` used in the optimization. The number of grid points is (`dens*(n+d+1)`). The default is 20. `dens` can be specified as a single-element cell array. The grid is not equally spaced.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p,dens,...initnum,initden)` allows for the specification of the initial estimate of the filter numerator and denominator coefficients in vectors `initnum` and `initden`. This may be useful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initnum` and `initden`.

`[num,den,err] = iirlpnormc(...)` returns the least-Pth approximation error `err`.

`[num,den,err,sos,g] = iirlpnormc(...)` returns the second-order section representation in the matrix SOS and gain G. For numerical reasons you may find SOS and G beneficial in some cases.

Hints
- This is a weighted least-pth optimization.

- Check the radii and location of the resulting poles and zeros.

- If the zeros are all on the unit circle and the poles are well inside of the unit circle, try increasing the order of the numerator or reducing the error weighting in the stopband.

- Similarly, if several poles have a large radius and the zeros are well inside of the unit circle, try increasing the order of the denominator or reducing the error weight in the passband.

- If you reduce the pole radius, you might need to increase the order of the denominator.

The message

```
Poorly conditioned matrix. See the "help" file.
```

indicates that iirlpnormc cannot accurately compute the optimization because either:

1 The approximation error is extremely small (try reducing the number of poles or zeros — refer to the hints above).

2 The filter specifications have huge variation, such as a=[1 1e9 0 0].

Examples

This example returns a lowpass filter whose pole radius is constrained to 0.8

```
[b,a,err,s,g] = iirlpnormc(6,6,[0 .4 .5 1],[0 .4 .5 1],...
[1 1 0 0],[1 1 1 1],.8);
hd = dfilt.df1sos(s,g); % Construct second-order sections filter.
fvtool(hd); % View filter's magnitude response
```

From the magnitude response shown here you see the lowpass nature of the filter. The pole/zero plot following shows that the poles are constrained to 0.8 as specified in the command.

Magnitude Response (dB)

Purpose   RLS IIR filter from specification object

Syntax   ```
hd = design(d,'iirls')
hd = design(d,'iirls',designoption,value,designoption,value,
    ...)
```

**Description**  `hd = design(d,'iirls')` designs a least-squares filter specified by the filter specification object `d`.

---

**Note** The `iirls` algorithm might not be well behaved in all cases. Experience is your best guide to determining if the resulting filter meets your needs. When you use `iirls` to design a filter, review the filter carefully to ensure that it is appropriate for your use.

---

```
hd =
design(d,'iirls',designoption,value,designoption,value,...)
```
returns a least-squares IIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `iirls`, refer to the command line help system. For example, to get specific information about using `iirls` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'iirls')
```

Examples   Starting from an arbitrary magnitude and phase design object `d`, generate a complex bandpass filter of order = 5. To make the example a little easier to do, use the default values for F, and H, the frequency vector and the complex desired frequency response.

```
d = fdesign.arbmagnphase('N,F,H',5);
d =

            Response: 'Arbitrary Magnitude and Phase'
       Specification: 'N,F,H'
         Description: {'Filter Order';'Frequency Vector';'
                       Complex Desired Frequency Response'
 NormalizedFrequency: true
          FilterOrder: 5
          Frequencies: [1x655 double]
         FreqResponse: [1x655 double]

design(d,'iirls'); % Opens FVTool to show the filter.
```

Displaying both the phase and magnitude response in FVTool shows you the filter.

iirnotch

Purpose	Second-order IIR notch filter
Syntax	[num,den] = iirnotch(w0,bw)
	[num,den] = iirnotch(w0,bw,ab)

Description   [num,den] = iirnotch(w0,bw) turns a digital notching filter with the notch located at w0, and with the bandwidth at the -3 dB point set to bw. To design the filter, w0 must meet the condition 0.0 w0 1.0, where 1.0 corresponds to π adians per sample in the frequency range.

The quality factor (Q factor) q for the filter is related to the filter bandwidth by q w0/bw where ω_0 is w0, the frequency to remove from the signal.

[num,den] = iirnotch(w0,bw,ab) returns a digital notching filter whose bandwidth, bw, is specified at a level of -ab decibels. Including the optional input argument ab lets you specify the magnitude response bandwidth at a level that is not the default -3 dB point, such as -6 dB or 0 dB.

Examples   Design and plot an IIR notch filter that removes a 60 Hz tone (f0) from a signal at 300 Hz (fs). For this example, set the Q factor for the filter to 35 and use it to specify the filter bandwidth:

```
wo = 60/(300/2);   bw = wo/35;
[b,a] = iirnotch(wo,bw);
fvtool(b,a);
```

Shown in the next plot, the notch filter has the desired bandwidth with the notch located at 60 Hz, or 0.4π radians per sample. Compare this plot to the comb filter plot shown on the reference page for iircomb.

See Also   firgr | iircomb | iirpeak

iirpeak

Purpose	Second-order IIR peak or resonator filter
Syntax	`[num,den] = iirpeak(w0,bw)` `[num,den] = iirpeak(w0,bw,ab)`

Description `[num,den] = iirpeak(w0,bw)` turns a second-order digital peaking filter with the peak located at `w0`, and with the bandwidth at the +3 dB point set to `bw`. To design the filter, `w0` must meet the condition $0.0 < w0 < 1.0$, where 1.0 corresponds to π radians per sample in the frequency range.

The quality factor (Q factor) q for the filter is related to the filter bandwidth by `q = w0/bw` where ω_0 is `w0` the signal frequency to boost.

`[num,den] = iirpeak(w0,bw,ab)` returns a digital peaking filter whose bandwidth, `bw`, is specified at a level of +`ab` decibels. Including the optional input argument `ab` lets you specify the magnitude response bandwidth at a level that is not the default +3 dB point, such as +6 dB or 0 dB.

Examples Design and plot an IIR peaking filter that boosts the frequency at 1.75 Khz in a signal and has bandwidth of 500 Hz at the -3 dB point:

```
fs = 10000; wo = 1750/(fs/2);  bw = 500/(fs/2);
[b,a] = iirpeak(wo,bw);
fvtool(b,a);
```

Shown in the next plot, the peak filter has the desired gain and bandwidth at 1.75 KHz.

iirpowcomp

Purpose   Power complementary IIR filter

Syntax   ```
[bp,ap] = iirpowcomp(b,a)
[bp,ap,c] = iirpowcomp(b,a)
```
Description   `[bp,ap] = iirpowcomp(b,a)` returns the coefficients of the power complementary IIR filter g(z) = bp(z)/ap(z) in vectors `bp` and `ap`, given the coefficients of the IIR filter h(z) = b(z)/a(z) in vectors `b` and `a`. `b` must be symmetric (Hermitian) or antisymmetric (antihermitian) and of the same length as `a`. The two power complementary filters satisfy the relation

$$|H(w)|^2 + |G(w)|^2 = 1.$$

`[bp,ap,c] = iirpowcomp(b,a)` where `c` is a complex scalar of magnitude = 1, forces `bp` to satisfy the generalized hermitian property

`conj(bp(end:-1:1)) = c*bp`.

When `c` is omitted, it is chosen as follows:

- When `b` is real, chooses C as 1 or -1, whichever yields `bp` real

- When `b` is complex, C defaults to 1

`ap` is always equal to `a`.

Examples   ```
[b,a]=cheby1(10,.5,.4);
[bp,ap]=iirpowcomp(b,a);
Hd1 = dfilt.df2(b,a);
Hd2 = dfilt.df2(bp,ap);
hfvt = fvtool([Hd1,Hd2],'MagnitudeDisplay','Magnitude');
legend(hfvt,'Original Filter','Power Complementary Version');
```

The next figure presents the results of applying `iirpowcomp` to the Chebyshev filter — the power complementary version of the original filter.

# iirrateup

**Purpose**

Upsample IIR filter by integer factor

**Syntax**

`[Num,Den,AllpassNum,AllpassDen] = iirrateup(B,A,N)`

**Description**

`[Num,Den,AllpassNum,AllpassDen] = iirrateup(B,A,N)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter being transformed from any prototype by applying an `N`th-order rateup frequency transformation, where `N` is the upsample ratio. Transformation creates `N` equal replicas of the prototype filter frequency response.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

The relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, $F_1$ and $F_2$, with $F_1$ preceding $F_2$. Feature $F_1$ will still precede $F_2$ after the transformation. However, the distance between $F_1$ and $F_2$ will not be the same before and after the transformation.

**Examples**

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
[num, den] = iirrateup(b, a, 4);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

As shown in the figure produced by FVTool, the transformed filter appears as expected.

Magnitude Response in dB

Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
N	Frequency multiplication ratio
Num	Numerator of the target filter
Den	Denominator of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

iirrateup

See Also   iirtransf | allpassrateup | zpkrateup

Purpose   Shift frequency response of IIR filter

Syntax   `[Num,Den,AllpassNum,AllpassDen] = iirshift(B,A,Wo,Wt)`

Description `[Num,Den,AllpassNum,AllpassDen] = iirshift(B,A,Wo,Wt)` returns
the numerator and denominator vectors, `Num` and `Den` respectively,
of the target filter transformed from the real lowpass prototype by
applying a second-order real shift frequency mapping.

It also returns the numerator, `AllpassNum`, and the denominator of the
allpass mapping filter, `AllpassDen`. The prototype lowpass filter is
given with the numerator specified by `B` and the denominator specified
by `A`.

This transformation places one selected feature of an original filter
located at frequency W_o to the required target frequency location, W_t.
This transformation implements the "DC Mobility," which means that
the Nyquist feature stays at Nyquist, but the DC feature moves to a
location dependent on the selection of W_o and W_t.

Relative positions of other features of an original filter do not change in
the target filter. This means that it is possible to select two features of
an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still
precede F_2 after the transformation. However, the distance between F_1
and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the real shift transformation is not
restricted to the cutoff frequency of an original lowpass filter. In general
it is possible to select any feature; e.g., the stopband edge, the DC, the
deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of
filters; e.g., notch filters or resonators can change their position in a
simple way without designing them from the beginning.

Examples   Design a prototype real IIR halfband filter using a standard elliptic
approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Perform the real frequency shift by defining where the selected feature of the prototype filter, originally at W_o=0.5, should be placed in the target filter, W_t=0.75:

```
Wo = 0.5; Wt = 0.75;
[num, den] = iirshift(b, a, Wo, Wt);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Shifting the specified feature from the prototype to the target generates the response shown in the figure.

Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Num	Numerator of the target filter
Den	Denominator of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

See Also   iirftransf | allpassshift | zpkshift

iirshiftc

Purpose

Shift frequency response of IIR complex filter

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,Wo,Wc)
[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,0.5)
[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,-0.5)
```

Description

`[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,Wo,Wc)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a first-order complex frequency shift transformation. This transformation rotates all the features of an original filter by the same amount specified by the location of the selected feature of the prototype filter, originally at W_o, placed at W_t in the target filter.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with the numerator specified by `B` and the denominator specified by `A`.

`[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,0.5)` calculates the allpass filter for doing the Hilbert transformation, i.e. a 90 degree counterclockwise rotation of an original filter in the frequency domain.

`[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,-0.5)` calculates the allpass filter for doing an inverse Hilbert transformation, i.e. a 90 degree clockwise rotation of an original filter in the frequency domain.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Rotate all features of the prototype filter in the frequency domain by the same amount by specifying where the selected feature of an original filter, W_o= 0.5, should appear in the target filter, W_t= 0.25:

```
[num, den] = iirshiftc(b, a, 0.5, 0.25);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

After applying the shift, the selected feature from the original filter is just where it should be, at W_t = 0.25.

Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter

iirshiftc

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Num	Numerator of the target filter
Den	Denominator of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

Purpose   Filter impulse response

Syntax   ```
[h,t] = impz(hfilt)
[h,t] = impz(hfilt,n)
[h,t] = impz(hfilt,n,fs)
[h,t] = impz(hfilt,[],fs)
impz(hfilt)
[h,t] = impz(hs)
[h,t] = impz(hs,Name,Value)
impz(hs)
```

Description   impz returns the impulse response based on the current filter
                   coefficients. This section describes common impz operation with
                   adaptive filters, discrete-time filters, multirate filters, and filter System
                   objects. For more input options, refer to impz in Signal Processing
                   Toolbox documentation.

                   [h,t] = impz(hfilt) returns the impulse response h and the
                   corresponding time points w at which the impulse response of hfilt
                   is computed. The impulse response is evaluated at 10 1-second
                   intervals—(0:9)'.

                   [h,t] = impz(hfilt,n) returns the impulse response evaluated at
                   floor(n) 1-second intervals—(0:floor(n)-1)'.

                   [h,t] = impz(hfilt,n,fs) returns the impulse response evaluated at
                   floor(n) 1/fs-second intervals—(0:floor(n)-1)'/fs.

                   [h,t] = impz(hfilt,[],fs) returns the impulse response evaluated
                   at 10 1/fs-second intervals—(0:9)'/fs.

                   impz(hfilt) uses FVTool to plot the impulse response of the filter. You
                   can also provide the optional input arguments n and fs with this syntax.

                   [h,t] = impz(hs) returns the impulse response for the filter
                   System object hs. The impulse response is evaluated at 10 1-second
                   intervals—(0:9)'. You can also provide the optional input arguments
                   n and fs with this syntax.

impz

`[h,t] = impz(hs,Name,Value)` returns an impulse response with additional options specified by one or more `Name,Value` pair arguments.

`impz(hs)` uses FVTool to plot the impulse response of the filter System object `hs`.

Note You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

Input Arguments

hfilt

`hfilt` is either:

- An adaptive `adaptfilt`, discrete-time `dfilt`, or multirate `mfilt` filter object
- A vector of adaptive, discrete-time, or multirate filter objects

The multirate filter impulse response is computed relative to the rate at which the filter is running. When you specify `fs` (the sampling rate) as an input argument, `impz` assumes the filter is running at that rate.

For multistage cascades, `impz` forms a single-stage multirate filter that is equivalent to the cascade. It then computes the response relative to the rate at which the equivalent filter is running. `impz` does not support all multistage cascades. The function analyzes only those cascades for which there exists an equivalent single-stage filter.

As an example, consider a 2-stage interpolator where the first stage has an interpolation factor of 2 and the second stage has an interpolation factor of 4. In this case, an equivalent single-stage filter exists with an overall interpolation factor of 8. `impz` uses this equivalent filter for the analysis. If a sampling frequency `fs` is specified as an input argument to `impz`, the function interprets `fs` as the rate at which the equivalent filter is running.

hs

Filter System object. The function supports the following filter structures.

- `dsp.FIRFilter`
- `dsp.BiquadFilter`
- `dsp.FIRInterpolator`
- `dsp.CICInterpolator`
- `dsp.FIRDecimator`
- `dsp.CICDecimator`
- `dsp.FIRRateConverter`

n

Number of samples.

> **Default:** 10

fs

Sampling frequency.

> **Default:** 1

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Arithmetic

```
`double' | 'single' | 'fixed'
```

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

System Object State	Coefficient Data Type	Rule
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

h

Complex, n-element impulse response vector. If hfilt is a vector of filters, h is a complex, length(hfilt)-by-n matrix of impulse response vectors corresponding to each filter in hfilt. If n is not specified, the function uses a default value of 8192.

For adaptive filters, h is the instantaneous impulse response.

t

Time vector of length n, in seconds. t consists of n points equally spaced from 0 to floor(n)/fs. If n is not specified, the function uses a default value of 10. If fs is not specified, the function uses a default value of 1.

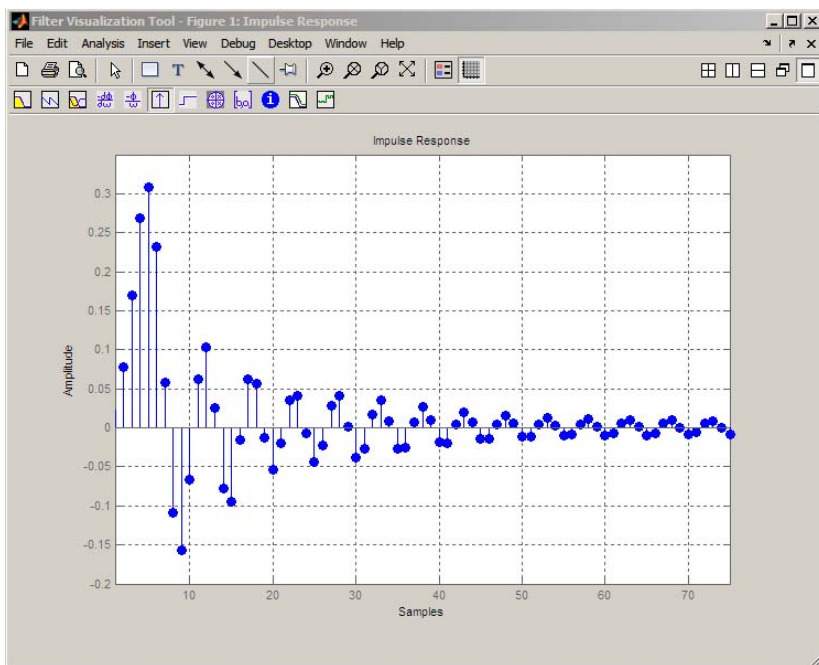
Examples   Create a discrete-time filter for a fourth-order, lowpass elliptic filter with a cutoff frequency of 0.4 times the Nyquist frequency. Use a second-order sections structure to resist quantization errors. Plot the first 50 samples of the impulse response, along with the reference impulse response.

```
d = fdesign.lowpass(.4,.5,1,80);
% Create a design object for the prototype filter.
```

Use ellip to design a minimum order discrete-time filter in second-order section form.

```
hd=design(d,'ellip');
```

Convert hd to fixed-point, and plot the impulse response:

```
impz(hd);
axis([1 75 -0.2 0.35])
```


See Also   filter | stepz

info

Purpose	Information about filter

Syntax

```
info(h)
info(h,'short')
info(h,'long')
s = info(h)
```

Description   info(h) returns very basic information about the filter. The particulars depend on the filter type and structure.

info(h,'short') returns the same information as info(h).

info(h,'long') returns the following information about the filter:

- Specifications such as the filter structure and filter order

- Information about the design method and options

- Performance measurements for the filter response, such as the passband cutoff or stopband attenuation, included in the measure method

- Cost of implementing the filter in terms of operations required to apply the filter to data, included in the cost method

When the filter uses fixed-point arithmetic, the function returns additional information about the filter, including the arithmetic setting and details about the filter internals.

s = info(h) returns filter information in the variable s. You can also provide the optional arguments 'short' and 'long' with this syntax.

Input Arguments

h

One of the following types of filter object or filter System object:

- Discrete-time filter (dfilt) object

- Multirate filter (mfilt) object

- Adaptive filter (adaptfilt) object

- Filter System object. The function supports the following structures:

- dsp.FIRFilter

- dsp.BiquadFilter

- dsp.FIRInterpolator

- dsp.CICInterpolator

- dsp.FIRDecimator

- dsp.CICDecimator

- dsp.FIRRateConverter

'short'

Input string that instructs the function to return basic information about the filter.

'long'

Input string that instructs the function to return in-depth information about the filter.

Output Arguments	**s**

Variable for storing filter information.

Examples   Obtain short-format and long-format information about a filter.

```
>> d = fdesign.lowpass;
>> f = design(d);
>> info(f)

int

Purpose   States from CIC filter

Syntax   `integerstates = int(hm.states)`

Description   `integerstates = int(hm.states)` returns the states of a CIC filter in matrix form, rather than as the native `filtstates` object. An important point about `int` is that it quantizes the state values to the smallest number of bits possible while maintaining the values accurately.

Examples   For many users, the states of multirate filters are most useful as a matrix, but the CIC filters store the states as objects. Here is how you get the states from you CIC filter as a matrix.

```
hm = mfilt.cicdecim;
hs = hm.states; % Returns a FILTSTATES.CIC object hs.
states = int(hs); % Convert object hs to a signed integer matrix.
```

After using int to convert the states object to a matrix, here is what you get.

Before converting:

```
hm.states

ans =

    Integrator: [2x1 States]
          Comb: [2x1 States]
```

After the conversion and assigning the states to `states`:

```
states

states =

        0          0
        0          0
```

See Also   filtstates.cic | mfilt.cicdecim | mfilt.cicinterp

isallpass

Purpose	Determine whether filter is allpass

Syntax	`isallpass(hd)`
	`isallpass(hd,tolerance)`
	`isallpass(hs,...)`
	`isallpass(hs,'Arithmetic',`*`arithtype`*`)`

Description   `isallpass(hd)` determines whether the filter object `hd` is an allpass filter, returning `1` if true and `0` if false.

`isallpass(hd,tolerance)` uses input argument `tolerance` to determine whether the numerator and denominator transfer functions for the filter are close enough in value to be considered equal, and thus allpass. The function returns `1` if true (the difference between the numbers is less than `tolerance`) and `0` if not.

Given an allpass filter with this transfer function

$$H(z) = \frac{\alpha_n + \ldots + \alpha_1 z^{-(n-1)} + z^{-n}}{1 + \alpha_1 z^{-1} + \ldots + \alpha_n z^{-n}}$$

if the numerator and denominator transfer functions are equal, the filter is allpass. The `tolerance` input argument lets you determine how closely the transfer functions have to match to be considered equal. This approach may be most helpful in fixed-point allpass filters.

Lattice coupled allpass filters always have allpass sections, this function always returns `1` for filters whose structure is `latticeca`.

`isallpass(hs,...)` determines whether the filter System object `hs` is an allpass filter, returning `1` if true and `0` if false.

`isallpass(hs,'Arithmetic',`*`arithtype`*`)` analyzes the filter System object `hs` based on the specified *arithtype*. *arithtype* can be `'double'`, `'single'`, or `'fixed'`. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of

the CoefficientDataType property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on

isallpass

System Object State	Coefficient Data Type	Rule
		the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Examples   Use `dfilt.allpass` to construct an allpass filter. Then, use `isallpass` to test whether the filter is allpass.

```
c=[.8,1.5,0.4, 0.7]; % Allpass coefficients.
hd=dfilt.allpass(c);
AllPass = isallpass(hd);
% Returns a 1 indicated hd is all pass.
```

See Also   isfir | islinphase | ismaxphase | isminphase | isreal | issos | isstable

Purpose   Determine whether filter is FIR

Syntax   isfir(h)
                isfir(hs)

Description isfir(h) determines whether filter h is an FIR filter, returning 1 when
                the filter is an FIR filter, and 0 when it is IIR. isfir applies to dfilt,
                mfilt, and adaptfilt objects.

                To determine whether h is an FIR filter, isfir(h) inspects filter h and
                determines whether the filter, in transfer function form, has a scalar
                denominator. If it does, it is an FIR filter.

                isfir(hs) determines whether the filter System object hs is an FIR
                filter, returning 1 if true and 0 if false.

Examples   d = fdesign.lowpass;
                h = design(d);
                isfir(h)
                ans =

                      1

                returns 1 for the status of filter h. The filter is an FIR structure with
                denominator reference coefficient equal to 1.

                For multirate filters, isfir works the same way.

                d = fdesign.interpolator(5); % Interpolate by 5.
                h = design(d); % Use the default design method.
                isfir(h)

                ans =

                      1

                Use isfir with adaptive filters as well.

isfir

See Also   isallpass | islinphase | ismaxphase | isminphase | isreal | issos | isstable

Purpose   Determine whether filter is linear phase

Syntax   islinphase(h)
                 islinphase(h,tolerance)
                 islinphase(hs,...)
                 islinphase(hs,'Arithmetic',*arithtype*)

Description islinphase(h) determines if the filter object h is linear phase, and
                 returns 1 if true and 0 if false. adapfilt, dfilt, and mfilt objects
                 work with islinphase.

                 islinphase(h,tolerance) uses input argument tolerance to
                 determine whether the filter coefficients are close enough in value to
                 be considered symmetric or antisymmetric, returning 1 if true (the
                 difference between the values is less than tolerance) and 0 if not.

                 The phase determination is based on the reference coefficients. A filter
                 has linear phase if it is FIR and its transfer function coefficients are
                 symmetric or antisymmetric. If it is IIR, has poles on or outside the
                 unit circle, and both numerator and denominator are symmetric or
                 antisymmetric, it is linear phase also.

                 islinphase(hs,...) determines whether the filter System object hs is
                 linear phase, returning 1 if true and 0 if false.

                 islinphase(hs,'Arithmetic',*arithtype*) analyzes the filter
                 System object hs based on the specified *arithtype*. *arithtype* can
                 be 'double', 'single', or 'fixed'. When you specify 'double' or
                 'single', the function performs double- or single-precision analysis.
                 When you specify 'fixed' , the arithmetic changes depending on the
                 setting of the CoefficientDataType property and whether the System
                 object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Examples   This IIR filter has linear phase.

```
d = fdesign.lowpass('n,fc',10,0.55);
h = design(d,'window');
islinphase(h)
```

Using the specification nb,na,fp,fst results in an IIR filter that is not linear phase in this design.

```
nb=15
na=10
d=fdesign.lowpass('nb,na,fp,fst',nb,na,0.45,0.55)
h=design(d) % Use the default design method iirlpnorm.
islinphase(h)
```

ismaxphase

Purpose	Determine whether filter is maximum phase

Syntax	`ismaxphase(h)`
	`ismaxphase(h,tolerance)`
	`ismaxphase(hs,...)`
	`ismaxphase(hs,'Arithmetic',`*`arithtype`*`)`

Description

`ismaxphase(h)` determines if the filter object h is maximum phase, and returns 1 if true and 0 if false. `adapfilt`, `dfilt`, and `mfilt` objects work with `ismaxphase`.

`ismaxphase(h,tolerance)` uses input argument `tolerance` to determine whether the zeros of the filter transfer function have values that are close enough to 1 to be considered 1 or greater. Such values are on or outside the unit circle. The function returns 1 if true (the difference between the coefficient value and 1 is less than `tolerance`) and 0 if not.

The phase determination is based on the reference coefficients. A filter is maximum phase when the zeros of its transfer function are on or outside the unit circle, or when the numerator is a scalar.

`ismaxphase(hs,...)` determines whether the filter System object hs is maximum phase, returning 1 if true and 0 if false.

`ismaxphase(hs,'Arithmetic',`*`arithtype`*`)` analyzes the filter System object hs based on the specified *arithtype*. *arithtype* can be `'double'`, `'single'`, or `'fixed'`. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

ismaxphase

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Examples   Use `ismaxphase` to determine whether the following filters are maximum phase. The first is a discrete-time `dfilt` object and the second an adaptive filter.

```
fp = 100;
fst= 120;
fs = 800;
ap = 1;
ast= 60;
d = fdesign.lowpass('fp,fst,ap,ast',fp,fst,ap,ast,fs);
h = design(d,'equiripple','maxphase',true);
ismaxphase(h)
```

To make this a minimum phase filter, use `fliplr` to change the coefficient order. Reordering the coefficients this way changes the phase from maximum to minimum.

```
h.numerator=fliplr(h.numerator);
isminphase(h)
```

returns 1, so this filter is minimum phase.

For the adaptive filter example, try the following code:

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
mu = 1;                % NLMS step size
offset = 50;           % NLMS offset
ha = adaptfilt.nlms(32,mu,1,offset);
[y,e] = filter(ha,x,d);
```

After adapting, ha is an FIR filter that does not exhibit maximum phase.

```
ismaxphase(ha)
```

isminphase

Purpose	Determine whether filter is minimum phase
Syntax	isminphase(h) isminphase(h,tolerance) isminphase(hs,...) isminphase(hs,'Arithmetic',*arithtype*)
Description	isminphase(h) determines if the filter object h is minimum phase, and returns 1 if true and 0 if false. isminphase works with adapfilt, dfilt, and mfilt objects.

isminphase(h,tolerance) uses the input argument tolerance to determine whether the filter transfer function zeros are outside the unit circle by more than tolerance. If the zeros do not lie outside the unit circle by more than tolerance, isminphase returns a 1. If any zeros are more than tolerance outside the unit circle, isminphase returns a 0.

A filter is *minimum phase* when all the zeros of its transfer function are on or inside the unit circle, or the numerator is a scalar. An equivalent definition for a minimum phase filter is a causal and stable system with a causal and stable inverse.

isminphase(hs,...) determines whether the filter System object hs is minimum phase, returning 1 if true and 0 if false.

isminphase(hs,'Arithmetic',*arithtype*) analyzes the filter System object hs based on the specified *arithtype*. *arithtype* can be 'double', 'single', or 'fixed'. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed' , the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

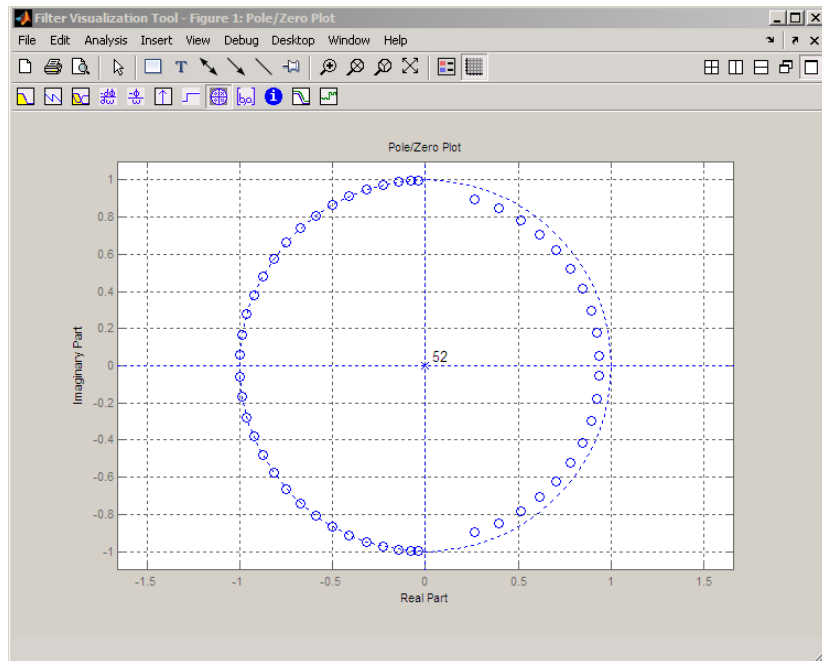
Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

isminphase

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

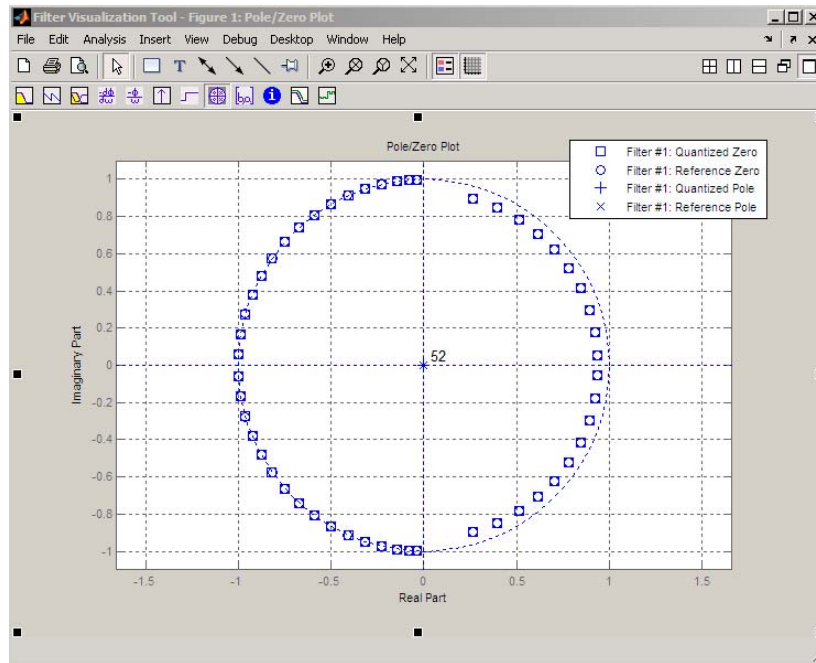
Examples   Create a minimum-phase filter.

```
fp = 200;
fst= 230;
fs = 900;
ap = 1;
ast= 60;
d = fdesign.lowpass('fp,fst,ap,ast',fp,fst,ap,ast,fs);
h = design(d,'equiripple','minphase',true);
isminphase(h)
% Returns a 1
fvtool(h,'analysis','polezero')
```


The zeros of the FIR filter are all on or inside the unit circle.

To illustrate the effect of coefficient quantization, make h a fixed-point filter. The quantization process results in the filter no longer being minimum phase. However, if the tolerance is increased to 0.01, the quantized design satisfies the definition of a minimum phase filter.

```
h.arithmetic='fixed';
isminphase(h)
% Returns a 0
fvtool(h,'analysis','polezero');
isminphase(h,0.01)
% Returns a 1
```

isminphase


See Also   isallpass | isfir | islinphase | ismaxphase | isreal | issos |
isstable

isreal

Purpose   Determine whether filter uses real coefficients

Syntax   isreal(hd)
              isreal(hs)

Description   isreal(hd) returns 1 (or true) if all filter coefficients for the filter hd
                 are real, and returns 0 (or false) otherwise. Complex filters have one or
                 more coefficients with nonzero imaginary parts.

                 isreal(hs) determines whether the filter coefficients of the filter
                 System object hs are real, returning 1 if true and 0 if false.

                 Note Quantizing a filter cannot make a real filter into a complex filter.

Examples   Create a double-precision filter and a fixed-point filter. Then, test the
               coefficients of the fixed-point filter to see if they are strictly real.

               d=fdesign.lowpass('n,fp,ap,ast',5,0.4,0.5,20);
               hd=design(d,'ellip');
               hd.arithmetic='fixed';
               IsReal =isreal(hd);
               % Returns a 1

See Also   isfir | islinphase | ismaxphase | isminphase | issos | isstable |
               isallpass

issos

Purpose	Determine whether filter is SOS form
Syntax	`issos(hd)` `issoss(hs)`
Description	`issos(hd)` determines whether quantized filter `hq` consists of second-order sections. Returns `1` if all sections of quantized filter `hq` have order less than or equal to two, and `0` otherwise. `issoss(hs)` determines whether the filter System object `hs` consists of second-order sections, returning `1` if true and `0` if false.
Examples	By default, fdesign and design return SOS filters when possible. This example designs a lowpass SOS filter that uses fixed-point arithmetic. ```\nd=fdesign.lowpass('n,fp,ap,ast',40,0.55,0.1,60);\nhd=design(d,'ellip');\nhd.arithmetic='fixed';\nIsSOS=issos(hd);\n``` The fixed-point filter `hd` is in second-order section form, as is the double-precision version.
See Also	`isallpass` | `isfir` | `islinphase` | `ismaxphase` | `isminphase` | `isreal` | `isstable`

Purpose   Determine whether filter is stable

Syntax
```
isstable(hq)
isstable(hs)
isstable(hs,'Arithmetic',arithtype)
```

Description   isstable(hq) tests quantized filter hq to determine whether its poles are inside the unit circle. If the poles lie on or outside the circle, isstable returns 0. If the poles are inside the circle, isstable returns 1.

To determine the filter stability, isstable checks the filter coefficients. When the poles lie on or inside the unit circle, the filter is stable. FIR filters are stable by design because the defining transfer functions do not have denominator polynomials, thus no feedback to cause instability.

isstable(hs) determines whether the filter System object hs is stable, returning 1 if true and 0 if false.

isstable(hs,'Arithmetic',*arithtype*) analyzes the filter System object hs based on the specified *arithtype*. *arithtype* can be 'double', 'single', or 'fixed'. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed' , the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point

| System Object State	Coefficient Data Type	Rule
		analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Examples   Because filter stability is very important in your design process, use
isstable to determine whether your double-precision or fixed-point
IIR filter is stable.

```
d=fdesign.nyquist(2,'n,tw',24,0.1);
hd=design(d,'iirlinphase')
isstable(hd)
hd2=design(d,'equiripple');
isstable(hd2)
```

kaiserwin

Purpose	Kaiser window filter from specification object
Syntax	h = design(d,'kaiserwin') h = design(d,'kaiserwin',designoption,value,designoption,... value,...)

Description   h = design(d,'kaiserwin') designs a digital filter hd, or a multirate filter hm that uses a Kaiser window. For kaiserwin to work properly, the filter order in the specifications object must be even. In addition, higher order filters (filter order greater than 120) tend to be more accurate for smaller transition widths. kaiserwin returns a warning when your filter order may be too low to design your filter accurately.

h =
design(d,'kaiserwin',designoption,value,designoption,...
value,...) returns a filter where you specify design options as input arguments and the design process uses the Kaiser window technique.

To determine the available design options, use designopts with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using kaiserwin, refer to the command line help system. For example, to get specific information about using kaiserwin with d, the specification object, enter the following at the MATLAB prompt.

```
help(d,'kaiserwin')
```

Examples   This example designs a direct form FIR filter from a halfband filter specification object.

```
d=fdesign.halfband('n,tw',200,0.01)
hd= design(d,'kaiserwin','filterstructure','dffir')
```

In this example, kaiserwin uses an interpolating filter specification object:

```
d=fdesign.interpolator(4,'lowpass');
h = design(d,'kaiserwin');
```

See Also   equiripple | firls

lagrange

Purpose	Fractional delay filter from `fdesign.fracdelay` specification object
Syntax	`Hd = design(d,'lagrange')` `hd = design(d,'lagrange',FilterStructure,`*`structure`*`)`
Description	`Hd = design(d,'lagrange')` designs a fractional delay filter using the Lagrange method based on the specifications in `d`. `hd = design(d,'lagrange',FilterStructure,`*`structure`*`)` specifies the Lagrange design method and the *structure* filter structure for `hd`. The sole valid filter structure string for `structure` is `fd`, describing the fractional delay structure.
Examples	This example uses a fractional delay of 0.30 samples. The `help` and `designopts` commands provide the details about designing fractional delay filters.

```
d=fdesign.fracdelay(.30)

d =

                Response: 'Fractional Delay'
           Specification: 'N'
             Description: {'Filter Order'}
               FracDelay: 0.3
       NormalizedFrequency: true
             FilterOrder: 3

designmethods(d)

Design Methods for class fdesign.fracdelay (N):

lagrange

help(d,'lagrange')
```

```
 DESIGN Design a Lagrange fractional delay filter.
 HD = DESIGN(D, 'lagrange') designs a Lagrange filter
specified by the FDESIGN object D.

HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns
a filter with the structure STRUCTURE.  STRUCTURE is 'fd'
by default and can be any of the following:

    'fd'

% Example #1 - Design a linear Lagrange fractional
% delay filter of 0.2 samples.
h = fdesign.fracdelay(0.2,'N',2);
Hd = design(h, 'lagrange', 'FilterStructure', 'fd')

% Example #2 - Design a cubic Lagrange fractional
% delay filter.
Fs = 8000;      % Sampling frequency of 8kHz
fdelay = 50e-6; % Fractional delay of 50 microseconds.
h  = fdesign.fracdelay(fdelay,'N',3,Fs);
Hd = design(h, 'lagrange', 'FilterStructure', 'fd');
```

This example designs a linear Lagrange fractional delay filter where
you set the delay to 0.2 seconds and the filter order N to 2.

```
h = fdesign.fracdelay(0.2,'N',2); .
hd = design(h,'lagrange','FilterStructure','fd')
```

Design a cubic Lagrange fractional delay filter with filter order equal
to 3..

```
Fs = 8000;      % Sampling frequency of 8 kHz.
fdelay = 50e-6; % Fractional delay of 50 microseconds.
h  = fdesign.fracdelay(fdelay,'N',3,Fs);
hd = design(h,'lagrange','FilterStructure','fd');
```

lagrange

Purpose   Check model for blocks from specific DSP System Toolbox libraries

Syntax   liblinks(lib)
                   liblinks(lib,sys)
                   liblinks(lib,sys,c)

Description   liblinks(lib) returns a cell array of strings that lists the blocks in the
                   current model that are linked to the specified libraries. The input lib
                   provides a cell array of strings with the library names. Use the library
                   name visible in the title bar when you open a library model.

                   liblinks(lib,sys) acts on the named model sys.

                   liblinks(lib,sys,c) changes the foreground color of the returned
                   blocks to the color c. Possible values of c are 'blue', 'green', 'red',
                   'cyan', 'magenta', 'yellow', or 'black'.

Examples   Check for blocks from the Sources library in the specified model:

                   rlsdemo
                   liblinks('dspsrcs4',gcs)

See Also   dsp_links

limitcycle

Purpose   Response of single-rate, fixed-point IIR filter

Syntax   report = limitcycle(hd)
                 report = limitcycle(hd,ntrials,inputlengthfactor,stopcriterion)

Description report = limitcycle(hd) returns the structure report that contains
                 information about how filter hd responds to a zero-valued input vector.
                 By default, the input vector has length equal to twice the impulse
                 response length of the filter.

                 limitcycle returns a structure whose elements contain the details
                 about the limit cycle testing. As shown in this table, the report includes
                 the following details.

Output Object Property	Description
LimitCycleType	Contains one of the following results: • Granular — indicates that a granular overflow occurred. • Overflow — indicates that an overflow limit cycle occurred. • None — indicates that the test did not find any limit cycles.
Zi	Contains the initial condition value(s) that caused the detected limit cycle to occur.
Output	Contains the output of the filter in the steady state.
Trial	Returns the number of the Monte Carlo trial on which the limit cycle testing stopped. For example, Trial = 10 indicates that testing stopped on the tenth Monte Carlo trial.

Using an input vector longer than the filter impulse response ensures that the filter is in steady-state operation during the limit cycle testing. `limitcycle` ignores output that occurs before the filter reaches the steady state. For example, if the filter impulse length is 500 samples, `limitcycle` ignores the filter output from the first 500 input samples.

To perform limit cycle testing on your IIR filter, you must set the filter `Arithmetic` property to `fixed` and `hd` must be a fixed-point IIR filter of one of the following forms:

- `df1` — direct-form I
- `df1t` — direct-form I transposed
- `df1sos` — direct-form I with second-order sections
- `df1tsos` — direct-form I transposed with second-order sections
- `df2` — direct-form II
- `df2t` — direct-form II transposed
- `df2sos` — direct-form II with second-order sections
- `df2tsos` — direct-form II transposed with second-order sections

When you use `limitcycle` without optional input arguments, the default settings are

- Run 20 Monte Carlo trials
- Use an input vector twice the length of the filter impulse response
- Stop testing if the simulation process encounters either a granular or overflow limit cycle

To determine the length of the filter impulse response, use `impzlength`:

```
impzlength(hd)
```

During limit cycle testing, if the simulation runs reveal both overflow and granular limit cycles, the overflow limit cycle takes precedence and is the limit cycle that appears in the report.

Each time you run `limitcycle`, it uses a different sequence of random initial conditions, so the results can differ from run to run.

Each Monte Carlo trial uses a new set of randomly determined initial states for the filter. Test processing stops when `limitcycle` detects a zero-input limit cycle in filter `hd`. `report = limitcycle(hd,ntrials,inputlengthfactor,stopcriterion)` lets you set the following optional input arguments:

- `ntrials` — Number of Monte Carlo trials (default is 20).

- `inputlengthfactor` — integer factor used to calculate the length of the input vector. The length of the input vector comes from (`impzlength(hd) * inputlengthfactor`), where `inputlengthfactor = 2` is the default value.

- `stopcriterion` — the criterion for stopping the Monte Carlo trial processing. `stopcriterion` can be set to **either** (the default), **granular**, **overflow**. This table describes the results of each stop criterion.

stopcriterion Setting	Description
either	Stop the Monte Carlo trials when `limitcycle` detects either a granular or overflow limit cycle.
granular	Stop the Monte Carlo trials when `limitcycle` detects a granular limit cycle.
overflow	Stop the Monte Carlo trials when `limitcycle` detects an overflow limit cycle.

> **Note** An important feature is that if you specify a specific limit cycle stop criterion, such as overflow, the Monte Carlo trials do not stop when testing encounters a granular limit cycle. You receive a warning that no overflow limit cycle occurred, but consider that a granular limit cycle might have occurred.

Examples   In this example, there is a region of initial conditions in which no limit cycles occur and a region where they do. If no limit cycles are detected before the Monte Carlo trials are over, the state sequence converges to zero. When a limit cycle is found, the states do not end at zero. Each time you run this example, it uses a different sequence of random initial conditions, so the plot you get can differ from the one displayed in the following figure.

```
s = [1 0 0 1 0.9606 0.9849];
hd = dfilt.df2sos(s);
hd.arithmetic = 'fixed';
greport = limitcycle(hd,20,2,'granular')
oreport = limitcycle(hd,20,2,'overflow')
figure,
subplot(211),plot(greport.Output(1:20)), title('Granular Limit Cycle');
subplot(212),plot(oreport.Output(1:20)), title('Overflow Limit Cycle');

greport =

    LimitCycle: 'granular'
            Zi: [2x1 double]
        Output: [1303x1 embedded.fi]
         Trial: 1

oreport =

    LimitCycle: 'overflow'
            Zi: [2x1 double]
        Output: [1303x1 embedded.fi]
```

```
Trial: 2
```

The plots shown in this figure present both limit cycle types — the first displays the small amplitude granular limit cycle, the second the larger amplitude overflow limit cycle.
As you see from the plots, and as is generally true, overflow limit cycles are much greater magnitude than granular limit cycles. This is why `limitcycle` favors overflow limit cycle detection and reporting.

Purpose   Maxflat FIR filter

Syntax   hd = design(d,'maxflat')
                 hd = design(d,'maxflat','FilterStructure',structure)

Description hd = design(d,'maxflat') designs a maximally flat filter, hd, from a filter specification object, d.

hd = design(d,'maxflat','FilterStructure',structure) designs a maximally flat filter where structure is one of the following:

- 'dffir', a discrete-time, direct-form FIR filter (the default value)

- 'dffirt', a discrete-time, direct-form FIR transposed filter

- 'dfsymfir', a discrete-time, direct-form symmetric FIR filter

- 'fftfir', a discrete-time, overlap-add, FIR filter

Examples   Example 1: Design a lowpass filter with a maximally flat FIR structure.

```
d  = fdesign.lowpass('N,F3dB', 50, 0.3);
Hd = design(d, 'maxflat');
```

Example 2: Design a highpass filter with a maximally flat overlap-add FIR structure.

```
d  = fdesign.highpass('N,F3dB', 50, 0.7);
Hd=design(d,'maxflat','FilterStructure','fftfir');
```

maximizestopband

Purpose	Maximize stopband attenuation of fixed-point filter
Syntax	`Hq = maximizestopband(Hd,Wordlength)` `Hq = maximizestopband(Hd,Wordlength,'Ntrials',N)`
Description	`Hq = maximizestopband(Hd,Wordlength)` quantizes the single-stage or multistage FIR filter `Hd` and returns the fixed-point filter `Hq` with wordlength `wordlength` that maximizes the stopband attenuation. `Hd` must be generated using `fdesign` and `design`. For multistage filters, `wordlength` can either be a scalar or vector. If `wordlength` is a scalar, the same wordlength is used for all stages. If `wordlength` is a vector, each stage uses the corresponding element in the vector. The vector length must equal the number of stages. `maximizestopband` uses a stochastic noise-shaping procedure by default to minimize the wordlength. To obtain repeatable results on successive function calls, initialize the uniform random number generator `rand`
	`Hq = maximizestopband(Hd,Wordlength,'Ntrials',N)` specifies the number of Monte Carlo trials to use in the maximization. `Hq` is the fixed-point filter with the largest stopband attenuation among the trials. The number of Monte Carlo trials `N` defaults to 1.
	You must have the Fixed-Point Toolbox software installed to use this function.
Examples	Maximize stopband attenuation for 16–bit fixed-point filter.

```
Hf = fdesign.lowpass('Fp,Fst,Ap,Ast',0.4,0.45,0.5,60);
Hd = design(Hf,'equiripple');
WL = 16; % use 16 bits to represent coefficients
Hq = maximizestopband(Hd,WL);
% Compare stopband attenuation
md = measure(Hd);
mq = measure(Hq);
hfvt=fvtool(Hd,Hq,'showreference','off');
legend(hfvt,'Floating-point Filter','Fixed-point Filter');
```

maxstep

Purpose   Maximum step size for adaptive filter convergence

Syntax   mumax = maxstep(ha,x)
                 [mumax,mumaxmse] = maxstep(ha,x)

Description mumax = maxstep(ha,x) predicts a bound on the step size to provide
                 convergence of the mean values of the adaptive filter coefficients. The
                 columns of the matrix x contain individual input signal sequences. The
                 signal set is assumed to have zero mean or nearly so.

                 [mumax,mumaxmse] = maxstep(ha,x) predicts a bound on the adaptive
                 filter step size to provide convergence of the LMS adaptive filter
                 coefficients in the mean-square sense. maxstep issues a warning when
                 ha.stepsize is outside of the range 0 < ha.stepsize < mumaxmse/2.

                 maxstep is available for the following adaptive filter objects:

                 • adaptfilt.blms

                 • adaptfilt.blmsfft

                 • adaptfilt.lms

                 • adaptfilt.nlms (uses a different syntax. Refer to the text below.)

                 • adaptfilt.se

                 Note With adaptfilt.nlms filter objects, maxstep uses the following
                 slightly different syntax:

                 mumax = maxstep(ha)
                 [mumax,mumaxmse] = maxstep(ha)

                 The maximum step size for convergence is fully defined by the filter
                 object ha. Matrix x is not necessary. If you include an x input matrix,
                 MATLAB returns an error.

Examples   Analyze and simulate a 32-coefficient (31st-order) LMS adaptive filter
object. To demonstrate the adaptation process, run 2000 iterations
and 50 trials.

```
% Specify [numiterations,numexamples] = size(x);
x = zeros(2000,50);
d = x;
obj = fdesign.lowpass('n,fc',31,0.5);
hd = design(obj,'window'); % FIR filter to identified.
coef = cell2mat(hd.coefficients); % Convert cell array to matrix.

for k=1:size(x,2);   % Create input and desired response signal
                        % matrices.
% Set the (k)th input to the filter.
  x(:,k) = filter(sqrt(0.75),[1 -0.5],sign(randn(size(x,1),1)));
  n = 0.1*randn(size(x,1),1);  % (k)th observation noise signal.
  d(:,k) = filter(coef,1,x(:,k))+n; % (k)th desired signal end.
end
mu = 0.1;                       % LMS step size.
ha = adaptfilt.lms(32,mu);
[mumax,mumaxmse] = maxstep(ha,x);

Warning: Step size is not in the range 0 < mu < mumaxmse/2:
Erratic behavior might result.

mumax

mumax =

    0.0623

mumaxmse

mumaxmse =

    0.0530
```

Purpose   Measure filter magnitude response

Syntax   measure(hd)
measure(hm)
measure(hs)
measure(hs)

Description   measure(hd) returns measured values for specific points in the
magnitude response curve for filter object hd. When you use a design
object d to create a filter (by using fdesign.*type* to create d), you
specify one or more values that define your desired filter response.
measure(hd) tests the filter to determine the actual values in the
magnitude response of the filter, such as the stopband attenuation or
the passband ripple. Comparing the results returned by measure to
the specifications you provided in the design object helps you assess
whether the filter meets your design criteria.

Note To use measure, hd, hm, or hs must result from using a filter
design method with a filter specifications object. measure works with
multirate filters and discrete-time filters. The function does not support
adaptive filters because you cannot use fdesign.*type* to construct
adaptive filter specifications objects.

---

measure(hd) returns measurements for the discrete-time filter hd. The
function determines the relevant specifications based on the response
type of the design object you use to create the filter. For example, for
single-rate lowpass filters made from design objects, measure(hd)
returns the following filter specifications.

Lowpass Filter Specification	Description
Sampling Frequency	Filter sampling frequency.
Passband Edge	Location of the edge of the passband as it enters transition.

Lowpass Filter Specification	Description
3-dB Point	Location of the –3 dB point on the response curve.
6-dB Point	Location of the –6 dB point on the response curve.
Stopband Edge	Location of the edge of the transition band as it enters the stopband.
Passband Ripple	Ripple in the passband.
Stopband Atten.	Attenuation in the stopband.
Transition Width	Width of the transition between the passband and stopband, in normalized frequency or absolute frequency. Measured between Fpass and Fstop.

In contrast, when you use a bandstop design object, measure(hd) returns these specifications for the resulting bandstop filter.

Bandstop Filter Specification	Description
Sampling Frequency	Filter sampling frequency.
First Passband Edge	Location of the edge of the first passband.
First 3-dB Point	Location of the edge of the –3 dB point in the first transition band.
First 6-dB Point	Location of the edge of the –6 dB point in the first transition band.
First Stopband Edge	Location of the start of the stopband.
Second Stopband Edge	Location of the end of the stopband.

Bandstop Filter Specification	Description
Second 6-dB Point	Location of the edge of the −6 dB point in the second transition band.
Second 3-dB Point	Location of the edge of the −3 dB point in the second transition band.
Second Passband Edge	Location of the start of the second passband.
First Passband Ripple	Ripple in the first passband.
Stopband Atten.	Attenuation in the stopband.
Second Passband Edge	Ripple in the second passband.
First Transition Width	Width of the first transition region. Measured between the −3 and −6 dB points.
Second Transition Width	Width of the second transition region. Measured between the −6 and −3 dB points.

measure(hm) returns measurements for the multirate filter hm. The set of filter specifications that measure returns for multirate filters might be different from those for discrete-time filters.

The set of response measurements that measure returns depends on the response you use to design the filter. For example, when hm is an FIR lowpass interpolator (whose response is lowpass), measure(hm) returns the following set of measurements.

Interpolator Filter Specification	Description
First Passband Edge	Location of the edge of the passband as it enters transition.
3-dB Point	Location of the −3 dB point on the response curve.

Interpolator Filter Specification	Description
`6-dB Point`	Location of the –6 dB point on the response curve.
`Stopband Edge`	Location of the edge of the transition band as it enters the stopband.
`Passband Ripple`	Ripple in the passband.
`Stopband Atten.`	Attenuation in the stopband.
`Transition Width`	Width of the transition between the passband and stopband, in normalized frequency or absolute frequency. Measured between `Fpass` and `Fstop`.

For reference, the specification object d created the interpolator specifications shown in the preceding table:

```
d=fdesign.interpolator(6,'lowpass')

d =

        MultirateType: 'Interpolator'
   InterpolationFactor: 6
             Response: 'Lowpass'
        Specification: 'Fp,Fst,Ap,Ast'
          Description: {4x1 cell}
   NormalizedFrequency: true
                Fpass: 0.133333333333333
                Fstop: 0.166666666666667
                Apass: 1
                Astop: 60
```

measure(hs) returns measurements for the filter System object hs. You must construct hs using design with the optional name-value pair argument 'SystemObject',true.

measure(hs) returns measurements for the filter System object hs with additional options specified by one or more Name,Value pair arguments.

Tips   For designs that do not specify some of the frequency constraints, the function may not be able to determine corresponding magnitude measurements. In these cases, a constraint can be passed in to measure to determine such measurements. For example:

```
f = fdesign.lowpass('N,F3dB,Ast',8,0.5,80);
H = design(f,'cheby2','SystemObject',true);
measure(H)
```

returns values of Unknown for the passband edge, passband ripple, and transition width measurements, but

```
f = fdesign.lowpass('N,F3dB,Ast',8,0.5,80);
H = design(f,'cheby2','SystemObject',true);
measure(H,'Fpass',0.4)
```

provides measurements for all returned values.

Input Arguments

hd

Discrete-time dfilt filter object.

hm

Multirate mfilt filter object.

hs

Filter System object. The function supports the following filter structures.

- dsp.FIRFilter

- dsp.BiquadFilter

- dsp.FIRInterpolator

- dsp.CICInterpolator

- dsp.FIRDecimator

- dsp.CICDecimator

- dsp.FIRRateConverter

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments, where Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Arithmetic

`double' | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point

System Object State	Coefficient Data Type	Rule
		analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Examples   For the first example, create a lowpass filter and check whether the
actual filter meets the specifications. For this case, use normalized
frequency for Fs, the default setting.

```
d2=fdesign.lowpass('Fp,Fst,Ap,Ast',0.45,0.55,0.1,80)

d2 =

                   Response: 'Lowpass'
              Specification: 'Fp,Fst,Ap,Ast'
                Description: {4x1 cell}
        NormalizedFrequency: true
                      Fpass: 0.45
                      Fstop: 0.55
                      Apass: 0.1
                      Astop: 80

designmethods(d2)

Design Methods for class fdesign.lowpass (Fp,Fst,Ap,Ast):

butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage

hd2=design(d2) % Use the default equiripple design method.

hd2 =

      FilterStructure: 'Direct-Form FIR'
```

```
         Arithmetic: 'double'
          Numerator: [1x68 double]
    PersistentMemory: false

measure(hd2)

ans =

Sampling Frequency : N/A (normalized frequency)
Passband Edge      : 0.45
3-dB Point         : 0.47794
6-dB Point         : 0.48909
Stopband Edge      : 0.55
Passband Ripple    : 0.09615 dB
Stopband Atten.    : 80.2907 dB
Transition Width   : 0.1
```

`Stopband Edge`, `Passband Edge`, `Passband Ripple`, and `Stopband Atten.` all meet the specifications.

Now, using `Fs` in linear frequency, create a bandpass filter, and measure the magnitude response characteristics.

```
d=fdesign.bandpass

d =

               Response: 'Bandpass'
          Specification: 'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2'
            Description: {7x1 cell}
    NormalizedFrequency: true
                 Fstop1: 0.35
                 Fpass1: 0.45
                 Fpass2: 0.55
                 Fstop2: 0.65
                 Astop1: 60
                  Apass: 1
                 Astop2: 60
```

```
normalizefreq(d,false,1.5e3) % Convert to linear freq.

hd=design(d,'cheby2');

measure(hd)

ans =

Sampling Frequency      : 1.5 kHz
First Stopband Edge     : 0.2625 kHz
First 6-dB Point        : 0.31996 kHz
First 3-dB Point        : 0.32497 kHz
First Passband Edge     : 0.3375 kHz
Second Passband Edge    : 0.4125 kHz
Second 3-dB Point       : 0.42503 kHz
Second 6-dB Point       : 0.43004 kHz
Second Stopband Edge    : 0.4875 kHz
First Stopband Atten.   : 60 dB
Passband Ripple         : 0.17985 dB
Second Stopband Atten.  : 60 dB
First Transition Width  : 0.075 kHz
Second Transition Width : 0.075 kHz
```

measure(hd) returns the actual response values, in the units you
chose. In this example, all frequencies appear in kilohertz because the
sampling frequency is in kilohertz.

See Also   design | fdesign | normalizefreq

Purpose   Multirate filter

Syntax   hm = mfilt.*structure*(input1,input2,...)

Description hm = mfilt.*structure*(input1,input2,...) returns the object hm
                 of type *structure*. As with dfilt and adaptfilt objects, you must
                 include the *structure* string to construct a multirate filter object.
                 You can, however, construct a default multirate filter object of a given
                 structure by not including input arguments in your calling syntax.

                 Multirate filters include decimators and interpolators, and fractional
                 decimators and fractional interpolators where the resulting
                 interpolation or decimation factor is not an integer.

Structures

Each of the following multirate filter structures has a reference page
of its own.

Filter Structure String	Description of Resulting Multirate Filter	Coefficient Mapping Support in `realizemdl` and `block`
mfilt.cascade	Cascade multirate filters to form another filter	Supported
mfilt.cicdecim	Cascaded integrator-comb decimator	Not supported
mfilt.cicinterp	Cascaded integrator-comb interpolator	Not supported
mfilt.farrowsrc	Multirate Farrow filter	Supported.

Filter Structure String	Description of Resulting Multirate Filter	Coefficient Mapping Support in `realizemdl` and `block`
`mfilt.fftfirinterp`	Overlap-add FIR polyphase interpolator	Not supported
`mfilt.firdecim`	Direct-form FIR polyphase decimator	Supported
`mfilt.firinterp`	Direct-form FIR polyphase interpolator	Supported
`mfilt.firsrc`	Direct-form FIR polyphase sample rate converter	Supported
`mfilt.firtdecim`	Direct-form transposed FIR polyphase decimator	Supported
`mfilt.holdinterp`	FIR hold interpolator	Not supported
`mfilt.iirdecim`	IIR decimator	Supported
`mfilt.iirinterp`	IIR interpolator	Supported
`mfilt.linearinterp`	FIR Linear interpolator	Supported
`mfilt.iirwdfdecim`	IIR wave digital filter decimator	Supported
`mfilt.iirwdfinterp`	IIR wave digital filter interpolator	Supported

Copying mfilt Objects

To create a copy of an `mfilt` object, use the copy method.

```
h2 = copy(hd)
```

Note The syntax hd2 = hd copies only the object handle. It does not create a new object. hd2 and hd are not independent. If you change the property value for one of the two, such as hd2, you are changing the property for both.

Examples Decimation by a factor of two. Convert input sampled at 48 kHz to 24 kHz:

```
Fs = 4.8e4;
t =0:1/Fs:1-(1/Fs);
x = cos(2*pi*4000*t);
Hm=mfilt.firdecim(2);
% Note cutoff frequency of 1/2 normalized frequency
fvtool(Hm);
% Note the group delay of 34 samples
fvtool(Hm,'analysis','grpdelay');
y = filter(Hm,x);
% Note delay in output is consistent with 36/2
stem(y(1:48),'markerfacecolor',[0 0 1]);
```

Using existing coefficients to decimate a signal by a factor of two:

```
M = 2; % Decimation factor
  b = firhalfband('minorder',.45,0.0001);
  Hm = mfilt.firdecim(M,b);
  % Decimate a signal which consists of the sum of 2 sinusoids.
  N = 160;
  x = sin(2*pi*.05*[0:N-1]+pi/3)+cos(2*pi*.03*[0:N-1]+pi/3);
  y = filter(Hm,x);
```

mfilt

> **Note** Multirate filters can also have complex coefficients. For example, you can specify complex coefficients in the argument num passed to the filter structure. This works for all multirate filter structures.
>
> ```
> m = 2;
> num = [0.5 0.5+1j*0.2];
> Hm = mfilt.firdecim(m, num);
> y = filter(Hm, [1:10]);
> ```

See Also   mfilt.firinterp | mfilt.firsrc | mfilt.firtdecim

Purpose   Cascade filter objects

Syntax   hm = cascade(hm1,hm2,...,hmn)

Description   hm = cascade(hm1,hm2,...,hmn) creates filter object hm by cascading
                 (connecting in series) the individual filter objects hm1, hm2, and so on
                 to hmn.

                 In block diagram form, the cascade looks like this, with x as the input to
                 the filter hm and y the output from the cascade filter hm:

                 mfilt.cascade accepts any combination of mfilt and dfilt objects
                 (discrete time filters) to cascade, as well as Farrow filter objects.

Examples   Create a variety of mfilt objects and cascade them together.

```
hm(1) = mfilt.firdecim(12);
hm(2) = mfilt.firdecim(4);
h1 = mfilt.cascade(hm(1),hm(2));
hm(3) = mfilt.firinterp(4);
hm(4) = mfilt.firinterp(12);
h2 = mfilt.cascade(hm(3),hm(4));
% Cascade h1 and h2 together
h3 = mfilt.cascade(h1,h2,9600);
```

See Also   dfilt.cascade

mfilt.cicdecim

Purpose	Fixed-point CIC decimator

Syntax   hm = mfilt.cicdecim(r,m,n,iwl,owl,wlps)

Description hm = mfilt.cicdecim(r,m,n,iwl,owl,wlps) returns a cascaded
integrator-comb (CIC) decimation filter object.

All of the input arguments are optional. To enter any optional value,
you must include all optional values to the left of your desired value.

When you omit one or more input options, the omitted option applies
the default values shown in the table below.

The following table describes the input arguments for creating hm.

Input Arguments	Description
r	Decimation factor applied to the input signal. Sharpens the response curve to let you change the shape of the response. r must be an integer value greater than or equal to 1. The default value is 2.
m	Differential delay. Changes the shape, number, and location of nulls in the filter response. Increasing m increases the sharpness of the nulls and the response between nulls. In practice, differential delay values of 1 or 2 are the most common. m must be an integer value greater than or equal to 1. The default value is 1.
n	Number of sections. Deepens the nulls in the response curve. Note that this is the number of either comb or integrator sections, not the total section count. 2 is the default value.
iwl	Word length of the input signal. Use any integer number of bits. The default value is 16 bits.

Input Arguments	Description
owl	Word length of the output signal. It can be any positive integer number of bits. By default, owl is 16 bits.
wlps	Defines the number of bits per word in each filter section while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter wlps as a scalar or vector of length 2*n, where n is the number of sections. When wlps is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the decimator.
	When you elect to specify wlps as an input argument, the FilterInternals property automatically switches from the default value of 'FullPrecision' to 'SpecifyWordLengths'.

Constraints and Word Length Considerations

CIC decimators have the following constraint — the word lengths of the filter section must be monotonically decreasing. The word length of each filter section must be the same size as, or smaller than, the word length of the previous filter section.

The formula for B_{max}, the most significant bit at the filter output, is given in the Hogenauer paper in the References below.

$$B_{\max} = (N \log_2 RM + B_{in} - 1)$$

where B_{in} is the number of bits of the input.

The cast operations shown in the diagram in "Algorithms" on page 7-1023 perform the changes between the word lengths of each section. When you specify word lengths that do not follow the constraints above, the constructor returns an error.

When you specify the word lengths correctly, the most significant bit B_{max} stays the same throughout the filter, while the word length of each section either decreases or stays the same. This can cause the fraction length to change throughout the filter as least significant bits are truncated to decrease the word length, as shown in "Algorithms" on page 7-1023.

Properties of the Object

Objects have properties that control the way the object behaves. This table lists all the properties for the filter, with a description of each.

Name	Values	Default	Description
Arithmetic	fixed	fixed	Reports the kind of arithmetic the filter uses. CIC decimators are always fixed-point filters.
DecimationFactor	Any positive integer	2	Amount to reduce the input sampling rate.
DifferentialDelay	Any positive integer	1	Sets the differential delay for the filter. Usually a value of one or two is appropriate.
FilterStructure	mfilt structure string	None	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt objects.
FilterInternals	FullPrecision, MinWordLengths, SpecifyPrecision, SpecifyWordLengths	FullPrecision	Set the usage mode for the filter. Refer to "Usage Modes" on page 7-1015 below for details.

Name	Values	Default	Description
InputFracLength	Any positive integer	15	The number of bits applied to the fraction length to interpret the input data to the filter.
InputOffset	Integers in the range $0 \leq \text{InputOffset} \leq r-1$	0	Contains a value derived from the number of input samples and the decimation factor — InputOffset = mod(length(nx),m) where nx is the number of input samples that have been processed so far and m is the decimation factor. The InputOffset property applies only when you set the PersistentMemory property to true. See "InputOffset" on page 8-125 for more information.
InputWordLength	Any positive integer	16	The number of bits applied to the word length to interpret the input data to the filter.

Name	Values	Default	Description
NumberOfSections	Any positive integer	2	Number of sections used in the decimator. Generally called n. Reflects either the number of decimator or comb sections, not the total number of sections in the filter.
OutputFracLength	Any positive integer	15	The number of bits applied to the fraction length to interpret the output data from the filter. Read-only.
OutputWordLength	Any positive integer	16	The number of bits applied to the word length to interpret the output data from the filter.
PersistentMemory	false or true	false	Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States

Name	Values	Default	Description
			that the filter does not change are not affected. When `PersistentMemory` is `false`, you cannot access the filter states. Setting `PersistentMemory` to `true` reveals the `States` property so you can modify the filter states.

Name	Values	Default	Description
SectionWord Lengths	Any integer or a vector of length 2*n.	16	Defines the bits per section used while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter `SectionWordLengths` as a scalar or vector of length 2*n, where n is the number of sections. When `SectionWordLengths` is a scalar, the scalar value is applied to each filter section. When `SectionWordLengths` is a vector of values,

Name	Values	Default	Description
			the values apply to the sections in order. The default is 16 for each section in the decimator. Available when `FilterInternals` is `'SpecifyWordLengths'`.
States	`filtstates.cic` object	m+1-by-n matrix of zeros, after you call function `int`.	Stored conditions for the filter, including values for the integrator and comb sections before and after filtering. m is the differential delay of the comb section and n is the number of sections in the filter. The integrator states are stored in the first matrix row. States for the comb section fill the remaining rows in the matrix. Available for modification when `PersistentMemory` is `true`. Refer to the `filtstates` object in Signal Processing Toolbox documentation for more general information about the `filtstates` object.

Usage Modes

There are four modes of usage for this which are set using the `FilterInternals` property

- `FullPrecision` — All word and fraction lengths set to B_{max} + 1, called B_{accum} by Fred Harris in [3]. Full Precision is the default setting.

- `MinWordLengths` — Automatically set the sections for minimum word lengths.

- `SpecifyWordLengths` — Specify the word lengths for each section.

- `SpecifyPrecision` — Specify precision by providing values for the word and fraction lengths for each section.

Full Precision

In full precision mode, the word lengths of all sections and the output are set to B_{accum} as defined by

$$B_{accum} = ceil(N_{secs}(Log_2(D \times M)) + InputWordLength)$$

where N_{secs} is the number of filter sections.

Section fraction lengths and the fraction length of the output are set to the input fraction length.

Here is the display for this mode:

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'FullPrecision'
```

Minimum Wordlengths

In minimum word length mode, you control the output word length explicitly. When the output word length is less than B_{accum}, roundoff noise is introduced at the output of the filter. Hogenauer's bit pruning theory (refer to [1]) states that one valid design criterion is to make the word lengths of the different sections of the filter smaller than B_{accum} as well, so that the roundoff noise introduced by all sections does not exceed the roundoff noise introduced at the output.

In this mode, the design calculates the word lengths of each section to meet the Hogenauer criterion. The algorithm subtracts the number of bits computed using eq. 21 in Hogenauer's paper from B_{accum} to determine the word length each section.

To compute the fraction lengths of the different sections, the algorithm notes that the bits thrown out for this word length criterion are least significant bits (LSB), therefore each bit thrown out at a particular section decrements the fraction length of that section by one bit compared to the input fraction length. Setting the output wordlength for the filter automatically sets the output fraction length as well.

Here is the display for this mode:

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'MinWordLengths'

OutputWordLength: 16
```

Specify word lengths

In this mode, the design algorithm discards the LSBs, adjusting the fraction length so that unrecoverable overflow does not occur, always producing a reasonable output.

You can specify the word lengths for all sections and the output, but you cannot control the fraction lengths for those quantities.

To specify the word lengths, you enter a vector of length `2*(NumberOfSections)`, where each vector element represents the word length for a section. If you specify a scalar, such as B_{accum}, the full-precision output word length, the algorithm expands that scalar to a vector of the appropriate size, applying the scalar value to each section.

The CIC design does not check that the specified word lengths are monotonically decreasing. There are some cases where the word lengths are not necessarily monotonically decreasing, for example

```
hcic=mfilt.cicdecim;
hcic.FilterInternals='minwordlengths';
hcic.Outputwordlength=14;
```

which are valid CIC filters but the word lengths do not decrease monotonically across the sections.

Here is the display for the `SpecifyWordLengths` mode.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'SpecifyWordLengths'

SectionWordLengths: [19 18 18 17]
```

```
OutputWordLength: 16
```

Specify precision

In this mode, you have full control over the word length and fraction lengths of all sections and the filter output.

When you elect the `SpecifyPrecision` mode, you must enter a vector of length 2*(`NumberOfSections`) with elements that represent the word length for each section. When you enter a scalar such as B_{accum}, `mfilt.cicdecim` expands that scalar to a vector of the appropriate size and applies the scalar value to each section and the output. The design does not check that this vector is monotonically decreasing.

Also, you must enter a vector of length 2*(`NumberOfSections`) with elements that represent the fraction length for each section as well. When you enter a scalar such as B_{accum}, `mfilt.cicdecim` applies scalar expansion as done for the word lengths.

Here is the `SpecifyPrecision` display.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'SpecifyPrecision'

SectionWordLengths: [19 18 18 17]
SectionFracLengths: [14 13 13 12]

OutputWordLength: 16
OutputFracLength: 11
```

About the States of the Filter

In the states property you find the states for both the integrator and comb portions of the filter. states is a matrix of dimensions m + 1-by-n, with the states apportioned as follows:

- States for the integrator portion of the filter are stored in the first row of the state matrix.

- States for the comb portion fill the remaining rows in the state matrix..

To review the states of a CIC filter, use int to assign the states to a variable in MATLAB. As an example, here are the states for a CIC decimator hm before and after filtering a data set.

```
x = fi(ones(1,10),true,16,0); % Fixed-point input data.
hm = mfilt.cicdecim(2,1,2,16,16,16);
sts=int(hm.states)
set(hm,'InputFracLength',0); % Integer input specified.
y=filter(hm,x);
sts=int(hm.states)
```

STS is an integer matrix that int returns from the contents of the filtstates.cic object in hm.

Design Considerations

When you design your CIC decimation filter, remember the following general points:

- The filter output spectrum has nulls at $\omega = k * 2\pi/rm$ radians, $k = 1,2,3....$

- Aliasing and imaging occur in the vicinity of the nulls.

- n, the number of sections in the filter, determines the passband attenuation. Increasing n improves the filter ability to reject aliasing and imaging, but it also increases the droop (or rolloff) in the filter passband. Using an appropriate FIR filter in series after the CIC decimation filter can help you compensate for the induced droop.

- The DC gain for the filter is a function of the decimation factor. Raising the decimation factor increases the DC gain.

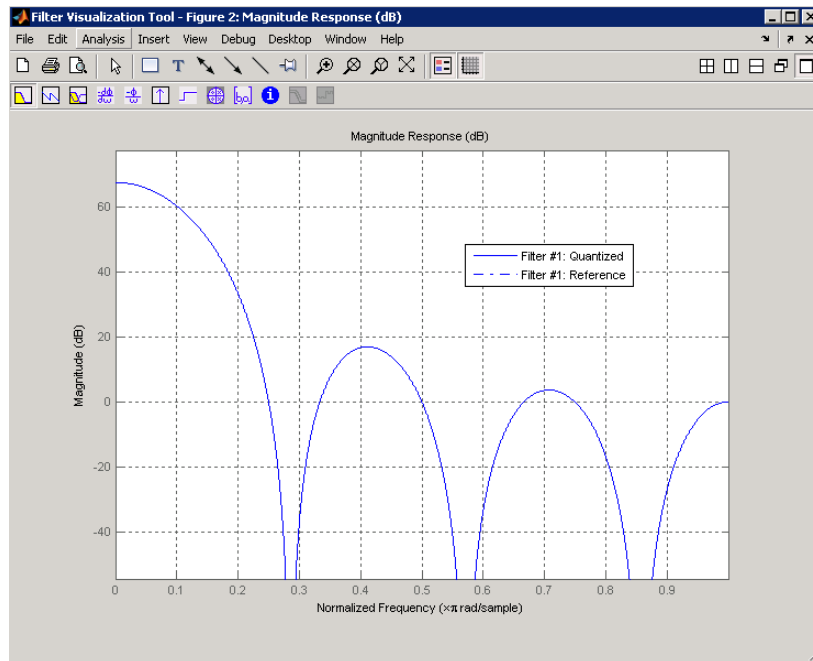
Examples

This example applies a decimation factor r equal to 8 to a 160-point impulse signal. The signal output from the filter has 160/r, or 20, points or samples. Choosing 10 bits for the word length represents a fairly common setting for analog to digital converters. The plot shown after the code presents the stem plot of the decimated signal, with 20 samples remaining after decimation:

```
m = 2;  % Differential delays in the filter.
n = 4;  % Filter sections
r = 8;   % Decimation factor
x = int16(zeros(160,1)); x(1) = 1;    % Create a 160-point
                                      % impulse signal.
hm = mfilt.cicdecim(r,m,n); % Expects 16-bit input
                            % by default.
y = filter(hm,x);
stem(double(y));     % Plot output as a stem plot.
xlabel('Samples'); ylabel('Amplitude');
title('Decimated Signal');
```

Decimated Signal
The next example demonstrates one way to compute the filter frequency response, using a 4-section decimation filter with the decimation factor set to 7:

```
hm = mfilt.cicdecim(7,1,4);
fvtool(hm)
```

FVTool provides ways for you to change the title and x labels to match the figure shown. Here's the frequency response plot for the filter. For details about the transfer function used to produce the frequency response, refer to [1] in the References section.


mfilt.cicdecim

This final example demonstrates the decimator for converting from 44.1 kHz audio to 22.05 kHz — decimation by two. To overlay the before and after signals, scale the output and plot the signals on a stem plot.

```
r = 2;                  % Decimation factor.
hm = mfilt.cicdecim(r); % Use default NumberOfSections &
                        % DifferentialDelay property values.
fs = 44.1e3;            % Original sampling frequency: 44.1kHz.
n = 0:10239;            % 10240 samples, 0.232 second long signal.
x  = sin(2*pi*1e3/fs*n);% Original signal, sinusoid at 1kHz.

y_fi = filter(hm,x); % 5120 samples, still 0.232 seconds.

% Scale the output to overlay the stem plots.
x = double(x);
y = double(y_fi);
```
```
y = y/max(abs(y));
stem(n(1:44)/fs,x(2:45)); hold on;  % Plot original signal
                                    % sampled at 44.1kHz.
stem(n(1:22)/(fs/r),y(3:24),'r','filled'); % Plot decimated
                                    % signal (22.05kHz)
                                    % in red.
xlabel('Time (seconds)');ylabel('Signal Value');
```

Algorithms   To show how the CIC decimation filter is constructed, the following figure presents a block diagram of the filter structure for a two-section CIC decimation filter (n = 2). *fs* is the high sampling rate, the input to the decimation process.

For details about the bits that are removed in the Comb section, refer to [1] in References.

mfilt.cicdecim

`mfilt.cicdecim` calculates the fraction length at each section of the decimator to avoid overflows at the output of the filter.

See Also `mfilt` | `mfilt.cicinterp`

Purpose   Fixed-point CIC interpolator

Syntax   hm = mfilt.cicinterp(R,M,N,ILW,OWL,WLPS)
                     hm = mfilt.cicinterp
                     hm = mfilt.cicinterp(R,...)

Description   hm = mfilt.cicinterp(R,M,N,ILW,OWL,WLPS) constructs a cascaded
                    integrator-comb (CIC) interpolation filter object that uses fixed-point
                    arithmetic.

                    All of the input arguments are optional. To enter any optional value,
                    you must include all optional values to the left of your desired value.

                    When you omit one or more input options, the omitted option applies
                    the default values shown in the table below.

                    The following table describes the input arguments for creating hm.

Input Arguments	Description
R	Interpolation factor applied to the input signal. Sharpens the response curve to let you change the shape of the response. R must be an integer value greater than or equal to 1. The default value is 2.
M	Differential delay. Changes the shape, number, and location of nulls in the filter response. Increasing M increases the sharpness of the nulls and the response between nulls. In practice, differential delay values of 1 or 2 are the most common. M must be an integer value greater than or equal to 1. The default value is 1.
N	Number of sections. Deepens the nulls in the response curve. Note that this is the number of either comb or integrator sections, not the total section count. By default, the filter has two sections.

Input Arguments	Description
IWL	Word length of the input signal. Use any integer number of bits. The default value is 16 bits.
OWL	Word length of the output signal. It can be any positive integer number of bits. By default, OWL is 16 bits.
WLPS	Defines the number of bits per word in each filter section while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter WLPS as a scalar or vector of length 2*N, where N is the number of sections. When WLPS is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the integrator. When you elect to specify wlps as an input argument, the FilterInternals property automatically switches from the default value of 'FullPrecision' to 'SpecifyWordLengths'.

hm = mfilt.cicinterp constructs the CIC interpolator using the default values for the optional input arguments.

hm = mfilt.cicinterp(R,...) constructs the CIC interpolator applying the values you provide for R and any other values you specify as input arguments.

Constraints and Conversions

In Hogenauer [1], the author describes the constraints on CIC interpolator filters. mfilt.cicinterp enforces a constraint—the word lengths of the filter sections must be non-decreasing. That is, the word length of each filter section must be the same size as, or greater than, the word length of the previous filter section.

The formula for W_j, the minimum register width, is derived in [1]. The formula for W_j is given by

$$W_j = ceil(B_{in} + \log_2 G_j)$$

where G_j, the maximum register growth up to the jth section, is given by

$$G_j = \begin{cases} 2^j, & j = 1, 2, \ldots, N \\ \dfrac{2^{2N-j}(RM)^{j-N}}{R}, & j = N+1, \ldots, 2N \end{cases}$$

When the differential delay, M, is 1, there is also a special condition for the register width of the last comb, W_N, that is given by

$$W_N = B_{in} + N - 1 \quad if \quad M = 1$$

The conversions denoted by the cast blocks in the integrator diagrams in "Algorithms" on page 7-1035 perform the changes between the word lengths of each section. When you specify word lengths that do not follow the constraints described in this section, mfilt.cicinterp returns an error.

The fraction lengths and scalings of the filter sections do not change. At each section the word length is either staying the same or increasing. The signal scaling can change at the output after the final filter section if you choose the output word length to be less than the word length of the final filter section.

Properties of the Object

The following table lists the properties for the filter with a description of each.

Name	Values	Default	Description
Arithmetic	`fixed`	`fixed`	Reports the kind of arithmetic the filter uses. CIC interpolators are always fixed-point filters.
InterpolationFactor	Any positive integer	2	Amount to increase the input sampling rate.
DifferentialDelay	Any positive integer	1	Sets the differential delay for the filter. Usually a value of one or two is appropriate.
FilterStructure	mfilt structure string	None	Reports the type of filter object, such as a interpolator or fractional integrator. You cannot set this property — it is always read only and results from your choice of `mfilt` objects.
FilterInternals	`FullPrecision`, `MinWordLengths`, `SpecifyWordLengths`, `SpecifyPrecision`	`FullPrecision`	Set the usage mode for the filter. Refer to "Usage Modes" on page 7-1031 below for details.
InputFracLength	Any positive integer	16	The number of bits applied as the fraction length to interpret the input data to the filter.

Name	Values	Default	Description
InputWordLength	Any positive integer	16	The number of bits applied to the word length to interpret the input data to the filter.
NumberOfSections	Any positive integer	2	Number of sections used in the interpolator. Generally called n. Reflects either the number of interpolator or comb sections, not the total number of sections in the filter.
OutputFracLength	Any positive integer	15	The number of bits applied to the fraction length to interpret the output data from the filter. Read-only.
OutputWordLength	Any positive integer	16	The number of bits applied to the word length to interpret the output data from the filter.
PersistentMemory	false or true	false	Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing.

Name	Values	Default	Description
			States that the filter does not change are not affected. When `PersistentMemory` is `false`, you cannot access the filter states. Setting `PersistentMemory` to `true` reveals the `States` property so you can modify the filter states.
SectionWordLengths	Any integer or a vector of length 2^N, where N is a positive integer. This property only applies when the `FilterInternals` is `SpecifyWordLengths`.	16	Defines the bits per section used while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter `SectionWordLengths` as a scalar or vector of length 2*n, where n is the number of sections. When `SectionWordLengths` is a scalar, the scalar value is applied to each filter section. When `SectionWordLengths` is a vector of values, the values apply to the sections in order. The default is 16 for each section in the interpolator. Available

Name	Values	Default	Description
			when `FilterInternals` is `'SpecifyWordLengths'`.
States	`filtstates.cic` object	m+1-by-n matrix of zeros, after you call function int.	Stored conditions for the filter, including values for the integrator and comb sections before and after filtering. m is the differential delay of the comb section and n is the number of sections in the filter. The integrator states are stored in the first matrix row. States for the comb section fill the remaining rows in the matrix. Available for modification when `PersistentMemory` is `true`. Refer to the `filtstates` object in Signal Processing Toolbox documentation for more general information about the `filtstates` object.

Usage Modes

There are usage modes which are set using the `FilterInternals` property:

- `FullPrecision` — In this mode, the word and fraction lengths of the filter sections and outputs are automatically selected for you. The output and last section word lengths are set to:

$$\text{wordlength} = \text{ceil}(\log_2((RM)^N / R)) + I,$$

where *R* is the interpolation factor, *M* is the differential delay, *N* is the number of filter sections, and *I* denotes the input word length.

- `MinWordLengths` — In this mode, you specify the word length of the filter output in the `OutputWordLength` property. The word lengths of the filter sections are automatically set in the same way as in the `FullPrecision` mode. The section fraction lengths are set to the input fraction length. The output fraction length is set to the input fraction length minus the difference between the last section and output word lengths.

- `SpecifyWordLengths` — In this mode, you specify the word lengths of the filter sections and output in the `SectionWordLengths` and `OutputWordLength` properties. The fraction lengths of the filter sections are set such that the spread between word length and fraction length is the same as in full-precision mode. The output fraction length is set to the input fraction length minus the difference between the last section and output word lengths.

- `SpecifyPrecision` — In this mode, you specify the word and fraction lengths of the filter sections and output in the `SectionWordLengths`, `SectionFracLengths`,`OutputWordLength`, and `OutputFracLength` properties.

About the States of the Filter

In the `states` property you find the states for both the integrator and comb portions of the filter. `states` is a matrix of dimensions `m+1-by-n`, with the states apportioned as follows:

- States for the integrator portion of the filter are stored in the first row of the state matrix.

- States for the comb portion fill the remaining rows in the state matrix.

mTo review the states of a CIC filter, use the `int` method to assign the states. As an example, here are the states for a CIC interpolator `hm` before and after filtering data:

```
x = fi(cos(pi/4*[0:99]),true,16,0); % Fixed-point input data
```

```
hm = mfilt.cicinterp(2,1,2,16,16,16);
% get initial states-all zero
sts=int(hm.states)
set(hm,'InputFracLength',0); % Integer input specified
y=filter(hm,x);
sts=int(hm.states)
%sts =
%
%    -1    -1
%    -1    -1
```

Design Considerations

When you design your CIC interpolation filter, remember the following general points:

- The filter output spectrum has nulls at $\omega = k * 2\pi/rm$ radians, $k = 1,2,3....$

- Aliasing and imaging occur in the vicinity of the nulls.

- n, the number of sections in the filter, determines the passband attenuation. Increasing n improves the filter ability to reject aliasing and imaging, but it also increases the droop or rolloff in the filter passband. Using an appropriate FIR filter in series after the CIC interpolation filter can help you compensate for the induced droop.

- The DC gain for the filter is a function of the interpolation factor. Raising the interpolation factor increases the DC gain.

Examples   Demonstrate interpolation by a factor of two, in this case from 22.05 kHz to 44.1 kHz. Note the scaling required to see the results in the stem plot and to use the full range of the int16 data type.

```
R = 2;                    % Interpolation factor.
hm = mfilt.cicinterp(R);  % Use default NumberOfSections and
                          % DifferentialDelay property values.
fs = 22.05e3;             % Original sample frequency:22.05 kHz.
n = 0:5119;               % 5120 samples, .232 second long signal.
x = sin(2*pi*1e3/fs*n);   % Original signal, sinusoid at 1 kHz.
```

```
y_fi = filter(hm,x); % 5120 samples, still 0.232 seconds.

% Scale the output to overlay stem plots correctly.
x = double(x);
y = double(y_fi);
y = y/max(abs(y));
stem(n(1:22)/fs,x(1:22),'filled'); % Plot original signal sampled
                                   % at 22.05 kHz.
hold on;
stem(n(1:44)/(fs*R),y(4:47),'r');  % Plot interpolated signal
                                   % (44.1 kHz) in red.
xlabel('Time (sec)');ylabel('Signal Value');
```

As you expect, the plot shows that the interpolated signal matches the input sine shape, with additional samples between each original sample.
Use the filter visualization tool (FVTool) to plot the response of the interpolator object. For example, to plot the response of an interpolator with an interpolation factor of 7, 4 sections, and 1 differential delay, do something like the following:

```
hm = mfilt.cicinterp(7,1,4)
fvtool(hm)
```

Algorithms To show how the CIC interpolation filter is constructed, the following figure presents a block diagram of the filter structure for a two-section CIC interpolation filter (n = 2). *fs* is the high sampling rate, the output from the interpolation process.

For details about the bits that are removed in the integrator section, refer to [1] in References.
When you select MinWordLengths, the filter section word lengths are automatically set to the minimum number of bits possible in a valid CIC interpolator. mfilt.cicinterp computes the wordlength for each section so the roundoff noise introduced by all sections is less than the roundoff noise introduced by the quantization at the output.

[3] Harris, Fredric J., *Multirate Signal Processing for Communication Systems*, Prentice-Hall PTR, 2004 , pp. 343

Purpose   Sample rate converter with arbitrary conversion factor

Syntax   hm = mfilt.farrowsrc(L,M,C)
                   hm = mfilt.farrowsrc
                   hm = mfilt.farrowsrc(l,...)

Description   hm = mfilt.farrowsrc(L,M,C) returns a filter object that is a natural
                   extension of dfilt.farrowfd with a time-varying fractional delay. It
                   provides a economical implementation of a sample rate converter
                   with an arbitrary conversion factor. This filter works well in the
                   interpolation case, but may exhibit poor anti-aliasing properties in the
                   decimation case.

Note You can use the realizemdl method to create a Simulink block
of a filter created using mfilt.farrowsrc.

Input Arguments

The following table describes the input arguments for creating hm.

Input Argument	Description
l	Interpolation factor for the filter. l specifies the amount to increase the input sampling rate. The default value of l is 3.
m	Decimation factor for the filter. m specifies the amount to decrease the input sampling rate. The default value for m is 2.
c	Coefficients for the filter. When no input arguments are specified, the default coefficients are [-1 1; 1, 0]

hm = mfilt.farrowsrc constructs the filter using the default values
for l, m, and c.

hm = mfilt.farrowsrc(l,...) constructs the filter using the input arguments you provide and defaults for the argument you omit.

mfilt.farrowsrc Object Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating mfilt.farrowsrc objects. The next table describes each property for an mfilt.farrowsrc filter object.

| Name	Values	Description
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt object.
Arithmetic	String	Reports the arithmtetic precision used by the filter.
Coefficients	Vector	Vector containing the coefficients of the FIR lowpass filter
InterpolationFactor	Integer	Interpolation factor for the filter. It specifies the amount to increase the input sampling rate.

Name	Values	Description
DecimationFactor	Integer	Decimation factor for the filter. It specifies the amount to increase the input sampling rate.
PersistentMemory	false or true	Determines whether the filter states are restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.

Examples   Interpolation by a factor of 8. This object removes the spectral replicas in the signal after interpolation.

```
[L,M] = rat(48/44.1);
Hm = mfilt.farrowsrc(L,M);          % We use the default filter
Fs = 44.1e3;                        % Original sampling frequency
n = 0:9407;                         % 9408 samples, 0.213 seconds long
x = sin(2*pi*1e3/Fs*n);            % Original signal, sinusoid at 1kHz
y = filter(Hm,x);                   % 10241 samples, still 0.213 seconds
stem(n(1:45)/Fs,x(1:45))            % Plot original sampled at 44.1kHz
hold on
% Plot fractionally interpolated signal (48kHz) in red
stem((n(2:50)-1)/(Fs*L/M),y(2:50),'r','filled')
xlabel('Time (sec)');ylabel('Signal value')
legend('44.1 kHz sample rate','48kHz sample rate')
```

The results of the example are shown in the following figure:

mfilt.farrowsrc
Purpose   Overlap-add FIR polyphase interpolator

Syntax   hm = mfilt.fftfirinterp(l,num,bl)
                 hm = mfilt.fftfirinterp
                 hm = mfilt.fftfirinterp(l,...)

Description hm = mfilt.fftfirinterp(l,num,bl) returns a discrete-time FIR
                 filter object that uses the overlap-add method for filtering input data.

The input arguments are optional. To enter any optional value, you
must include all optional values to the left of your desired value.

When you omit one or more input options, the omitted option applies
the default values shown in the table below.

The number of FFT points is given by [bl+ceil(length(num)/l)-1]. It
is to your advantage to choose bl such that the number of FFT points is
a power of two—using powers of two can improve the efficiency of the
FFT and the associated interpolation process.

Input Arguments

The following table describes the input arguments for creating hm.

Input Argument	Description
l	Interpolation factor for the filter. l specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for l it defaults to 2.
num	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When num is not provided as an input, fftfirinterp uses a lowpass Nyquist filter with gain equal to l and cutoff frequency equal to π/l by default.
bl	Length of each block of input data used in the filtering. bl must be an integer. When you omit input bl, it defaults to 100

hm = `mfilt.fftfirinterp` constructs the filter using the default values for `l`, `num`, and `bl`.

hm = `mfilt.fftfirinterp(l,...)` constructs the filter using the input arguments you provide and defaults for the argument you omit.

mfilt.fftfirinterp Object Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.fftfirinterp` objects. The next table describes each property for an `mfilt.fftfirinterp` filter object.

Name	Values	Description
FilterStructure		Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of `mfilt` object.
Numerator		Vector containing the coefficients of the FIR lowpass filter used for interpolation.
InterpolationFactor		Interpolation factor for the filter. It specifies the amount to increase the input sampling rate. It must be an integer.
BlockLength		Length of each block of input data used in the filtering.

Name	Values	Description
PersistentMemory	false or true	Determines whether the filter states are restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.
States		Stored conditions for the filter, including values for the interpolator states.

Examples   Interpolation by a factor of 8. This object removes the spectral replicas in the signal after interpolation.

```
l = 8;                         % Interpolation factor
hm = mfilt.fftfirinterp(l);    % We use the default filter
n = 8192;                      % Number of points
hm.blocklength = n;            % Set block length to number of points
fs = 44.1e3;                   % Original sample freq: 44.1 kHz.
n = 0:n-1;                     % 0.1858 secs of data
x = sin(2*pi*n*22e3/fs);       % Original signal, sinusoid at 22 kHz
y = filter(hm,x);              % Interpolated sinusoid
xu = l*upsample(x,8);          % Upsample to compare--the spectrum
                               % does not change
[px,f]=periodogram(xu,[],65536,l*fs);% Power spectrum of original
                                     % signal
[py,f]=periodogram(y,[],65536,l*fs); % Power spectrum of
                                     % interpolated signal
```
```
plot(f,10*log10(([fs*px,l*fs*py])))
legend('22  kHz sinusoid sampled at 44.1  kHz',...
'22  kHz sinusoid sampled at 352.8  kHz')
xlabel('Frequency (Hz)'); ylabel('Power Spectrum');
```

To see the results of the example, look at this figure.

Purpose   Direct-form FIR polyphase decimator

Syntax   `hm = mfilt.firdecim(m)`
                   `hm = mfilt.firdecim(m,num)`

Description `hm = mfilt.firdecim(m)` returns a direct-form FIR polyphase decimator object `hm` with a decimation factor of `m`. A lowpass Nyquist filter of gain 1 and cutoff frequency of π/m is designed by default. This filter allows some aliasing in the transition band but it very efficient because the first polyphase component is a pure delay.

`hm = mfilt.firdecim(m,num)` uses the coefficients specified by `num` for the decimation filter. This lets you specify more completely the FIR filter to use for the decimator.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter

  `set(hm,'arithmetic','single');`

- To change to fixed-point filtering, enter

  `set(hm,'arithmetic','fixed');`

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
m	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for m it defaults to 2.
num	Vector containing the coefficients of the FIR lowpass filter used for decimation. When num is not provided as an input, mfilt.firdecim constructs a lowpass Nyquist filter with gain of 1 and cutoff frequency equal to π/m by default. The default length for the Nyquist filter is 24*m. Therefore, each polyphase filter component has length 24.

Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating mfilt.firdecim objects. The next table describes each property for an mfilt.firdecim filter object.

Name	Values	Description
Arithmetic	Double, single, fixed	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operation mode for your filter.
DecimationFactor	Integer	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of

Name	Values	Description
		the input signal. It must be an integer.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt object. Describes the signal flow for the filter object.
InputOffset	Integers	Contains a value derived from the number of input samples and the decimation factor — InputOffset = mod(length(nx),m) where nx is the number of input samples that have been processed so far and m is the decimation factor.
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.
PersistentMemory	false, true	Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory set to false returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to

Name	Values	Description
		`true` allows you to modify the `States`, `InputOffset`, and `PolyphaseAccum` properties.
`PolyphaseAccum`	`0` in `double`, `single`, or `fixed` for the different filter arithmetic settings.	Differentiates between the adders in the filter that work in full precision at all times (`PolyphaseAccum`) and the adders in the filter that the user controls and that may introduce quantization effects when `FilterInternals` is set to `SpecifyPrecision`.
`States`	`Double`, `single`, or `fi` matching the filter arithmetic setting.	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. Double is the default setting for floating-point filters in double arithmetic.

Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the filter. You see one or more of these properties when you set Arithmetic to fixed. Some of the properties have different default values when they refer fixed point filters. One example is the property `PolyphaseAccum` which stores data as doubles when you use your filter in double-precision mode, but stores a `fi` object in fixed-point mode.

Note The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use info(hm) where hm is a filter.

For further information about the properties of this filter or any mfilt object, refer to "Multirate Filter Properties" on page 8-115.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters.
AccumWordLength	Any integer number of bits [39]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to fixed allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.

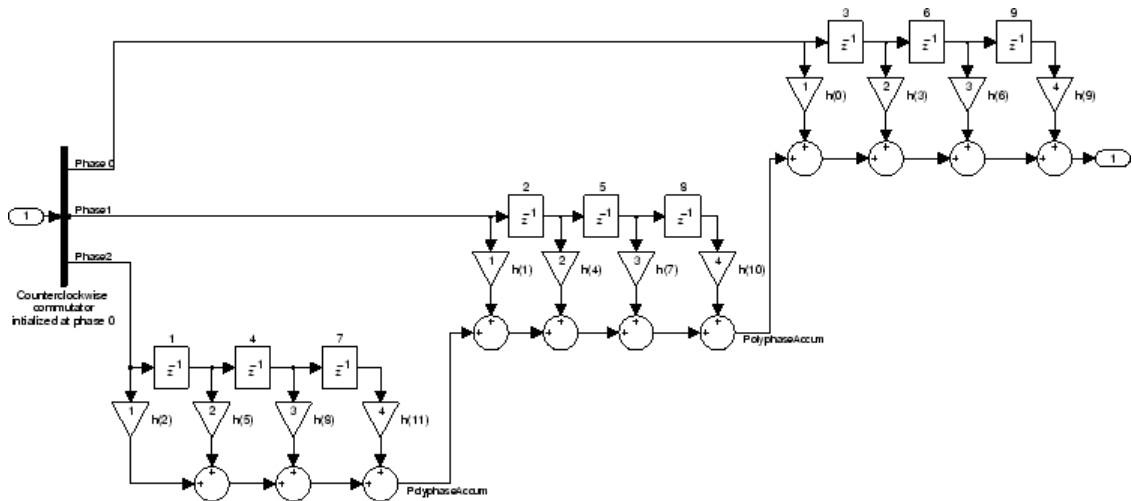
Name	Values	Description
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits[16]	Specifies the word length applied to interpret input data.
OutputFracLength	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.

Name	Values	Description
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
RoundMode	[convergent], ceil, fix, floor, nearest, round	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.

| Name	Values	Description
		The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Toolbox documentation. For information about the ordering of the states, refer to the filter structure section.

Filter Structure

To provide decimation, mfilt.firdecim uses the following structure. At the input you see a commutator that operates counterclockwise, moving from position 0 to position 2, position 1, and back to position 0 as input samples enter the filter.

The following figure details the signal flow for the direct form FIR filter implemented by mfilt.firdecim.


Notice the order of the states in the filter flow diagram. States 1 through 9 appear in the diagram above each delay element. State 1 applies to the first delay element in phase 2. State 2 applies to the first delay element in phase 1. State 3 applies to the first delay element in phase 0. State 4 applies to the second delay in phase 2, and so on. When you provide the states for the filter as a vector to the States property, the above description explains how the filter assigns the states you specify.

In property value form, the states for a filter hm are

```
hm.states=[1:9];
```

Examples   Convert an input signal from 44.1 kHz to 22.05 kHz using decimation by a factor of 2. In the figure that appears after the example code, you see the results of the decimation.

```
m = 2;                    % Decimation factor.
hm = mfilt.firdecim(m);   % Use the default filter.
fs = 44.1e3;              % Original sample freq: 44.1kHz.
n = 0:10239;              % 10240 samples, 0.232 second long
                          % signal.
x  = sin(2*pi*1e3/fs*n);  % Original signal--sinusoid at 1kHz.
```

```
y = filter(hm,x);              % 5120 samples, 0.232 seconds.
stem(n(1:44)/fs,x(1:44))       % Plot original sampled at 44.1 kHz.
hold on                        % Plot decimated signal (22.05 kHz)
                               % in red.
stem(n(1:22)/(fs/m),y(13:34),'r','filled')
xlabel('Time (sec)');ylabel('Signal Value')
```

Purpose   Direct-form FIR polyphase fractional decimator

Syntax   hm = mfilt.firfracdecim(l,m,num)

Description mfilt.firfracdecim will be removed in a future release. Use
mfilt.firsrc instead.

hm = mfilt.firfracdecim(l,m,num) returns a direct-form FIR
polyphase fractional decimator. Input argument l is the interpolation
factor. l must be an integer. When you omit l in the calling syntax, it
defaults to 2. m is the decimation factor. It must be an integer. If not
specified, it defaults to l+1.

num is a vector containing the coefficients of the FIR lowpass filter used
for decimation. If you omit num, a lowpass Nyquist filter of gain l and
cutoff frequency of π/max(l,m) is used by default.

By specifying both a decimation factor and an interpolation factor, you
can decimate your input signal by noninteger amounts. The fractional
decimator first interpolates the input, then decimates to result in an
output signal whose sample rate is l/m of the input rate. By default, the
resulting decimation factor is 2/3 when you do not provide l and m in
the calling syntax. Specify l smaller than m for proper decimation.

Input Arguments

The following table describes the input arguments for creating hm.

Input Argument	Description
l	Interpolation factor for the filter. It must be an integer. When you do not specify a value for l it defaults to 2.
num	Vector containing the coefficients of the FIR lowpass filter used for decimation. When num is not provided as an input, firfracdecim uses a lowpass Nyquist

mfilt.firfracdecim (Obsolete)

Input Argument	Description
	filter with gain equal to l and cutoff frequency equal to π/max(l,m) by default.
m	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for m it defaults to l + 1.

mfilt.firfracdecim Object Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating mfilt.firfracdecim objects. The next table describes each property for an mfilt.firfracdecim filter object.

Name	Values	Description
FilterStructure	String	Reports the type of filter object, such as a decimator or fractional decimator. You cannot set this property — it is always read only and results from your choice of mfilt object.
InputOffset	Integers	Contains the number of input data samples processed without generating an output sample. The default value is 0.
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for interpolation.

| Name	Values	Description
RateChangeFactors	[l,m]	Reports the decimation (m) and interpolation (l) factors for the filter object. Combining these factors results in the final rate change for the signal.
PersistentMemory	false or true	Determines whether the filter states are restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.
States	Matrix	Stored conditions for the delays between each interpolator phase, the filter states, and the states at the output of each phase in the filter.
		The number of states is (lh-1)*m+(l-1)*(lo+mo) where lh is the length of each subfilter, and l and m are the interpolation and decimation factors. lo and mo, the input and output delays between each interpolation phase, are integers from Euclid's theorem such that lo*l-mo*m = -1 (refer to the reference for more details). Use euclidfactors to get lo and mo for an mfilt.firfracdecim object

mfilt.firfracdecim (Obsolete)

Examples

To demonstrate `firfracdecim`, perform a fractional decimation by a factor of 2/3. This is one way to downsample a 48 kHz signal to 32 kHz, commonly done in audio processing.

```
l  = 2; m = 3;                    % Interpolation/decimation factors.
hm = mfilt.firfracdecim(l,m);     % We use the default
fs = 48e3;                        % Original sample freq: 48 kHz.
n  = 0:10239;                     % 10240 samples, 0.213 second long
                                  % signal
x  = sin(2*pi*1e3/fs*n);          % Original signal, sinusoid at 1 kHz
y  = filter(hm,x);                % 9408 samples, still 0.213 seconds
stem(n(1:49)/fs,x(1:49)); hold on; % Plot original signal sampled
                                      % at 48 kHz
stem(n(1:32)/(fs*l/m),y(13:44),'r','filled') % Plot decimated
                                                % signal at 32 kHz
xlabel('Time (sec)');
```

As shown, the plot clearly demonstrates the reduced sampling frequency of 32 kHz.

See Also   `mfilt.firsrc` | `mfilt.firinterp` | `mfilt.firdecim`

mfilt.firfracinterp (Obsolete)

Purpose   Direct-form FIR polyphase fractional interpolator

Syntax   `hm = mfilt.firfracinterp(l,m,num)`

Description   `mfilt.firfracinterp` will be removed in a future release. Use `mfilt.firsrc` instead.

`hm = mfilt.firfracinterp(l,m,num)` returns a direct-form FIR polyphase fractional interpolator mfilt object. `l` is the interpolation factor. It must be an integer. If not specified, `l` defaults to 3.

`m` is the decimation factor. Like `l`, it must be an integer. If you do not specify `m` in the calling syntax, it defaults to 1. If you also do not specify a value for `l`, `m` defaults to 2.

`num` is a vector containing the coefficients of the FIR lowpass filter used for interpolation. If omitted, a lowpass Nyquist filter of gain `l` and cutoff frequency of π/`max(l,m)` is used by default.

By specifying both a decimation factor and an interpolation factor, you can interpolate your input signal by noninteger amounts. The fractional interpolator first interpolates the input, then decimates to result in an output signal whose sample rate is `l`/`m` of the input rate. For proper interpolation, you specify `l` to be greater than `m`. By default, the resulting interpolation factor is 3/2 when you do not provide `l` and `m` in the calling syntax.

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
l	Interpolation factor for the filter. l specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for l it defaults to 3.
num	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When num is not provided as an input, firfracinterp uses a lowpass Nyquist filter with gain equal to l and cutoff frequency equal to $\pi/\max(l,m)$ by default.
m	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for m it defaults to 1. When you do not specify l as well, m defaults to 2.

mfilt.firfracinterp Object Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating mfilt.firfracinterp objects. The next table describes each property for an mfilt.firfracinterp filter object.

Name	Values	Description
FilterStructure		Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt object.
Numerator		Vector containing the coefficients of the FIR lowpass filter used for interpolation.

mfilt.firfracinterp (Obsolete)

Name	Values	Description
RateChangeFactors	[l,m]	Reports the decimation (m) and interpolation (l) factors for the filter object. Combining these factors results in the final rate change for the signal.
PersistentMemory	false or true	Determines whether the filter states are restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to the default values any state that the filter changes during processing. States that the filter does not change are not affected.
States	Matrix	Stored conditions for the filter, including values for the interpolator and comb states.

Examples To convert a signal from 32 kHz to 48 kHz requires fractional interpolation. This example uses the mfilt.firfracinterp object to upsample an input signal. Setting l = 3 and m = 2 returns the same mfilt object as the default mfilt.firfracinterp object.

```
l  = 3; m = 2;            % Interpolation/decimation factors.
hm = mfilt.firfracinterp(l,m);    % We use the default filter
fs = 32e3;               % Original sample freq: 32 kHz.
n = 0:6799;              % 6800 samples, 0.212 second long signal
x  = sin(2*pi*1e3/fs*n);   % Original signal, sinusoid at 1 kHz
```

```
y = filter(hm,x);              % 10200 samples, still 0.212 seconds
stem(n(1:32)/fs,x(1:32),'filled') % Plot original sampled at
                                    % 32 kHz
hold on;
% Plot fractionally interpolated signal (48 kHz) in red
stem(n(1:48)/(fs*l/m),y(20:67),'r')
xlabel('Time (sec)');ylabel('Signal Value')
```

The ability to interpolate by fractional amounts lets you raise the sampling rate from 32 to 48 kHz, something you cannot do with integral interpolators. Both signals appear in the following figure.
See Also   mfilt.firsrc | mfilt.firinterp | mfilt.firdecim

Purpose	FIR filter-based interpolator

Syntax

```
Hm = mfilt.firinterp(L)
Hm = mfilt.firinterp(L,num)
```

Description

`Hm = mfilt.firinterp(L)` returns a FIR polyphase interpolator object `Hm` with an interpolation factor of `L` and gain equal to `L`. `L` defaults to 2 if unspecified.

`Hm = mfilt.firinterp(L,num)` uses the values in the vector `num` as the coefficients of the interpolation filter.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `Hm` as follows:

- To change to single-precision filtering, enter

  ```
  set(hm,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hm,'arithmetic','fixed');
  ```

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
l	Interpolation factor for the filter. l specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for l it defaults to 2.
num	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When num is not provided as an input, firinterp uses a lowpass Nyquist filter with gain equal to l and cutoff frequency equal to π/l by default. The default length for the Nyquist filter is 24*l. Therefore, each polyphase filter component has length 24.

Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.firinterp` objects. The next table describes each property for an `mfilt.firinterp` filter object.

Name	Values	Description
Arithmetic	Double, single, fixed	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operation mode for your filter.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of `mfilt` object. Describes the signal flow for the filter object.
InterpolationFactor	Integer	Interpolation factor for the filter. 1 specifies the amount to increase the sampling rate of the input signal. It must be an integer.
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.

Name	Values	Description
PersistentMemory	[false], true	Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory set to false returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to true allows you to modify the States property.
States	Double, single, matching the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.

Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the mfilt.firinterp filter.

Note The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

```
info(hm)
```

where hm is a filter.

For further information about the properties of this filter or any mfilt object, refer to "Multirate Filter Properties" on page 8-115.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits. [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.
AccumWordLength	Any integer number of bits[39]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to fixed allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.

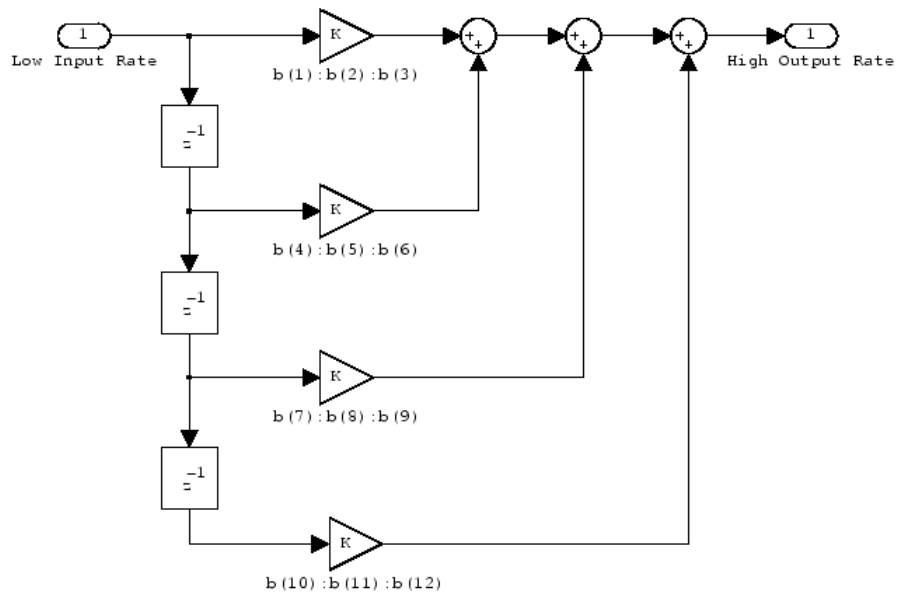
Name	Values	Description
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.

Name	Values	Description
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
RoundMode	[convergent], ceil, fix, floor, nearest, round	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.

| Name	Values	Description
		The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object to match the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Toolbox documentation.

Filter Structure

To provide interpolation, mfilt.firinterp uses the following structure.

The following figure details the signal flow for the direct form FIR filter implemented by mfilt.firinterp. In the figure, the delay line updates happen at the lower input rate. The remainder of the filter — the sums and coefficients — operate at the higher output rate.


Examples   This example uses `mfilt.firinterp` to double the sample rate of a 22.05 kHz input signal. The output signal ends up at 44.1 kHz. Although l is set explicitly to 2, this represents the default interpolation value for `mfilt.firinterp` objects.

```
L = 2;                    % Interpolation factor.
Hm = mfilt.firinterp(L);  % Use the default filter.
fs = 22.05e3;             % Original sample freq: 22.05 kHz.
n = 0:5119;               % 5120 samples, 0.232s long signal.
x  = sin(2*pi*1e3/fs*n);  % Original signal, sinusoid at 1 kHz.
y = filter(Hm,x);         % 10240 samples, still 0.232s.
stem(n(1:22)/fs,x(1:22),'filled') % Plot original sampled at
                                  % 22.05 kHz.

hold on;

% Plot interpolated signal (44.1 kHz) in red
stem(n(1:44)/(fs*L),y(25:68),'r')
xlabel('Time (sec)');ylabel('Signal Value')
```

```
legend('Original Signal','Interpolated Signal');
```

With interpolation by 2, the resulting signal perfectly matches the
original, but with twice as many samples — one between each original
sample, as shown in the following figure.

mfilt.firsrc | mfilt.cicinterp

Purpose   Direct-form FIR polyphase sample rate converter

Syntax   `hm = mfilt.firsrc(l,m,num)`

Description   `hm = mfilt.firsrc(l,m,num)` returns a direct-form FIR polyphase sample rate converter. `l` specifies the interpolation factor. It must be an integer and when omitted in the calling syntax, it defaults to 2.

`m` is the decimation factor. It must be an integer. If not specified, `m` defaults to 1. If `l` is also not specified, `m` defaults to 3 and the overall rate change factor is 2/3.

You specify the coefficients of the FIR lowpass filter used for sample rate conversion in `num`. If omitted, a lowpass Nyquist filter with gain `l` and cutoff frequency of $\pi/\texttt{max}(\texttt{l,m})$ is the default.

Combining an interpolation factor and a decimation factor lets you use `mfilt.firsrc` to perform fractional interpolation or decimation on an input signal. Using an `mfilt.firsrc` object applies a rate change factor defined by `l/m` to the input signal. For proper rate changing to occur, `l` and `m` must be relatively prime — meaning the ratio `l/m` cannot be reduced to a ratio of smaller integers.

When you are doing sample-rate conversion with large values of `l` or `m`, such as `l` or `m` greater than 20, using the `mfilt.firsrc` structure is the most effective approach.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter

  ```
  set(hm,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hm,'arithmetic','fixed');
  ```

> **Note** You can use the `realizemdl` method to create a Simulink block of a filter created using `mfilt.firsrc`.

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
l	Interpolation factor for the filter. l specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for l, it defaults to 2.
num	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When num is not provided as an input, mfilt.firsrc uses a lowpass Nyquist filter with gain equal to l and cutoff frequency equal to π/max(l,m) by default. The default length for the Nyquist filter is 24*m. Therefore, each polyphase filter component has length 24.
m	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for m, it defaults to 1. When l is unspecified as well, m defaults to 3.

Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also

input arguments for creating `mfilt.firsrc` objects. The next table describes each property for an `mfilt.firsrc` filter object.

Name	Values	Description
Arithmetic	[Double], single, fixed	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operation mode for your filter.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt object. Describes the signal flow for the filter object.
InputOffset	Integers	Contains a value derived from the number of input samples and the decimation factor — InputOffset = mod(length(nx),m) where nx is the number of input samples and m is the decimation factor.
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.
PersistentMemory	false, true	Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory set to false returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to true allows you to modify the States, InputOffset, and PolyphaseAccum properties.

Name	Values	Description
RateChangeFactors	Positive integers. [2 3]	Specifies the interpolation and decimation factors [l m] (the rate change factors) for changing the input sample rate by nonintegral amounts.
States	Double, single, matching the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.

Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the mfilt.firsrc filter.

Note The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

info(hm)

where hm is a filter.

For further information about the properties of this filter or any mfilt object, refer to "Multirate Filter Properties" on page 8-115.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits. [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters.
AccumWordLength	Any integer number of bits [39]	Sets the word length used to store data in the accumulator.

Name	Values	Description
Arithmetic	fixed for fixed-point filters	Setting this to fixed allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.

Name	Values	Description
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
RateChangeFactors	Positive integers [2 3]	Specifies the interpolation and decimation factors [1 m] (the rate change factors) for changing the input sample rate by nonintegral amounts.

Name	Values	Description
RoundMode	[convergent], ceil, fix, floor, nearest, round	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.

Name	Values	Description
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Toolbox documentation. For information about the ordering of the states, refer to the filter structure section.

Examples   This is an example of a common audio rate change process — changing the sample rate of a high end audio (48 kHz) signal to the compact disc sample rate (44.1 kHz). This conversion requires a rate change factor of 0.91875, or l = 147 and m = 160.

```
l  = 147; m = 160;          % Interpolation/decimation factors.
hm = mfilt.firsrc(l,m);     % Use the default FIR filter.
fs = 48e3;                  % Original sample freq: 48 kHz.
n = 0:10239;                % 10240 samples, 0.213 seconds long.
x  = sin(2*pi*1e3/fs*n);    % Original signal, sinusoid at 1 kHz.
y = filter(hm,x);           % 9408 samples, still 0.213 seconds.
stem(n(1:49)/fs,x(1:49))    % Plot original sampled at 48 kHz.
hold on

% Plot fractionally decimated signal (44.1 kHz) in red
stem(n(1:45)/(fs*l/m),y(13:57),'r','filled')
xlabel('Time (sec)');ylabel('Signal Value')
```

Fractional decimation provides you the flexibility to pick and choose the sample rates you want by carefully selecting l and m, the interpolation and decimation factors, that result in the final fractional decimation.

The following figure shows the signal after applying the rate change filter `hm` to the original signal.
See Also   `mfilt.firsrc` | `mfilt.firinterp` | `mfilt.firdecim`

mfilt.firtdecim

Purpose   Direct-form transposed FIR filter

Syntax
```
hm = mfilt.firtdecim(m)
hm = mfilt.firtdecim(m,num)
```

Description   `hm = mfilt.firtdecim(m)` returns a polyphase decimator `mfilt` object `hm` based on a direct-form transposed FIR structure with a decimation factor of `m`. A lowpass Nyquist filter of gain 1 and cutoff frequency of π/m is the default.

`hm = mfilt.firtdecim(m,num)` uses the coefficients specified by `num` for the decimation filter. `num` is a vector containing the coefficients of the transposed FIR lowpass filter used for decimation. If omitted, a lowpass Nyquist filter with gain of 1 and cutoff frequency of π/m is the default.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter

  ```
  set(hm,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hm,'arithmetic','fixed');
  ```

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
num	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When num is not provided as an input, firtdecim uses a lowpass Nyquist filter with gain equal to 1 and cutoff frequency equal to π/m by default. The default length for the Nyquist filter is 24*m. Therefore, each polyphase filter component has length 24.
m	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for m it defaults to 2.

Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating mfilt.firtdecim objects. The next table describes each property for an mfilt.firtdecim filter object.

Name	Values	Description
Arithmetic	Double, single, fixed	Specifies the arithmetic the filter uses to process data while filtering.
DecimationFactor	Integer	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer.

Name	Values	Description
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of `mfilt` object. Also describes the signal flow for the filter object.
InputOffset	Integers	Contains a value derived from the number of input samples and the decimation factor — `InputOffset = mod(length(nx),m)` where `nx` is the number of input samples that have been processed so far and `m` is the decimation factor.
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.
PersistentMemory	[false], true	Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` set to `false` returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to `true` allows you to modify the `States`, `InputOffset`, and `PolyphaseAccum` properties.

Name	Values	Description
PolyphaseAccum	Double, single [0]	The idea behind having both PolyphaseAccum and Accum is to differentiate between the adders in the filter that work in full precision at all times (PolyphaseAccum) from the adders in the filter that the user controls and that may introduce quantization effects when FilterInternals is set to SpecifyPrecision.
States	Double, single matching the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.

Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the mfilt.firtdecim filter.

Note The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

```
info(hm)
```

where hm is a filter.

For further information about the properties of this filter or any mfilt object, refer to "Multirate Filter Properties" on page 8-115.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits. [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.
AccumWordLength	Any integer number of bits [39]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to fixed allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.

Name	Values	Description
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.

Name	Values	Description
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
PolyphaseAccum	fi object with zeros to start	Differentiates between the adders in the filter that work in full precision at all times (PolyphaseAccum) and the adders in the filter that the user controls and that may introduce quantization effects when FilterInternals is set to SpecifyPrecision.
RoundMode	[convergent], ceil, fix, floor, nearest, round	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity.

Name	Values	Description
		• round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.
		The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Toolbox documentation. For information about the ordering of the states, refer to the filter structure section.

Filter Structure

To provide sample rate changes, mfilt.firtdecim uses the following structure. At the input you see a commutator that operates counterclockwise, moving from position 0 to position 2, position 1, and back to position 0 as input samples enter the filter. To keep track of the position of the commutator, the mfilt object uses the property InputOffset which reports the current position of the commutator in the filter.

The following figure details the signal flow for the direct form FIR filter implemented by mfilt.firtdecim.

mfilt.firtdecim
Notice the order of the states in the filter flow diagram. States 1 through 3 appear in the following diagram at each delay element. State 1 applies to the third delay element in phase 2. State 2 applies to the second delay element in phase 2. State 3 applies to the first delay element in phase 2. When you provide the states for the filter as a vector to the `States` property, the above description explains how the filter assigns the states you specify.

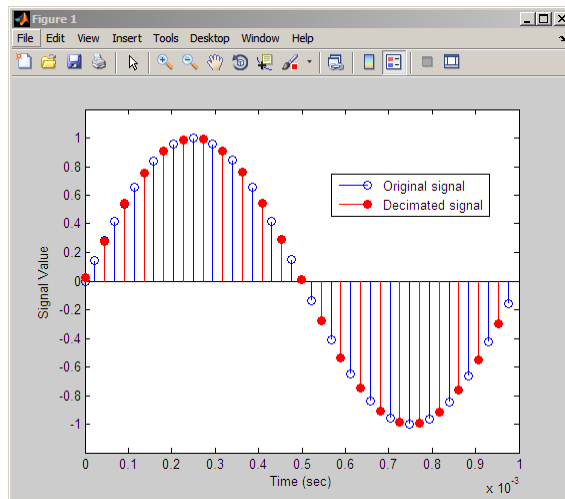
In property value form, the states for a filter `hm` are

```
hm.states=[1:3];
```

Examples   Demonstrate decimating an input signal by a factor of 2, in this case converting from 44.1 kHz down to 22.05 kHz. In the figure shown following the code, you see the results of decimating the signal.

```
m = 2;                  % Decimation factor.
hm = mfilt.firtdecim(m); % Use the default filter coeffs.
fs = 44.1e3;            % Original sample freq: 44.1 kHz.
n = 0:10239;            % 10240 samples, 0.232 second long signal
x  = sin(2*pi*1e3/fs*n); % Original signal--sinusoid at 1 kHz.
y = filter(hm,x);       % 5120 samples, 0.232 seconds.
```

```
stem(n(1:44)/fs,x(1:44)) % Plot original sampled at 44.1 kHz.
axis([0 0.001 -1.2 1.2]);
hold on                   % Plot decimated signal (22.05 kHz) in red
stem(n(1:22)/(fs/m),y(13:34),'r','filled')
xlabel('Time (sec)');ylabel('Signal Value');
legend('Original signal','Decimated signal','location','best');
```



See Also   mfilt.firdecim | mfilt.firsrc | mfilt.cicdecim

mfilt.holdinterp

Purpose   FIR hold interpolator

Syntax   hm = mfilt.holdinterp(l)

Description   hm = mfilt.holdinterp(l) returns the object hm that represents a hold interpolator with the interpolation factor l. To work, l must be an integer. When you do not include l in the calling syntax, it defaults to 2. To perform interpolation by noninteger amounts, use one of the fractional interpolator objects, such as mfilt.firsrc.

When you use this hold interpolator, each sample added to the input signal between existing samples has the value of the most recent sample from the original signal. Thus you see something like a staircase profile where the interpolated samples form a plateau between the previous and next original samples. The example demonstrates this profile clearly. Compare this to the interpolation process for other interpolators in the toolbox, such as mfilt.linearinterp.

Make this filter a fixed-point or single-precision filter by changing the value of the Arithmetic property for the filter hm as follows:

- To change to single-precision filtering, enter

  ```
  set(hm,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hm,'arithmetic','fixed');
  ```

Input Arguments

The following table describes the input arguments for creating hm.

Input Argument	Description
l	Interpolation factor for the filter. l specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for l it defaults to 2.

Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.holdinterp` objects. The next table describes each property for an `mfilt.interp` filter object.

Name	Values	Description
Arithmetic	Double, single, fixed	Specifies the arithmetic the filter uses to process data while filtering.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of `mfilt` object.
Interpolation-Factor	Integer	Interpolation factor for the filter. `l` specifies the amount to increase the input sampling rate. It must be an integer.

mfilt.holdinterp

Name	Values	Description
PersistentMemory	'false' or 'true'	Determines whether the filter states are restored to zero for each filtering operation.
States	Double or single array	Filter states. states defaults to a vector of zeros that has length equal to nstates (hm). Always available, but visible in the display only when PersistentMemory is true.

Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the mfilt.holdinterp filter.

Note The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

info(hm)

where hm is a filter.

For further information about the properties of this filter or any mfilt object, refer to "Multirate Filter Properties" on page 8-115.

Name	Values	Description
Arithmetic	Double, single, fixed	Specifies the arithmetic the filter uses to process data while filtering.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt object.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
Interpolation-Factor	Integer	Interpolation factor for the filter. l specifies the amount to increase the input sampling rate. It must be an integer.
PersistentMemory	'false' or 'true'	Determine whether the filter states get restored to zero for each filtering operation
States	fi object	Contains the filter states before, during, and after filter operations. For hold interpolators, the states are always empty — hold interpolators do not have states. The states use fi objects, with the

mfilt.holdinterp

Name	Values	Description
		associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Toolbox documentation.

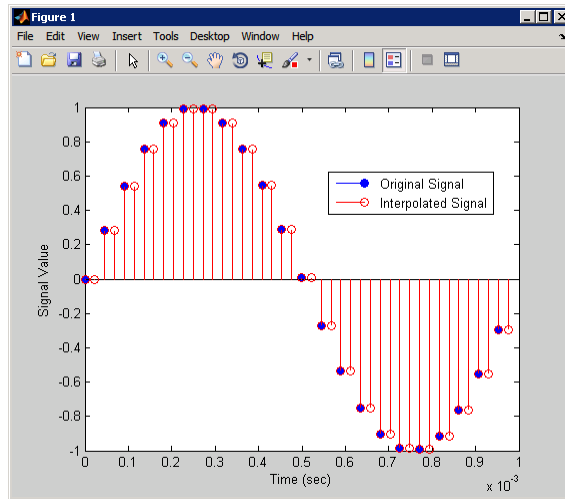
Filter Structure

Hold interpolators do not have filter coefficients and their filter structure is trivial.

Examples

To see the effects of hold-based interpolation, interpolate an input sine wave from 22.05 to 44.1 kHz. Note that each added sample retains the value of the most recent original sample.

```
l = 2;                          % Interpolation factor
hm = mfilt.holdinterp(l);
fs = 22.05e3;                   % Original sample freq: 22.05 kHz.
n = 0:5119;                     % 5120 samples, 0.232 second long signal
x  = sin(2*pi*1e3/fs*n);        % Original signal, sinusoid at 1 kHz
y = filter(hm,x);               % 10240 samples, still 0.232 seconds
stem(n(1:22)/fs,x(1:22),'filled')  % Plot original sampled at
                                % 22.05 kHz
hold on                         % Plot interpolated signal (44.1 kHz)
stem(n(1:44)/(fs*l),y(1:44),'r')
legend('Original Signal','Interpolated Signal','Location','best');
xlabel('Time (sec)');ylabel('Signal Value')
```

The following figure shows clearly the step nature of the signal that comes from interpolating the signal using the hold algorithm approach. Compare the output to the linear interpolation used in `mfilt.linearinterp`.


See Also   mfilt.linearinterp | mfilt.firinterp | mfilt.firsrc | mfilt.cicinterp

mfilt.iirdecim

Purpose   IIR decimator

Syntax   `hm = mfilt.iirdecim(c1,c2,...)`

Description   `hm = mfilt.iirdecim(c1,c2,...)` constructs an IIR decimator filter given the coefficients specified in the cell arrays `c1`, `c2`, and so on. The resulting IIR decimator is a polyphase IIR filter where each phase is a cascade allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadeallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirdecim` interprets them same way as `mfilt.cascadeallpass`.

The following exception applies to interpreting the contents of a cell array — if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and one element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadeallpass` section. This exception case occurs with quasi-linear phase IIR decimators.

Although the first example shows how to construct an IIR decimators explicitly, one usually constructs an IIR decimators filter as a result of designing an decimators, as shown in the subsequent examples.

Examples   When the coefficients are known, you can construct the IIR decimator directly using `mfilt.iirdecim`. For example, if the filter's coefficients are [0.6 0.5] for the first phase in the first stage, 0.7 for the second phase in the first stage and 0.8 for the third phase in the first stage; as well as 0.5 for the first phase in the second stage and 0.4 for the second phase in the second stage, construct the filter as shown here.

`Hm = mfilt.iirdecim({[0.6 0.5] 0.7 0.8},{0.5 0.4})`

Also refer to the "Quasi-Linear Phase Halfband and Dyadic Halfband Designs" section of the "IIR Polyphase Filter Design" example, iirallpassdemo example.

When the coefficients are not known, use the approach given by the following set of examples. Start by designing an elliptic halfband decimator with a decimation factor of 2. The example specifies the optional sampling frequency argument.

```
tw = 100;   % Transition width of filter.
ast = 80;   % Stopband attenuation of filter.
fs = 2000;  % Sampling frequency of signal to filter.
m = 2;      % Decimation factor.
hm = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

hm contains the specifications for a decimator defined by tw, ast, m, and fs.

Use the specification object hm to design a mfilt.iirdecim filter object.

```
d = design(hm,'ellip','filterstructure','iirdecim');
% Note that realizemdl requires Simulink
realizemdl(d)       % Build model of the filter.
```

Designing a linear phase decimator is similar to the previous example. In this case, design a halfband linear phase decimator with decimation factor of 2.

```
tw  = 100;  % Transition width of filter.
ast = 60;   % Stopband attenuation of filter.
fs  = 2000; % Sampling frequency of signal to filter.
m = 2;      % Decimation factor.
```

Create a specification object for the decimator.

```
hm = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

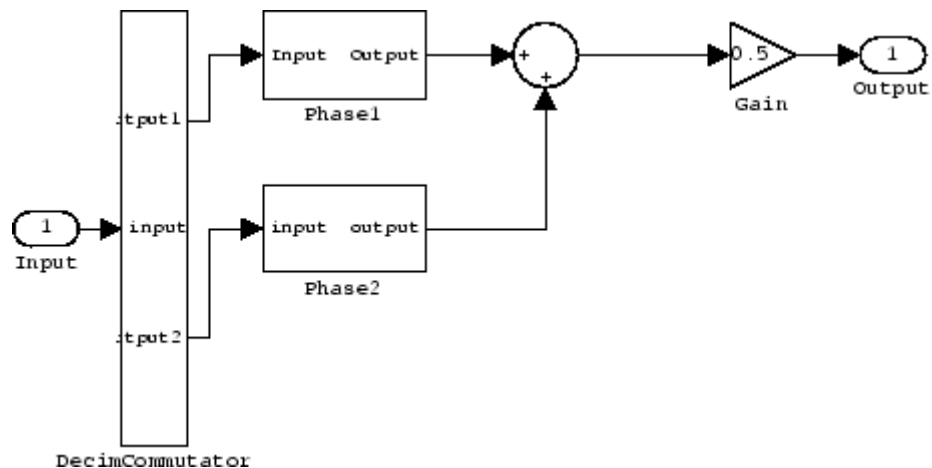
Finally, design the filter d.

```
d = design(hm,'iirlinphase','filterstructure','iirdecim');
```

```
% Note that realizemdl requires Simulink
realizemdl(d)  % Build model of the filter.
```

The filter implementation appears in this model, generated by `realizemdl` and Simulink.

Given the design specifications shown here

the first phase is a delay section with 0s and a 1 for coefficients and the second phase is a linear phase decimator, shown in the next models.
Phase 1 model
Phase 2 model


Overall model

For more information about Multirate Filter Constructors see the "Getting Started with Multirate Filter (MFILT) Objects" example, mfiltgettingstarteddemo.

See Also   dfilt.cascadeallpass | mfilt | mfilt.iirinterp | mfilt.iirwdfdecim

Purpose   IIR interpolator

Syntax   hm = mfilt.iirinterp(c1,c2,...)

Description   hm = mfilt.iirinterp(c1,c2,...) constructs an IIR interpolator filter given the coefficients specified in the cell arrays C1, C2, etc.

The IIR interpolator is a polyphase IIR filter where each phase is a cascade allpass IIR filter.

Each cell array ci contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to dfilt.cascadeallpass. The contents of the cell arrays are the same for both filter constructors and mfilt.iirdecim interprets them same way as mfilt.cascadeallpass.

The following exception applies to interpreting the contents of a cell array—if one of the cell arrays ci contains only one vector, and that vector comprises a series of 0s and a unique element equal to 1, that cell array represents a dfilt.delay section with latency equal to the number of zeros, rather than a dfilt.cascadeallpass section. This exception case occurs with quasi-linear phase IIR interpolators.

Although the first example shows how to construct an IIR interpolator explicitly, one usually constructs an IIR interpolator filter as a result of designing an interpolator, as shown in the subsequent examples.

Examples   When the coefficients are known, you can construct the IIR interpolator directly using mfilt.iirinterp. In the following example, a cascaded polyphase IIR interpolator filter is constructed using 2 phases for each of three stages. The coefficients are given below:

```
Phase1Sect1=0.0603;Phase1Sect2=0.4126; Phase1Sect3=0.7727;
Phase2Sect1=0.2160; Phase2Sect2=0.6044; Phase2Sect3=0.9239;
```

Next the filter is implemented by passing the above coefficients to `mfilt.iirinterp` as cell arrays, where each cell array represents a different phase.

```
Hm = mfilt.iirinterp({Phase1Sect1,Phase1Sect2,Phase1Sect3},...
{Phase2Sect1,Phase2Sect2,Phase2Sect3})

Hm =

        FilterStructure: 'IIR Polyphase Interpolator'
              Polyphase: Phase1: Section1: 0.0603
                                 Section2: 0.4126
                                 Section3: 0.7727
                         Phase2: Section1: 0.216
                                 Section2: 0.6044
                                 Section3: 0.9239

   InterpolationFactor: 2
      PersistentMemory: false
```

Also refer to the "Quasi-Linear Phase Halfband and Dyadic Halfband Designs" section of the "IIR Polyphase Filter Design" example, iirallpassdemo example.

When the coefficients are not known, use the approach given by the following set of examples. Start by designing an elliptic halfband interpolator with a interpolation factor of 2.

```
tw = 100;  % Transition width of filter.
ast = 80;   % Stopband attenuation of filter.
fs = 2000; % Sampling frequency of filter.
l  = 2;    % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

Specification object d stores the interpolator design specifics. With the details in d, design the filter, returning hm, an `mfilt.iirinterp` object. Use hm to realize the filter if you have Simulink installed.

```
hm = design(d,'ellip','filterstructure','iirinterp');
```

```
% Note that realizemdl requires Simulink
realizemdl(hm)     % Build model of the filter.
```

Designing a linear phase halfband interpolator follows the same pattern.

```
tw = 100;  % Transition width of filter.
ast= 60;   % Stopband attenuation of filter.
fs = 2000; % Sampling frequency of filter.
l = 2;     % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

`fdesign.interpolator` returns a specification object that stores the design features for an interpolator.

Now perform the actual design that results in an `mfilt.iirinterp` filter, `hm`.

```
hm = design(d,'iirlinphase','filterstructure','iirinterp');
% Note that realizemdl requires Simulink
realizemdl(hm)     % Build model of the filter.
```

The toolbox creates a Simulink model for `hm`, shown here. Phase1, Phase2, and InterpCommutator are all subsystem blocks.
For more information about Multirate Filter Constructors see the "Getting Started with Multirate Filter (MFILT) Objects" example, mfiltgettingstarteddemo.

See Also   dfilt.cascadeallpass | mfilt | mfilt.iirdecim | mfilt.iirwdfinterp

Purpose   IIR wave digital filter decimator

Syntax   hm = mfilt.iirwdfdecim(c1,c2,...)

Description   hm = mfilt.iirwdfdecim(c1,c2,...) constructs an IIR wave digital decimator given the coefficients specified in the cell arrays c1, c2, and so on. The IIR decimator hm is a polyphase IIR filter where each phase is a cascade wave digital allpass IIR filter.

Each cell array ci contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to dfilt.cascadewdfallpass. The contents of the cell arrays are the same for both filter constructors and mfilt.iirwdfdecim interprets them same way as mfilt.cascadewdfallpass.

The following exception applies to interpreting the contents of a cell array — if one of the cell arrays ci contains only one vector, and that vector comprises a series of 0s and one element equal to 1, that cell array represents a dfilt.delay section with latency equal to the number of zeros, rather than a dfilt.cascadewdfallpass section. This exception occurs with quasi-linear phase IIR decimators.

Usually you do not construct IIR wave digital filter decimators explicitly. Instead, you obtain an IIR wave digital filter decimator as a result of designing a halfband decimator. The first example in the following section illustrates this case.

Examples   Design an elliptic halfband decimator with a decimation factor equal to 2. Both examples use the iirwdfdecim filter structure (an input argument to the design method) to design the final decimator.

The first portion of this example generates a filter specification object d that stores the specifications for the decimator.

```
tw  = 100; % Transition width of filter to design, 100 Hz.
ast = 80;  % Stopband attenuation of filter 80 dB.
fs  = 2000; % Sampling frequency of the input signal.
m   = 2;   % Decimation factor.
```

```
d = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

Now perform the actual design using d. Filter object hm is an
mfilt.iirwdfdecim filter.

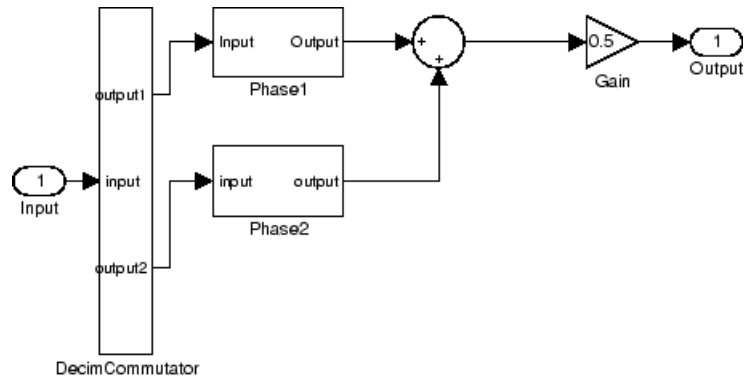
```
Hm = design(d,'ellip','FilterStructure','iirwdfdecim');
% Note that realizemdl requires Simulink
realizemdl(hm)      % Build model of the filter.
```

Design a linear phase halfband decimator for decimating a signal by a
factor of 2.

```
tw  = 100;  % Transition width of filter, 100 Hz.
ast = 60;   % Filter stopband attenuation = 80 dB
fs  = 2000; % Input signal sampling frequency.
m   = 2;    % Decimation factor.
d = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

Use d to design the final filter hm, an mfilt.iirwdfdecim object.

```
hm = design(d,'iirlinphase','filterstructure',...
'iirwdfdecim');
% Note that realizemdl requires Simulink
realizemdl(hm)      % Build model of the filter.
```

The models that `realizemdl` returns for each example appear below. At this level, the realizations of the filters are identical. The differences appear in the subsystem blocks Phase1 and Phase2.


This is the Phase1 subsystem from the halfband model.
Phase1 subsystem from the linear phase model is less revealing—an allpass filter.
See Also dfilt.cascadewdfallpass | mfilt | mfilt.iirdecim | mfilt.iirwdfinterp

mfilt.iirwdfinterp

Purpose　　IIR wave digital filter interpolator

Syntax　　`hm = mfilt.iirwdfinterp(c1,c2,...)`

Description　　`hm = mfilt.iirwdfinterp(c1,c2,...)` constructs an IIR wave digital interpolator given the coefficients specified in the cell arrays `c1`, `c2`, and so on. The IIR interpolator `hm` is a polyphase IIR filter where each phase is a cascade wave digital allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadewdfallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirwdfinterp` interprets them same way as `mfilt.cascadewdfallpass`.

The following exception applies to interpreting the contents of a cell array — if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and one element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadewdfallpass` section. This exception occurs with quasi-linear phase IIR interpolators.

Usually you do not construct IIR wave digital filter interpolators explicitly. Rather, you obtain an IIR wave digital interpolator as a result of designing a halfband interpolator. The first example in the following section illustrates this case.

Examples　　Design an elliptic halfband interpolator with interpolation factor equal to 2. At the end of the design process, hm is an IIR wave digital filter interpolator.

```
tw  = 100;  % Transition width of filter, 100 Hz.
ast = 80;   % Stopband attenuation of filter, 80 dB.
fs  = 2000; % Sampling frequency after interpolation.
l   = 2;    % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

The specification object d stores the interpolator design requirements. Now use d to design the actual filter hm.

```
hm = design(d,'ellip','filterstructure','iirwdfinterp');
```

If you have Simulink installed, you can realize your filter as a model built from DSP System Toolbox blocks.

```
% Note that realizemdl requires Simulink
realizemdl(hm)     % Build model of the filter.
```

For variety, design a linear phase halfband interpolator with an interpolation factor of 2.

```
tw  = 100;  % Transition width of filter, 100 Hz.
ast = 80;   % Stopband attenuation of filter, 80 dB.
fs  = 2000; % Sampling frequency after interpolation.
l   = 2;    % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

Now perform the actual design process with d. Filter hm is an IIR wave digital filter interpolator. As in the previous example, realizemdl returns a Simulink model of the filter if you have Simulink installed.

```
hm = design(d,'iirlinphase','filterstructure',...
'iirwdfinterp');
% Note that realizemdl requires Simulink
realizemdl(hm)     % Build model of the filter.
```

See Also   dfilt.cascadewdfallpass | mfilt.iirinterp | mfilt.iirwdfdecim

mfilt.linearinterp

Purpose	Linear interpolator

Syntax   hm = mfilt.linearinterp(l)

Description   hm = mfilt.linearinterp(l) returns an FIR linear interpolator hm
with an integer interpolation factor l. Provide l as a positive integer.
The default value for the interpolation factor is 2 when you do not
include the input argument l.

When you use this linear interpolator, the samples added to the input
signal have values between the values of adjacent samples in the
original signal. Thus you see something like a smooth profile where the
interpolated samples continue a line between the previous and next
original samples. The example demonstrates this smooth profile clearly.
Compare this to the interpolation process for mfilt.holdinterp, which
creates a stairstep profile.

Make this filter a fixed-point or single-precision filter by changing the
value of the Arithmetic property for the filter hm as follows:

- To change to single-precision filtering, enter

  ```
  set(hm,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hm,'arithmetic','fixed');
  ```

Input Arguments

The following table describes the input argument for
mfilt.linearinterp.

Input Argument	Description
l	Interpolation factor for the filter. l specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for l it defaults to 2.

Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.linearinterp` objects. The next table describes each property for an `mfilt.linearinterp` filter object.

Name	Values	Description
Arithmetic	Double, single, fixed	Specifies the arithmetic the filter uses to process data while filtering.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt object.
InterpolationFactor	Integer	Interpolation factor for the filter. l specifies the amount to increase the input sampling rate. It must be an integer.
PersistentMemory	'false' or 'true'	Determine whether the filter states get restored to zero for each filtering operation
States	Double or single array	Filter states. states defaults to a vector of zeros that has length equal to nstates(hm). Always available, but visible in the display only when PersistentMemory is true.

Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.holdinterp` filter.

Note The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

```
info(hm)
```

where `hm` is a filter.

For further information about the properties of this filter or any `mfilt` object, refer to "Multirate Filter Properties" on page 8-115.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits. Depends on L. [29 when L=2]	Specifies the fraction length used to interpret data output by the accumulator.
AccumWordLength	Any integer number of bits [33]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to `fixed` allows you to modify other filter properties to customize your fixed-point filter.

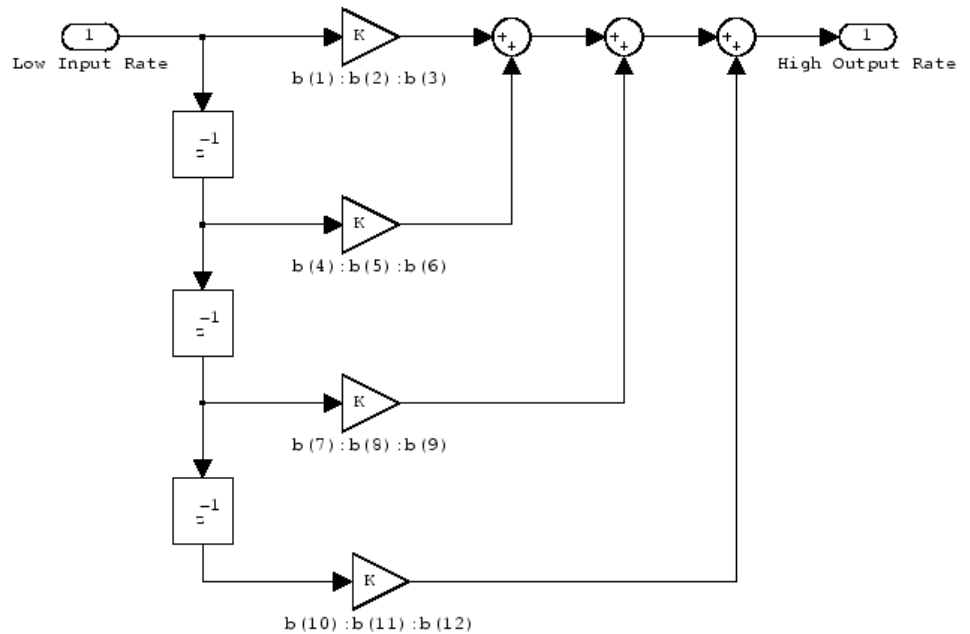
Name	Values	Description
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.

Name	Values	Description
OutputFracLength	Any positive or negative integer number of bits [29]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [33]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.

Name	Values	Description
RoundMode	[convergent], ceil, fix, floor, nearest, round	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.

Name	Values	Description
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Toolboxdocumentation. For information about the ordering of the states, refer to the filter structure in the following section.

Filter Structure

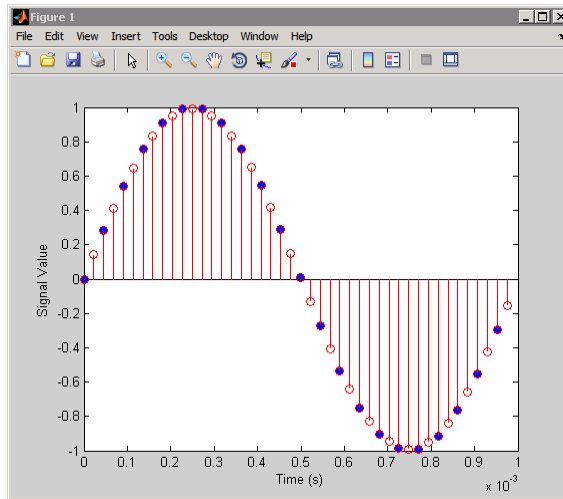
Linear interpolator structures depend on the FIR filter you use to implement the filter. By default, the structure is direct-form FIR.


Examples

Interpolation by a factor of 2 (used to convert the input signal sampling rate from 22.05 kHz to 44.1 kHz).

```
l = 2;                    % Interpolation factor
hm = mfilt.linearinterp(l);
fs = 22.05e3;             % Original sample freq: 22.05 kHz.
n = 0:5119;               % 5120 samples, 0.232 second long signal
x  = sin(2*pi*1e3/fs*n);  % Original signal, sinusoid at 1 kHz
y = filter(hm,x);         % 10240 samples, still 0.232 seconds
stem(n(1:22)/fs,x(1:22),'filled') % Plot original sampled at
                                  % 22.05 kHz
hold on                   % Plot interpolated signal (44.1
                          % kHz) in red
```

```
stem(n(1:44)/(fs*l),y(2:45),'r')
xlabel('Time (s)');ylabel('Signal Value')
```

Using linear interpolation, as compared to the hold approach of `mfilt.holdinterp`, provides greater fidelity to the original signal.


See Also   `mfilt.holdinterp` | `mfilt.firinterp` | `mfilt.firsrc` | `mfilt.cicinterp`

minimizecoeffwl

Purpose   Minimum wordlength fixed-point filter

Syntax   Hq = minimizecoeffwl(Hd)
                 Hq = minimizecoeffwl(Hd,...,'NoiseShaping',NSFlag)
                 Hq = inimizecoeffwl(Hd,...,'NTrials',N)
                 Hq = minimizecoeffwl(Hd,...'Apasstol',Apasstol)
                 Hq = minimizecoeffwl(Hd,...,'Astoptol',Astoptol)
                 Hq = minimizecoeffwl(Hd,...,'MatchrefFilter',RefFiltFlag)

Description Hq = minimizecoeffwl(Hd) returns the minimum wordlength
                 fixed-point filter object Hq that meets the design specifications of the
                 single-stage or multistage FIR filter object Hd. Hd must be generated
                 using fdesign and design. If Hd is a multistage filter object, the
                 procedure minimizes the wordlength for each stage separately.
                 minimizecoeffwl uses a stochastic noise-shaping procedure by default
                 to minimize the wordlength. To obtain repeatable results on successive
                 function calls, initialize the uniform random number generator rand.

                 Hq = minimizecoeffwl(Hd,...,'NoiseShaping',NSFlag) enables or
                 disables the stochastic noise-shaping procedure in the minimization of
                 the wordlength. By default NSFlag is true. Setting NSFlag to false
                 minimizes the wordlength without using noise-shaping.

                 Hq = inimizecoeffwl(Hd,...,'NTrials',N) specifies the number of
                 Monte Carlo trials to use in the minimization. Hq is the filter with the
                 minimum wordlength among the N trials that meets the specifications
                 in Hd. 'NTrials' defaults to one.

                 Hq = minimizecoeffwl(Hd,...'Apasstol',Apasstol) specifies the
                 passband ripple tolerance in dB. 'Apasstol' defaults to 1e-4.

                 Hq = minimizecoeffwl(Hd,...,'Astoptol',Astoptol) specifies the
                 stopband tolerance in dB. 'Astoptol' defaults to 1e-2.

                 Hq = minimizecoeffwl(Hd,...,'MatchrefFilter',RefFiltFlag)
                 determines whether the fixed-point filter matches the filter order and
                 transition width of the floating-point design. Setting 'MatchRefFilter'
                 to true returns a fixed-point filter with the same order and transition
                 width as Hd. The 'MatchRefFilter' property defaults to false and the

resulting fixed-point filter may have a different order and transition width than the floating-point design Hd.

You must have the Fixed-Point Toolbox software installed to use this function.

Examples   Minimize wordlength for lowpass FIR equiripple filter:

```
f=fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.3,1,60);
% Design filter with double-precision floating point
Hd=design(f,'equiripple');
% Find minimum wordlength fixed-point filter
% with 0.15 dB stopband tolerance
Hq=minimizecoeffwl(Hd,'MatchRefFilter',true,'Astoptol',0.15);
Hq1=minimizecoeffwl(Hd,'Astoptol',0.15);
% Hq.coeffwordlength is 14 bits.
% Hq1.coeffwordlength is 11 bits
hfvt=fvtool(Hd,Hq,Hq1,'showreference','off');
legend(hfvt,'44 coefficients floating-point',...
'44 coefficients 14 bits','48 coefficients 11 bits');
```
See Also   constraincoeffwl | design | fdesign | maximizestopband | measure | rand

Tutorials   • "Fixed-Point Data Types"

msepred

Purpose   Predicted mean-squared error for adaptive filter

Syntax
```
[mmse,emse] = msepred(ha,x,d)
[mmse,emse,meanw,mse,tracek] = msepred(ha,x,d)
[mmse,emse,meanw,mse,tracek] = msepred(ha,x,d,m)
```

Description   `[mmse,emse] = msepred(ha,x,d)` predicts the steady-state values at convergence of the minimum mean-squared error (`mmse`) and the excess mean-squared error (`emse`) given the input and desired response signal sequences in `x` and `d` and the property values in the adaptfilt object `ha`.

`[mmse,emse,meanw,mse,tracek] = msepred(ha,x,d)` calculates three sequences corresponding to the analytical behavior of the LMS adaptive filter defined by `ha`:

- `meanw` — contains the sequence of coefficient vector means. The columns of matrix `meanw` contain predictions of the mean values of the LMS adaptive filter coefficients at each time instant. The dimensions of `meanw` are `(size(x,1))`-by-`(ha.length)`.

- `mse` — contains the sequence of mean-square errors. This column vector contains predictions of the mean-square error of the LMS adaptive filter at each time instant. The length of `mse` is equal to `size(x,1)`.

- `tracek` — contains the sequence of total coefficient error powers. This column vector contains predictions of the total coefficient error power of the LMS adaptive filter at each time instant. The length of `tracek` is equal to `size(x,1)`.

`[mmse,emse,meanw,mse,tracek] = msepred(ha,x,d,m)` specifies an optional input argument `m` that is the decimation factor for computing `meanw`, `mse`, and `tracek`. When `m > 1`, `msepred` saves every `m`th predicted value of each of these sequences. When you omit the optional argument `m`, it defaults to one.

Note msepred is available for the following adaptive filters only:
— adaptfilt.blms — adaptfilt.blmsfft — adaptfilt.lms —
adaptfilt.nlms — adaptfilt.se Using msepred is the same for any
adaptfilt object constructed by the supported filters.

Examples   Analyze and simulate a 32-coefficient adaptive filter using 25 trials of
2000 iterations each.

```
x = zeros(2000,25); d = x;     % Initialize variables
ha = fir1(31,0.5);             % FIR system to be identified
x = filter(sqrt(0.75),[1 -0.5],sign(randn(size(x))));
n = 0.1*randn(size(x));        % observation noise signal
d = filter(ha,1,x)+n;          % desired signal
l = 32;                        % Filter length
mu = 0.008;                    % LMS step size.
m = 5;                         % Decimation factor for analysis
                               % and simulation results
ha = adaptfilt.lms(l,mu);
[mmse,emse,meanW,mse,traceK] = msepred(ha,x,d,m);
[simmse,meanWsim,Wsim,traceKsim] = msesim(ha,x,d,m);
nn = m:m:size(x,1);
subplot(2,1,1);
plot(nn,meanWsim(:,12),'b',nn,meanW(:,12),'r',nn,...
meanWsim(:,13:15),'b',nn,meanW(:,13:15),'r');
PlotTitle ={'Average Coefficient Trajectories for';...
            'W(12), W(13), W(14), and W(15)'};
title(PlotTitle);
legend('Simulation','Theory');
xlabel('Time Index'); ylabel('Coefficient Value');
subplot(2,2,3);
semilogy(nn,simmse,[0 size(x,1)],[(emse+mmse)...
(emse+mmse)],nn,mse,[0 size(x,1)],[mmse mmse]);
title('Mean-Square Error Performance');
axis([0 size(x,1) 0.001 10]);
legend('MSE (Sim.)','Final MSE','MSE','Min. MSE');
```

```
xlabel('Time Index'); ylabel('Squared Error Value');
subplot(2,2,4);
semilogy(nn,traceKsim,nn,traceK,'r');
title('Sum-of-Squared Coefficient Errors'); axis([O size(x,1)...
0.0001 1]);
legend('Simulation','Theory');
xlabel('Time Index'); ylabel('Squared Error Value');
```

Viewing the plots in this figure you see the various error values plotted in both simulation and theory. Each subplot reveals more information about the results as the simulation converges with the theoretical performance.

Purpose   Measured mean-squared error for adaptive filter

Syntax   mse = msesim(ha,x,d)
                   [mse,meanw,w,tracek] = msesim(ha,x,d)
                   [mse,meanw,w,tracek] = msesim(ha,x,d,m)

Description   mse = msesim(ha,x,d) returns the sequence of mean-square errors in
                   column vector mse. The vector contains estimates of the mean-square
                   error of the adaptive filter at each time instant during adaptation. The
                   length of mse is equal to size(x,1). The columns of matrix x contain
                   individual input signal sequences, and the columns of the matrix d
                   contain corresponding desired response signal sequences.

                   [mse,meanw,w,tracek] = msesim(ha,x,d) calculates three
                   parameters that correspond to the simulated behavior of the adaptive
                   filter defined by ha:

                   • meanw — sequence of coefficient vector means. The columns of this
                     matrix contain estimates of the mean values of the LMS adaptive
                     filter coefficients at each time instant. The dimensions of meanw are
                     (size(x,1))-by-(ha.length).

                   • w — estimate of the final values of the adaptive filter coefficients for
                     the algorithm corresponding to ha.

                   • tracek — sequence of total coefficient error powers. This column
                     vector contains estimates of the total coefficient error power of the
                     LMS adaptive filter at each time instant. The length of tracek is
                     equal to size(X,1).

                   [mse,meanw,w,tracek] = msesim(ha,x,d,m) specifies an optional
                   input argument m that is the decimation factor for computing meanw,
                   mse, and tracek. When m > 1, msepsim saves every mth predicted value
                   of each of these sequences. When you omit the optional argument m, it
                   defaults to one.

Examples   Simulation of a 32-coefficient FIR filter using 25 trials, each trial
                   having 2000 iterations of the adaptation process.

```
x = zeros(2000,25); d = x;          % Initialize variables
ha = fir1(31,0.5);                  % FIR system to be identified
x = filter(sqrt(0.75),[1 -0.5],sign(randn(size(x))));
n = 0.1*randn(size(x));             % Observation noise signal
d = filter(ha,1,x)+n;               % Desired signal
l = 32;                             % Filter length
mu = 0.008;                         % LMS Step size.
m  = 5;                             % Decimation factor for analysis
                                    % and simulation results
ha = adaptfilt.lms(l,mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(ha,x,d,m);
nn = m:m:size(x,1);
subplot(2,1,1);
plot(nn,meanWsim(:,12),'b',nn,meanWsim(:,13:15),'b');
PlotTitle ={'Average Coefficient Trajectories for';...
            'W(12), W(13), W(14), and W(15)'};
title(PlotTitle);
xlabel('Time Index'); ylabel('Coefficient Value');
subplot(2,2,3);
semilogy(nn,simmse);
title('Mean-Square Error Performance'); axis([0 size(x,1) 0.001...
10]);
legend('Measured MSE');
xlabel('Time Index'); ylabel('Squared Error Value');
subplot(2,2,4);
semilogy(nn,traceKsim);
title('Sum-of-Squared Coefficient Errors'); axis([0 size(x,1)...
0.0001 1]);
xlabel('Time Index'); ylabel('Squared Error Value');
```

Calculating the mean squared error for an adaptive filter is one measure
of the performance of the adapting algorithm. In this figure, you see a
variety of measures of the filter, including the error values.

multistage

Purpose   Multistage filter from specification object

Syntax
```
hd = design(d,'multistage')
hd = design(...,'filterstructure',structure)
hd = design(...,'nstages',nstages)
hd = design(...,'usehalfbands',hb)
```

Description   `hd = design(d,'multistage')` designs a multistage filter whose response you specified by the filter specification object `d`.

`hd = design(...,'filterstructure',structure)` returns a filter with the structure specified by `structure`. Input argument `structure` is `dffir` by default and can also be one of the following strings.

structure String	Valid with These Responses
firdecim	Lowpass or Nyquist response
firtdecim	Lowpass or Nyquist response
firinterp	Lowpass or Nyquist response
lowpass	Default lowpass only

Multistage design applies to the default lowpass filter specification object and to decimators and interpolators that use either lowpass or Nyquist responses.

`hd = design(...,'nstages',nstages)` specifies `nstages`, the number of stages to be used in the design. `nstages` must be an integer or the string `auto`. To allow the design algorithm to use the optimal number of stages while minimizing the cost of using the resulting filter, `nstages` is `auto` by default. When you specify an integer for `nstages`, the design algorithm minimizes the cost for the number of stages you specify.

`hd = design(...,'usehalfbands',hb)` uses halfband filters when you set `hb` to `true`. The default value for `hb` is `false`.

Note To see a list of the design methods available for your filter, use designmethods(hd).

Examples

Design a minimum-order, multistage Nyquist interpolator.

```
l = 15;   % Interpolation factor. Also the Nyquist band.
tw = 0.05; % Normalized transition width
ast = 40;   % Minimum stopband attenuation in dB
d = fdesign.interpolator(l,'nyquist',l,'tw,ast',tw,ast);
hm = design(d,'multistage');
fvtool(hm);
```

Design a multistage lowpass interpolator with an interpolation factor of 8.

```
m = 8; % Interpolation factor;
```

```
d = fdesign.interpolator(m,'lowpass');
% Use halfband filters if possible.
hm = design(d,'multistage','Usehalfbands',true);
fvtool(hm);
```

This figure shows the response for `hm`.

Purpose   Power spectral density of filter output due to roundoff noise

Syntax   hpsd = noisepsd(H,L)
               hpsd = noisepsd(H,L,param1,value1,param2,value2,...)
               hpsd = noisepsd(H,L,opts)
               noisepsd(H,...)

Description   hpsd = noisepsd(H,L) computes the power spectral density (PSD) at
                    the output of dfilt object or filter System object, H, occurring because of
                    roundoff noise. This noise is produced by quantization errors within the
                    filter. L is the number of trials used to compute the average. The PSD is
                    computed from the average over the L trials. The more trials you specify,
                    the better the estimate, but at the expense of longer computation time.
                    When you do not explicitly specify L, the default is 10 trials.

                    hpsd is a psd data object. To extract the PSD vector (the data from
                    the PSD) from hpsd, enter

                    get(hpsd,'data')

                    at the prompt. Plot the PSD data with plot(hpsd). The average power
                    of the output noise (the integral of the PSD) can be computed with
                    avgpower, a method of dspdata objects:

                    avgpwr = avgpower(hpsd).

                    hpsd = noisepsd(H,L,param1,value1,param2,value2,...) where H
                    can be either a dfilt object or a filter System object, specifies optional
                    parameters via propertyname/propertyvalue pairs. Valid psd object
                    property values are:

Property Name	Default Value	Description and Valid Entries
Nfft	512	Specify the number of FFT points to use to calculate the PSD.
NormalizedFrequency	true	Determine whether to use normalized frequency. Enter a logical value of `true` or `false`. Because this property is a logical value, and not a string, do not enclose the single quotation marks.
Fs	normalized	Specify the sampling frequency to use when you set `NormalizedFrequency` to `false`. Use any integer value greater than 1. Enter the value in Hz.
SpectrumType	onesided	Specify how `noisepsd` should generate the PSD. Options are `onesided` or `twosided`. If you choose a two-sided computation, you can also choose `CenterDC = true`. Otherwise, `CenterDC` must be `false`. • `onesided` converts the type to a spectrum that is calculated over half the Nyquist interval. All properties affected by the new frequency range are adjusted automatically. • `twosided` converts the type to a spectrum that is calculated over the whole Nyquist interval. All properties affected by the new frequency range are adjusted automatically.

Property Name	Default Value	Description and Valid Entries
CenterDC	false	Shift the zero-frequency component to the center of a two-sided spectrum. • When you set SpectrumType to onesided, it is changed to twosided and the data is converted to a two-sided spectrum. • Setting CenterDC to false shifts the data and the frequency values in the object so that DC is in the left edge of the spectrum. This operation does not affect the SpectrumType property setting.
Arithmetic (only for filter System objects)	ARITH	Analyze the filter System object, based on the arithmetic specified in the ARITH input. ARITH can be set to double, single, or fixed. The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state.

Note If the spectrum data you specify is calculated over half the Nyquist interval and you do not specify a corresponding frequency vector, the default frequency vector assumes that the number of points in the whole FFT was even. Also, the plot option to convert to a whole or two-sided spectrum assumes the original whole FFT length is even.

If H is a filter System object, noisepsd requires knowledge of the input data type. Analysis cannot be performed if the input data type is not available. If you do not specify the Arithmetic parameter, i.e., use the syntax [h,w] = noisepsd(H) , then the following rules apply to this method:

- The System object state is `Unlocked` — `noisepsd` performs double-precision analysis.

- The System object state is `Locked` — `noisepsd` performs analysis based on the locked input data type.

If you do specify the `Arithmetic` parameter, i.e., use the syntax `[h,w] = noisepsd(H,'Arithmetic', ARITH))`, review the following rules for this method. Which rule applies depends on the value you set for the `Arithmetic` parameter.

Value	System Object State	Rule
`ARITH = 'double'`	Unlocked	`noisepsd` performs double-precision analysis.
	Locked	`noisepsd` performs double-precision analysis.
``ARITH = `single'``	Unlocked	`noisepsd` performs single-precision analysis.
	Locked	`noisepsd` performs single-precision analysis.

Value	System Object State	Rule
ARITH = `fixed'	Unlocked	noisepsd produces an error because the fixed-point input data type is unknown.
	Locked	When the input data type is double or single, then noisepsd produces an error because since the fixed-point input data type is unknown.
		When the input data is of fixed-point type, noisepsd performs analysis based on the locked input data type.

noisepsd supports only the following filter System objects:

- dsp.FIRFilter

- dsp.IIRFilter

- dsp.AllpoleFilter

- dsp.BiquadFilter

Regardless of whether H is a dfilt object or a filter System object, hpsd = noisepsd(H,L,opts) uses an options object, opts, to specify the optional input arguments. This specification is not made using property-value pairs in the command. Use opts = noisepsdopts(H) to create the object. opts then has the noisepsd settings from H. After creating opts, you change the property values before calling noisepsd:

```
set(opts,'fs',48e3); % Set Fs to 48 kHz.
```

Regardless of whether H is a `dfilt` object or a filter System object, `noisepsd(H,...)` with no output argument launches FVTool.

Examples   Compute the PSD of the output noise caused by the quantization processes in a fixed-point, direct form FIR filter.

```
b = firgr(27,[0 .4 .6 1],[1 1 0 0]);
h = dfilt.dffir(b); % Create the filter object.
% Quantize the filter to fixed-point.
h.arithmetic = 'fixed';
hpsd = noisepsd(h);
plot(hpsd)
```

`hpsd` looks similar to the following figure—the data resulting from the noise PSD calculation. You can review the data in `hpsd.data`.

noisepsdopts

Purpose	Options for running filter output noise PSD

Syntax   `opts = noisepsdopts(H)`

Description   `opts = noisepsdopts(H)` uses the current settings in the `dfilt` object or the filter System object, `H`, to create an options object, `opts`, that contains specified options for computing the output noise PSD. You can pass `opts` to the `scale` method as an input argument to apply scaling settings to a second-order filter.

`noisepsdopts` returns the options object, `opts`, with which you can set the following properties for `noisepsd`:

Property Name	**Default Value**	**Description and Valid Entries**
`Nfft`	`512`	Specify the number of FFT points to use to calculate the PSD.
`NormalizedFrequency`	`true`	Determine whether to use normalized frequency. Enter a logical value of the logical `true` or `false`. Because this property is a logical value, and not a string, do not enclose with single quotation marks.
`Fs`	`normalized`	Specify the sampling frequency to use when you set `NormalizedFrequency` to `false`. Use any integer value greater than 1. Enter the value in Hz.

Property Name	Default Value	Description and Valid Entries
SpectrumType	onesided	Specify how noisepsd should generate the PSD. Options are onesided or twosided. If you choose a two-sided computation, you can also choose centerdc = true. Otherwise, centerdc must be false. • onesided converts the type to a spectrum that is calculated over half the Nyquist interval. All properties affected by the new frequency range are adjusted automatically. • twosided converts the type to a spectrum that is calculated over the whole Nyquist interval. All properties affected by the new frequency range are adjusted automatically.
CenterDC	false	Shift the zero-frequency component to the center of a two-sided spectrum. • When you set SpectrumType to onesided, it is changed to twosided and the data is converted to a two-sided spectrum. • Setting CenterDC to false shifts the data and the frequency values in the object so that DC is in the left edge of the spectrum.

Property Name	Default Value	Description and Valid Entries
		This operation does not effect the SpectrumType property setting.
Arithmetic (only for filter System objects)	ARITH	Analyze the filter System object, based on the arithmetic specified in the ARITH input. ARITH can be set to double, single, or fixed. The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state.

See Also   noisepsd

Purpose   P-norm of filter

Syntax   l = norm(ha)
                  l = norm(ha,pnorm)
                  l = norm(hd)
                  l = norm(hd,pnorm)
                  l = norm(hm)
                  l = norm(hm,pnorm)

Description   All of the variants of norm return the filter p-norm for the object in the
                  syntax, either an adaptive filter, a digital filter, or a multirate filter.
                  When you omit the pnorm argument, norm returns the L2-norm for
                  the object.

                  Note that by Parseval's theorem, the L2-norm of a filter is equal to the
                  l2 norm. This equality is not true for the other norm variants.

                  ### For adaptfilt Objects

                  l = norm(ha) returns the L2-norm of an adaptive filter.l =
                  norm(ha,pnorm) adds the input argument pnorm to let you specify the
                  norm returned. pnorm can be either

                  • Frequency-domain norms specified by one of L1, L2, or Linf

                  • Discrete-time domain norms specified by one of l1, l2, or linf

                  ### For dfilt Objects

                  l = norm(hd) returns the L2-norm of a discrete-time filter.

                  l = norm(hd,pnorm) includes input argument pnorm that lets you
                  specify the norm returned. pnorm can be either

                  • Frequency-domain norms specified by one of L1, L2, or Linf

                  • Discrete-time domain norms specified by one of l1, l2, or linf

                  By Parseval's theorem, the L2-norm of a filter is equal to the l2 norm.
                  This equality is not true for the other norm variants.

                  IIR filters respond slightly differently to norm. When you compute the
                  l2, linf, L1, and L2 norms for an IIR filter, norm(...,L2,tol) lets you

specify the tolerance for the accuracy in the computation. For l1, l2, L2, and linf, norm uses the tolerance to truncate the infinite impulse response that it uses to calculate the norm. For L1, norm passes the tolerance to the numerical integration algorithm. Refer to Examples to see this in use. You cannot specify Linf for the norm and include the tol option.

For mfilt Objects

l = norm(hm) returns the L2-norm of a multirate filter.

l = norm(hm,pnorm) includes argument pnorm to let you specify the norm returned. pnorm can be either

- Frequency-domain norms specified by one of L1, L2, or Linf

- Discrete-time domain norms specified by one of l1, l2, or linf

Note that, by Parseval's theorem, the L2-norm of a filter is equal to the l2 norm. This equality is not true for the other norm variants.

Examples

Adaptfilt Objects

For the adaptive filter example, compute the 2-norm of an adaptfilt object, here an LMS-based adaptive filter.

```
Ha = adaptfilt.lms; % norm(ha) is zero because all coeffs are zero
% Create some data to filter to generate filter coeffs
x = randn(100,1);
d = x + randn(100,1);
[y,e] = filter(Ha,x,d);
L2 = norm(Ha); % Now norm(ha) is nonzero
```

Dfilt Objects

To demonstrate the tolerance option used with an IIR filter (dfilt object), compute the 2-norm of filter hd with a tolerance of 1e-10.

```
H =fdesign.lowpass('n,fc',5,0.4);
Hd = butter(H);
L2=norm(Hd,'l2',1e-10);
```

Mfilt Objects

In this example, compute the infinity norm of an FIR polyphase interpolator, which is an mfilt object.

```
Hm = mfilt.firinterp;
Linf = norm(Hm,'linf');
```

See Also   reorder | scale | scalecheck

normalize

Purpose	Normalize filter numerator or feed-forward coefficients
Syntax	`normalize(hq)` `g = normalize(hd)`

Description   `normalize(hq)` normalizes the filter numerator coefficients for a quantized filter to have values between -1 and 1. The coefficients of `hq` change — `normalize` does not copy `hq` and return the copy. To restore the coefficients of `hq` to the original values, use `denormalize`.

Note that for lattice filters, the feed-forward coefficients stored in the property `lattice` are normalized.

`g = normalize(hd)` normalizes the numerator coefficients for the filter `hq` to between -1 and 1 and returns the gain `g` due to the normalization operation. Calling `normalize` again does not change the coefficients. `g` always returns the gain returned by the first call to normalize the filter.

Examples   Create a direct form II quantized filter that uses second-order sections. Then use `normalize` to maximize the use of the range of representable coefficients.

```
d=fdesign.lowpass('n,fp,ap,ast',8,.5,2,40);
hd=design(d,'ellip');
hd.arithmetic ='fixed';
```

Check the filter coefficients. Note that `InitialSOSMatrix(3,2)>1`

```
InitialSOSMatrix = hd.sosMatrix;
```

Use `normalize` to modify the coefficients into the range between -1 and 1. The output `g` contains the gains applied to each section of the SOS filter.

```
g = normalize(hd);
```

None of the numerator coefficients exceed -1 or 1.

See Also   denormalize

normalizefreq

Purpose	Switch filter specification between normalized frequency and absolute frequency

Syntax	`normalizefreq(d)`
	`normalizefreq(d,flag)`
	`normalizefreq(d,`**`false`**`,fs)`

Description	`normalizefreq(d)` normalizes the frequency specifications in filter specifications object `d`. By default, the `NormalizedFrequency` property is set to `true` when you create a design object. You provide the design specifications in normalized frequency units. `normalizefreq` does not affect filters that already use normalized frequency.

If you use this syntax when `d` does not use normalized frequency specifications, all of the frequency specifications are normalized by `fs/2` so they lie between 0 and 1, where `fs` is specified in the object. Included in the normalization are the filter properties that define the filter pass and stopband edge locations by frequency:

- `F3 dB` — Used by IIR filter specifications objects to describe the passband cutoff frequency

- `Fcutoff` — Used by FIR filter specifications objects to describe the passband cutoff frequency

- `Fpass` — Describes the passband edges

- `Fstop` — Describes the stopband edges

In this syntax, `normalizefreq(d)` assumes you specified `fs` when you created `d` or changed `d` to use absolute frequency specifications.

`normalizefreq(d,flag)` where `flag` is either **true** or **false**, specifies whether the `NormalizedFrequency` property value is `true` or `false` and therefore whether the filter normalizes the sampling frequency `fs` and other related frequency specifications. `fs` defaults to 1 for this syntax.

When you do not provide the input argument `flag`, it defaults to `true`. If you set `flag` to `false`, affected frequency specifications are multiplied by `fs/2` to remove the normalization. Use this syntax to switch your

filter between using normalized frequency specifications and not using normalized frequency specifications.

normalizefreq(d,**false**,fs) lets you specify a new sampling frequency fs when you set the NormalizedFrequency property to false.

Examples   These examples demonstrate using normalizefreq in both of the major syntax applications—setting the design object frequency specifications to use absolute frequency (normalizefreq(hd,**false**,fs)) and resetting a design object to using normalized frequencies (normalizefreq(d)).

Construct a highpass filter specifications object by specifying the passband and stopband edges and the desired attenuations in the bands. By default, provide the frequency specifications in normalized values between 0 and 1.

d=fdesign.highpass(0.35, 0.45, 60, 40);

Fstop and Fpass are in normalized form, and the property NormalizedFrequency is true.

Now use normalizedfreq to convert to absolute frequency specifications, with a sampling frequency of 1000 Hz.

normalizefreq(d,false,1e3);

Both of the attenuation specifications remain the same. The passband and stopband edge definitions now appear in Hz, where the new value represents the normalized values multiplied by Fs/2, or 500 Hz.

Converting to using normalized frequencies consists of using normalizefreq with the design object d.

normalizefreq(d)

For bandstop, bandpass, and multiple band filter specifications objects, normalizefreq works the same way for all band edge definitions. When you do not provide the sampling frequency Fs as an input argument and you are converting to absolute frequency specifications, normalizefreq sets Fs to 1, as shown in this example.

normalizefreq

```
d=fdesign.bandstop(0.25,0.35,0.55,0.65,50,60);
normalizefreq(d,false)
```

fdesign.interpolator

Purpose   Number of filter states

Syntax   n = nstates(hd)
                   n = nstates(hm)

Description   **Discrete-Time Filters**

                   n = nstates(hd) returns the number of states n in the discrete-time
                   filter hd. The number of states depends on the filter structure and the
                   coefficients.

                   Multirate Filters

                   n = nstates(hm) returns the number of states n in the multirate
                   filter hm. The number of states depends on the filter structure and the
                   coefficients.

Examples   Check the number of states for two different filters, one a direct form
                   FIR filter, the other a multirate filter.

```
h = firls(30,[0 .1 .2 .5]*2,[1 1 0 0]);
hd = dfilt.dffir(h);
NstateDF = nstates(hd);
hm = mfilt.firsrc(2,3);
NstateMR = nstates(hm);
```

See Also   mfilt

order

Purpose	Order of fixed-point filter

Syntax

```
n = order(hq)
n = order(hs)
```

Description n = order(hq) returns the order n of the quantized filter hq. When hq is a single-section filter, n is the number of delays required for a minimum realization of the filter.

When hq has more than one section, n is the number of delays required for a minimum realization of the overall filter.

n = order(hs) returns the order n of the filter System object hs. The order depends on the filter structure and the reference double-precision floating-point coefficients. hs can be one of the following filter structures:

- dsp.FIRFilter
- dsp.BiquadFilter
- dsp.FIRInterpolator
- dsp.CICInterpolator
- dsp.FIRDecimator
- dsp.CICDecimator
- dsp.FIRRateConverter

Examples Create a discrete-time filter, quantize it, and convert it to second-order section form. Then, use order to check the order of the filter.

```
[b,a] = ellip(4,3,20,.6); % Create the reference filter.
hq = dfilt.df2(b,a);
% Quantize the filter and convert to second-order sections.
set(hq,'arithmetic','fixed');

n=order(hq); % Check the order of the overall filter.
```

Purpose   Multirate parallel filter structure

Syntax   `hmp = parallel(hm1,hm2,...,hmn)`

Description `hmp = parallel(hm1,hm2,...,hmn)` returns a multirate filter `hmp` that is two or more `mfilt` objects `hm1`, `hm2`, and so on connected in a parallel structure. Each filter in the structure is one stage and all stages must have the same rate change factor.

Access the individual filters in the parallel structure by

phasedelay

Purpose   Phase delay of filter

Syntax
```
[phi,w]=phasedelay(hfilt)
[phi,w]=phasedelay(hfilt,n)
phasedelay(hfilt)
[phi,w] = phasedelay(hs)
[phi,w] = phasedelay(hs,n)
[phi,w] = phasedelay(hs,Name,Value)
phasedelay(hs)
```

Description   phasedelay returns the phase delay based on the current filter coefficients. This section describes phasedelay operation for discrete-time filters and multirate filters. For more information about optional input arguments for phasedelay, refer to phasedelay in Signal Processing Toolbox documentation.

[phi,w]=phasedelay(hfilt) returns the phase response phi of the filter hfilt and the corresponding frequencies w at which the function evaluates the phase delay.

The phase delay is evaluated at 8192 points equally spaced around the upper half of the unit circle.

[phi,w]=phasedelay(hfilt,n) returns the phase delay phi of the filter hfilt and the corresponding frequencies w at which the function evaluates the phase delay. The phase delay is evaluated at n points equally spaced around the upper half of the unit circle.

phasedelay(hfilt) displays the phase delay of hfilt in the Filter Visualization Tool (FVTool).

[phi,w] = phasedelay(hs) returns the phase delay for the filter System object hs using 8192 samples.

[phi,w] = phasedelay(hs,n) returns the phase delay for the filter System object hs using n samples.

[phi,w] = phasedelay(hs,Name,Value) returns the phase delay with additional options specified by one or more Name,Value pair arguments.

phasedelay(hs) uses FVTool to plot the phase delay of the filter
System object hs.

**Input
Arguments**

hfilt

hfilt is either:

- A discrete-time dfilt, or multirate mfilt filter object

- A vector of discrete-time, or multirate filter objects

The multirate filter delay response is computed relative to the rate at
which the filter is running. When you specify fs (the sampling rate) as
an input argument, phasedelay assumes the filter is running at that
rate.

For multistage cascades, phasedelay forms a single-stage multirate
filter that is equivalent to the cascade. It then computes the response
relative to the rate at which the equivalent filter is running. phasedelay
does not support all multistage cascades. The function analyzes only
those cascades for which there exists an equivalent single-stage filter.

As an example, consider a 2-stage interpolator where the first stage has
an interpolation factor of 2 and the second stage has an interpolation
factor of 4. In this case, an equivalent single-stage filter exists with
an overall interpolation factor of 8. phasedelay uses this equivalent
filter for the analysis. If a sampling frequency fs is specified as an
input argument to phasedelay, the function interprets fs as the rate at
which the equivalent filter is running.

hs

Filter System object. The function supports the following filter
structures.

- dsp.FIRFilter

- dsp.BiquadFilter

- dsp.FIRInterpolator

- dsp.CICInterpolator

- `dsp.FIRDecimator`

- `dsp.CICDecimator`

- `dsp.FIRRateConverter`

n

Number of samples. For an FIR filter where n is a power of two, the computation is done faster using FFTs.

Default: 8192

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Arithmetic
`` `double' `` | `'single'` | `'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

phasedelay

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

phi

Complex, n-element phase-delay vector. If `hfilt` is a vector of filters, `phi` is a complex, `length(hfilt)`-by-n matrix of phase-delay vectors whose columns correspond to each filter in `hfilt`. If n is not specified, the function uses a default value of 8192.

For adaptive filters, `phi` is the instantaneous phase delay.

w

Frequency vector of length n, in radians/sample. `w` consists of n points equally spaced around the upper half of the unit circle (from 0 to π radians/sample). If `hfilt` is a vector of filters, `w` is a complex, `length(hfilt)`-by-n matrix of phase-delay vectors whose columns correspond to each filter in `hfilt`. If n is not specified, the function uses a default value of 8192.

Algorithms

You can provide `fs`, the sampling frequency, as an input as well. `phasedelay` uses `fs` to calculate the delay response and plots the response to `fs/2`.

Purpose   Unwrapped phase response for filter

Syntax   [phi,w]=phasez(hfilt)
                  [phi,w]=phasez(hfilt,n)
                  phasez(hfilt)
                  [phi,w] = phasez(hs)
                  [phi,w] = phasez(hs,n)
                  [phi,w] = phasez(hs,Name,Value)
                  phasez(hs)

Description   phasez returns the unwrapped phase response based on the current
                  filter coefficients. This section describes phasez operation for adaptive
                  filters, discrete-time filters, multirate filters, and filter System objects.
                  For more information about optional input arguments for phasez, refer
                  to phasez in Signal Processing Toolbox documentation.

                  [phi,w]=phasez(hfilt) returns the phase response phi of the filter
                  hfilt and the corresponding frequencies w at which the function
                  evaluates the phase response. The phase response is evaluated at 8192
                  points equally spaced around the upper half of the unit circle.

                  [phi,w]=phasez(hfilt,n) returns the phase response phi of the
                  filter hfilt and the corresponding frequencies w at which the function
                  evaluates the phase response. The phase response is evaluated at n
                  points equally spaced around the upper half of the unit circle.

                  phasez(hfilt) displays the phase response of hfilt in the Filter
                  Visualization Tool (FVTool).

                  [phi,w] = phasez(hs) returns a phase response for the filter System
                  object hs using 8192 samples.

                  [phi,w] = phasez(hs,n) returns a phase response for the filter
                  System object hs using n samples.

                  [phi,w] = phasez(hs,Name,Value) returns a phase response
                  with additional options specified by one or more Name,Value pair
                  arguments.

phasez

phasez(hs) uses FVTool to plot the phase response of the filter System object hs.

Input Arguments

hfilt

hfilt is either:

- An adaptive adaptfilt, discrete-time dfilt, or multirate mfilt filter object

- A vector of adaptive, discrete-time, or multirate filter objects

The multirate filter response is computed relative to the rate at which the filter is running. When you specify fs (the sampling rate) as an input argument, phasez assumes the filter is running at that rate.

For multistage cascades, phasez forms a single-stage multirate filter that is equivalent to the cascade. It then computes the response relative to the rate at which the equivalent filter is running. phasez does not support all multistage cascades. The function analyzes only those cascades for which there exists an equivalent single-stage filter.

As an example, consider a 2-stage interpolator where the first stage has an interpolation factor of 2 and the second stage has an interpolation factor of 4. In this case, an equivalent single-stage filter exists with an overall interpolation factor of 8. phasez uses this equivalent filter for the analysis. If a sampling frequency fs is specified as an input argument to phasez, the function interprets fs as the rate at which the equivalent filter is running.

hs

Filter System object. The function supports the following filter structures.

- dsp.FIRFilter

- dsp.BiquadFilter

- dsp.FIRInterpolator

- dsp.CICInterpolator

- dsp.FIRDecimator

- dsp.CICDecimator

- dsp.FIRRateConverter

n

Number of samples. For an FIR filter where n is a power of two, the computation is done faster using FFTs.

>   **Default:** 8192

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments, where Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Arithmetic

`double' | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed' , the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

phi

Complex, n-element phase response vector. If `hfilt` is a vector of filters, `phi` is a complex, `length(hfilt)`-by-n matrix of phase response vectors whose columns correspond to each filter in `hfilt`. If n is not specified, the function uses a default value of 8192.

For adaptive filters, `phi` is the instantaneous phase response.

w

Frequency vector of length n, in radians/sample. `w` consists of n points equally spaced around the upper half of the unit circle (from 0 to π radians/sample). If `hfilt` is a vector of filters, `w` is a complex, `length(hfilt)`-by-n matrix of phase response vectors whose columns correspond to each filter in `hfilt`. If n is not specified, the function uses a default value of 8192.

polyphase

Purpose	Polyphase decomposition of multirate filter

Syntax
```
p = polyphase(hm)
polyphase(hm)
p = polyphase(hs)
p = polyphase(hs,Name,Value)
polyphase(hs)
```

Description p = polyphase(hm) returns the polyphase matrix p of the multirate filter hm.

polyphase(hm) launches the Filter Visualization Tool (FVTool) with all the polyphase subfilters to allow you to analyze each component subfilter individually.

p = polyphase(hs) returns the polyphase matrix p of the multirate filter System object hs.

p = polyphase(hs,Name,Value) returns the polyphase matrix p of the multirate filter System object hs.

polyphase(hs) launches the Filter Visualization Tool (FVTool) with all the polyphase subfilters to allow you to analyze each component subfilter individually.

Input Arguments

hm

Multirate mfilt filter object. CIC-based filters do not have coefficients, so the function does not support CIC filter structures such as mfilt.cicdecim.

hs

Filter System object. The function supports the following filter structures.

- dsp.FIRInterpolator
- dsp.CICInterpolator
- dsp.FIRDecimator

- dsp.CICDecimator

- dsp.FIRRateConverter

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments, where Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Arithmetic

`double' | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the

System Object State	Coefficient Data Type	Rule
		CustomCoefficientsDataType property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

p

Polyphase matrix p of the multirate filter. Each row in the matrix represents one subfilter of the multirate filter. The first row of matrix p represents the first subfilter, the second row the second subfilter, and so on to the last subfilter.

Examples   When you create a multirate filter that uses polyphase decomposition, polyphase lets you analyze the component filters individually by returning the components as rows in a matrix.

First, create an interpolate-by-eight filter.

```
hm=mfilt.firinterp(8)

hm =

        FilterStructure: 'Direct-Form FIR Polyphase Interpolator'
              Numerator: [1x192 double]
    InterpolationFactor: 8
       PersistentMemory: false
                 States: [23x1 double]
```

In this syntax, the matrix p contains all of the subfilters for hm, one filter per matrix row.

```
p=polyphase(hm)

p =

qreport

Purpose   Most recent fixed-point filtering operation report

Syntax   rlog = qreport(h)

Description rlog = qreport(h) returns the logging report stored in the filter object
h in the object rlog. The ability to log features of the filtering operation
is integrated in the fixed-point filter object and the filter method.

Each time you filter a signal with h, new log data overwrites the results
in the filter from the previous filtering operation. To save the log from a
filtering simulation, change the name of the output argument for the
operation before subsequent filtering runs.

Note qreport requires Fixed-Point Toolbox software and that filter h is
a fixed-point filter. Data logging for fi operations is a preference you set
for each MATLAB session. To learn more about logging, LoggingMode,
and fi object preferences, refer to fipref in the Fixed-Point Toolbox
documentation.

Also, you cannot use qreport to log the filtering operations from a
fixed-point Farrow filter.

Enable logging during filtering by setting LoggingMode to on for fi
objects for your MATLAB session. Trigger logging by setting the
Arithmetic property for h to fixed, making h a fixed-point filter and
filtering an input signal.

Using Fixed-Point Filtering Logging

Filter operation logging with qreport requires some preparation in
MATLAB. Complete these steps before you use qreport.

1 Set the fixed-point object preference for LoggingMode to on for your
MATLAB session. This setting enables data logging.

```
fipref('LoggingMode','on')
```

2 Create your fixed-point filter.

3 Filter a signal with the filter.

4 Use qreport to return the filtering information stored in the filter object.

qreport provides a way to instrument your fixed-point filters and the resulting data log offers insight into how the filter responds to a particular input data signal.

Report object rlog contains a filter-structure-specific list of internal signals for the filter. Each signal contains

• Minimum and maximum values that were recorded during the last simulation. Minimum and maximum values correspond to values before quantization.

• Representable numerical range of the word length and fraction length format

• Number of overflows during filtering for that signal.

Examples   qreport depends on the LoggingMode preference for fixed-point objects. This example demonstrates the process for enabling and using qreport to log the results of filtering with a fixed-point filter. hd is a fixed-point direct-form FIR filter.

```
f = fipref('loggingmode','on');
hd = design(fdesign.lowpass,'equiripple');
hd.arithmetic = 'fixed';
fs = 1000;          % Input sampling frequency.
t = 0:1/fs:1.5;     % Signal length = 1501 samples.
x = sin(2*pi*10*t); % Amplitude = 1 sinusoid.
y = filter(hd,x);
rlog = qreport(hd)
```

View the logging report of a direct-form II, second-order sections IIR filter the same way. While this example sets loggingmode to on, you

do that only once for a MATLAB session, unless you reset the mode to `off` during the session.

```
fipref('loggingmode','on');
hd = design(fdesign.lowpass,'ellip');
hd.arithmetic = 'fixed';
y = filter(hd,rand(100,1));
rlog = qreport(hd)
```

Purpose   Simulink subsystem block for filter

Syntax   ```
realizemdl(hq)
realizemdl(hq,Name,Value)
```

**Description**  realizemdl(hq) generates a model of filter hq in a Simulink subsystem block using sum, gain, and delay blocks from Simulink. The properties and values of hq define the resulting subsystem block parameters.

realizemdl requires Simulink. To accurately realize models of quantized filters, use Simulink Fixed-Point.

realizemdl(hq,Name,Value) generates the model for hq with additional options specified by one or more Name,Value pair arguments. Using name-value pair arguments lets you control more fully the way the block subsystem model gets built. You can specify such details as where the block goes, what the name is, or how to optimize the block structure.

**Note** Subsystem filter blocks that you use realizemdl to create support sample-based input and output only. You cannot input or output frame-based signals with the block.

**Input Arguments**

**hq**

One of the following types of filter object or filter System object:

- Discrete-time filter (dfilt) object

- Multirate filter (mfilt) object.

- Filter System object. The function supports the following structures:

  - dsp.FIRFilter

  - dsp.BiquadFilter

  - dsp.FIRInterpolator

- dsp.CICInterpolator

- dsp.FIRDecimator

- dsp.CICDecimator

- dsp.FIRRateConverter

## Name-Value Pair Arguments

### Destination

'current' (default) | 'new' | subsystemname

Specify whether to add the block to your current Simulink model or create a new model to contain the block. If you provide the name of a current subsystem in *subsystemname*, realizemdl adds the new block to the specified subsystem.

### Blockname

'filter' (default)

Provide the name for the new subsystem block. By default the block is named Filter.

### MapCoeffstoPorts

'off' (default) | 'on'

Specify whether to map the coefficients of the filter to the ports of the block.

### MapStates

'off' (default) | 'on'

Specify whether to apply the current filter states to the realized model. Such specification allows you to save states from a filter object you may have used or configured in a specific way. The default setting of 'off' means the states are not transferred to the model. Setting the property to 'on' preserves the current filter states in the realized model.

### OverwriteBlock

'off' (default) | 'on'

Specify whether to overwrite an existing block with the same name or create a new block.

### OptimizeZeros
`'off'` (default) | `'on'`

Specify whether to remove zero-gain blocks.

### OptimizeOnes
`'off'` (default) | `'on'`

Specify whether to replace unity-gain blocks with direct connections.

### OptimizeNegOnes
`'off'` (default) | `'on'`

Specify whether to replace negative unity-gain blocks with a sign change at the nearest sum block.

### OptimizeDelayChains
`'off'` (default) | `'on'`

Specify whether to replace delay chains made up of $n$ unit delays with a single delay by $n$.

### CoeffNames
`{'Num'}` (default FIR) | `{'Num','Den'}` (default direct form IIR) | `{'Num','Den','g'}` (default IIR SOS) | `{'Num_1','Num_2','Num_3'...}` (default multistage) | `{'K'}` (default form lattice)

Specify the coefficient variable names as string variables in a cell array. `MapCoeffsToPorts` must be set to `'on'` for this property to apply.

### InputProcessing
`'columns as channels'` (default) | `'elements as channels'` | `'inherited'`

Specify sample-based (`'elements as channels'`) or frame-based (`'columns as channels'`) processing.

# realizemdl

---

**Note** The `inherited` option will be removed in a future release.

---

**RateOption**

`'enforce single rate'` (default) | `'allow multirate'`

Specify how the block adjusts the rate at the output to accommodate the reduced number of samples. This parameter applies only when `InputProcessing` is `'columns as channels'`.

**Arithmetic**

`'double' | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

**Details for Fixed-Point Arithmetic**

| System Object State | Coefficient Data Type | Rule |
|---|---|---|
| Unlocked | `'Same as input'` | The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption. |
| Unlocked | `'Custom'` | The function performs fixed-point analysis based on the setting of the |

| System Object State | Coefficient Data Type | Rule |
|---|---|---|
| | | CustomCoefficientsDataType property. |
| Locked | `'Same as input'` | When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption. |
| Locked | `'Custom'` | The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property. |

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

**Examples**   Realize Simulink model of lowpass Butterworth filter:

```
d = fdesign.lowpass('N,F3dB',4,0.25);
Hd = design(d,'butter');
realizemdl(Hd);
```

The realized model is shown in the figure:

Realize Simulink model with coefficients mapped to ports:

```
d = fdesign.lowpass('N,F3dB',4,0.25);
Hd = design(d,'butter');
%Realize Simulink model and export coefficients
realizemdl(Hd,'MapCoeffsToPorts','on');
```

In this case, the filter is an IIR filter with a direct form II second-order sections structure. Setting MapCoeffstoPorts to 'on' exports the numerator coefficients, the denominator coefficients, and the gains to the MATLAB workspace using the default variable names Num, Den, and g. Each column of Num and Den represents one second-order section. You can modify the filter coefficients directly in the MATLAB workspace providing tunability to the realized Simulink model.

Purpose	Number of samples of delay introduced by buffering and unbuffering operations

Syntax

```
d = rebuffer_delay(f,n,v)
d = rebuffer_delay(f,n,v,'mode')
```

Description $d = rebuffer\_delay(f,n,v)$ returns the delay, in samples, introduced by the Buffer or Unbuffer block in multitasking operations.

$d = rebuffer\_delay(f,n,v,'mode')$ returns the delay, in samples, introduced by the Buffer or Unbuffer block in the specified tasking mode.

Input Arguments

f

Frame size of the input to the Buffer or Unbuffer block.

n

Size of the output buffer. Specify one of the following:

- The value of the **Output buffer size** parameter, if you are computing the delay introduced by a Buffer block.

- 1, if you are computing the delay introduced by an Unbuffer block.

v

Amount of buffer overlap. Specify one of the following:

- The value of the **Buffer overlap** parameter, if you are computing the delay introduced by a Buffer block.

- 0, if you are computing the delay introduced by an Unbuffer block.

'mode'

The tasking mode of the model. Specify one of the following options:

- 'singletasking'

- 'multitasking'

rebuffer_delay

Default: `'multitasking'`

Definitions

Multitasking

When you run a model in `MultiTasking` mode, Simulink processes groups of blocks with the same execution priority through each stage of simulation based on task priority. Multitasking mode helps to create valid models of real-world multitasking systems, where sections of your model represent concurrent tasks. The **Tasking mode for periodic sample times** parameter on the Solver pane of the Configuration Parameters dialog box controls this setting.

Singletasking

When you run a model in `SingleTasking` mode, Simulink processes all blocks through each stage of simulation together. The **Tasking mode for periodic sample times** parameter on the Solver pane of the Configuration Parameters dialog box controls this setting.

Examples

Compute the delay introduced by a Buffer block in a multitasking model:

1 Open a model containing a Buffer block. For this example, open the ex_buffer_tut4 model by typing ex_buffer_tut4 at the MATLAB command line.

2 Double-click the Buffer block to open the block mask. Verify that you have the following settings:

- **Output buffer size** = 3
- **Buffer overlap** = 1
- **Initial conditions** = 0

Based on these settings, two of the required inputs to the rebuffer_delay function are as follows:

- n = 3
- v = 1

3 To determine the frame size of the input signal to the Buffer block, open the Signal From Workspace block mask. Verify that you have the following settings:

- **Signal** = sp_examples_src

- **Sample time** = 1

- **Samples per frame** = 4

Because **Samples per frame** = 4, you know the f input to the rebuffer_delay function is 4.

4 After you verify the values of all the inputs to the rebuffer_delay function, determine the delay that the Buffer block introduces in this multitasking model. To do so, type the following at the MATLAB command line:

```
d = rebuffer_delay(4,3,1)

d =
    8
```

Compute the delay introduced by an Unbuffer block in a multitasking model:

1 Open a model containing an Unbuffer block. For this example, open the ex_unbuffer_ref1 model by typing ex_unbuffer_ref1 at the MATLAB command line.

2 To determine the frame size of the input to the Buffer block, open the Signal From Workspace block mask by double-clicking the block in your model. Verify that you have the following settings:

- **Signal** = sp_examples_src

- **Sample time** = 1

- **Samples per frame** = 3

Because **Samples per frame** = 3, you know the f input to the rebuffer_delay function is 3.

3 Use the rebuffer_delay function to determine the amount of delay that the Unbuffer block introduces in this multitasking model. To compute the delay introduced by the Unbuffer block, use f = 3, n = 1 and v = 0.

```
d = rebuffer_delay(3,1,0)

d =
    3
```

How To   • "Buffer Delay and Initial Conditions"

Purpose	Reference filter for fixed-point or single-precision filter
Syntax	`href = reffilter(hd)`
Description	`href = reffilter(hd)` returns a new filter `href` that has the same structure as `hd`, but uses the reference coefficients and has its arithmetic property set to `double`. Note that `hd` can be either a fixed-point filter (arithmetic property set to 'fixed', or a single-precision floating-point filter whose arithmetic property is 'single').

`reffilter(hd)` differs from `double(hd)` in that

- the filter `href` returned by `reffilter` has the reference coefficients of `hd`.

- `double(hd)` returns the quantized coefficients of `hd` represented in double-precision.

To check the performance of your fixed-point filter, use `href = reffilter(hd)` to quickly have the floating-point, double-precision version of `hd` available for comparison.

Examples   Compare several fixed-point quantizations of a filter with the same double-precision floating-point version of the filter.

```
h = dfilt.dffir(firceqrip(87,.5,[1e-3,1e-6])); % Lowpass filter.
h1 = copy(h); h2 = copy(h); % Create copies of h.
h.arithmetic = 'fixed';    % Set h to filter using fixed-point...
                           % arithmetic.
h1.arithmetic = 'fixed'; % Same for h1.
h2.arithmetic = 'fixed'; % Same for h2.
h.CoeffWordLength  = 16; % Use 16 bits to represent the...
                           % coefficients.
h1.CoeffWordLength = 12; % Use 12 bits to represent the...
                           % coefficients.
h2.CoeffWordLength =  8; % Use 8 bits to represent the...
                           % coefficients.
href = reffilter(h);
hfvt = fvtool(href,h,h1,h2);
```

```
set(hfvt,'ShowReference','off'); % Reference displayed once
                                 % already.
legend(hfvt,'Reference filter','16-bits','12-bits','8-bits');
```

The following plot, taken from FVTool, shows `href`, the reference filter, and the effects of using three different word lengths to represent the coefficients.

As expected, the fidelity of the fixed-point filters suffers as you change the representation of the coefficients. With `href` available, it is easy to see just how the fixed-point filter compares to the ideal.

See Also   double

Purpose   Rearrange sections in SOS filter

Syntax
```
reorder(hd,order)
reorder(hd,numorder,denorder)
reorder(hd,numorder,denorder,svorder)
reorder(hd,filter_type)
reorder(hd,dir_flag)
reorder(hd,dir_flag,sv)
reorder(hs,...)
reorder(hs,...,Name,Value)
```

Description   reorder(hd,order) rearranges the sections of filter hd using the vector of indices provided in order.

reorder(hd,numorder,denorder) reorders the numerator and denominator separately using the vectors of indices in numorder and denorder.

reorder(hd,numorder,denorder,svorder) specifies that the scale values can be independently reordered.

reorder(hd,filter_type) reorders hd in a way suitable for the specified filter type. This reordering mode can be especially helpful for fixed-point implementations where the order of the filter sections can significantly affect your filter performance.

reorder(hd,dir_flag) specifies rearranges the sections according to proximity to the origin of the poles of the sections.

reorder(hd,dir_flag,sv) reorders scale values in addition to rearranging sections according to pole-origin proximity.

reorder(hs,...) rearranges the sections of the filter System object hs according to any of the preceding input arguments.

reorder(hs,...,Name,Value) rearranges the sections of the filter System object hs with additional options specified by one or more Name,Value pair arguments.

reorder

Input Arguments

hd

Discrete-time `dfilt.df1sos`, `dfilt.df2tsos`, `dfilt.df2sos`, or `dfilt.df1tsos`filter object.

hs

`dsp.BiquadFilter` filter System object.

order

Vector of indices used to reorder the filter sections. `order` does not need to contain all of the indices of the filter. Omitting one or more filter section indices removes the omitted sections from the filter. You can use a logical array to remove sections from the filter, but not to reorder it.

numorder

Vector of indices used to reorder the numerator. `numorder` and `denorder` must be the same length.

denorder

Vector of indices used to reorder the numerator. `numorder` and `denorder` must be the same length.

svorder

Independent reordering of scale values. When `svorder` is not specified, the scale values are reordered with the numerator. The output scale value always remains on the end when you use the argument `numorder` to reorder the scale values.

filter_type
`'auto'` | `'bandpass'` | `'bandstop'` | `'highpass'` | `'lowpass'`

Filter type. The `'auto'` option and automatic ordering only apply to filters that you used `fdesign` to create. With the `'auto'` option as an input argument, `reorder` automatically rearranges the filter sections depending on the specification response type of the design.

dir_flag

`'down' | 'up'`

Pole direction flag. When `dir_flag` is `'up'`, the first filter section contains the poles closest to the origin, and the last section contains the poles closest to the unit circle. When `ir_flag` is `'down'`, the sections are ordered in the opposite direction. `reorder` always pairs zeros with the poles closest to them.

sv

`'poles' | 'zeros'`

Reorder scale values according to poles or zeros. By default the scale values are not reordered when you use the `dir_flag` input argument.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Arithmetic

`` `double' | 'single' | 'fixed' ``

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

Examples
Being able to rearrange the order of the sections in a filter can be a powerful tool for controlling the filter process. This example uses reorder to change the sections of a df2sos filter. Let reorder do the reordering automatically in the first example. In the second, use reorder to specify the new order for the sections.

First use the automatic reordering option on a lowpass filter.

```
d = fdesign.lowpass('n,f3db',15,0.75);
hd = design(d,'butter');
hdreorder=reorder(hd,'auto');
```

For another example of using reorder, create an SOS filter in the direct form II implementation.

```
[z,p,k] = butter(15,.5);
[sos, g] = zp2sos(z,p,k);
hd = dfilt.df2sos(sos,g);
reorder(hd, [1 3:7 2 8]);
hfvt = fvtool(hd, 'analysis', 'coefficients');
```

Reorder the sections by moving the second section to be between the seventh and eighth sections.

```
reorder(hd, [1 3:7 2 8]);
hfvt = fvtool(hd, 'analysis', 'coefficients');
```

Remove the third, fourth, and seventh sections.

```
hd1 = copy(hd);
reorder(hd1, logical([1 1 0 0 1 1 0 1]));
setfilter(hfvt, hd1);
```

Move the first filter to the end, and remove the eighth section

```
    hd2 = copy(hd);
reorder(hd2, [2:7 1]);
setfilter(hfvt, hd2);
```

Move the numerator and denominator independently.

```
hd3 = copy(hd);
reorder(hd3, [1 3:8 2], [1:8]);
setfilter(hfvt, hd3);
```

References Schlichthärle, Dietrich, *Digital Filters Basics and Design*,
Springer-Verlag Berlin Heidelberg, 2000.

See Also cumsec | scale | scaleopts

Purpose   Reset filter properties to initial conditions

Syntax
```
reset(ha)
reset(hd)
reset(hm)
```

Description reset(ha) resets all the properties of the adaptive filter ha that are
updated when filtering to the value specified at construction. If you
do not specify a value for any particular property when you construct
an adaptive filter, the property value for that property is reset to the
default value for the property.

reset(hd) resets all the properties of the discrete-time filter hd to their
factory values that are modified when you run the filter. In particular,
the States property is reset to zero.

reset(hm) resets all the properties of the multirate filter hm to their
factory value that are modified when the filter is run. In particular, the
States property is reset to zero when hm is a decimator. Additionally,
the filter internal properties are also reset to their factory values.

Examples   Denoise a sinusoid and reset the filter after filtering with it.

```
h = adaptfilt.lms(5,.05,1,[0.5,0.5,0.5,0.5,0.5]);
n = filter(1,[1 1/2 1/3],.2*randn(1,2000));
d = sin((0:1999)*2*pi*0.005) + n; % Noisy sinusoid
x = n;
[y,e]= filter(h,x,d);              % e has denoised signal
disp(h)
reset(h); % Reset the coefficients and states.
disp(h)
```

See Also   set

scale

Purpose   Scale sections of SOS filter

Syntax
```
scale(hd)
scale(hd,pnorm)
scale(hd,pnorm,Name,Value)
scale(hd,pnorm,opts)
scale(hs)
```

Description   `scale(hd)` scales the second-order section filter `hd` using peak magnitude response scaling (L-infinity, `'Linf'`). This scaling reduces the possibility of overflows when your filter `hd` operates in fixed-point arithmetic mode.

`scale(hd,pnorm)` specifies the norm used to scale the filter.

`scale(hd,pnorm,Name,Value)` scales the SOS filter with additional options specified by one or more `Name,Value` pair arguments.

`scale(hd,pnorm,opts)` uses an input scale options object `opts` to specify the optional scaling parameters instead of specifying parameter-value pairs.

`scale(hs)` scales the filter System object `hs`. You can also use `pnorm`, name-value pair arguments, or scale option objects with this syntax.

Input Arguments

hd

Discrete-time `dfilt` filter object.

With the `Arithmetic` property of `hd` set to `double` or `single`, the filter uses the default values for all options that you do not specify explicitly. When you set `Arithmetic` to `fixed`, the values used for the scaling options are set according to the settings in filter `hd`. However, if you specify a scaling option different from the settings in `hd`, the filter uses your explicit option selection for scaling purposes, but does not change the property setting in `hd`.

hs

`dsp.BiquadFilter` filter System object.

pnorm

`'l1'` | `'l2'` | `'linf'` | `'L1'` | `'L2'` | `'Linf'` (default)

Discrete-time-domain norm or a frequency-domain norm.

Valid time-domain norm values for `pnorm` are `'l1'`, `'l2'`, and `'linf'`. Valid frequency-domain norm values are `'L1'`, `'L2'`, and `'Linf'`. The `'L2'` norm is equal to the `'l2'` norm (by Parseval's theorem), but this equivalency does not hold for other norms — `'l1'` is not the same as `'L1'` and `'Linf'` is not the same as `'linf'`.

Filter norms can be ordered in terms of how stringent they are, as follows from most stringent to least: `'l1'`, `'Linf'`, `'l2'` (`'L2'`), `'linf'`. Using `'l1'`, the most stringent scaling, produces a filter that is least likely to overflow, but has the worst signal-to-noise ratio performance. The default scaling `'Linf'` is the most commonly used scaling norm.

opts

Scale options object. You can create the `opts` object using the `scaleopts` function.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Arithmetic

`` `double' `` | `'single'` | `'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

MaxNumerator

Maximum allowed value for numerator coefficients.

Default: 2

MaxScaleValue

Maximum allowed scale values. The filter applies the MaxScaleValue limit only when you set ScaleValueConstraint to a value other than unit (the default setting). Setting MaxScaleValue to any numerical value automatically changes the ScaleValueConstraint setting to none.

Default: 'Not Used'

NumeratorConstraint
'none' (default) | 'normalize' | 'po2' | 'unit'

Specifies whether and how to constrain numerator coefficient values.

OverflowMode
satall | saturate | wrap (default)

Sets the way the filter handles arithmetic overflow situations during scaling. If your device does not have guard bits available, and you are using saturation arithmetic for filtering, use 'satall' instead of 'saturate'.

ScaleValueConstraint
'none' | 'po2' | 'unit' (default)

Specify whether to constrain the filter scale values, and how to constrain them. Choosing 'unit' for the constraint disables the MaxScaleValue

scale

property setting. `'po2'` constrains the scale values to be powers of 2, while `'none'` removes any constraint on the scale values.

sosReorder

auto (default) | down | none | up

Reorder filter sections prior to applying scaling.

Examples

Demonstrate the Linf-norm scaling of a lowpass elliptic filter with second-order sections. Start by creating a lowpass elliptical filter in zero, pole, gain (z,p,k) form.

```
[z,p,k] = ellip(5,1,50,.3);
[sos,g] = zp2sos(z,p,k);
hd = dfilt.df2sos(sos,g);
scale(hd,'linf','scalevalueconstraint','none','maxscalevalue',2)
```

Purpose   Check scaling of SOS filter

Syntax   s = scalecheck(hd,pnorm)
                 s = scalecheck(hs,pnorm)
                 s = scalecheck(hs,pnorm,Name,Value)

Description s = scalecheck(hd,pnorm) checks the scaling second-order section
                 (SOS) dfilt filter object hd.

                 s = scalecheck(hs,pnorm) checks the scaling of the filter System
                 object hs.

                 s = scalecheck(hs,pnorm,Name,Value) checks the scaling of the
                 filter System object hs with additional options specified by one or more
                 Name,Value pair arguments.

Input   **hd**
Arguments
                 Discrete-time dfilt.df1sos, dfilt.df2tsos, dfilt.df2sos, or
                 dfilt.df1tsosfilter object.

                 hs

                 dsp.BiquadFilter filter System object.

                 pnorm
                 'l1' | 'l2' | 'linf' | 'L1' | 'L2' | 'Linf'

                 Discrete-time-domain norm or a frequency-domain norm.

                 Valid time-domain norm values for pnorm are 'l1', 'l2', and 'linf'.
                 Valid frequency-domain norm values are 'L1', 'L2', and 'Linf'. The
                 'L2' norm is equal to the 'l2' norm (by Parseval's theorem), but this
                 equivalency does not hold for other norms — 'l1' is not the same as
                 'L1' and 'Linf' is not the same as 'linf'.

                 Name-Value Pair Arguments

                 Specify optional comma-separated pairs of Name,Value arguments,
                 where Name is the argument name and Value is the corresponding

value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Arithmetic

`'double' | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

System Object State	Coefficient Data Type	Rule
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

Output Arguments

s

Filter scaling for a given p-norm. An optimally scaled filter has partial norms equal to one. In such cases, s contains all ones.

For direct-form I (dfilt.df1sos) and direct-form II transposed (dfilt.df2tsos) filters, the function returns the p-norm of the filter computed from the filter input to the output of each second-order section. Therefore, the number of elements in s is one less than the number of sections in the filter. This p-norm computation does not include the trailing scale value of the filter, which you can find by entering hd.scalevalue(end) at the MATLAB prompt.

scalecheck

For direct-form II (`dfilt.df2sos`) and direct-form I transposed (`dfilt.df1tsos`) filters, the function returns a row vector whose elements contain the p-norm from the filter input to the input of the recursive part of each second-order section. This computation of the p-norm corresponds to the input to the multipliers in these filter structures. These inputs correspond to the locations in the signal flow where overflow should be avoided.

When `hd` has nontrivial scale values, that is, if any scale values are not equal to one, `s` is a two-row matrix, rather than a vector. The first row elements of `s` report the p-norm of the filter computed from the filter input to the output of each second-order section. The elements of the second row of `s` contain the p-norm computed from the input of the filter to the input of each scale value between the sections. For `df2sos` and `df1tsos` filter structures, the last numerator and the trailing scale value for the filter are not included when `scalecheck` checks the scaling.

Examples   Check the Linf-norm scaling of a filter.

```
% Create filter design specifications
hs = fdesign.lowpass;
object.
hd = ellip(hs);       % Design an elliptic sos filter
scale(hd,'Linf');
s = scalecheck(hd,'Linf')
```

In another form:

```
[b,a]=ellip(10,.5,20,0.5);
[s,g]=tf2sos(b,a);
hd=dfilt.df1sos(s,g)

hd =

        FilterStructure: 'Direct-Form I, Second-Order Sections'
              Arithmetic: 'double'
                sosMatrix: [5x6 double]
              ScaleValues: [6x1 double]
```

```
          PersistentMemory: false
                    States: [1x1 filtstates.dfiir]

1x1 struct array with no fields.

scalecheck(hd,'Linf')

ans =

    0.7631    0.9627    0.9952    0.9994    1.0000
```

See Also   norm | reorder | scale | scaleopts

scaleopts

Purpose	Options for scaling SOS filter

Syntax	`opts = scaleopts(hd)`
	`opts = scaleopts(hs)`
	`opts = scaleopts(hs,Name,Value)`

Description	`opts = scaleopts(hd)` uses the current settings in the `dfilt` filter `hd` to create an options object `opts` that contains specified scaling options for second-order section scaling. You can pass `opts` as an input to `scale` to apply scaling settings to a second-order filter. `opts = scaleopts(hs)` creates an options object based on the current settings of the filter System object `hs`. `opts = scaleopts(hs,Name,Value)` creates an options object with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

hd

Discrete-time `dfilt.df1sos`, `dfilt.df2tsos`, `dfilt.df2sos`, or `dfilt.df1tsos`filter object.

hs

`dsp.BiquadFilter` filter System object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Arithmetic
`` `double' `` | `'single'` | `'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function

performs double- or single-precision analysis. When you specify
`'fixed'` , the arithmetic changes depending on the setting of the
`CoefficientDataType` property and whether the System object is
locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis

System Object State	Coefficient Data Type	Rule
		based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

Output Arguments

opts

Scaling object. The following table lists the properties of opts.

Parameter	Default	Description and Valid Value
MaxNumerator	2	Maximum allowed value for numerator coefficients.
MaxScaleValue	No default value	Maximum allowed scale values. The filter applies the MaxScaleValue limit only when you set ScaleValueConstraint to a value other than unit. Setting MaxScaleValue to a numerical value automatically changes the ScaleValueConstraint setting to none.

Parameter	Default	Description and Valid Value
NumeratorConstraint	none	Specifies whether and how to constrain numerator coefficient values. Options are none, normalize, po2, and unit.
OverflowMode	wrap	Sets the way the filter handles arithmetic overflow situations during scaling. Choose one ofwrap or saturate or satall.
ScaleValueConstraint	unit	Specify whether to constrain the filter scale values, and how to constrain them. Valid options are none, po2, and unit.

Examples   From a filter hd, you can create an options scaling object that contains the scaling options settings you require.

```
[b,a]=ellip(10,.5,20,0.5);
[s,g]=tf2sos(b,a);
hd=dfilt.df1sos(s,g)
opts=scaleopts(hd)

opts =

          MaxNumerator: 2
    NumeratorConstraint: 'none'
          OverflowMode: 'wrap'
    ScaleValueConstraint: 'unit'
```

```
MaxScaleValue: 'Not used'
```

Purpose   Configure filter for integer filtering

Syntax
```
set2int(h)
set2int(h,coeffwl)
set2int(...,inwl)
g = set2int(...)
```

Description   These sections apply to both discrete-time (`dfilt`) and multirate (`mfilt`) filters.

set2int(h) scales the filter coefficients to integer values and sets the filter coefficient and input fraction lengths to zero.

set2int(h,coeffwl) uses the number of bits specified by coeffwl as the word length it uses to represent the filter coefficients.

set2int(...,inwl) uses the number of bits specified by coeffwl as the word length it uses to represent the filter coefficients and the number of bits specified by inwl as the word length to represent the input data.

g = set2int(...) returns the gain g introduced into the filter by scaling the filter coefficients to integers. g is always calculated to be a power of 2.

Note set2int does not work with CIC decimators or interpolators because they do not have coefficients.

Examples   These examples demonstrate some uses and ideas behind set2int.

The second parts of both examples depend on the following — after you filter a set of data, the input data and output data cover the same range of values, unless the filter process introduces gain in the output. Converting your filter object to integer form, and then filtering a set of data, does introduce gain into the system. When the examples refer to resetting the output to the same range as the input, the examples are accounting for this added gain feature.

Discrete-Time Filter Example

Two parts comprise this example. Part 1 compares the step response of an FIR filter in both the fractional and integer filter modes. Fractional mode filtering is essentially the opposite of integer mode. Integer mode uses a filter which has coefficients represented by integers. Fractional mode filters have coefficients represented in fractional form (nonzero fraction length).

```
b = firrcos(100,.25,.25,2,'rolloff','sqrt');
hd = dfilt.dffir(b);
hd.Arithmetic = 'fixed';
hd.InputFracLength = 0; % Integer inputs.
x = ones(100,1);
yfrac = filter(hd,x); % Fractional mode output.
g = set2int(hd);      % Convert to integer coefficients.
yint = filter(hd,x);  % Integer mode output.
```

Note that `yint` and `yfrac` are `fi` objects. Later in this example, you use the `fi` object properties `WordLength` and `FractionLength` to work with the output data.

Now use the gain `g` to rescale the output from the integer mode filter operation. Verify that the scaled integer output is equal to the fractional output.

```
yints = double(yint)/g;
MaxDiff=max(abs(yints-double(yfrac)));
```

Verify that the scaled integer output is equal to the fractional output.

```
 max(abs(yints-double(yfrac)))
```

In part two, the example reinterprets the output binary data, putting the input and the output on the same scale by weighting the most significant bits in the input and output data equally.

```
WL = yint.WordLength;
FL = yint.Fractionlength + log2(g);
```

```
yints2 = fi(zeros(size(yint)),true,WL,FL);
yints2.bin = yint.bin;
MaxDiff=max(abs(double(yints2)-double(yfrac)));
```

Multirate Filter Example

This two-part example starts by comparing the step response of a multirate filter in both fractional and integer modes. Fractional mode filtering is essentially the opposite of integer mode. Integer mode uses a filter which has coefficients represented by integers. Fractional mode filters have coefficients in fractional form with nonzero fraction lengths.

```
hm = mfilt.firinterp;
hm.Arithmetic = 'fixed';
hm.InputFracLength = 0; % Integer inputs.
x = ones(100,1);
yfrac = filter(hm,x);  % Fractional mode output.
g = set2int(hm);        %Convert to integer coefficients.
yint = filter(hm,x);   % Integer mode output.
```

Note that `yint` and `yfrac` are `fi` objects. In part 2 of this example, you use the `fi` object properties `WordLength` and `FractionLength` to work with the output data.

Now use the gain `g` to rescale the output from the integer mode filter operation.

```
yints = double(yint)/g;
```

Verify that the scaled integer output is equal to the fractional output.

```
max(abs(yints-double(yfrac)))
```

Part 2 demonstrates reinterpreting the output binary data by using the properties of `yint` to create a scaled version of `yint` named `yints2`. This process puts `yint` and `yints2` on the same scale by weighing the most significant bits of each object equally.

```
wl = yint.wordlength;
fl = yint.fractionlength + log2(g);
```

```
yints2 = fi(zeros(size(yint)),true,wl,fl);
yints2.bin = yint.bin;
max(abs(double(yints2)-double(yfrac)))
```

Purpose   Specifications for filter specification object

Syntax   setspecs(D,specvalue1,specvalue2,...)
                 setspecs(D,Specification,specvalue1,specvalue2,...)
                 setspecs(...Fs)
                 setspecs(...,MAGUNITS)

Description setspecs(D,specvalue1,specvalue2,...) sets the specifications
                in filter specification object, D, in the same order they appear in the
                Specification property.

                setspecs(D,Specification,specvalue1,specvalue2,...) changes
                the specifications for an existing filter specification object and sets
                values for the new Specification property.

                setspecs(...Fs) specifies the sampling frequency, Fs, in Hz. The
                sampling frequency must be a scalar trailing all other specifications.
                Entering a sampling frequency causes all other frequency specifications
                to be in Hz.

                setspecs(...,MAGUNITS) specifies the units for any magnitude
                specifications. MAGUNITS can be one of the following: 'linear', 'dB',
                or 'squared'. The default is 'dB'. The magnitude specifications are
                always converted and stored in dB regardless of how the units are
                specified.

                Use SET(D,'SPECIFICATION') to get the list of all available
                specification types for the filter specification object, D.

Examples   Construct a lowpass filter with specifications for the filter order and
                cutoff frequency (-6 dB). Use setspecs after construction to set the
                values of the filter order and cutoff frequency. Display the values in
                the MATLAB command window.

                ```
                D = fdesign.lowpass('N,Fc');
                setspecs(D,10,0.2);
                D.FilterOrder
                D.Fcutoff
                ```

Construct a highpass filter with specifications for the numerator order, denominator order, and 3-dB frequency. Assume the sampling frequency is 1 kHz. Use `setspecs` to set the numerator and denominator orders to 6. Set the 3-dB frequency to 250 Hz. In order to use frequency specifications in Hz, specify the sampling frequency as a trailing scalar.

```
D = fdesign.highpass('Nb,Na,F3dB');
setspecs(D,6,6,250,1000);
```

See Also   design | designmethods | designopts | fdesign

Purpose	Convert quantized filter to second–order sections (SOS) form

Syntax

```
Hq2 = sos(Hq)
Hq2 = sos(Hq, order)
Hq2 = sos(Hq, order, scale)
```

Description   Hq2 = sos(Hq) returns a quantized filter Hq2 that has second-order sections and the dft2 structure. Use the same optional arguments used in tf2sos.

Hq2 = sos(Hq, order) specifies the order of the sections in Hq2, where order is either of the following strings:

- 'down' — to order the sections so the first section of Hq2 contains the poles closest to the unit circle (L_∞ norm scaling)

- 'up' — to order the sections so the first section of Hq2 contains the poles farthest from the unit circle (L_2 norm scaling and the default)

Hq2 = sos(Hq, order, scale) also specifies the desired scaling of the gain and numerator coefficients of all second-order sections, where scale is one of the following strings:

- 'none' — to apply no scaling (default)

- 'inf' — to apply infinity-norm scaling

- 'two' — to apply 2-norm scaling

Use infinity-norm scaling in conjunction with up-ordering to minimize the probability of overflow in the filter realization. Consider using 2-norm scaling in conjunction with down-ordering to minimize the peak round-off noise.

When Hq is a fixed-point filter, the filter coefficients are normalized so that the magnitude of the maximum coefficient in each section is 1. The gain of the filter is applied to the first scale value of Hq2.

sos uses the direct form II transposed (dft2) structure to implement second- order section filters.

Examples
```
[b,a]=butter(8,.5);
Hq = dfilt.df2t(b,a);
Hq.arithmetic = 'fixed';
Hq1 = sos(Hq)

Hq1 =

            FilterStructure: 'Direct-Form II Transposed, Second-Order Sections'
                 Arithmetic: 'double'
                  sosMatrix: [4x6 double]
                ScaleValues: [0.00927734375;1;1;1;1]
        OptimizeScaleValues: true
           PersistentMemory: false
```

See Also   convert | dfilt | tf2sos

Purpose   Fixed-point scaling modes in direct-form FIR filter

Syntax   specifyall(hd)
specifyall(hd,false)
specifyall(hd,true)
specifyall(hs)
specifyall(hs,false)

Description   specifyall sets all of the autoscale property values of direct-form
FIR filters to false and all *modes of the filters to SpecifyPrecision.
In this table, you see the results of using specifyall with direct-form
FIR filters.

Property Name	Default	Setting After Applying specifyall
CoeffAutoScale	true	false
OutputMode	AvoidOverflow	SpecifyPrecision
ProductMode	FullPrecision	SpecifyPrecision
AccumMode	KeepMSB	SpecifyPrecision
RoundMode	convergent	convergent
OverflowMode	wrap	wrap

specifyall(hd) gives you maximum control over all settings in a filter
hd by setting all of the autoscale options that are true to false, turning
off all autoscaling and resetting all modes — OutputMode, ProductMode,
and AccumMode — to SpecifyPrecision. After you use specifyall,
you must supply the property values for the mode- and scaling related
properties.

specifyall provides an alternative to changing all these properties
individually. Using specifyall changes all of the settings. To set some
but not all of the modes, set each property as you require.

specifyall(hd,false) performs the opposite operation of
specifyall(hd) by setting all of the autoscale options to true; all

specifyall

of the modes to their default values; and hiding the fraction length properties in the display, meaning you cannot access them to set them or view them.

`specifyall(hd,true)` is equivalent to `specifyall(hd)`.

`specifyall(hs)` sets all the data type fixed-point properties of the filter System object `hs` to `'Custom'` so that you can easily specify all the fixed-point settings. If the object has a `FullPrecisionOverride` property, its value is set to `false`. `specifyall` is intended as a shortcut to changing all the fixed-point properties one by one.

`specifyall(hs,false)` sets all fixed-point properties of the filter System object `hs` to their default values and sets the filter to full-precision mode, if possible.

Examples This example demonstrates using `specifyall` to provide access to all of the fixed-point settings of an FIR filter implemented with the direct-form structure. Using `specifyall` disables all of the automatic filter scaling and reset the mode values.

```
b = fircband(12,[0 0.4 0.5 1],[1 1 0 0],[1 0.2],{'w' 'c'});
hd = dfilt.dffir(b);
hd.arithmetic = 'fixed'
specifyall(hd)
```

The mode properties `InputMode`, `ProductMode`, and `AccumMode` have the value `SpecifyPrecision` and the fraction length properties appear in the display. Now you use the properties (`InputFracLength`, `ProdFracLength`, `AccumFracLength`) to set the precision the filter applies to the input, product, and accumulator operations. `CoeffAutoScale` switches to `false`, which means that the filter coefficients will not be scaled automatically to prevent overflows. None of the other filter properties change when you apply `specifyall`.

Purpose   Step response for filter

Syntax
```
[h,t] = stepz(hfilt)
[h,t] = stepz(hfilt,n)
[h,t] = stepz(hfilt,n,fs)
[h,t] = stepz(hfilt,[],fs)
stepz(hfilt)
[h,t] = stepz(hs)
[h,t] = stepz(hs,Name,Value)
stepz(hs)
```

Description   stepz returns the step response based on the current filter coefficients. This section describes common stepz operation with adaptive filters, discrete-time filters, multirate filters, and filter System objects. For more input options, refer to stepz in Signal Processing Toolbox documentation.

[h,t] = stepz(hfilt) returns the impulse response h and the corresponding time points w at which the step response of hfilt is computed. The step response is evaluated at 10 1-second intervals—(0:9)'.

[h,t] = stepz(hfilt,n) returns the step response evaluated at floor(n) 1-second intervals—(0:floor(n)-1)'.

[h,t] = stepz(hfilt,n,fs) returns the step response evaluated at floor(n) 1/fs-second intervals—(0:floor(n)-1)'/fs.

[h,t] = stepz(hfilt,[],fs) returns the step response evaluated at 10 1/fs-second intervals—(0:9)'/fs.

stepz(hfilt) uses FVTool to plot the step response of the filter. You can also provide the optional input arguments n and fs with this syntax.

[h,t] = stepz(hs) returns the step response for the filter System object hs. The impulse response is evaluated at 10 1-second intervals—(0:9)'. You can also provide the optional input arguments n and fs with this syntax.

[h,t] = stepz(hs,Name,Value) returns an step response with additional options specified by one or more Name,Value pair arguments.

stepz(hs) uses FVTool to plot the step response of the filter System object hs.

Note stepz works for both real and complex filters. When you omit the output arguments, stepz plots only the real part of the step response.

Input Arguments

hfilt

hfilt is either:

- An adaptive adaptfilt, discrete-time dfilt, or multirate mfilt filter object

- A vector of adaptive, discrete-time, or multirate filter objects

The multirate filter step response is computed relative to the rate at which the filter is running. When you specify fs (the sampling rate) as an input argument, stepz assumes the filter is running at that rate.

For multistage cascades, stepz forms a single-stage multirate filter that is equivalent to the cascade. It then computes the response relative to the rate at which the equivalent filter is running. stepz does not support all multistage cascades. The function analyzes only those cascades for which there exists an equivalent single-stage filter.

As an example, consider a 2-stage interpolator where the first stage has an interpolation factor of 2 and the second stage has an interpolation factor of 4. In this case, an equivalent single-stage filter exists with an overall interpolation factor of 8. stepz uses this equivalent filter for the analysis. If a sampling frequency fs is specified as an input argument to stepz, the function interprets fs as the rate at which the equivalent filter is running.

hs

Filter System object. The function supports the following filter structures.

- `dsp.FIRFilter`

- `dsp.BiquadFilter`

- `dsp.FIRInterpolator`

- `dsp.CICInterpolator`

- `dsp.FIRDecimator`

- `dsp.CICDecimator`

- `dsp.FIRRateConverter`

n

Number of samples.

> **Default:** 10

fs

Sampling frequency.

> **Default:** 1

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Arithmetic

`` `double' `` | `'single'` | `'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify

'fixed' , the arithmetic changes depending on the setting of the
CoefficientDataType property and whether the System object is
locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point

System Object State	Coefficient Data Type	Rule
		analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

h

Complex, n-element step response vector. If `hfilt` is a vector of filters, h is a complex, `length(hfilt)`-by-n matrix of step response vectors corresponding to each filter in `hfilt`. If n is not specified, the function uses a default value of 8192.

For adaptive filters, h is the instantaneous step response.

t

Time vector of length n, in seconds. t consists of n points equally spaced from 0 to `floor(n)/fs`. If n is not specified, the function uses a default value of 10. If `fs` is not specified, the function uses a default value of 1.

See Also   freqz | impz

sysobj

Purpose   Create filter System object from discrete-time filter or multirate filter

Syntax   `hs = sysobj(hfilt)`

Description   `hs = sysobj(hfilt)` creates a new filter System object `hs` from the `dfilt` or `mfilt` object, `hfilt`.

The function supports a subset of `dfilt` and `mfilt` objects. The following table lists supported filter structures for `hfilt` and the filter System object that the function creates.

Single-rate or multirate filter	Filter System object
Lattice AR(`dfilt.latticear`)	`dsp.AllpoleFilter`
Direct Form I (`dfilt.df1`)	`dsp.IIRFilter`
Direct Form I transposed (`dfilt.df1t`)	`dsp.IIRFilter`
Direct Form II (`dfilt.df2`)	`dsp.IIRFilter`
Direct Form II transposed (`dfilt.df2t`)	`dsp.IIRFilter`
Direct-form FIR (`dfilt.dffir`)	`dsp.FIRFilter`
Direct-form FIR transposed (`dfilt.dffirt`)	`dsp.FIRFilter`
Direct-form symmetric FIR (`dfilt.dfsymfir`)	`dsp.FIRFilter`
Direct-form antisymmetric FIR (`dfilt.dfasymfir`)	`dsp.FIRFilter`
Discrete-time, lattice, moving-average (`dfilt.latticemamin`)	`dsp.FIRFilter`
Discrete-time, second-order section, direct-form I (`dfilt.df1sos`)	`dsp.BiquadFilter`

Single-rate or multirate filter	Filter System object
Discrete-time, second-order section, direct-form I transposed (`dfilt.df1tsos`)	`dsp.BiquadFilter`
Discrete-time, second-order section, direct-form II (`dfilt.df2sos`)	`dsp.BiquadFilter`
Discrete-time, second-order section, direct-form II transposed (`dfilt.df2tsos`)	`dsp.BiquadFilter`
Direct-form FIR polyphase decimator (`mfilt.firdecim`)	`dsp.FIRDecimator`
Direct-form transposed FIR polyphase decimator (`mfilt.firtdecim`)	`dsp.FIRDecimator`
Fixed-point CIC decimator (`mfilt.cicdecim`)	`dsp.CICDecimator`
FIR polyphase interpolator (`mfilt.firinterp`)	`dsp.FIRInterpolator`
FIR linear interpolator (`mfilt.linearinterp`)	`dsp.FIRInterpolator`
Fixed-point CIC interpolator (`mfilt.cicinterp`)	`dsp.CICInterpolator`
Direct-form FIR polyphase sample rate converter (`mfilt.firsrc`)	`dsp.FIRRateConverter`

Input Arguments

hfilt

Discrete-time filter (`dfilt`) or multirate filter (`mfilt`) object. The preceding table lists supported filter structures.

sysobj

The function interprets the `PersistentMemory` property differently for discrete-time and multirate filters:

- If `hfilt` is a discrete-time filter with the `PersistentMemory` property set to `true`, then the filter states are copied into the initial conditions properties of `hs`. Otherwise, initial conditions are ignored.

- Multirate-filter System objects do not have initial conditions. If `hfilt` is a multirate filter with the `PersistentMemory` property set to `true`, the initial conditions are not copied into `hs`, and the function issues a warning.

The function does not support some properties for SOS filter structures:

- If the `CastBeforeSum` property is set to `false`, the function issues a warning. `dsp.BiquadFilter` System objects always have a cast before a sum.

- If the `Signed` property is `false`, the function issues an error. `dsp.BiquadFilter` System objects do not support unsigned arithmetic.

Output Arguments

hs

Filter System object. The function maps almost all properties of `hfilt` into the filter System object. However, some properties are not mapped exactly:

- Filter System objects do not have a `CoeffAutoScale` property. The function specifies a word length and a fraction length regardless of whether the `CoeffAutoScale` property of `hfilt` is `true` or `false`.

- `dsp.BiquadFilter` System objects do not have a `FullPrecisionOverride` property. Full-precision values in `hfilt` are mapped to word and fraction lengths in `hs`. These settings correspond to the full-precision setting of the input data type.

Examples

Convert a discrete-time filter object to a System object:

```
hfilt = dfilt.df1sos; %Direct-form I SOS
hs = sysobj(hfilt);    %Biquadratic IIR filter
```

See Also block

tf2ca

Purpose   Transfer function to coupled allpass

Syntax   ```
[d1,d2] = tf2ca(b,a)
[d1,d2] = tf2ca(b,a)
```

Description   `[d1,d2] = tf2ca(b,a)` where `b` is a real, symmetric vector of
numerator coefficients and `a` is a real vector of denominator coefficients,
corresponding to a stable digital filter, returns real vectors `d1` and `d2`
containing the denominator coefficients of the allpass filters *H1(z)* and
H2(z) such that

$$H(z) = \frac{B(z)}{A(z)} = \frac{1}{2[H1(z) + H2(z)]}$$

representing a coupled allpass decomposition.

`[d1,d2] = tf2ca(b,a)` where `b` is a real, antisymmetric vector of
numerator coefficients and `a` is a real vector of denominator coefficients,
corresponding to a stable digital filter, returns real vectors `d1` and `d2`
containing the denominator coefficients of the allpass filters *H1(z)* and
H2(z) such that

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)[H1(z) - H2(z)]$$

In some cases, the decomposition is not possible with real *H1(z)* and
H2(z). In those cases a generalized coupled allpass decomposition may
be possible, whose syntax is

```
[d1,d2,beta] = tf2ca(b,a)
```

to return complex vectors `d1` and `d2` containing the denominator
coefficients of the allpass filters *H1(z)* and *H2(z)*, and a complex scalar
`beta`, satisfying `|beta| = 1`, such that

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)\left[\bar{\beta} \cdot H1(z) + \beta \cdot H2(z)\right]$$

representing the generalized allpass decomposition.

In the above equations, *H1(z)* and *H2(z)* are real or complex allpass IIR filters given by

$$H1(z) = \frac{fliplr(\overline{(D1(z))})}{D1(z)}, H2(1)(z) = \frac{fliplr(\overline{(D2(1)(z))})}{D2(1)(z)}$$

where *D1(z)* and *D2(z)* are polynomials whose coefficients are given by d1 and d2.

Note A coupled allpass decomposition is not always possible. Nevertheless, Butterworth, Chebyshev, and Elliptic IIR filters, among others, can be factored in this manner. For details, refer to Signal Processing Toolbox User's Guide.

Examples

```
[b,a]=cheby1(9,.5,.4);
[d1,d2]=tf2ca(b,a);  % TF2CA returns denominators of the allpass.
num = 0.5*conv(fliplr(d1),d2)+0.5*conv(fliplr(d2),d1);
den = conv(d1,d2);  % Reconstruct numerator and denonimator.
MaxDiff=max([max(b-num),max(a-den)]); % Compare original and reconstructed
        % numerator and denominators.
```

See Also   ca2tf | cl2tf | iirpowcomp | latc2tf | tf2latc

tf2cl

Purpose   Transfer function to coupled allpass lattice

Syntax   ```
[k1,k2] = tf2cl(b,a)
[k1,k2] = tf2cl(b,a)
```

**Description**    `[k1,k2] = tf2cl(b,a)` where `b` is a real, symmetric vector of
                   numerator coefficients and `a` is a real vector of denominator coefficients,
                   corresponding to a stable digital filter, will perform the coupled allpass
                   decomposition

$$H(z) = \frac{B(z)}{A(z)} = \frac{1}{2\left[H1(z) + H2(z)\right]}$$

of a stable IIR filter *H(z)* and convert the allpass transfer functions
*H1(z)* and *H2(z)* to a coupled lattice allpass structure with coefficients
given in vectors `k1` and `k2`.

`[k1,k2] = tf2cl(b,a)` where `b` is a real, antisymmetric vector of
numerator coefficients and `a` is a real vector of denominator coefficients,
corresponding to a stable digital filter, performs the coupled allpass
decomposition

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)\left[H1(z) - H2(z)\right]$$

of a stable IIR filter *H(z)* and converts the allpass transfer functions
*H1(z)* and *H2(z)* to a coupled lattice allpass structure with coefficients
given in vectors `k1` and `k2`.

In some cases, the decomposition is not possible with real *H1(z)* and
*H2(z)*. In those cases, a generalized coupled allpass decomposition may
be possible, using the command syntax

```
[k1,k2,beta] = tf2cl(b,a)
```

to perform the generalized allpass decomposition of a stable IIR filter
H(z) and convert the complex allpass transfer functions *H1(z)* and *H2(z)*
to corresponding lattice allpass filters

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)\left[\overline{\beta} \cdot H1(z) + \beta \cdot H2(z)\right]$$

where `beta` is a complex scalar of magnitude equal to 1.

Note Coupled allpass decomposition is not always possible. Nevertheless, Butterworth, Chebyshev, and Elliptic IIR filters, among others, can be factored in this manner. For details, refer to Signal Processing Toolbox User's Guide.

Examples

```
[b,a]=cheby1(9,.5,.4);
[k1,k2]=tf2cl(b,a); % Get the reflection coeffs. for the lattices.
[num1,den1]=latc2tf(k1,'allpass'); % Convert each allpass lattice
[num2,den2]=latc2tf(k2,'allpass'); % back to transfer function.
num = 0.5*conv(num1,den2)+0.5*conv(num2,den1);
den = conv(den1,den2); % Reconstruct numerator and denonimator.
MaxDiff=max([max(b-num),max(a-den)]); % Compare original and reconstructed
        % numerator and denominators.
```

validstructures

Purpose	Structures for specification object with design method

Syntax	`filtstruct = validstructures(D)`
	`C = validstructures(D,METHOD)`
	`Cs = validstructures(D,...,'SystemObject',sysobjflag)`

Description	`filtstruct = validstructures(D)` returns a structure array containing all valid filter structures for the filter specification object, `D`, organized by design method. Each design method is a field in the structure array, `filtstruct`. The fields contain a cell array of strings. `C = validstructures(D,METHOD)` returns the valid structures for the filter specification object, `D`, and the design method, `METHOD`, in a cell array of strings. `Cs = validstructures(D,...,'SystemObject',sysobjflag)` returns the valid structures for designing a filter System object when sysobjflag is `true`. To use System objects, you must have the DSP System Toolbox product installed. When sysobjflag is `false`, the function returns valid structures for designing `dfilt` and `mfilt` objects, as described previously. Design methods and design options for filter System objects are not necessarily the same as those for `dfilt` and `mfilt` objects.

Examples	Design a default lowpass filter specification object. Return all valid design methods and structures in a structure array. Display the fieldnames to see all valid design methods. Display the valid filter structures for the `equiripple` field.
	
	`D = fdesign.lowpass;`
	`filtstruct = validstructures(D);`
	`fieldnames(filtstruct)`
	`filtstruct.equiripple`

Create a highpass filter of order 50 with a 3-dB frequency of 0.2. Obtain the available structures for a Butterworth design.

```
D = fdesign.highpass('N,F3dB',50,0.2);
C = validstructures(D,'butter');
```

If you have DSP System Toolbox software installed, use the
'SystemObject',*sysobjflag* syntax to return valid structures for a
filter System object:

```
Cs = validstructures(D,'butter','SystemObject',true);
```

window

Purpose	FIR filter using windowed impulse response
Syntax	`h = window(d,fcnhndl,fcnarg)`
	`h = window(d,win)`

description   `h = window(d,fcnhndl,fcnarg)` designs an FIR filter using the specifications in filter specification object `d`. Depending on the specification type of `d`, the returned filter is either a single-rate digital filter — a `dfilt`, or a multirate digital filter — an `mfilt`.

`fcnhndl` is a handle to a filter design function that returns a window vector, such as the `hamming` or `blackman` functions. `fcnarg` is an optional argument that returns a window. You pass the function to `window`. Refer to example 1 in the following section to see the function argument used to design the filter.

`h = window(d,win)` designs a filter using the vector you supply in `win`. The length of vector `win` must be the same as the impulse response of the filter, which is equal to the filter order plus one. Example 2 shows this being done.

Examples   These examples design filters using the two design techniques of specifying a function handle or passing a window vector as an input argument.

Example 1

Use a function handle and optional input arguments to design a multirate filter. We use a function handle to `hamming` to provide the window. Since this example creates a decimator filter specifications object, `window` returns a multirate filter.

```
d = fdesign.decimator(4,'lowpass','N,Fc',30,1000,10000);
% Lowpass decimator with a 6-dB down frequency of 1 kHz
% Order equal to 30 and sampling frequency 10 kHz
Hd =window(d,'window',@hamming);
fvtool(Hd)
```

Example 2

Use a window vector provided by the kaiser window function to design a Nyquist filter. The window length must be the filter order plus one. .

```
d = fdesign.nyquist(5,'n',150);
% Kaiser window with beta parameter 2.5
Hd = window(d,'window',kaiser(151,2.5));
fvtool(Hd)
```

window

Purpose   Zero-phase response for filter

Syntax
```
[hr,w] = zerophase(hfilt)
[hr,w] = zerophase(hfilt,n)
zerophase(hfilt)
[hr,w] = zerophase(hs)
[hr,w] = zerophase(hs,n)
[hr,w] = zerophase(hs,Name,Value)
zerophase(hs)
```

Description   zerophase returns the zero-phase response based on the current filter coefficients. This section describes common zerophase operation with adaptive, discrete-time, and multirate filters. For more input options, refer to zerophase in Signal Processing Toolbox documentation.

[hr,w] = zerophase(hfilt) returns the instantaneous zero-phase response hr and the frequencies w in radians at which zerophase evaluated the response. The zero-phase response is evaluated at 8192 points equally spaced around the upper half of the unit circle.

[hr,w] = zerophase(hfilt,n) returns the instantaneous zero-phase response hr and the frequencies w in radians at which zerophase evaluated the response. The zero-phase response is evaluated at n points equally spaced around the upper half of the unit circle.

zerophase(hfilt) displays the zero-phase response of ha in the Filter Visualization Tool (FVTool).

[hr,w] = zerophase(hs) returns a zero-phase response for the filter System object hs using 8192 samples.

[hr,w] = zerophase(hs,n) returns a zero-phase response for the filter System object hs using n samples.

[hr,w] = zerophase(hs,Name,Value) returns a zero-phase response with additional options specified by one or more Name,Value pair arguments.

zerophase(hs) uses FVTool to plot the zero-phase response of the filter System object hs.

zerophase

**Input
Arguments**

hfilt

`hfilt` is either:

- An adaptive `adaptfilt`, discrete-time `dfilt`, or multirate `mfilt` filter object

- A vector of adaptive, discrete-time, or multirate filter objects

The multirate filter zero-phase response is computed relative to the rate at which the filter is running. When you specify `fs` (the sampling rate) as an input argument, `zerophase` assumes the filter is running at that rate.

For multistage cascades, `zerophase` forms a single-stage multirate filter that is equivalent to the cascade. It then computes the response relative to the rate at which the equivalent filter is running. `zerophase` does not support all multistage cascades. The function analyzes only those cascades for which there exists an equivalent single-stage filter.

As an example, consider a 2-stage interpolator where the first stage has an interpolation factor of 2 and the second stage has an interpolation factor of 4. In this case, an equivalent single-stage filter exists with an overall interpolation factor of 8. `zerophase` uses this equivalent filter for the analysis. If a sampling frequency `fs` is specified as an input argument to `zerophase`, the function interprets `fs` as the rate at which the equivalent filter is running.

hs

Filter System object. The function supports the following filter structures.

- `dsp.FIRFilter`

- `dsp.BiquadFilter`

- `dsp.FIRInterpolator`

- `dsp.CICInterpolator`

- `dsp.FIRDecimator`

- `dsp.CICDecimator`

- `dsp.FIRRateConverter`

n

Number of samples. For an FIR filter where `n` is a power of two, the computation is done faster using FFTs.

> **Default:** 8192

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Arithmetic
`'double' | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

hr

Complex, n-element zero-phase response vector. If hfilt is a vector of filters, hr is a complex, length(hfilt)-by-n matrix of phase response vectors whose columns correspond to each filter in hfilt. If n is not specified, the function uses a default value of 8192.

For adaptive filters, hr is the instantaneous zero-phase response.

w

Frequency vector of length n, in radians/sample. w consists of n points equally spaced around the upper half of the unit circle (from 0 to π radians/sample). If hfilt is a vector of filters, w is a complex, length(hfilt)-by-n matrix of phase response vectors whose columns correspond to each filter in hfilt. If n is not specified, the function uses a default value of 8192.

zpkbpc2bpc

Purpose   Zero-pole-gain complex bandpass frequency transformation

Syntax   `[Z2,P2,K2,AllpassNum,AllpassDen] = zpkbpc2bpc(Z,P,K,Wo,Wt)`

Description `[Z2,P2,K2,AllpassNum,AllpassDen] = zpkbpc2bpc(Z,P,K,Wo,Wt)`
returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter
transformed from the complex bandpass prototype by applying
a first-order complex bandpass to complex bandpass frequency
transformation.

It also returns the numerator, `AllpassNum`, and the denominator,
`AllpassDen`, of the allpass mapping filter. The original lowpass filter is
given with zeros, `Z`, poles, `P`, and gain factor, `K`.

This transformation effectively places two features of an original
filter, located at frequencies W_{o1} and W_{o2}, at the required target
frequency locations, W_{t1}, and W_{t2} respectively. It is assumed that W_{t2}
is greater than W_{t1}. In most of the cases the features selected for the
transformation are the band edges of the filter passbands. In general
it is possible to select any feature; e.g., the stopband edge, the DC, the
deep minimum in the stopband, or other ones.

Relative positions of other features of an original filter do not change in
the target filter. This means that it is possible to select two features of
an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still
precede F_2 after the transformation. However, the distance between F_1
and F_2 will not be the same before and after the transformation.

This transformation can also be used for transforming other types of
filters; e.g., complex notch filters or resonators can be repositioned at
two distinct desired frequencies at any place around the unit circle;
e.g., in the adaptive system.

Examples   Design a prototype real IIR halfband filter using a standard elliptic
approach:

`[b, a] = ellip(3,0.1,30,0.409);`

Create a complex passband from 0.25 to 0.75:

```
[b, a] = iirlp2bpc(b,a,0.5,[0.25,0.75]);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpkbpc2bpc(z,p,k,[0.25, 0.75],[-0.75, -0.25]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Comparing the filters in FVTool shows the example results. Use the features in FVTool to check the filter coefficients, or other filter analyses.

zpkbpc2bpc

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

See Also   zpkftransf | allpassbpc2bpc | iirbpc2bpc

Purpose   Zero-pole-gain frequency transformation

Syntax   [Z2,P2,K2] = zpkftransf(Z,P,K,AllpassNum,AllpassDen)

Description   [Z2,P2,K2] = zpkftransf(Z,P,K,AllpassNum,AllpassDen) returns
                       zeros, Z_2, poles, P_2, and gain factor, K_2, of the transformed lowpass
                       digital filter. The prototype lowpass filter is given with zeros, Z, poles,
                       P, and gain factor, K. If AllpassDen is not specified it will default to 1.
                       If neither AllpassNum nor AllpassDen is specified, then the function
                       returns the input filter.

Examples   Design a prototype real IIR halfband filter using a standard elliptic
                       approach:

```
[b, a] = ellip(3,0.1,30,0.409);
[AlpNum, AlpDen] = allpasslp2lp(0.5, 0.25);
[z2, p2, k2] = zpkftransf(roots(b),roots(a),b(1),AlpNum,AlpDen);
```

                       Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

                       After transforming the filter, you get the response shown in the figure,
                       where the passband has been shifted towards zero.

zpkftransf

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
FTFNum	Numerator of the mapping filter
FTFDen	Denominator of the mapping filter
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter

See Also   iirftransf

Purpose   Zero-pole-gain lowpass to bandpass frequency transformation

Syntax   [Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bp(Z,P,K,Wo,Wt)

Description   [Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bp(Z,P,K,Wo,Wt)
                   returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter
                   transformed from the real lowpass prototype by applying a second-order
                   real lowpass to real bandpass frequency mapping.

                   It also returns the numerator, AllpassNum, and the denominator
                   AllpassDen, of the allpass mapping filter. The prototype lowpass filter
                   is given with zeros, Z, poles, P, and gain factor, K.

                   This transformation effectively places one feature of an original filter,
                   located at frequency -W_o, at the required target frequency location,
                   W_{t1}, and the second feature, originally at +W_o, at the new location,
                   W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. This transformation
                   implements the "DC Mobility," which means that the Nyquist feature
                   stays at Nyquist, but the DC feature moves to a location dependent
                   on the selection of W_t.

                   Relative positions of other features of an original filter do not change in
                   the target filter. This means that it is possible to select two features of
                   an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still
                   precede F_2 after the transformation. However, the distance between F_1
                   and F_2 will not be the same before and after the transformation.

                   Choice of the feature subject to the lowpass to bandpass transformation
                   is not restricted only to the cutoff frequency of an original lowpass filter.
                   In general it is possible to select any feature; e.g., the stopband edge,
                   the DC, the deep minimum in the stopband, or other ones.

                   Real lowpass to bandpass transformation can also be used for
                   transforming other types of filters; e.g., real notch filters or resonators
                   can be easily doubled and positioned at two distinct, desired frequencies.

Examples   Design a prototype real IIR halfband filter using a standard elliptic
                   approach:

```
[B,A] = ellip(3,0.1,30,0.409);
Z = roots(B);
P = roots(A);
K = B(1);
[Z2,P2,K2] = zpklp2bp(Z,P,K, 0.5, [0.2 0.3]);
hfvt = fvtool(B,A,K2*poly(Z2),poly(P2));
legend(hfvt,'Prototype Lowpass Filter', 'Bandpass Filter');
axis([0 1 -70 10]);
```

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

zpklp2bpc

Purpose   Zero-pole-gain lowpass to complex bandpass frequency transformation

Syntax   `[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bpc(Z,P,K,Wo,Wt)`

Description `[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bpc(Z,P,K,Wo,Wt)`
returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter
transformed from the real lowpass prototype by applying a first-order
real lowpass to complex bandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator,
`AllpassDen`, of the allpass mapping filter. The prototype lowpass filter
is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

This transformation effectively places one feature of an original filter,
located at frequency $-W_o$, at the required target frequency location, W_{t1},
and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is
assumed that W_{t2} is greater than W_{t1}.

Relative positions of other features of an original filter do not change in
the target filter. This means that it is possible to select two features of
an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still
precede F_2 after the transformation. However, the distance between F_1
and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation
is not restricted only to the cutoff frequency of an original lowpass filter.
In general it is possible to select any feature; e.g., the stopband edge,
the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming
other types of filters; e.g., real notch filters or resonators can be doubled
and positioned at two distinct desired frequencies at any place around
the unit circle forming a pair of complex notches/resonators. This
transformation can be used for designing bandpass filters for radio
receivers from the high-quality prototype lowpass filter.

Examples   Design a prototype real IIR halfband filter using a standard elliptic
approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2bpc(z, p, k, 0.5, [0.2 0.3]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

zpklp2bs

Purpose   Zero-pole-gain lowpass to bandstop frequency transformation

Syntax   `[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bs(Z,P,K,Wo,Wt)`

Description   `[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bs(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying a second-order real lowpass to real bandstop frequency mapping.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. This transformation implements the "Nyquist Mobility," which means that the DC feature stays at DC, but the Nyquist feature moves to a location dependent on the selection of W_o and W_ts.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. After the transformation feature F_2 will precede F_1 in the target filter. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Examples   Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
```

```
k = b(1);
[z2,p2,k2] = zpklp2bs(z, p, k, 0.5, [0.2 0.3]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Purpose   Zero-pole-gain lowpass to complex bandstop frequency transformation

Syntax   [Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bsc(Z,P,K,Wo,Wt)

Description [Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bsc(Z,P,K,Wo,Wt)
returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter
transformed from the real lowpass prototype by applying a first-order
real lowpass to complex bandstop frequency transformation.

It also returns the numerator, AllpassNum, and the denominator,
AllpassDen, of the allpass mapping filter. The prototype lowpass filter
is given with zeros, Z, poles, P, and gain factor, K.

This transformation effectively places one feature of an original filter,
located at frequency -W_o, at the required target frequency location, W_{t1},
and the second feature, originally at +W_o, at the new location, W_{t2}. It is
assumed that W_{t2} is greater than W_{t1}. Additionally the transformation
swaps passbands with stopbands in the target filter.

Relative positions of other features of an original filter do not change in
the target filter. This means that it is possible to select two features of
an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still
precede F_2 after the transformation. However, the distance between F_1
and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation
is not restricted only to the cutoff frequency of an original lowpass filter.
In general it is possible to select any feature; e.g., the stopband edge,
the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming
other types of filters; e.g., real notch filters or resonators can be doubled
and positioned at two distinct desired frequencies at any place around
the unit circle forming a pair of complex notches/resonators.

Examples   Design a prototype real IIR halfband filter using a standard elliptic
approach:

```
[b, a] = ellip(3,0.1,30,0.409);
```

```
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2bsc(z, p, k, 0.5, [0.2, 0.3]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Purpose   Zero-pole-gain lowpass to highpass frequency transformation

Syntax   [Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2hp(Z,P,K,Wo,Wt)

Description   [Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2hp(Z,P,K,Wo,Wt)
                     returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter
                     transformed from the real lowpass prototype by applying a first-order
                     real lowpass to real highpass frequency mapping. This transformation
                     effectively places one feature of an original filter, located at frequency
                     W_o, at the required target frequency location, W_t, at the same time
                     rotating the whole frequency response by half of the sampling frequency.
                     Result is that the DC and Nyquist features swap places.

                     It also returns the numerator, AllpassNum, and the denominator,
                     AllpassDen, of the allpass mapping filter. The prototype lowpass filter
                     is given with zeros, Z, poles, P, and the gain factor, K.

                     Relative positions of other features of an original filter change in the
                     target filter. This means that it is possible to select two features
                     of an original filter, F_1 and F_2, with F_1 preceding F_2. After the
                     transformation feature F_2 will precede F_1 in the target filter. However,
                     the distance between F_1 and F_2 will not be the same before and after
                     the transformation.

                     Choice of the feature subject to the lowpass to highpass transformation
                     is not restricted to the cutoff frequency of an original lowpass filter. In
                     general it is possible to select any feature; e.g., the stopband edge, the
                     DC, or the deep minimum in the stopband, or other ones.

                     Lowpass to highpass transformation can also be used for transforming
                     other types of filters; e.g., notch filters or resonators can change their
                     position in a simple way without designing them again.

Examples   Design a prototype real IIR halfband filter using a standard elliptic
                     approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
```

```
k = b(1);
[z2,p2,k2] = zpklp2hp(z, p, k, 0.5, 0.25);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

zpklp2lp

Purpose   Zero-pole-gain lowpass to lowpass frequency transformation

Syntax   `[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2lp(Z,P,K,Wo,Wt)`

Description   `[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2lp(Z,P,K,Wo,Wt)`
returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter
transformed from the real lowpass prototype by applying a first-order
real lowpass to real lowpass frequency mapping. This transformation
effectively places one feature of an original filter, located at frequency
W_o, at the required target frequency location, W_t.

It also returns the numerator, `AllpassNum`, and the denominator,
`AllpassDen`, of the allpass mapping filter. The prototype lowpass filter
is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

Relative positions of other features of an original filter do not change in
the target filter. This means that it is possible to select two features of
an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still
precede F_2 after the transformation. However, the distance between F_1
and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to lowpass transformation
is not restricted to the cutoff frequency of an original lowpass filter. In
general it is possible to select any feature; e.g., the stopband edge, the
DC, the deep minimum in the stopband, or other ones.

Lowpass to lowpass transformation can also be used for transforming
other types of filters; e.g., notch filters or resonators can change their
position in a simple way without designing them again.

Examples   Design a prototype real IIR halfband filter using a standard elliptic
approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2lp(z, p, k, 0.5, 0.25);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Using zpklp2lp creates the desired half band IIR filter with the transformed features that you specify in the transformation function. This figure shows the results.

Magnitude Response (dB)

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter

zpklp2lp

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Purpose   Zero-pole-gain lowpass to M-band frequency transformation

Syntax   [Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2mb(Z,P,K,Wo,Wt)
                 [Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2mb(Z,P,K,Wo,Wt,Pass)

Description [Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2mb(Z,P,K,Wo,Wt)
                 returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter
                 transformed from the real lowpass prototype by applying an Mth-order
                 real lowpass to real multibandpass frequency mapping. By default the
                 DC feature is kept at its original location.

                 [Z2,P2,K2,AllpassNum,AllpassDen] =
                 zpklp2mb(Z,P,K,Wo,Wt,Pass) allows you to specify an additional
                 parameter, Pass, which chooses between using the "DC Mobility" and
                 the "Nyquist Mobility". In the first case the Nyquist feature stays at its
                 original location and the DC feature is free to move. In the second
                 case the DC feature is kept at an original frequency and the Nyquist
                 feature is allowed to move.

                 It also returns the numerator, AllpassNum, and the denominator,
                 AllpassDen, of the allpass mapping filter. The prototype lowpass filter
                 is given with zeros, Z, poles, P, and gain factor, K.

                 This transformation effectively places one feature of an original filter,
                 located at frequency W_o, at the required target frequency locations,
                 $W_{t1},...,W_{tM}$.

                 Relative positions of other features of an original filter do not change in
                 the target filter. This means that it is possible to select two features of
                 an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still
                 precede F_2 after the transformation. However, the distance between F_1
                 and F_2 will not be the same before and after the transformation.

                 Choice of the feature subject to this transformation is not restricted
                 to the cutoff frequency of an original lowpass filter. In general it is
                 possible to select any feature; e.g., the stopband edge, the DC, the deep
                 minimum in the stopband, or other ones.

                 This transformation can also be used for transforming other types of
                 filters; e.g., notch filters or resonators can be easily replicated at a

number of required frequency locations. A good application would be
an adaptive tone cancellation circuit reacting to the changing number
and location of tones.

Examples Design a prototype real IIR halfband filter using a standard elliptic
approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z1,p1,k1] = zpklp2mb(z, p, k, 0.5, [2 4 6 8]/10, 'pass');
[z2,p2,k2] = zpklp2mb(z, p, k, 0.5, [2 4 6 8]/10, 'stop');
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k1*poly(z1), poly(p1), k2*poly(z2), poly(p2));
```

The resulting multiband filter that replicates features from the
prototype appears in the figure shown. Note the accuracy of the
replication process.

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Pass	Choice (`'pass'`/`'stop'`) of passband/stopband at DC, `'pass'` being the default
Z2	Zeros of the target filter

Variable	Description
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Purpose   Zero-pole-gain lowpass to complex M-band frequency transformation

Syntax   `[Z2,P2,K2,AllpassNum,AllpassDen] = zpklpmbc(Z,P,K,Wo,Wt)`

Description   `[Z2,P2,K2,AllpassNum,AllpassDen] = zpklpmbc(Z,P,K,Wo,Wt)`
                     returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter
                     transformed from the real lowpass prototype by applying an Mth-order
                     real lowpass to complex multibandpass frequency transformation.

                     It also returns the numerator, `AllpassNum`, and the denominator,
                     `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter
                     is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

                     This transformation effectively places one feature of an original filter,
                     located at frequency W_o, at the required target frequency locations,
                     $W_{t1},...,W_{tM}$.

                     Choice of the feature subject to this transformation is not restricted
                     to the cutoff frequency of an original lowpass filter. In general it is
                     possible to select any feature, for example, the stopband edge, the DC,
                     the deep minimum in the stopband, or other ones.

                     Relative positions of other features of an original filter do not change in
                     the target filter. This means that it is possible to select two features of
                     an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still
                     precede F_2 after the transformation. However, the distance between F_1
                     and F_2 will not be the same before and after the transformation.

                     This transformation can also be used for transforming other types of
                     filters; e.g., to replicate notch filters and resonators at any required
                     location.

Examples   Design a prototype real IIR halfband filter using a standard elliptic
                     approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
```

```
[z1,p1,k1] = zpklp2mbc(z, p, k, 0.5, [2 4 6 8]/10);
[z2,p2,k2] = zpklp2mbc(z, p, k, 0.5, [2 4 6 8]/10);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k1*poly(z1), poly(p1), k2*poly(z2), poly(p2));
```

You could review the coefficients to compare the filters, but the graphical comparison shown here is quicker and easier.

However, looking at the coefficients in FVTool shows the complex nature desired.

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

See Also   zpkftransf | allpasslp2mbc | iirlp2mbc

zpklp2xc

Purpose   Zero-pole-gain lowpass to complex N-point frequency transformation

Syntax   `[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xc(Z,P,K,Wo,Wt)`

Description   `[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xc(Z,P,K,Wo,Wt)`
returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter
transformed from the real lowpass prototype by applying an `Nth`-order
real lowpass to complex multipoint frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator,
`AllpassDen`, of the allpass mapping filter. The prototype lowpass filter
is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

Parameter `N` also specifies the number of replicas of the prototype
filter created around the unit circle after the transformation. This
transformation effectively places `N` features of an original filter, located
at frequencies $W_{o1},...,W_{oN}$, at the required target frequency locations,
$W_{t1},...,W_{tM}$.

Relative positions of other features of an original filter are the same
in the target filter for the Nyquist mobility and are reversed for the
DC mobility. For the Nyquist mobility this means that it is possible to
select two features of an original filter, F_1 and F_2, with F_1 preceding F_2.
Feature F_1 will still precede F_2 after the transformation. However,
the distance between F_1 and F_2 will not be the same before and after
the transformation. For DC mobility feature F_2 will precede F_1 after
the transformation.

Choice of the feature subject to this transformation is not restricted
to the cutoff frequency of an original lowpass filter. In general it is
possible to select any feature; e.g., the stopband edge, the DC, the deep
minimum in the stopband, or other ones. The only condition is that the
features must be selected in such a way that when creating `N` bands
around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of
filters; e.g., notch filters or resonators can be easily replicated at a
number of required frequency locations. A good application would be

an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples   Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2xc(z, p, k, [-0.5 0.5], [-0.25 0.25]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Plotting the filters on the same axes lets you compare the results graphically, shown here.

zpklp2xc

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency values to be transformed from the prototype filter. They should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

See Also   zpkftransf | allpasslp2xc | iirlp2xc

Purpose   Zero-pole-gain lowpass to N-point frequency transformation

Syntax   [Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xn(Z,P,K,Wo,Wt)
                [Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xn(Z,P,K,Wo,Wt,Pass)

Description [Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xn(Z,P,K,Wo,Wt)
                returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter
                transformed from the real lowpass prototype by applying an Nth-order
                real lowpass to real multipoint frequency transformation, where N is the
                number of features being mapped. By default the DC feature is kept at
                its original location.

                [Z2,P2,K2,AllpassNum,AllpassDen] =
                zpklp2xn(Z,P,K,Wo,Wt,Pass) allows you to specify an additional
                parameter, Pass, which chooses between using the "DC Mobility" and
                the "Nyquist Mobility". In the first case the Nyquist feature stays at its
                original location and the DC feature is free to move. In the second
                case the DC feature is kept at an original frequency and the Nyquist
                feature is allowed to move.

                It also returns the numerator, AllpassNum, and the denominator,
                AllpassDen, of the allpass mapping filter. The prototype lowpass filter
                is given with zeros, Z, poles, P, and gain factor, K.

                Parameter N also specifies the number of replicas of the prototype
                filter created around the unit circle after the transformation. This
                transformation effectively places N features of an original filter, located
                at frequencies W_{o1},...,W_{oN}, at the required target frequency locations,
                W_{t1},...,W_{tM}.

                Relative positions of other features of an original filter are the same
                in the target filter for the Nyquist mobility and are reversed for the
                DC mobility. For the Nyquist mobility this means that it is possible to
                select two features of an original filter, F_1 and F_2, with F_1 preceding F_2.
                Feature F_1 will still precede F_2 after the transformation. However,
                the distance between F_1 and F_2 will not be the same before and after
                the transformation. For DC mobility feature F_2 will precede F_1 after
                the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating N bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples   Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2xn(z, p, k, [-0.5 0.5], [0 0.25], 'pass');
hfvt = fvtool(b, a, k2*poly(z2), poly(p2));
legend(hfvt,'Original Filter','Half-band Filter');
```

As demonstrated by the figure, the target filter has the desired response shape and values replicated from the prototype.

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter

Variable	Description
Wt	Desired frequency location in the transformed target filter
Pass	Choice ('pass'/'stop') of passband/stopband at DC, 'pass' being the default
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassDen	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

zpkrateup

Purpose	Zero-pole-gain complex bandpass frequency transformation
Syntax	`[Z2,P2,K2,AllpassNum,AllpassDen] = zpkrateup(Z,P,K,N)`

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpkrateup(Z,P,K,N)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter being transformed from any prototype by applying an Nth-order rateup frequency transformation, where N is the upsample ratio. Transformation creates N equal replicas of the prototype filter frequency response.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The original lowpass filter is given with zeros, Z, poles, P, and gain factor, K.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
% Upsample the prototype filter 4 times
[z2,p2,k2] = zpkrateup(z, p, k, 4);
% Compare prototype filter with target filter
fvtool(b, a, k2*poly(z2), poly(p2));
```

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter

Variable	Description
K	Gain factor of the prototype lowpass filter
N	Integer upsampling ratio
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

See Also zpkrateup | allpassrateup | iirrateup

zpkshift

Purpose   Zero-pole-gain real shift frequency transformation

Syntax   [*Z2*,*P2*,*K2*,*AllpassNum*,*AllpassDen*] = zpkshift(*Z*,*P*,*K*,*Wo*,*Wt*)

Description   [*Z2*,*P2*,*K2*,*AllpassNum*,*AllpassDen*] = zpkshift(*Z*,*P*,*K*,*Wo*,*Wt*)
                 returns the zeros,*Z2* , poles, *P2*, and gain factor, *K2*, of the target filter
                 transformed from the zeros, poles, and gain factor of real lowpass
                 prototype by applying a second-order real shift frequency mapping.
                 It also returns the numerator, *AllpassNum*, and the denominator,
                 AllpassDen of the allpass mapping filter.

                 This transformation places one selected feature of an original filter,
                 located at frequency W_o, at the required target frequency location, W_t.
                 This transformation implements the "DC Mobility," which means that
                 the Nyquist feature stays at Nyquist, but the DC feature moves to a
                 location dependent on the selection of W_o and W_t.

                 Relative positions of other features of an original filter do not change in
                 the target filter. This means that it is possible to select two features of
                 an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still
                 precede F_2 after the transformation. However, the distance between F_1
                 and F_2 will not be the same before and after the transformation.

                 Choice of the feature subject to the real shift transformation is not
                 restricted to the cutoff frequency of an original lowpass filter. In general
                 it is possible to select any feature; e.g., the stopband edge, the DC, the
                 deep minimum in the stopband, or other ones.

                 This transformation can also be used for transforming other types of
                 filters; e.g., notch filters or resonators can change their position in a
                 simple way without the need to design them again.

Examples   Rotate frequency response by π/2 radians/sample:

```
[B,A] = ellip(10,0.1,40,0.25);
% Elliptic lowpass filter with passband frequency 0.25*pi rad/sample
Z = roots(B); % get roots of numerator polynomial- filter zeros
P = roots(A); % get roots of denominator polynomial- filter poles
K = B(1);
```

```
[Z2,P2,K2] = zpkshift(Z,P,K,0.25,0.75); % shift by 0.25*pi rad/sample
Num = poly(Z2);
Den = poly(P2);
hfvt = fvtool(B,A,K2*Num,Den);
legend(hfvt,'Original Filter','Rotate by \pi/2 radians/sample');
axis([0 1 -90 10]);
```

See Also   zpkftransf | allpassshift | iirshift

zpkshiftc

Purpose   Zero-pole-gain complex shift frequency transformation

Syntax   ```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshiftc(Z,P,K,Wo,Wt)
[Num,Den,AllpassNum,AllpassDen] = zpkshiftc(Z,P,K,0,0.5)
[Num,Den,AllpassNum,AllpassDen] = zpkshiftc(Z,P,K,0,-0.5)
```
Description `[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshiftc(Z,P,K,Wo,Wt)`
returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter
transformed from the real lowpass prototype by applying a first-order
complex frequency shift transformation. This transformation rotates all
the features of an original filter by the same amount specified by the
location of the selected feature of the prototype filter, originally at W_o,
placed at W_t in the target filter.

It also returns the numerator, `AllpassNum`, and the denominator,
`AllpassDen`, of the allpass mapping filter. The prototype lowpass filter
is given with zeros, `Z`, poles, `P`, and the gain factor, `K`.

`[Num,Den,AllpassNum,AllpassDen] = zpkshiftc(Z,P,K,0,0.5)`
performs the Hilbert transformation, i.e. a 90 degree counterclockwise
rotation of an original filter in the frequency domain.

`[Num,Den,AllpassNum,AllpassDen] = zpkshiftc(Z,P,K,0,-0.5)`
performs the inverse Hilbert transformation, i.e. a 90 degree clockwise
rotation of an original filter in the frequency domain.

Examples   Design a prototype real IIR halfband filter using a standard elliptic
approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
```

Rotation by /4 Radians/Sample

Rotation by -0.25:

```
[z2,p2,k2] = zpkshiftc(z, p, k, 0.5, 0.25);
```

```
hfvt = fvtool(b,a,k2*poly(z2),poly(p2));
```

Rotation by /2 Radians/Sample

```
[z3,p3,k3] = zpkshiftc(z, p, k, 0, 0.5);
addfilter(hfvt,k3*poly(z3),poly(p3));
legend(hfvt,'Original Filter','Rotation by -\pi/4 radians/sample',...
    'Rotation by \pi/2 radians/sample');
```

Rotation by – /2 Radians/Sample

```
[z2,p2,k2] = zpkshiftc(z, p, k, 0.5, -0.5);
fvtool(b, a, k2*poly(z2), poly(p2));
```

Result of Example 1

After performing the rotation, the resulting filter shows the features desired.
Result of Example 2

Similar to the first example, performing the Hilbert transformation generates the desired target filter, shown here.
Result of Example 3

Finally, using the inverse Hilbert transformation creates yet a third filter, as the figure shows.

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter

zpkshiftc

Variable	Description
Wt	Desired frequency location in the transformed target filter
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassDen	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

Purpose   Zero-pole plot for filter

Syntax

```
zplane(Hq)
zplane(Hq,plotoption)
zplane(Hq,plotoption,plotoption2)
zplane(Hq,Name,Value)
[zq,pq,kq] = zplane(Hq)
[zq,pq,kq,zr,pr,kr] = zplane(Hq)
```

Description   zplane(Hq) plots the zeros and poles of a quantized filter Hq in the current figure window. The poles and zeros of the quantized and unquantized filters are plotted by default. The symbol o represents a zero of the unquantized reference filter, and the symbol x represents a pole of that filter. The symbols □ and + are used to plot the zeros and poles of the quantized filter Hq. The plot includes the unit circle for reference.

zplane(Hq,*plotoption*) plots the poles and zeros associated with the quantized filter Hq according to one specified plot option. The string *plotoption* can be either of the following reference filter display options:

- **'on'** to display the poles and zeros of both the quantized filter and the associated reference filter (default)

- **'off'** to display the poles and zeros of only the quantized filter

zplane(Hq,*plotoption*,*plotoption2*) plots the poles and zeros associated with the quantized filter Hq according to two specified plot options. The string *plotoption* can be selected from the reference filter display options listed in the previous syntax. The string *plotoption2* can be selected from the section-by-section plotting style options described in the following list:

- **'individual'** to display the poles and zeros of each section of the filter in a separate figure window

- **'overlay'** to display the poles and zeros of all sections of the filter on the same plot

zplane

- '**tile**' to display the poles and zeros of each section of the filter in a separate plot in the same figure window

zplane(Hq,Name,Value) returns a phase response with additional options specified by one or more Name,Value pair arguments. Name-value pair arguments are only available if Hq is a filter System object.

[zq,pq,kq] = zplane(Hq) returns the vectors of zeros zq, poles pq, and gains kq. If Hq has n sections, zq, pq, and kq are returned as 1-by-n cell arrays. If there are no zeros (or no poles), zq (or pq) is set to the empty matrix [].

[zq,pq,kq,zr,pr,kr] = zplane(Hq) returns the vectors of zeros zr, poles pr, and gains kr of the reference filter associated with the quantized filter Hq. It also returns the vectors of zeros zq, poles pq, and gains kq for the quantized filter Hq.

Input Arguments

Hq

hfilt is either:

- An adaptive adaptfilt, discrete-time dfilt, or multirate mfilt filter object

- A filter System object. The function supports the following filter structures

  - dsp.FIRFilter
  - dsp.BiquadFilter
  - dsp.FIRInterpolator
  - dsp.CICInterpolator
  - dsp.FIRDecimator
  - dsp.CICDecimator
  - dsp.FIRRateConverter

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments, where Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Arithmetic
`double' | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed' , the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

System Object State	Coefficient Data Type	Rule
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

zq

Zeros of quantized filter.

pq

Poles of quantized filter.

kq

Gains of quantized filter.

zr

Zeros of reference filter.

pr

Poles of reference filter.

kr

Gains of reference filter.

Examples   Create a quantized filter Hq from a fourth-order digital filter with cutoff frequency of 0.6. Plot the quantized and unquantized poles and zeros associated with this quantized filter.

```
[b,a] = ellip(4,.5,20,.6);
Hq = dfilt.df2(b, a);
Hq.arithmetic = 'fixed';
zplane(Hq);

Reference for the Properties of Filter Objects

Fixed-Point Filter Properties

In this section...

Overview of Fixed-Point Filters

There is a distinction between fixed-point filters and quantized filters — quantized filters represent a superset that includes fixed-point filters.

When `dfilt` objects have their `Arithmetic` property set to `single` or `fixed`, they are quantized filters. However, after you set the `Arithmetic` property to `fixed`, the resulting filter is both quantized and fixed-point. Fixed-point filters perform arithmetic operations without allowing the binary point to move in response to the calculation — hence the name fixed-point. You can find out more about fixed-point arithmetic in your Fixed-Point Toolbox documentation or from the Help system.

With the `Arithmetic` property set to `single`, meaning the filter uses single-precision floating-point arithmetic, the filter allows the binary point to move during mathematical operations, such as sums or products. Therefore these filters cannot be considered fixed-point filters. But they are quantized filters.

The following sections present the properties for fixed-point filters, which includes all the properties for double-precision and single-precision floating-point filters as well.

Fixed-Point Objects and Filters

Fixed-point filters depend in part on fixed-point objects from Fixed-Point Toolbox software. You can see this when you display a fixed-point filter at the command prompt.

```
hd=dfilt.df2t
```

```
hd =

         FilterStructure: 'Direct-Form II Transposed'
              Arithmetic: 'double'
                Numerator: 1
              Denominator: 1
         PersistentMemory: false
                   States: [0x1 double]

set(hd,'arithmetic','fixed')
hd

hd =

         FilterStructure: 'Direct-Form II Transposed'
              Arithmetic: 'fixed'
                Numerator: 1
              Denominator: 1
         PersistentMemory: false
                   States: [1x1 embedded.fi]

         CoeffWordLength: 16
          CoeffAutoScale: true
                   Signed: true

         InputWordLength: 16
          InputFracLength: 15

        OutputWordLength: 16
         OutputFracLength: 15

         StateWordLength: 16
          StateAutoScale: true

              ProductMode: 'FullPrecision'

         AccumWordLength: 40
            CastBeforeSum: true
```

```
                    RoundMode: 'convergent'
                 OverflowMode: 'wrap'
```

Look at the States property, shown here

```
States: [1x1 embedded.fi]
```

The notation `embedded.fi` indicates that the states are being represented by fixed-point objects, usually called `fi` objects. If you take a closer look at the property `States`, you see how the properties of the `fi` object represent the values for the filter states.

```
hd.states

ans =

[]

                 DataType: Fixed
                  Scaling: BinaryPoint
                   Signed: true
               WordLength: 16
           FractionLength: 15

                RoundMode: round
             OverflowMode: saturate
              ProductMode: FullPrecision
      MaxProductWordLength: 128
                  SumMode: FullPrecision
          MaxSumWordLength: 128
             CastBeforeSum: true
```

To learn more about `fi` objects (fixed-point objects) in general, refer to your Fixed-Point Toolbox documentation.

As inputs (data to be filtered), fixed-point filters accept both regular double-precision values and `fi` objects. Which you use depends on your needs. How your filter responds to the input data is determined by the settings of the filter properties, discussed in the next few sections.

Summary — Fixed-Point Filter Properties

Discrete-time filters in this toolbox use objects that perform the filtering and configuration of the filter. As objects, they include properties and methods that are often referred to as functions — not strictly the same as MATLAB functions but mostly so) to provide filtering capability. In discrete-time filters, or `dfilt` objects, many of the properties are dynamic, meaning they become available depending on the settings of other properties in the `dfilt` object or filter.

Dynamic Properties

When you use a `dfilt.`*`structure`* function to create a filter, MATLAB displays the filter properties in the command window in return (unless you end the command with a semicolon which suppresses the output display). Generally you see six or seven properties, ranging from the property `FilterStructure` to `PersistentMemory`. These first properties are always present in the filter. One of the most important properties is `Arithmetic`. The `Arithmetic` property controls all of the dynamic properties for a filter.

Dynamic properties become available when you change another property in the filter. For example, when you change the `Arithmetic` property value to `fixed`, the display now shows many more properties for the filter, all of them considered dynamic. Here is an example that uses a direct form II filter. First create the default filter:

```
hd=dfilt.df2

hd =

        FilterStructure: 'Direct-Form II'
             Arithmetic: 'double'
               Numerator: 1
             Denominator: 1
        PersistentMemory: false
                  States: [0x1 double]
```

With the filter `hd` in the workspace, convert the arithmetic to fixed-point. Do this by setting the property `Arithmetic` to `fixed`. Notice the display. Instead of a few properties, the filter now has many more, each one related

to a particular part of the filter and its operation. Each of the now-visible properties is dynamic.

```
hd.arithmetic='fixed'

hd =

        FilterStructure: 'Direct-Form II'
              Arithmetic: 'fixed'
               Numerator: 1
             Denominator: 1
        PersistentMemory: false
                  States: [1x1 embedded.fi]

        CoeffWordLength: 16
         CoeffAutoScale: true
                 Signed: true

        InputWordLength: 16
        InputFracLength: 15

       OutputWordLength: 16
             OutputMode: 'AvoidOverflow'

        StateWordLength: 16
        StateFracLength: 15

            ProductMode: 'FullPrecision'

        AccumWordLength: 40
          CastBeforeSum: true

              RoundMode: 'convergent'
           OverflowMode: 'wrap'
```

Even this list of properties is not yet complete. Changing the value of other properties such as the ProductMode or CoeffAutoScale properties may reveal even more properties that control how the filter works. Remember this feature about dfilt objects and dynamic properties as you review the rest of this section about properties of fixed-point filters.

An important distinction is you cannot change the value of a property unless you see the property listed in the default display for the filter. Entering the filter name at the MATLAB prompt generates the default property display for the named filter. Using get(filtername) does not generate the default display — it lists all of the filter properties, both those that you can change and those that are not available yet.

The following table summarizes the properties, static and dynamic, of fixed-point filters and provides a brief description of each. Full descriptions of each property, in alphabetical order, follow the table.

Property Name	Valid Values [Default Value]	Brief Description
AccumFracLength	Any positive or negative integer number of bits [29]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.
AccumWordLength	Any positive integer number of bits [40]	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	[Double], single, fixed	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	[True] or false	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.

Property Name	Valid Values [Default Value]	Brief Description
CoeffAutoScale	[True] or false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength and DenFracLength properties to specify the precision used.
CoeffFracLength	Any positive or negative integer number of bits [14]	Set the fraction length the filter uses to interpret coefficients. CoeffFracLength is not available until you set CoeffAutoScale to false. Scalar filters include this property.
CoeffWordLength	Any positive integer number of bits [16]	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of addition operations involving denominator coefficients.
DenFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
Denominator	Any filter coefficient value [1]	Holds the denominator coefficients for IIR filters.
DenProdFracLength	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value after you set ProductMode to SpecifyPrecision.

Property Name	Valid Values [Default Value]	Brief Description
DenStateFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
FracDelay	Any decimal value between 0 and 1 samples	Specifies the fractional delay provided by the filter, in decimal fractions of a sample.
FDAutoScale	[True] or false	Specifies whether the filter automatically chooses the proper scaling to represent the fractional delay value without overflowing. Turning this off by setting the value to false enables you to change the FDWordLength and FDFracLength properties to specify the data format applied.
FDFracLength	Any positive or negative integer number of bits [5]	Specifies the fraction length to represent the fractional delay.
FDProdFracLength	Any positive or negative integer number of bits [34]	Specifies the fraction length to represent the result of multiplying the coefficients with the fractional delay.
FDProdWordLength	Any positive or negative integer number of bits [39]	Specifies the word length to represent result of multiplying the coefficients with the fractional delay.
FDWordLength	Any positive or negative integer number of bits [6]	Specifies the word length to represent the fractional delay.
DenStateWordLength	Any positive integer number of bits [16]	Specifies the word length used to represent the states associated with denominator coefficients in the filter.

Property Name	Valid Values [Default Value]	Brief Description
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter sets the output word and fraction lengths, and the accumulator word and fraction lengths automatically to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision exposes the output and accumulator related properties so you can set your own word and fraction lengths for them.
FilterStructure	Not applicable.	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret data to be processed by the filter.
InputWordLength	Any positive integer number of bits [16]	Specifies the word length applied to represent input data.
Ladder	Any ladder coefficients in double-precision data type [1]	latticearma filters include this property to store the ladder coefficients.
LadderAccumFrac Length	Any positive or negative integer number of bits [29]	latticearma filters use this to define the fraction length applied to values output by the accumulator that stores the results of ladder computations.
LadderFracLength	Any positive or negative integer number of bits [14]	latticearma filters use ladder coefficients in the signal flow. This property determines the fraction length used to interpret the coefficients.

Property Name	Valid Values [Default Value]	Brief Description
Lattice	Any lattice structure coefficients. No default value.	Stores the lattice coefficients for lattice-based filters.
LatticeAccumFrac Length	Any positive or negative integer number of bits [29]	Specifies how the accumulator outputs the results of operations on the lattice coefficients.
LatticeFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length applied to the lattice coefficients.
MultiplicandFrac Length	Any positive or negative integer number of bits [15]	Sets the fraction length for values used in product operations in the filter. Direct-form I transposed (df1t) filter structures include this property.
MultiplicandWord Length	Any positive integer number of bits [16]	Sets the word length applied to the values input to a multiply operation (the multiplicands). The filter structure df1t includes this property.
NumAccumFracLength	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients.
Numerator	Any double-precision filter coefficients [1]	Holds the numerator coefficient values for the filter.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
NumProdFracLength	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. You can change the property value after you set ProductMode to SpecifyPrecision.

Property Name	Valid Values [Default Value]	Brief Description
NumStateFracLength	Any positive or negative integer number of bits [15]	For IIR filters, this defines the fraction length applied to the numerator states of the filter. Specifies the fraction length used to interpret the states associated with numerator coefficients in the filter.
NumStateWordLength	Any positive integer number of bits [16]	For IIR filters, this defines the word length applied to the numerator states of the filter. Specifies the word length used to interpret the states associated with numerator coefficients in the filter.
OutputFracLength	Any positive or negative integer number of bits — [15] or [12] bits depending on the filter structure	Determines how the filter interprets the filtered data. You can change the value of OutputFracLength after you set OutputMode to SpecifyPrecision.
OutputMode	[AvoidOverflow], BestPrecision, SpecifyPrecision	Sets the mode the filter uses to scale the filtered input data. You have the following choices: • AvoidOverflow — directs the filter to set the output data fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the fraction length used by the filtered data.
OutputWordLength	Any positive integer number of bits [16]	Determines the word length used for the filtered data.

Property Name	Valid Values [Default Value]	Brief Description
OverflowMode	Saturate or [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — hey maintain full precision.
ProductFracLength	Any positive or negative integer number of bits [29]	For the output from a product operation, this sets the fraction length used to interpret the numeric data. This property becomes writable (you can change the value) after you set ProductMode to SpecifyPrecision.
ProductMode	[FullPrecision], KeepLSB, KeepMSB, SpecifyPrecision	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.

Property Name	Valid Values [Default Value]	Brief Description
ProductWordLength	Any positive number of bits. Default is 16 or 32 depending on the filter structure	Specifies the word length to use for the results of multiplication operations. This property becomes writable (you can change the value) after you set ProductMode to SpecifyPrecision.
PersistentMemory	True or [false]	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. True is the default setting.
RoundMode	[Convergent], ceil, fix, floor, nearest, round	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.

Property Name	Valid Values [Default Value]	Brief Description
		The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
ScaleValueFracLength	Any positive or negative integer number of bits [29]	Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Available only when you disable CoeffAutoScale by setting it to false.
ScaleValues	[2 x 1 double] array with values of 1	Stores the scaling values for sections in SOS filters.
Signed	[True] or false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
sosMatrix	[1 0 0 1 0 0]	Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/section datatype]. A [15x6 double] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type double to represent the coefficients.

Property Name	Valid Values [Default Value]	Brief Description
SectionInputAuto Scale	[True] or false	Specifies whether the filter automatically chooses the proper fraction length to prevent overflow by data entering a section of an SOS filter. Setting this property to `false` enables you to change the `SectionInputFracLength` property to specify the precision used. Available only for SOS filters.
SectionInputFrac Length	Any positive or negative integer number of bits [29]	Section values work with SOS filters. Setting this property controls how your filter interprets the section values between sections of the filter by setting the fraction length. This applies to data entering a section. Compare to SectionOutputFracLength. Available only when you disable SectionInputAutoScale by setting it to `false`.
SectionInputWord Length	Any positive or negative integer number of bits [29]	Sets the word length used to represent the data moving into a section of an SOS filter.
SectionOutputAuto Scale	[True] or false	Specifies whether the filter automatically chooses the proper fraction length to prevent overflow by data leaving a section of an SOS filter. Setting this property to `false` enables you to change the SectionOutputFracLength property to specify the precision used.

Property Name	Valid Values [Default Value]	Brief Description
`SectionOutputFrac Length`	Any positive or negative integer number of bits [29]	Section values work with SOS filters. Setting this property controls how your filter interprets the section values between sections of the filter by setting the fraction length. This applies to data leaving a section. Compare to `SectionInputFracLength`. Available after you disable `SectionOutputAutoScale` by setting it to `false`.
`SectionOutputWord Length`	Any positive or negative integer number of bits [32]	Sets the word length used to represent the data moving out of one section of an SOS filter.
`StateFracLength`	Any positive or negative integer number of bits [15]	Lets you set the fraction length applied to interpret the filter states.
`States`	[1x1 embedded `fi`]	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. Notice that the states use `fi` objects, with the associated properties from those objects. For details, refer to `filtstates` in your Signal Processing Toolbox documentation or in the Help system.
`StateWordLength`	Any positive integer number of bits [16]	Sets the word length used to represent the filter states.
`TapSumFracLength`	Any positive or negative integer number of bits [15]	Sets the fraction length used to represent the filter tap values in addition operations. This is available after you set `TapSumMode` to `false`. Symmetric and antisymmetric FIR filters include this property.

Property Name	Valid Values [Default Value]	Brief Description
TapSumMode	FullPrecision, KeepLSB, [KeepMSB], SpecifyPrecision	Determines how the accumulator outputs stored that involve filter tap weights. Choose from full precision (FullPrecision) to prevent overflows, or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when outputting results from the accumulator. To let you set the precision (the fraction length) used by the output from the accumulator, set FilterInternals to SpecifyPrecision. Symmetric and antisymmetric FIR filters include this property.
TapSumWordLength	Any positive number of bits [17]	Sets the word length used to represent the filter tap weights during addition. Symmetric and antisymmetric FIR filters include this property.

Property Details for Fixed-Point Filters

When you create a fixed-point filter, you are creating a filter object (a dfilt object). In this manual, the terms filter, dfilt object, and filter object are used interchangeably. To filter data, you apply the filter object to your data set. The output of the operation is the data filtered by the filter and the filter property values.

Filter objects have properties to which you assign property values. You use these property values to assign various characteristics to the filters you create, including

- The type of arithmetic to use in filtering operations

- The structure of the filter used to implement the filter (not a property you can set or change — you select it by the dfilt.*structure* function you choose)

- The locations of quantizations and cast operations in the filter

- The data formats used in quantizing, casting, and filtering operations

Details of the properties associated with fixed-point filters are described in alphabetical order on the following pages.

AccumFracLength

Except for state-space filters, all `dfilt` objects that use fixed arithmetic have this property that defines the fraction length applied to data in the accumulator. Combined with `AccumWordLength`, `AccumFracLength` helps fully specify how the accumulator outputs data after processing addition operations. As with all fraction length properties, `AccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers.

AccumWordLength

You use `AccumWordLength` to define the data word length used in the accumulator. Set this property to a value that matches your intended hardware. For example, many digital signal processors use 40-bit accumulators, so set `AccumWordLength` to 40 in your fixed-point filter:

```
set(hq,'arithmetic','fixed');
set(hq,'AccumWordLength',40);
```

Note that `AccumWordLength` only applies to filters whose `Arithmetic` property value is `fixed`.

Arithmetic

Perhaps the most important property when you are working with `dfilt` objects, `Arithmetic` determines the type of arithmetic the filter uses, and the properties or quantizers that compose the fixed-point or quantized filter. You use strings to set the `Arithmetic` property value.

The next table shows the valid strings for the Arithmetic property. Following the table, each property string appears with more detailed information about what happens when you select the string as the value for `Arithmetic` in your `dfilt`.

Arithmetic Property String	Brief Description of Effect on the Filter
double	All filtering operations and coefficients use double-precision floating-point representations and math. When you use dfilt.*structure* to create a filter object, double is the default value for the Arithmetic property.
single	All filtering operations and coefficients use single-precision floating-point representations and math.
fixed	This string applies selected default values for the properties in the fixed-point filter object, including such properties as coefficient word lengths, fraction lengths, and various operating modes. Generally, the default values match those you use on many digital signal processors. Allows signed fixed data types only. Fixed-point arithmetic filters are available only when you install Fixed-Point Toolbox software with this toolbox.

double. When you use one of the dfilt.*structure* methods to create a filter, the Arithmetic property value is double by default. Your filter is identical to the same filter without the Arithmetic property, as you would create if you used Signal Processing Toolbox software.

Double means that the filter uses double-precision floating-point arithmetic in all operations while filtering:

- All input to the filter must be double data type. Any other data type returns an error.

- The states and output are doubles as well.

- All internal calculations are done in double math.

When you use double data type filter coefficients, the reference and quantized (fixed-point) filter coefficients are identical. The filter stores the reference coefficients as double data type.

single. When your filter should use single-precision floating-point arithmetic, set the `Arithmetic` property to `single` so all arithmetic in the filter processing gets restricted to single-precision data type.

- Input data must be single data type. Other data types return errors.
- The filter states and filter output use single data type.

When you choose `single`, you can provide the filter coefficients in either of two ways:

- Double data type coefficients. With `Arithmetic` set to `single`, the filter casts the double data type coefficients to single data type representation.
- Single data type. These remain unchanged by the filter.

Depending on whether you specified single or double data type coefficients, the reference coefficients for the filter are stored in the data type you provided. If you provide coefficients in double data type, the reference coefficients are double as well. Providing single data type coefficients generates single data type reference coefficients. Note that the arithmetic used by the reference filter is always double.

When you use `reffilter` to create a reference filter from the reference coefficients, the resulting filter uses double-precision versions of the reference filter coefficients.

To set the `Arithmetic` property value, create your filter, then use `set` to change the `Arithmetic` setting, as shown in this example using a direct form FIR filter.

```
b=fir1(7,0.45);

hd=dfilt.dffir(b)

hd =

         FilterStructure: 'Direct-Form FIR'
               Arithmetic: 'double'
                 Numerator: [1x8 double]
          PersistentMemory: false
```

```
                     States: [7x1 double]

set(hd,'arithmetic','single')
hd

hd =

        FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'single'
               Numerator: [1x8 double]
         PersistentMemory: false
                   States: [7x1 single]
```

fixed. Converting your `dfilt` object to use fixed arithmetic results in a filter structure that uses properties and property values to match how the filter would behave on digital signal processing hardware.

Note The `fixed` option for the property `Arithmetic` is available only when you install Fixed-Point Toolbox software as well as DSP System Toolbox software.

After you set `Arithmetic` to `fixed`, you are free to change any property value from the default value to a value that more closely matches your needs. You cannot, however, mix floating-point and fixed-point arithmetic in your filter when you select `fixed` as the `Arithmetic` property value. Choosing `fixed` restricts you to using either fixed-point or floating point throughout the filter (the data type must be homogenous). Also, all data types must be signed. `fixed` does not support unsigned data types except for unsigned coefficients when you set the property `Signed` to `false`. Mixing word and fraction lengths within the fixed object is acceptable. In short, using fixed arithmetic assumes

- fixed word length.

- fixed size and dedicated accumulator and product registers.

- the ability to do either saturation or wrap arithmetic.

- that multiple rounding modes are available.

Making these assumptions simplifies your job of creating fixed-point filters by reducing repetition in the filter construction process, such as only requiring you to enter the accumulator word size once, rather than for each step that uses the accumulator.

Default property values are a starting point in tailoring your filter to common hardware, such as choosing 40-bit word length for the accumulator, or 16-bit words for data and coefficients.

In this `dfilt` object example, `get` returns the default values for `dfilt.df1t` structures.

```
[b,a]=butter(6,0.45);
hd=dfilt.df1(b,a)

hd =

          FilterStructure: 'Direct-Form I'
                Arithmetic: 'double'
                 Numerator: [1x7 double]
               Denominator: [1x7 double]
          PersistentMemory: false
                    States: Numerator:  [6x1 double]
                            Denominator:[6x1 double]

set(hd,'arithmetic','fixed')
get(hd)
        PersistentMemory: false
         FilterStructure: 'Direct-Form I'
                  States: [1x1 filtstates.dfiir]
               Numerator: [1x7 double]
             Denominator: [1x7 double]
              Arithmetic: 'fixed'
          CoeffWordLength: 16
           CoeffAutoScale: 1
                   Signed: 1
                RoundMode: 'convergent'
             OverflowMode: 'wrap'
          InputWordLength: 16
```

```
            InputFracLength: 15

           CastBeforeSum: true

               RoundMode: 'convergent'
            OverflowMode: 'wrap'
```

Unlike the `single` or `double` options for `Arithmetic`, `fixed` uses properties to define the word and fraction lengths for each portion of your filter. By changing the property value of any of the properties, you control your filter performance. Every word length and fraction length property is independent — set the one you need and the others remain unchanged, such as setting the input word length with `InputWordLength`, while leaving the fraction length the same.

Notice that the properties for the lattice filter `hdlat` and direct-form II filter `hd` are different, as befits their differing filter structures. Also, some properties are common to both objects, such as `RoundMode` and `PersistentMemory` and behave the same way in both objects.

Notes About Fraction Length, Word Length, and Precision. Word length and fraction length combine to make the format for a fixed-point number, where word length is the number of bits used to represent the value and fraction length specifies, in bits, the location of the binary point in the fixed-point representation. Therein lies a problem — fraction length, which you specify in bits, can be larger than the word length, or a negative number of bits. This section explains how that idea works and how you might use it.

Unfortunately fraction length is somewhat misnamed (although it continues to be used in this User's Guide and elsewhere for historical reasons).

Fraction length defined as the number of fractional bits (bits to the right of the binary point) is true only when the fraction length is positive and less than or equal to the word length. In MATLAB format notation you can use [word length fraction length]. For example, for the format [16 16], the second 16 (the fraction length) is the number of fractional bits or bits to the right of the binary point. In this example, all 16 bits are to the right of the binary point.

But it is also possible to have fixed-point formats of [16 18] or [16 -45]. In these cases the fraction length can no longer be the number of bits to the right of the binary point since the format says the word length is 16 — there cannot be 18 fraction length bits on the right. And how can there be a negative number of bits for the fraction length, such as [16 -45]?

A better way to think about fixed-point format [word length fraction length] and what it means is that the representation of a fixed-point number is a weighted sum of powers of two driven by the fraction length, or the two's complement representation of the fixed-point number.

Consider the format [B L], where the fraction length L can be positive, negative, 0, greater than B (the word length) or less than B. (B and L are always integers and B is always positive.)

Given a binary string b(1) b(2) b(3) ... b(B), to determine the two's-complement value of the string in the format described by [B L], use the value of the individual bits in the binary string in the following formula, where b(1) is the first binary bit (and most significant bit, MSB), b(2) is the second, and on up to b(B).

The decimal numeric value that those bits represent is given by

```
value =-b(1)*2^(B-L-1)+b(2)*2^(B-L-2)+b(3)*2^(B-L-3)+...+ b(B)*2^(-L)
```

L, the fraction length, represents the negative of the weight of the last, or least significant bit (LSB). L is also the step size or the precision provided by a given fraction length.

Precision. Here is how precision works.

When all of the bits of a binary string are zero except for the LSB (which is therefore equal to one), the value represented by the bit string is given by $2^{(-L)}$. If L is negative, for example L=-16, the value is 2^{16}. The smallest step between numbers that can be represented in a format where L=-16 is given by 1×2^{16} (the rightmost term in the formula above), which is 65536. Note the precision does not depend on the word length.

Take a look at another example. When the word length set to 8 bits, the decimal value 12 is represented in binary by 00001100. That 12 is the decimal equivalent of 00001100 tells you that you are using [8 0] data format representation — the word length is 8 bits and fraction length 0 bits, and the step size or precision (the smallest difference between two adjacent values in the format [8,0], is 2^0=1.

Suppose you plan to keep only the upper 5 bits and discard the other three. The resulting precision after removing the right-most three bits comes from the weight of the lowest remaining bit, the fifth bit from the left, which is $2^3=8$, so the format would be [5,-3].

Note that in this format the step size is 8, I cannot represent numbers that are between multiples of 8.

In MATLAB, with Fixed-Point Toolbox software installed:

```
x=8;
q=quantizer([8,0]); % Word length = 8, fraction length = 0
xq=quantize(q,x);
binxq=num2bin(q,xq);
q1=quantizer([5 -3]); % Word length = 5, fraction length = -3
xq1 = quantize(q1,xq);
binxq1=num2bin(q1,xq1);
binxq

binxq =

00001000

binxq1

binxq1 =

00001
```

But notice that in [5,-3] format, 00001 is the two's complement representation for 8, not for 1; q = quantizer([8 0]) and q1 = quantizer([5 -3]) are not the same. They cover the about the same range — range(q)>range(q1) — but their quantization step is different — eps(q)= 8, and eps(q1)=1.

Look at one more example. When you construct a quantizer q

```
q = quantizer([a,b])
```

the first element in [a,b] is a, the word length used for quantization. The second element in the expression, b, is related to the quantization step — the numerical difference between the two closest values that the quantizer

can represent. This is also related to the weight given to the LSB. Note that `2^(-b) = eps(q)`.

Now construct two quantizers, `q1` and `q2`. Let `q1` use the format [32,0] and let `q2` use the format [16, -16].

```
q1 = quantizer([32,0])
q2 = quantizer([16,-16])
```

Quantizers `q1` and `q2` cover the same range, but `q2` has less precision. It covers the range in steps of 2^{16}, while `q` covers the range in steps of 1.

This lost precision is due to (or can be used to model) throwing out 16 least-significant bits.

An important point to understand is that in `dfilt` objects and filtering you control which bits are carried from the sum and product operations in the filter to the filter output by setting the format for the output from the sum or product operation.

For instance, if you use [16 0] as the output format for a 32-bit result from a sum operation when the original format is [32 0], you take the lower 16 bits from the result. If you use [16 -16], you take the higher 16 bits of the original 32 bits. You could even take 16 bits somewhere in between the 32 bits by choosing something like [16 -8], but you probably do not want to do that.

Filter scaling is directly implicated in the format and precision for a filter. When you know the filter input and output formats, as well as the filter internal formats, you can scale the inputs or outputs to stay within the format ranges. For more information about scaling filters, refer to "Floating-Point to Fixed-Point Filter Conversion".

Notice that overflows or saturation might occur at the filter input, filter output, or within the filter itself, such as during add or multiply or accumulate operations. Improper scaling at any point in the filter can result in numerical errors that dramatically change the performance of your fixed-point filter implementation.

CastBeforeSum

Setting the `CastBeforeSum` property determines how the filter handles the input values to sum operations in the filter. After you set your filter `Arithmetic` property value to `fixed`, you have the option of using `CastBeforeSum` to control the data type of some inputs (addends) to summations in your filter. To determine which addends reflect the `CastBeforeSum` property setting, refer to the reference page for the signal flow diagram for the filter structure.

`CastBeforeSum` specifies whether to cast selected addends to summations in the filter to the output format from the addition operation before performing the addition. When you specify `true` for the property value, the results of the affected sum operations match most closely the results found on most digital signal processors. Performing the cast operation before the summation adds one or two additional quantization operations that can add error sources to your filter results.

Specifying `CastBeforeSum` to be `false` prevents the addends from being cast to the output format before the addition operation. Choose this setting to get the most accurate results from summations without considering the hardware your filter might use.

Notice that the output format for every sum operation reflects the value of the output property specified in the filter structure diagram. Which input property is referenced by `CastBeforeSum` depends on the structure.

Property Value	Description
false	Configures filter summation operations to retain the addends in the format carried from the previous operation.
true	Configures filter summation operations to convert the input format of the addends to match the summation output format before performing the summation operation. Usually this generates results from the summation that more closely match those found from digital signal processors

Another point — with `CastBeforeSum` set to `false`, the filter realization process inserts an intermediate data type format to hold temporarily the full precision sum of the inputs. A separate Convert block performs the process of casting the addition result to the accumulator format. This intermediate data format occurs because the Sum block in Simulink always casts input (addends) to the output data type.

Diagrams of CastBeforeSum Settings. When `CastBeforeSum` is `false`, sum elements in filter signal flow diagrams look like this:
showing that the input data to the sum operations (the addends) retain their format word length and fraction length from previous operations. The addition process uses the existing input formats and then casts the output to the format defined by `AccumFormat`. Thus the output data has the word length and fraction length defined by `AccumWordLength` and `AccumFracLength`.

When `CastBeforeSum` is `true`, sum elements in filter signal flow diagrams look like this:
showing that the input data gets recast to the accumulator format word length and fraction length (AccumFormat) before the sum operation occurs. The data output by the addition operation has the word length and fraction length defined by `AccumWordLength` and `AccumFracLength`.

CoeffAutoScale

How the filter represents the filter coefficients depends on the property value of `CoeffAutoScale`. When you create a `dfilt` object, you use coefficients in double-precision format. Converting the `dfilt` object to fixed-point arithmetic forces the coefficients into a fixed-point representation. The representation the filter uses depends on whether the value of `CoeffAutoScale` is `true` or `false`.

- `CoeffAutoScale = true` means the filter chooses the fraction length to maintain the value of the coefficients as close to the double-precision values as possible. When you change the word length applied to the coefficients, the filter object changes the fraction length to try to accommodate the change. `true` is the default setting.

- `CoeffAutoScale = false` removes the automatic scaling of the fraction length for the coefficients and exposes the property that controls the coefficient fraction length so you can change it. For example, if the filter is a direct form FIR filter, setting `CoeffAutoScale = false` exposes the `NumFracLength` property that specifies the fraction length applied to numerator coefficients. If the filter is an IIR filter, setting `CoeffAutoScale = false` exposes both the `NumFracLength` and `DenFracLength` properties.

Here is an example of using `CoeffAutoScale` with a direct form filter.

```
hd2=dfilt.dffir([0.3 0.6 0.3])

hd2 =

        FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'double'
                Numerator: [0.3000 0.6000 0.3000]
        PersistentMemory: false
                  States: [2x1 double]
```

```
hd2.arithmetic='fixed'

hd2 =

          FilterStructure: 'Direct-Form FIR'
                Arithmetic: 'fixed'
                 Numerator: [0.3000 0.6000 0.3000]
          PersistentMemory: false
                    States: [1x1 embedded.fi]

           CoeffWordLength: 16
            CoeffAutoScale: true
                    Signed: true

           InputWordLength: 16
           InputFracLength: 15

          OutputWordLength: 16
                OutputMode: 'AvoidOverflow'

               ProductMode: 'FullPrecision'

           AccumWordLength: 40
             CastBeforeSum: true

                 RoundMode: 'convergent'
              OverflowMode: 'wrap'
```

To this point, the filter coefficients retain the original values from when you
created the filter as shown in the Numerator property. Now change the
CoeffAutoScale property value from true to false.

```
hd2.coeffautoScale=false

hd2 =

          FilterStructure: 'Direct-Form FIR'
                Arithmetic: 'fixed'
                 Numerator: [0.3000 0.6000 0.3000]
          PersistentMemory: false
```

```
              States: [1x1 embedded.fi]

    CoeffWordLength: 16
     CoeffAutoScale: false
       NumFracLength: 15
              Signed: true

    InputWordLength: 16
    InputFracLength: 15

   OutputWordLength: 16
         OutputMode: 'AvoidOverflow'

        ProductMode: 'FullPrecision'

    AccumWordLength: 40
       CastBeforeSum: true

          RoundMode: 'convergent'
       OverflowMode: 'wrap'
```

With the `NumFracLength` property now available, change the word length to 5 bits.

Notice the coefficient values. Setting `CoeffAutoScale` to `false` removes the automatic fraction length adjustment and the filter coefficients cannot be represented by the current format of [5 15] — a word length of 5 bits, fraction length of 15 bits.

```
hd2.coeffwordlength=5

hd2 =

        FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'fixed'
               Numerator: [4.5776e-004 4.5776e-004 4.5776e-004]
        PersistentMemory: false
                  States: [1x1 embedded.fi]

        CoeffWordLength: 5
```

```
                    CoeffAutoScale: false
                      NumFracLength: 15
                             Signed: true

                  InputWordLength: 16
                  InputFracLength: 15

                 OutputWordLength: 16
                       OutputMode: 'AvoidOverflow'

                       ProductMode: 'FullPrecision'

                   AccumWordLength: 40
                     CastBeforeSum: true

                         RoundMode: 'convergent'
                      OverflowMode: 'wrap'
```

Restoring `CoeffAutoScale` to `true` goes some way to fixing the coefficient values. Automatically scaling the coefficient fraction length results in setting the fraction length to 4 bits. You can check this with `get(hd2)` as shown below.

```
hd2.coeffautoScale=true

hd2 =

             FilterStructure: 'Direct-Form FIR'
                  Arithmetic: 'fixed'
                   Numerator: [0.3125 0.6250 0.3125]
             PersistentMemory: false
                       States: [1x1 embedded.fi]

              CoeffWordLength: 5
              CoeffAutoScale: true
                       Signed: true

              InputWordLength: 16
              InputFracLength: 15
```

```
        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

             ProductMode: 'FullPrecision'

          AccumWordLength: 40
            CastBeforeSum: true

                RoundMode: 'convergent'
             OverflowMode: 'wrap'

get(hd2)
        PersistentMemory: false
FilterStructure: 'Direct-Form FIR'
                   States: [1x1 embedded.fi]
                Numerator: [0.3125 0.6250 0.3125]
               Arithmetic: 'fixed'
           CoeffWordLength: 5
            CoeffAutoScale: 1
                   Signed: 1
                RoundMode: 'convergent'
             OverflowMode: 'wrap'
          InputWordLength: 16
          InputFracLength: 15
         OutputWordLength: 16
               OutputMode: 'AvoidOverflow'
              ProductMode: 'FullPrecision'
            NumFracLength: 4
         OutputFracLength: 12
        ProductWordLength: 21
        ProductFracLength: 19
          AccumWordLength: 40
          AccumFracLength: 19
            CastBeforeSum: 1
```

Clearly five bits is not enough to represent the coefficients accurately.

CoeffFracLength

Fixed-point scalar filters that you create using `dfilt.scalar` use this property to define the fraction length applied to the scalar filter coefficients. Like the coefficient-fraction-length-related properties for the FIR, lattice, and IIR filters, `CoeffFracLength` is not displayed for scalar filters until you set `CoeffAutoScale` to `false`. Once you change the automatic scaling you can set the fraction length for the coefficients to any value you require.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 14 bits, with the `CoeffWordlength` of 16 bits.

CoeffWordLength

One primary consideration in developing filters for hardware is the length of a data word. `CoeffWordLength` defines the word length for these data storage and arithmetic locations:

- Numerator and denominator filter coefficients
- Tap sum in `dfilt.dfsymfir` and `dfilt.dfasymfir` filter objects
- Section input, multiplicand, and state values in direct-form SOS filter objects such as `dfilt.df1t` and `dfilt.df2`
- Scale values in second-order filters
- Lattice and ladder coefficients in lattice filter objects, such as `dfilt.latticearma` and `dfilt.latticemamax`
- Gain in `dfilt.scalar`

Setting this property value controls the word length for the data listed. In most cases, the data words in this list have separate fraction length properties to define the associated fraction lengths.

Any positive, integer word length works here, limited by the machine you use to develop your filter and the hardware you use to deploy your filter.

DenAccumFracLength

Filter structures `df1`, `df1t`, `df2`, and `df2t` that use `fixed` arithmetic have this property that defines the fraction length applied to denominator coefficients in the accumulator. In combination with `AccumWordLength`, the properties fully specify how the accumulator outputs data stored there.

As with all fraction length properties, `DenAccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers. To be able to change the property value for this property, you set `FilterInternals` to `SpecifyPrecision`.

DenFracLength

Property `DenFracLength` contains the value that specifies the fraction length for the denominator coefficients for your filter. `DenFracLength` specifies the fraction length used to interpret the data stored in `C`. Used in combination with `CoeffWordLength`, these two properties define the interpretation of the coefficients stored in the vector that contains the denominator coefficients.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 15 bits, with the `CoeffWordLength` of 16 bits.

Denominator

The denominator coefficients for your IIR filter, taken from the prototype you start with, are stored in this property. Generally this is a 1-by-N array of data in double format, where N is the length of the filter.

All IIR filter objects include `Denominator`, except the lattice-based filters which store their coefficients in the `Lattice` property, and second-order section filters, such as `dfilt.df1tsos`, which use the `SosMatrix` property to hold the coefficients for the sections.

DenProdFracLength

A property of all of the direct form IIR `dfilt` objects, except the ones that implement second-order sections, `DenProdFracLength` specifies the fraction

length applied to data output from product operations that the filter performs on denominator coefficients.

Looking at the signal flow diagram for the `dfilt.df1t` filter, for example, you see that denominators and numerators are handled separately. When you set `ProductMode` to `SpecifyPrecision`, you can change the `DenProdFracLength` setting manually. Otherwise, for multiplication operations that use the denominator coefficients, the filter sets the fraction length as defined by the `ProductMode` setting.

DenStateFracLength

When you look at the flow diagram for the `dfilt.df1sos` filter object, the states associated with denominator coefficient operations take the fraction length from this property. In combination with the `DenStateWordLength` property, these properties fully specify how the filter interprets the states.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 15 bits, with the `DenStateWordLength` of 16 bits.

DenStateWordLength

When you look at the flow diagram for the `dfilt.df1sos` filter object, the states associated with the denominator coefficient operations take the data format from this property and the `DenStateFracLength` property. In combination, these properties fully specify how the filter interprets the state it uses.

By default, the value is 16 bits, with the `DenStateFracLength` of 15 bits.

FilterInternals

Similar to the FilterInternals pane in FDATool, this property controls whether the filter sets the output word and fraction lengths automatically, and the accumulator word and fraction lengths automatically as well, to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. Setting `FilterInternals` to `SpecifyPrecision` exposes the output

and accumulator related properties so you can set your own word and fraction lengths for them. Note that

FilterStructure

Every `dfilt` object has a `FilterStructure` property. This is a read-only property containing a string that declares the structure of the filter object you created.

When you construct filter objects, the `FilterStructure` property value is returned containing one of the strings shown in the following table. Property `FilterStructure` indicates the filter architecture and comes from the constructor you use to create the filter.

After you create a filter object, you cannot change the `FilterStructure` property value. To make filters that use different structures, you construct new filters using the appropriate methods, or use `convert` to switch to a new structure.

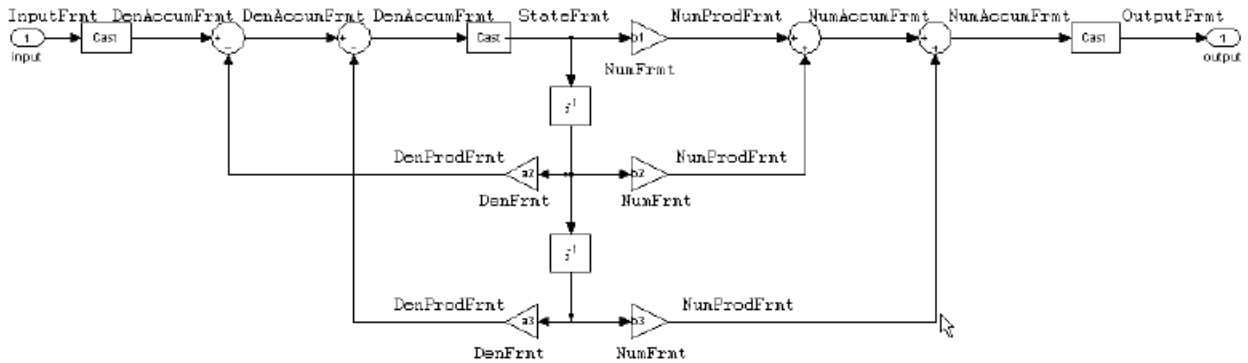
Default value. Since this depends on the constructor you use and the constructor includes the filter structure definition, there is no default value. When you try to create a filter without specifying a structure, MATLAB returns an error.

Filter Constructor Name	FilterStructure Property String and Filter Type
`'dfilt.df1'`	Direct form I
`'dfilt.df1sos'`	Direct form I filter implemented using second-order sections
`'dfilt.df1t'`	Direct form I transposed
`'dfilt.df2'`	Direct form II
`'dfilt.df2sos'`	Direct form II filter implemented using second order sections
`'dfilt.df2t'`	Direct form II transposed
`'dfilt.dfasymfir'`	Antisymmetric finite impulse response (FIR). Even and odd forms.

Filter Constructor Name	FilterStructure Property String and Filter Type
`'dfilt.dffir'`	Direct form FIR
`'dfilt.dffirt'`	Direct form FIR transposed
`'dfilt.latticeallpass'`	Lattice allpass
`'dfilt.latticear'`	Lattice autoregressive (AR)
`'dfilt.latticemamin'`	Lattice moving average (MA) minimum phase
`'dfilt.latticemamax'`	Lattice moving average (MA) maximum phase
`'dfilt.latticearma'`	Lattice ARMA
`'dfilt.dfsymfir'`	Symmetric FIR. Even and odd forms
`'dfilt.scalar'`	Scalar

Filter Structures with Quantizations Shown in Place. To help you understand how and where the quantizations occur in filter structures in this toolbox, the figure below shows the structure for a Direct Form II filter, including the quantizations (fixed-point formats) that compose part of the fixed-point filter. You see that one or more quantization processes, specified by the *format label, accompany each filter element, such as a delay, product, or summation element. The input to or output from each element reflects the result of applying the associated quantization as defined by the word length and fraction length format. Wherever a particular filter element appears in a filter structure, recall the quantization process that accompanies the element as it appears in this figure. Each filter reference page, such as the dfilt.df2 reference page, includes the signal flow diagram showing the formatting elements that define the quantizations that occur throughout the filter flow.

For example, a product quantization, either numerator or denominator, follows every product (gain) element and a sum quantization, also either numerator or denominator, follows each sum element. The figure shows the Arithmetic property value set to fixed.

df2 IIR Filter Structure Including the Formatting Objects, with Arithmetic Property Value fixed


When your `df2` filter uses the `Arithmetic` property set to `fixed`, the filter structure contains the formatting features shown in the diagram. The formats included in the structure are fixed-point objects that include properties to set various word and fraction length formats. For example, the `NumFormat` or `DenFormat` in the fixed-point arithmetic filter set the properties for quantizing numerator or denominator coefficients according to word and fraction length settings.

When the leading denominator coefficient a(1) in your filter is not 1, choose it to be a power of two so that a shift replaces the multiply that would otherwise be used.

Fixed-Point Arithmetic Filter Structures. You choose among several filter structures when you create fixed-point filters. You can also specify filters with single or multiple cascaded sections of the same type. Because quantization is a nonlinear process, different fixed-point filter structures produce different results.

To specify the filter structure, you select the appropriate `dfilt.`*`structure`* method to construct your filter. Refer to the function reference information for `dfilt` and `set` for details on setting property values for quantized filters.

The figures in the following subsections of this section serve as aids to help you determine how to enter your filter coefficients for each filter structure. Each subsection contains an example for constructing a filter of the given structure.

Scale factors for the input and output for the filters do not appear in the block diagrams. The default filter structures do not include, nor assume, the scale factors. For filter scaling information, refer to `scale` in the Help system.

About the Filter Structure Diagrams. In the diagrams that accompany the following filter structure descriptions, you see the active operators that define the filter, such as sums and gains, and the formatting features that control the processing in the filter. Notice also that the coefficients are labeled in the figure. This tells you the order in which the filter processes the coefficients.

While the meaning of the block elements is straightforward, the labels for the formats that form part of the filter are less clear. Each figure includes text in the form *labelFormat* that represents the existence of a formatting feature at that point in the structure. The *Format* stands for formatting object and the *label* specifies the data that the formatting object affects.

For example, in the `dfilt.df2` filter shown above, the entries `InputFormat` and `OutputFormat` are the formats applied, that is the word length and fraction length, to the filter input and output data. For example, filter properties like `OutputWordLength` and `InputWordLength` specify values that control filter operations at the input and output points in the structure and are represented by the formatting objects `InputFormat` and `OutputFormat` shown in the filter structure diagrams.

Direct Form I Filter Structure. The following figure depicts the *direct form I* filter structure that directly realizes a transfer function with a second-order numerator and denominator. The numerator coefficients are numbered $b(i)$, i =1, 2, 3; the denominator coefficients are numbered $a(i)$, $i = 1$, 2, 3; and the states (used for initial and final state values in filtering) are labeled $z(i)$. In the figure, the `Arithmetic` property is set to `fixed`.

Example — Specifying a Direct Form I Filter. You can specify a second-order direct form I structure for a quantized filter hq with the following code.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df1(b,a);
```

To create the fixed-point filter, set the Arithmetic property to fixed as shown here.

```
set(hq,'arithmetic','fixed');
```

Direct Form I Filter Structure With Second-Order Sections. The following figure depicts a *direct form I* filter structure that directly realizes a transfer function with a second-order numerator and denominator and second-order sections. The numerator coefficients are numbered $b(i)$, i =1, 2, 3; the denominator coefficients are numbered $a(i)$, i = 1, 2, 3; and the states (used for initial and final state values in filtering) are labeled $z(i)$. In the figure, the Arithmetic property is set to fixed to place the filter in fixed-point mode.

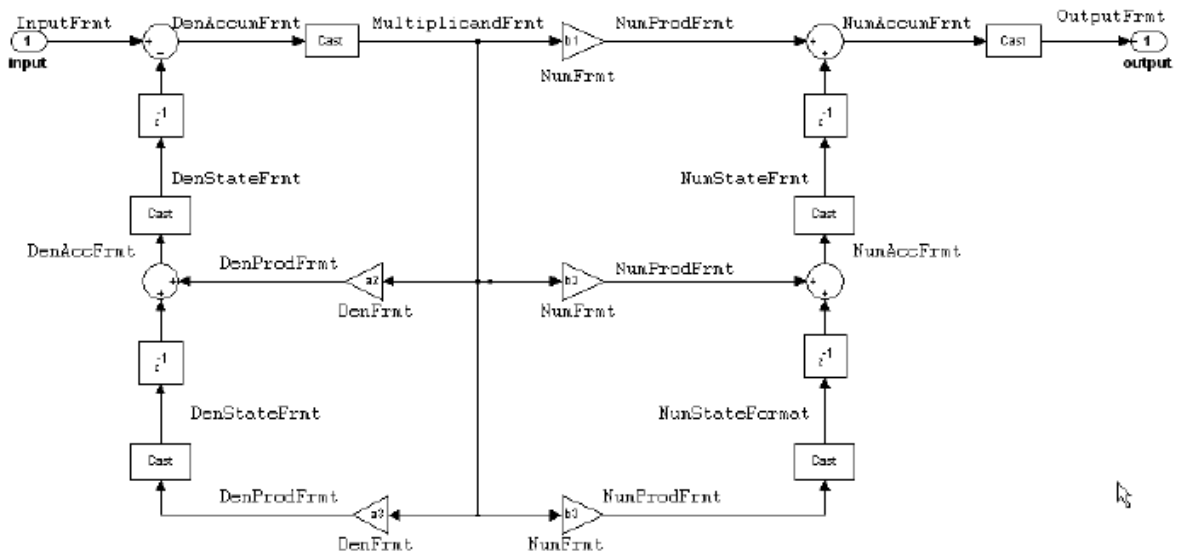
8-47

Example — Specifying a Direct Form I Filter with Second-Order Sections. You can specify an eighth-order direct form I structure for a quantized filter hq with the following code.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df1sos(b,a);
```

To create the fixed-point filter, set the Arithmetic property to fixed, as shown here.

```
set(hq,'arithmetic','fixed');
```

Direct Form I Transposed Filter Structure. The next signal flow diagram depicts a *direct form I transposed* filter structure that directly realizes a transfer function with a second-order numerator and denominator. The numerator coefficients are $b(i)$, $i = 1, 2, 3$; the denominator coefficients are $a(i)$, $i = 1, 2, 3$; and the states (used for initial and final state values in filtering) are labeled $z(i)$. With the Arithmetic property value set to fixed, the figure shows the filter with the properties indicated.


Example — Specifying a Direct Form I Transposed Filter. You can specify a second-order direct form I transposed filter structure for a quantized filter `hq` with the following code.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df1t(b,a);
set(hq,'arithmetic','fixed');
```

Direct Form II Filter Structure. The following graphic depicts a *direct form II* filter structure that directly realizes a transfer function with a second-order numerator and denominator. In the figure, the `Arithmetic` property value is `fixed`. Numerator coefficients are named $b(i)$; denominator coefficients are named $a(i)$, $i = 1, 2, 3$; and the states (used for initial and final state values in filtering) are named $z(i)$.

Use the method `dfilt.df2` to construct a quantized filter whose
`FilterStructure` property is `Direct-Form II`.

Example — Specifying a Direct Form II Filter. You can specify a
second-order direct form II filter structure for a quantized filter `hq` with the
following code.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df2(b,a);
hq.arithmetic = 'fixed'
```

To convert your initial double-precision filter `hq` to a quantized or fixed-point
filter, set the `Arithmetic` property to `fixed`, as shown.

Direct Form II Filter Structure With Second-Order Sections

The following figure depicts *direct form II* filter structure using second-order
sections that directly realizes a transfer function with a second-order
numerator and denominator sections. In the figure, the `Arithmetic` property
value is `fixed`. Numerator coefficients are labeled $b(i)$; denominator
coefficients are labeled $a(i)$, $i = 1, 2, 3$; and the states (used for initial and final
state values in filtering) are labeled $z(i)$.

Use the method `dfilt.df2sos` to construct a quantized filter whose `FilterStructure` property is `Direct-Form II`.

Example — Specifying a Direct Form II Filter with Second-Order Sections. You can specify a tenth-order direct form II filter structure that uses second-order sections for a quantized filter `hq` with the following code.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df2sos(b,a);
hq.arithmetic = 'fixed'
```

To convert your prototype double-precision filter `hq` to a fixed-point filter, set the `Arithmetic` property to `fixed`, as shown.

Direct Form II Transposed Filter Structure. The following figure depicts the *direct form II transposed* filter structure that directly realizes transfer functions with a second-order numerator and denominator. The numerator coefficients are labeled $b(i)$, the denominator coefficients are labeled $a(i)$, $i = 1, 2, 3$, and the states (used for initial and final state values in filtering) are labeled $z(i)$. In the first figure, the `Arithmetic` property value is `fixed`.

Use the constructor `dfilt.df2t` to specify the value of the `FilterStructure` property for a filter with this structure that you can convert to fixed-point filtering.

Example — Specifying a Direct Form II Transposed Filter. Specifying or constructing a second-order direct form II transposed filter for a fixed-point filter `hq` starts with the following code to define the coefficients and construct the filter.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df2t(b,a);
```

Now create the fixed-point filtering version of the filter from `hd`, which is floating point.

```
hq = set(hd,'arithmetic','fixed');
```

Direct Form Antisymmetric FIR Filter Structure (Any Order). The following figure depicts a *direct form antisymmetric FIR* filter structure that directly realizes a second-order antisymmetric FIR filter. The filter coefficients are labeled *b(i)*, and the initial and final state values in filtering are labeled *z*(*i*). This structure reflects the Arithmetic property set to fixed.
Use the method dfilt.dfasymfir to construct the filter, and then set the Arithmetic property to fixed to convert to a fixed-point filter with this structure.

Example — Specifying an Odd-Order Direct Form Antisymmetric FIR Filter. Specify a fifth-order direct form antisymmetric FIR filter structure for a fixed-point filter hq with the following code.

```
b = [-0.008 0.06 -0.44 0.44 -0.06 0.008];
hq = dfilt.dfasymfir(b);
set(hq,'arithmetic','fixed')

hq
```

```
hq =

        FilterStructure: 'Direct-Form Antisymmetric FIR'
             Arithmetic: 'fixed'
              Numerator: [-0.0080 0.0600 -0.4400 0.4400 -0.0600 0.0080]
       PersistentMemory: false
                 States: [1x1 fi object]

         CoeffWordLength: 16
          CoeffAutoScale: true
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

              TapSumMode: 'KeepMSB'
        TapSumWordLength: 17

             ProductMode: 'FullPrecision'

         AccumWordLength: 40

           CastBeforeSum: true
               RoundMode: 'convergent'
            OverflowMode: 'wrap'

        InheritSettings: false
```

Example — Specifying an Even-Order Direct Form Antisymmetric FIR Filter. You can specify a fourth-order direct form antisymmetric FIR filter structure for a fixed-point filter hq with the following code.

```
b = [-0.01 0.1 0.0 -0.1 0.01];
hq = dfilt.dfasymfir(b);
hq.arithmetic='fixed'

hq =
```

```
   FilterStructure: 'Direct-Form Antisymmetric FIR'
        Arithmetic: 'fixed'
         Numerator: [-0.0100 0.1000 0 -0.1000 0.0100]
  PersistentMemory: false
            States: [1x1 fi object]

  CoeffWordLength: 16
   CoeffAutoScale: true
           Signed: true

  InputWordLength: 16
  InputFracLength: 15

 OutputWordLength: 16
       OutputMode: 'AvoidOverflow'

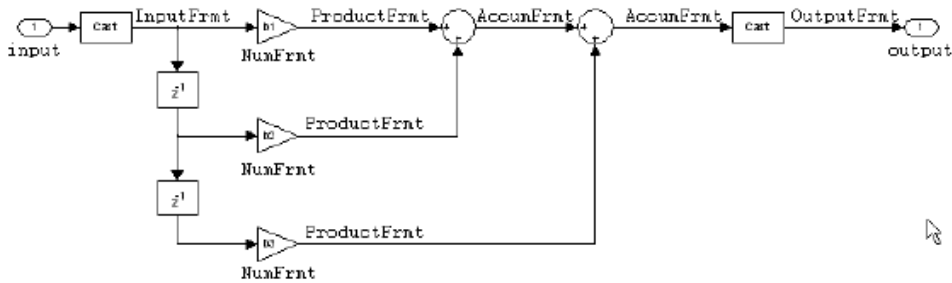
       TapSumMode: 'KeepMSB'
 TapSumWordLength: 17

      ProductMode: 'FullPrecision'

  AccumWordLength: 40

    CastBeforeSum: true
        RoundMode: 'convergent'
     OverflowMode: 'wrap'

  InheritSettings: false
```

Direct Form Finite Impulse Response (FIR) Filter Structure. In the next figure, you see the signal flow graph for a *direct form finite impulse response (FIR)* filter structure that directly realizes a second-order FIR filter. The filter coefficients are $b(i)$, $i = 1, 2, 3$, and the states (used for initial and final state values in filtering) are $z(i)$. To generate the figure, set the Arithmetic property to fixed after you create your prototype filter in double-precision arithmetic.


Use the `dfilt.dffir` method to generate a filter that uses this structure.

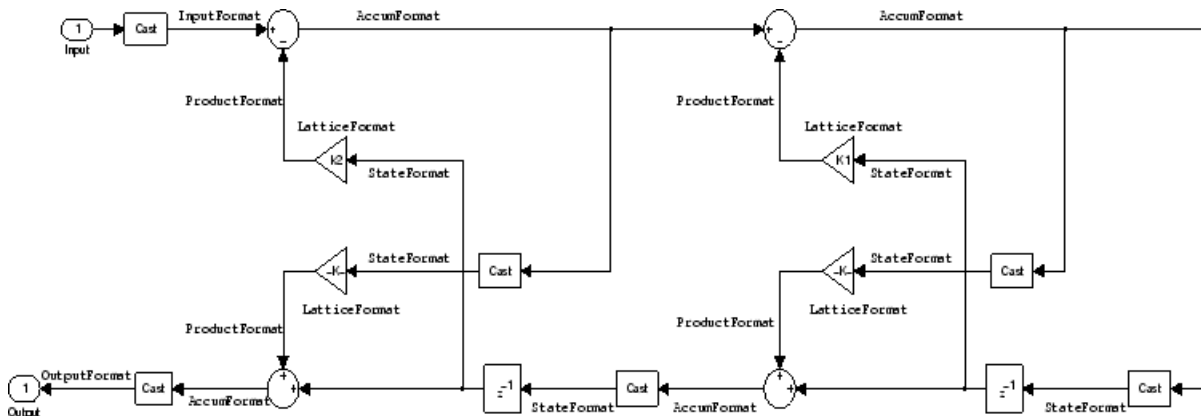
Example — Specifying a Direct Form FIR Filter. You can specify a second-order direct form FIR filter structure for a fixed-point filter `hq` with the following code.

```
b = [0.05 0.9 0.05];
hd = dfilt.dffir(b);
hq = set(hd,'arithmetic','fixed');
```

Direct Form FIR Transposed Filter Structure. This figure uses the filter coefficients labeled $b(i)$, i = 1, 2, 3, and states (used for initial and final state values in filtering) are labeled $z(i)$. These depict a *direct form finite impulse response (FIR) transposed* filter structure that directly realizes a second-order FIR filter.
With the `Arithmetic` property set to `fixed`, your filter matches the figure. Using the method `dfilt.dffirt` returns a double-precision filter that you convert to a fixed-point filter.

Example — Specifying a Direct Form FIR Transposed Filter. You can specify a second-order direct form FIR transposed filter structure for a fixed-point filter hq with the following code.

```
b = [0.05 0.9 0.05];
hd=dfilt.dffirt(b);
hq = copy(hd);
hq.arithmetic = 'fixed';
```

Lattice Allpass Filter Structure. The following figure depicts the *lattice allpass* filter structure. The pictured structure directly realizes third-order lattice allpass filters using fixed-point arithmetic. The filter reflection coefficients are labeled $k1(i)$, $i = 1, 2, 3$. The states (used for initial and final state values in filtering) are labeled $z(i)$.


To create a quantized filter that uses the lattice allpass structure shown in the figure, use the dfilt.latticeallpass method and set the Arithmetic property to fixed.

Example — Specifying a Lattice Allpass Filter. You can create a third-order lattice allpass filter structure for a quantized filter hq with the following code.

```
k = [.66 .7 .44];
hd=dfilt.latticeallpass(k);
set(hq,'arithmetic','fixed');
```

Lattice Moving Average Maximum Phase Filter Structure. In the next figure you see a *lattice moving average maximum phase* filter structure. This signal flow diagram directly realizes a third-order lattice moving average (MA) filter with the following phase form depending on the initial transfer function:

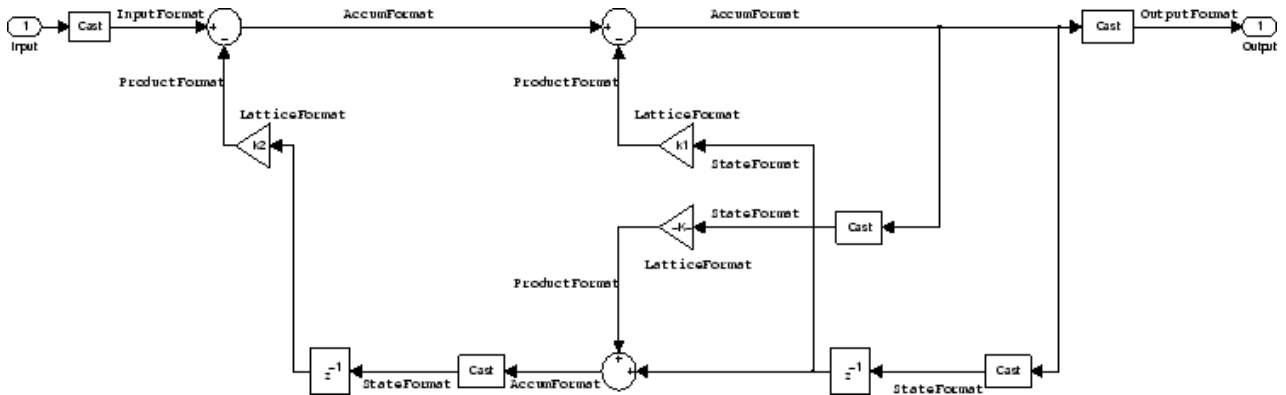
- When you start with a minimum phase transfer function, the upper branch of the resulting lattice structure returns a minimum phase filter. The lower branch returns a maximum phase filter.

- When your transfer function is neither minimum phase nor maximum phase, the lattice moving average maximum phase structure will not be maximum phase.

- When you start with a maximum phase filter, the resulting lattice filter is maximum phase also.

The filter reflection coefficients are labeled $k(i)$, $i = 1, 2, 3$. The states (used for initial and final state values in filtering) are labeled $z(i)$. In the figure, we set the Arithmetic property to fixed to reveal the fixed-point arithmetic format features that control such options as word length and fraction length.
Example — Constructing a Lattice Moving Average Maximum Phase Filter. Constructing a fourth-order lattice MA maximum phase filter structure for a quantized filter hq begins with the following code.

```
k = [.66 .7 .44 .33];
hd=dfilt.latticemamax(k);
```

Lattice Autoregressive (AR) Filter Structure. The method
`dfilt.latticear` directly realizes lattice autoregressive filters in the toolbox.
The following figure depicts the third-order *lattice autoregressive (AR)*
filter structure — with the `Arithmetic` property equal to `fixed`. The filter
reflection coefficients are labeled $k(i)$, i = 1, 2, 3, and the states (used for
initial and final state values in filtering) are labeled $z(i)$.


Example — Specifying a Lattice AR Filter. You can specify a third-order
lattice AR filter structure for a quantized filter `hq` with the following code.

```
k = [.66 .7 .44];
hd=dfilt.latticear(k);
hq.arithmetic = 'custom';
```

Lattice Moving Average (MA) Filter Structure for Minimum Phase.
The following figures depict *lattice moving average (MA)* filter structures
that directly realize third-order lattice MA filters for minimum phase. The
filter reflection coefficients are labeled $k(i)$, (i). = 1, 2, 3, and the states (used
for initial and final state values in filtering) are labeled $z(i)$. Setting the
`Arithmetic` property of the filter to `fixed` results in a fixed-point filter that
matches the figure.

This signal flow diagram directly realizes a third-order lattice moving average
(MA) filter with the following phase form depending on the initial transfer
function:

- When you start with a minimum phase transfer function, the upper branch of the resulting lattice structure returns a minimum phase filter. The lower branch returns a minimum phase filter.

- When your transfer function is neither minimum phase nor maximum phase, the lattice moving average minimum phase structure will not be minimum phase.

- When you start with a minimum phase filter, the resulting lattice filter is minimum phase also.

The filter reflection coefficients are labeled $k((i).)$, $i = 1, 2, 3$. The states (used for initial and final state values in filtering) are labeled $z((i).)$. This figure shows the filter structure when the Arithmetic property is set to fixed to reveal the fixed-point arithmetic format features that control such options as word length and fraction length.
Example — Specifying a Minimum Phase Lattice MA Filter. You can specify a third-order lattice MA filter structure for minimum phase applications using variations of the following code.

```
k = [.66 .7 .44];
hd=dfilt.latticemamin(k);
set(hq,'arithmetic','fixed');
```

Lattice Autoregressive Moving Average (ARMA) Filter Structure. The figure below depicts a *lattice autoregressive moving average (ARMA)* filter structure that directly realizes a fourth-order lattice ARMA filter. The filter reflection coefficients are labeled $k(i)$, (i). = 1, ..., 4; the ladder coefficients are labeled $v(i)$, (i). = 1, 2, 3; and the states (used for initial and final state values in filtering) are labeled $z(i)$.
Example — Specifying an Lattice ARMA Filter. The following code specifies a fourth-order lattice ARMA filter structure for a quantized filter hq, starting from hd, a floating-point version of the filter.

```
k = [.66 .7 .44 .66];
v = [1 0 0];
hd=dfilt.latticearma(k,v);
hq.arithmetic = 'fixed';
```

Direct Form Symmetric FIR Filter Structure (Any Order). Shown in the next figure, you see signal flow that depicts a *direct form symmetric FIR* filter structure that directly realizes a fifth-order direct form symmetric FIR filter. Filter coefficients are labeled $b(i)$, $i = 1, ..., n$, and states (used for initial and final state values in filtering) are labeled $z(i)$. Showing the filter structure used when you select fixed for the Arithmetic property value, the first figure details the properties in the filter object.
Example — Specifying an Odd-Order Direct Form Symmetric FIR Filter. By using the following code in MATLAB, you can specify a fifth-order direct form symmetric FIR filter for a fixed-point filter hq:

```
b = [-0.008 0.06 0.44 0.44 0.06 -0.008];
hd=dfilt.dfsymfir(b);
set(hq,'arithmetic','fixed');
```

Assigning Filter Coefficients. The syntax you use to assign filter coefficients for your floating-point or fixed-point filter depends on the structure you select for your filter.

Converting Filters Between Representations. Filter conversion functions in this toolbox and in Signal Processing Toolbox software let you convert filter transfer functions to other filter forms, and from other filter forms to transfer function form. Relevant conversion functions include the following functions.

Conversion Function	Description
ca2tf	Converts from a coupled allpass filter to a transfer function.
cl2tf	Converts from a lattice coupled allpass filter to a transfer function.
convert	Convert a discrete-time filter from one filter structure to another.
sos	Converts quantized filters to create second-order sections. We recommend this method for converting quantized filters to second-order sections.
tf2ca	Converts from a transfer function to a coupled allpass filter.
tf2cl	Converts from a transfer function to a lattice coupled allpass filter.
tf2latc	Converts from a transfer function to a lattice filter.
tf2sos	Converts from a transfer function to a second-order section form.
tf2ss	Converts from a transfer function to state-space form.
tf2zp	Converts from a rational transfer function to its factored (single section) form (zero-pole-gain form).
zp2sos	Converts a zero-pole-gain form to a second-order section form.
zp2ss	Conversion of zero-pole-gain form to a state-space form.
zp2tf	Conversion of zero-pole-gain form to transfer functions of multiple order sections.

Note that these conversion routines do not apply to `dfilt` objects.

The function `convert` is a special case — when you use convert to change
the filter structure of a fixed-point filter, you lose all of the filter states and
settings. Your new filter has default values for all properties, and it in not
fixed-point.

To demonstrate the changes that occur, convert a fixed-point direct form I
transposed filter to direct form II structure.

```
hd=dfilt.df1t

hd =

         FilterStructure: 'Direct-Form I Transposed'
              Arithmetic: 'double'
                Numerator: 1
              Denominator: 1
        PersistentMemory: false
                   States: Numerator:  [0x0 double]
                           Denominator:[0x0 double]

hd.arithmetic='fixed'
hd =

         FilterStructure: 'Direct-Form I Transposed'
              Arithmetic: 'fixed'
                Numerator: 1
              Denominator: 1
        PersistentMemory: false
                   States: Numerator:  [0x0 fi]
                           Denominator:[0x0 fi]

convert(hd,'df2')

Warning: Using reference filter for structure conversion.
Fixed-point attributes will not be converted.

ans =
```

```
     FilterStructure: 'Direct-Form II'
          Arithmetic: 'double'
           Numerator: 1
         Denominator: 1
    PersistentMemory: false
              States: [0x1 double]
```

You can specify a filter with *L* sections of arbitrary order by

1 Factoring your entire transfer function with `tf2zp`. This converts your transfer function to zero-pole-gain form.

2 Using `zp2tf` to compose the transfer function for each section from the selected first-order factors obtained in step 1.

Note You are not required to normalize the leading coefficients of each section's denominator polynomial when you specify second-order sections, though `tf2sos` does.

Gain
`dfilt.scalar` filters have a gain value stored in the `gain` property. By default the gain value is one — the filter acts as a wire.

InputFracLength
`InputFracLength` defines the fraction length assigned to the input data for your filter. Used in tandem with `InputWordLength`, the pair defines the data format for input data you provide for filtering.

As with all fraction length properties in `dfilt` objects, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, in this case `InputWordLength`, as well.

InputWordLength
Specifies the number of bits your filter uses to represent your input data. Your word length option is limited by the arithmetic you choose — up to 32 bits for

double, `float`, and `fixed`. Setting `Arithmetic` to `single` (single-precision floating-point) limits word length to 16 bits. The default value is 16 bits.

Ladder

Included as a property in `dfilt.latticearma` filter objects, `Ladder` contains the denominator coefficients that form an IIR lattice filter object. For instance, the following code creates a high pass filter object that uses the lattice ARMA structure.

```
[b,a]=cheby1(5,.5,.5,'high')

b =

    0.0282   -0.1409    0.2817   -0.2817    0.1409   -0.0282

a =

    1.0000    0.9437    1.4400    0.9629    0.5301    0.1620

hd=dfilt.latticearma(b,a)

hd =

        FilterStructure: [1x44 char]
              Arithmetic: 'double'
                  Lattice: [1x6 double]
                   Ladder: [1 0.9437 1.4400 0.9629 0.5301 0.1620]
        PersistentMemory: false
                   States: [6x1 double]

hd.arithmetic='fixed'

hd =

        FilterStructure: [1x44 char]
              Arithmetic: 'fixed'
                  Lattice: [1x6 double]
                   Ladder: [1 0.9437 1.4400 0.9629 0.5301 0.1620]
```

```
      PersistentMemory: false
                States: [1x1 embedded.fi]

      CoeffWordLength: 16
       CoeffAutoScale: true
               Signed: true

      InputWordLength: 16
      InputFracLength: 15

     OutputWordLength: 16
           OutputMode: 'AvoidOverflow'

      StateWordLength: 16
      StateFracLength: 15

          ProductMode: 'FullPrecision'

      AccumWordLength: 40
         CastBeforeSum: true

            RoundMode: 'convergent'
         OverflowMode: 'wrap'
```

LadderAccumFracLength

Autoregressive, moving average lattice filter objects (lattticearma) use ladder coefficients to define the filter. In combination with LadderFracLength and CoeffWordLength, these three properties specify or reflect how the accumulator outputs data stored there. As with all fraction length properties, LadderAccumFracLength can be any integer, including integers larger than AccumWordLength, and positive or negative integers. The default value is 29 bits.

LadderFracLength

To let you control the way your latticearma filter interprets the denominator coefficients, LadderFracLength sets the fraction length applied to the ladder coefficients for your filter. The default value is 14 bits.

As with all fraction length properties, `LadderFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers.

Lattice

When you create a lattice-based IIR filter, your numerator coefficients (from your IIR prototype filter or the default `dfilt` lattice filter function) get stored in the `Lattice` property of the `dfilt` object. The properties `CoeffWordLength` and `LatticeFracLength` define the data format the object uses to represent the lattice coefficients. By default, lattice coefficients are in double-precision format.

LatticeAccumFracLength

Lattice filter objects (`latticeallpass`, `latticearma`, `latticemamax`, and `latticemamin`) use lattice coefficients to define the filter. In combination with `LatticeFracLength` and `CoeffWordLength`, these three properties specify how the accumulator outputs lattice coefficient-related data stored there. As with all fraction length properties, `LatticeAccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers. By default, the property is set to 31 bits.

LatticeFracLength

To let you control the way your filter interprets the denominator coefficients, `LatticeFracLength` sets the fraction length applied to the lattice coefficients for your lattice filter. When you create the default lattice filter, `LatticeFracLength` is 16 bits.

As with all fraction length properties, `LatticeFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers.

MultiplicandFracLength

Each input data element for a multiply operation has both word length and fraction length to define its representation. `MultiplicandFracLength` sets the fraction length to use when the filter object performs any multiply operation during filtering. For default filters, this is set to 15 bits.

As with all word and fraction length properties, `MultiplicandFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers.

MultiplicandWordLength

Each input data element for a multiply operation has both word length and fraction length to define its representation. `MultiplicandWordLength` sets the word length to use when the filter performs any multiply operation during filtering. For default filters, this is set to 16 bits. Only the `df1t` and `df1tsos` filter objects include the `MultiplicandFracLength` property.

Only the `df1t` and `df1tsos` filter objects include the `MultiplicandWordLength` property.

NumAccumFracLength

Filter structures `df1`, `df1t`, `df2`, and `df2t` that use `fixed` arithmetic have this property that defines the fraction length applied to numerator coefficients in output from the accumulator. In combination with `AccumWordLength`, the `NumAccumFracLength` property fully specifies how the accumulator outputs numerator-related data stored there.

As with all fraction length properties, `NumAccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers. 30 bits is the default value when you create the filter object. To be able to change the value for this property, set `FilterInternals` for the filter to `SpecifyPrecision`.

Numerator

The numerator coefficients for your filter, taken from the prototype you start with or from the default filter, are stored in this property. Generally this is a 1-by-N array of data in double format, where N is the length of the filter.

All of the filter objects include `Numerator`, except the lattice-based and second-order section filters, such as `dfilt.latticema` and `dfilt.df1tsos`.

NumFracLength

Property `NumFracLength` contains the value that specifies the fraction length for the numerator coefficients for your filter. `NumFracLength` specifies the fraction length used to interpret the numerator coefficients. Used in combination with `CoeffWordLength`, these two properties define the interpretation of the coefficients stored in the vector that contains the numerator coefficients.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 15 bits, with the `CoeffWordLength` of 16 bits.

NumProdFracLength

A property of all of the direct form IIR `dfilt` objects, except the ones that implement second-order sections, `NumProdFracLength` specifies the fraction length applied to data output from product operations the filter performs on numerator coefficients.

Looking at the signal flow diagram for the `dfilt.df1t` filter, for example, you see that denominators and numerators are handled separately. When you set `ProductMode` to `SpecifyPrecision`, you can change the `NumProdFracLength` setting manually. Otherwise, for multiplication operations that use the numerator coefficients, the filter sets the word length as defined by the `ProductMode` setting.

NumStateFracLength

All the variants of the direct form I structure include the property `NumStateFracLength` to store the fraction length applied to the numerator states for your filter object. By default, this property has the value 15 bits, with the `CoeffWordLength` of 16 bits, which you can change after you create the filter object.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well.

NumStateWordLength

When you look at the flow diagram for the `df1sos` filter object, the states associated with the numerator coefficient operations take the data format from this property and the `NumStateFracLength` property. In combination, these properties fully specify how the filter interprets the state it uses.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 16 bits, with the `NumStateFracLength` of 11 bits.

OutputFracLength

To define the output from your filter object, you need both the word and fraction lengths. `OutputFracLength` determines the fraction length applied to interpret the output data. Combining this with `OutputWordLength` fully specifies the format of the output.

Your fraction length can be any negative or positive integer, or zero. In addition, the fraction length you specify can be larger than the associated word length. Generally, the default value is 11 bits.

OutputMode

Sets the mode the filter uses to scale the filtered (output) data. You have the following choices:

- `AvoidOverflow` — directs the filter to set the property that controls the output data fraction length to avoid causing the data to overflow. In a `df2` filter, this would be the `OutputFracLength` property.

- `BestPrecision` — directs the filter to set the property that controls the output data fraction length to maximize the precision in the output data. For `df1t` filters, this is the `OutputFracLength` property. When you change the word length (`OutputWordLength`), the filter adjusts the fraction length to maintain the best precision for the new word size.

- `SpecifyPrecision` — lets you set the fraction length used by the filtered data. When you select this choice, you can set the output fraction length using the `OutputFracLength` property to define the output precision.

All filters include this property except the direct form I filter which takes the output format from the filter states.

Here is an example that changes the mode setting to bestprecision, and then adjusts the word length for the output.

```
hd=dfilt.df2

      NumAccumFracLength: 29
      DenAccumFracLength: 29
           CastBeforeSum: 1
```

Changing the `OutputWordLength` to 8 bits caused the filter to change the `OutputFracLength` to 5 bits to keep the best precision for the output data.

OutputWordLength

Use the property `OutputWordLength` to set the word length used by the output from your filter. Set this property to a value that matches your intended hardware. For example, some digital signal processors use 32-bit output so you would set `OutputWordLength` to 32.

```
[b,a] = butter(6,.5);
hd=dfilt.df1t(b,a);

set(hd,'arithmetic','fixed')

hd

hd =
```

```
          FilterStructure: 'Direct-Form I Transposed'
               Arithmetic: 'fixed'
                Numerator: [1x7 double]
              Denominator: [1 0 0.7777 0 0.1142 0 0.0018]
         PersistentMemory: false
                   States: Numerator:  [6x1 fi]
                           Denominator:[6x1 fi]

           CoeffWordLength: 16
            CoeffAutoScale: true
                   Signed: true

           InputWordLength: 16
           InputFracLength: 15

                RoundMode: 'convergent'
             OverflowMode: 'wrap'
```

When you create a filter object, this property starts with the value 16.

OverflowMode

The OverflowMode property is specified as one of the following two strings indicating how to respond to overflows in fixed-point arithmetic:

- 'saturate' — saturate overflows.

When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the applicable word length and fraction length properties), these values are quantized to the value of either the largest or smallest representable value, depending on which is closest. `saturate` is the default value for `OverflowMode`.

- `'wrap'` — wrap all overflows to the range of representable values.

  When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the data format properties), these values are wrapped back into that range using modular arithmetic relative to the smallest representable number. You can learn more about modular arithmetic in Fixed-Point Toolbox documentation.

These rules apply to the `OverflowMode` property.

- Applies to the accumulator and output data only.
- Does not apply to coefficients or input data. These always saturate the results.
- Does not apply to products. Products maintain full precision at all times. Your filters do not lose precision in the products.

Note Numbers in floating-point filters that extend beyond the dynamic range overflow to ±inf.

ProductFracLength

After you set `ProductMode` for a fixed-point filter to `SpecifyPrecision`, this property becomes available for you to change. `ProductFracLength` sets the fraction length the filter uses for the results of multiplication operations. Only the FIR filters such as asymmetric FIRs or lattice autoregressive filters include this dynamic property.

Your fraction length can be any negative or positive integer, or zero. In addition, the fraction length you specify can be larger than the associated word length. Generally, the default value is 11 bits.

ProductMode

This property, available when your filter is in fixed-point arithmetic mode, specifies how the filter outputs the results of multiplication operations. All `dfilt` objects include this property when they use fixed-point arithmetic.

When available, you select from one of the following values for `ProductMode`:

- `FullPrecision` — means the filter automatically chooses the word length and fraction length it uses to represent the results of multiplication operations. The setting allow the product to retain the precision provided by the inputs (multiplicands) to the operation.

- `KeepMSB` — means you specify the word length for representing product operation results. The filter sets the fraction length to discard the LSBs, keep the higher order bits in the data, and maintain the precision.

- `KeepLSB` — means you specify the word length for representing the product operation results. The filter sets the fraction length to discard the MSBs, keep the lower order bits, and maintain the precision. Compare to the `KeepMSB` option.

- `SpecifyPrecision` — means you specify the word length and the fraction length to apply to data output from product operations.

When you switch to fixed-point filtering from floating-point, you are most likely going to throw away some data bits after product operations in your filter, perhaps because you have limited resources. When you have to discard some bits, you might choose to discard the least significant bits (LSB) from a result since the resulting quantization error would be small as the LSBs carry less weight. Or you might choose to keep the LSBs because the results have MSBs that are mostly zero, such as when your values are small relative to the range of the format in which they are represented. So the options for `ProductMode` let you choose how to maintain the information you need from the accumulator.

For more information about data formats, word length, and fraction length in fixed-point arithmetic, refer to "Notes About Fraction Length, Word Length, and Precision" on page 8-29.

ProductWordLength

You use `ProductWordLength` to define the data word length used by the output from multiplication operations. Set this property to a value that matches your intended application. For example, the default value is 32 bits, but you can set any word length.

```
set(hq,'arithmetic','fixed');
set(hq,'ProductWordLength',64);
```

Note that `ProductWordLength` applies only to filters whose `Arithmetic` property value is `fixed`.

PersistentMemory

Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter object. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false` — the filter does not retain memory about filtering operations from one to the next. Maintaining memory (setting `PersistentMemory` to `true`) lets you filter large data sets as collections of smaller subsets and get the same result.

In this example, filter `hd` first filters data `xtot` in one pass. Then you can use `hd` to filter `x` as two separate data sets. The results `ytot` and `ysec` are the same in both cases.

```
xtot=[x,x];
ytot=filter(hd,xtot)
ytot =

         0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
reset(hm1);  % Clear history of the filter
hm1.PersistentMemory='true';
ysec=[filter(hd,x) filter(hd,x)]

ysec =

         0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
```

This test verifies that `ysec` (the signal filtered by sections) is equal to `ytot` (the entire signal filtered at once).

RoundMode

The `RoundMode` property value specifies the rounding method used for quantizing numerical values. Specify the `RoundMode` property values as one of the following five strings.

RoundMode String	Description of Rounding Algorithm
Ceiling	Round toward positive infinity.
Floor	Round toward negative infinity.
Nearest	Round toward nearest. Ties round toward positive infinity.
Nearest(Convergent)	Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.
Round	Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.
Zero	Round toward zero.

The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.

ScaleValueFracLength

Filter structures `df1sos`, `df1tsos`, `df2sos`, and `df2tsos` that use `fixed` arithmetic have this property that defines the fraction length applied to the scale values the filter uses between sections. In combination with `CoeffWordLength`, these two properties fully specify how the filter interprets and uses the scale values stored in the property `ScaleValues`. As with fraction length properties, `ScaleValueFracLength` can be any integer,

including integers larger than `CoeffWordLength`, and positive or negative integers. 15 bits is the default value when you create the filter.

ScaleValues

The `ScaleValues` property values are specified as a scalar (or vector) that introduces scaling for inputs (and the outputs from cascaded sections in the vector case) during filtering:

- When you only have a single section in your filter:
    - Specify the `ScaleValues` property value as a scalar if you only want to scale the input to your filter.
    - Specify the `ScaleValues` property as a vector of length 2 if you want to specify scaling to the input (scaled with the first entry in the vector) and the output (scaled with the last entry in the vector).
- When you have *L* cascaded sections in your filter:
    - Specify the `ScaleValues` property value as a scalar if you only want to scale the input to your filter.
    - Specify the value for the `ScaleValues` property as a vector of length *L*+1 if you want to scale the inputs to every section in your filter, along with the output:

        The first entry of your vector specifies the input scaling

        Each successive entry specifies the scaling at the output of the next section

        The final entry specifies the scaling for the filter output.

The default value for `ScaleValues` is 0.

The interpretation of this property is described as follows with diagrams in "Interpreting the ScaleValues Property" on page 8-84.

Note The value of the `ScaleValues` property is not quantized. Data affected by the presence of a scaling factor in the filter is quantized according to the appropriate data format.

When you apply `normalize` to a fixed-point filter, the value for the `ScaleValues` property is changed accordingly.

It is good practice to choose values for this property that are either positive or negative powers of two.

Interpreting the ScaleValues Property. When you specify the values of the `ScaleValues` property of a quantized filter, the values are entered as a vector, the length of which is determined by the number of cascaded sections in your filter:

- When you have only one section, the value of the `Scalevalues` property can be a scalar or a two-element vector.

- When you have L cascaded sections in your filter, the value of the `ScaleValues` property can be a scalar or an $L+1$-element vector.

The following diagram shows how the `ScaleValues` property values are applied to a quantized filter with only one section.

**Application of ScaleValues
to a Single Section**
The following diagram shows how the `ScaleValues` property values are applied to a quantized filter with two sections.

**Application of ScaleValues
to Multiple Sections**
Signed

When you create a dfilt object for fixed-point filtering (you set the property Arithmetic to fixed, the property Signed specifies whether the filter interprets coefficients as signed or unsigned. This setting applies only to the coefficients. While the default setting is true, meaning that all coefficients are assumed to be signed, you can change the setting to false after you create the fixed-point filter.

For example, create a fixed-point direct-form II transposed filter with both negative and positive coefficients, and then change the property value for Signed from true to false to see what happens to the negative coefficient values.

```
hd=dfilt.df2t(-5:5)

hd =

        FilterStructure: 'Direct-Form II Transposed'
              Arithmetic: 'double'
                Numerator: [-5 -4 -3 -2 -1 0 1 2 3 4 5]
              Denominator: 1
         PersistentMemory: false
                   States: [10x1 double]

set(hd,'arithmetic','fixed')
hd.numerator

ans =

    -5    -4    -3    -2    -1    0
```

```
     1     2     3     4     5

set(hd,'signed',false)
hd.numerator

ans =

     0     0     0     0     0     0
     1     2     3     4     5
```

Using unsigned coefficients limits you to using only positive coefficients in your filter. Signed is a dynamic property — you cannot set or change it until you switch the setting for the Arithmetic property to fixed.

SosMatrix

When you convert a dfilt object to second-order section form, or create a second-order section filter, sosMatrix holds the filter coefficients as property values. Using the double data type by default, the matrix is in [sections coefficients per section] form, displayed as [15-x-6] for filters with 6 coefficients per section and 15 sections, [15 6].

To demonstrate, the following code creates an order 30 filter using second-order sections in the direct-form II transposed configuration. Notice the sosMatrix property contains the coefficients for all the sections.

```
d = fdesign.lowpass('n,fc',30,0.5);
hd = butter(d);

hd =

  FilterStructure: 'Direct-Form II, Second-Order Sections'
       Arithmetic: 'double'
         sosMatrix: [15x6 double]
      ScaleValues: [16x1 double]
PersistentMemory: false
           States: [2x15 double]

hd.arithmetic='fixed'

hd =
```

```
       FilterStructure: 'Direct-Form II, Second-Order Sections'
            Arithmetic: 'fixed'
              sosMatrix: [15x6 double]
           ScaleValues: [16x1 double]
      PersistentMemory: false
                 States: [1x1 embedded.fi]

       CoeffWordLength: 16
        CoeffAutoScale: true
                Signed: true

       InputWordLength: 16
       InputFracLength: 15

        SectionInputWordLength: 16
         SectionInputAutoScale: true

      SectionOutputWordLength: 16
       SectionOutputAutoScale: true

             OutputWordLength: 16
                   OutputMode: 'AvoidOverflow'

              StateWordLength: 16
              StateFracLength: 15

                  ProductMode: 'FullPrecision'

              AccumWordLength: 40
                CastBeforeSum: true

                    RoundMode: 'convergent'
                 OverflowMode: 'wrap'

hd.sosMatrix

ans =

    1.0000    2.0000    1.0000    1.0000         0    0.9005
```

1.0000	2.0000	1.0000	1.0000	0	0.7294
1.0000	2.0000	1.0000	1.0000	0	0.5888
1.0000	2.0000	1.0000	1.0000	0	0.4724
1.0000	2.0000	1.0000	1.0000	0	0.3755
1.0000	2.0000	1.0000	1.0000	0	0.2948
1.0000	2.0000	1.0000	1.0000	0	0.2275
1.0000	2.0000	1.0000	1.0000	0	0.1716
1.0000	2.0000	1.0000	1.0000	0	0.1254
1.0000	2.0000	1.0000	1.0000	0	0.0878
1.0000	2.0000	1.0000	1.0000	0	0.0576
1.0000	2.0000	1.0000	1.0000	0	0.0344
1.0000	2.0000	1.0000	1.0000	0	0.0173
1.0000	2.0000	1.0000	1.0000	0	0.0062
1.0000	2.0000	1.0000	1.0000	0	0.0007

The SOS matrix is an M-by-6 matrix, where M is the number of sections in the second-order section filter. Filter hd has M equal to 15 as shown above (15 rows). Each row of the SOS matrix contains the numerator and denominator coefficients (b's and a's) and the scale factors of the corresponding section in the filter.

SectionInputAutoScale

Second-order section filters include this property that determines who the filter handles data in the transitions from one section to the next in the filter.

How the filter represents the data passing from one section to the next depends on the property value of SectionInputAutoScale. The representation the filter uses between the filter sections depends on whether the value of SectionInputAutoScale is true or false.

- SectionInputAutoScale = true means the filter chooses the fraction length to maintain the value of the data between sections as close to the output values from the previous section as possible. true is the default setting.

- SectionInputAutoScale = false removes the automatic scaling of the fraction length for the intersection data and exposes the property that controls the coefficient fraction length (SectionInputFracLength) so you can change it. For example, if the filter is a second-order, direct form FIR filter, setting SectionInputAutoScale to false exposes the

SectionInputFracLength property that specifies the fraction length applied to data between the sections.

SectionInputFracLength

Second-order section filters use quantizers at the input to each section of the filter. The quantizers apply to the input data entering each filter section. Note that the quantizers for each section are the same. To set the fraction length for interpreting the input values, use the property value in SectionInputFracLength.

In combination with CoeffWordLength, SectionInputFracLength fully determines how the filter interprets and uses the state values stored in the property States. As with all word and fraction length properties, SectionInputFracLength can be any integer, including integers larger than CoeffWordLength, and positive or negative integers. 15 bits is the default value when you create the filter object.

SectionInputWordLength

SOS filters are composed of sections, each one a second-order filter. Filtering data input to the filter involves passing the data through each filter section. SectionInputWordLength specifies the word length applied to data as it enters one filter section from the previous section. Only second-order implementations of direct-form I transposed and direct-form II transposed filters include this property.

The following diagram shows an SOS filter composed of sections (the bottom part of the diagram) and a possible internal structure of each Section (the top portion of the diagram), in this case — a direct form I transposed second order sections filter structure. Note that the output of each section is fed through a multiplier. If the gain of the multiplier =1, then the last Cast block of the Section is ignored, and the format of the output is NumSumQ.

* : only if CastBeforeSum is True
`SectionInputWordLength` defaults to 16 bits.

SectionOutputAutoScale

Second-order section filters include this property that determines who the filter handles data in the transitions from one section to the next in the filter.

How the filter represents the data passing from one section to the next depends on the property value of `SectionOutputAutoScale`. The representation the filter uses between the filter sections depends on whether the value of `SectionOutputAutoScale` is `true` or `false`.

- `SectionOutputAutoScale` = `true` means the filter chooses the fraction length to maintain the value of the data between sections as close to the output values from the previous section as possible. `true` is the default setting.

- `SectionOutputAutoScale` = `false` removes the automatic scaling of the fraction length for the intersection data and exposes the property that controls the coefficient fraction length (`SectionOutputFracLength`) so you can change it. For example, if the filter is a second-order, direct form FIR filter, setting `SectionOutputAutoScale` = `false` exposes the `SectionOutputFracLength` property that specifies the fraction length applied to data between the sections.

SectionOutputFracLength

Second-order section filters use quantizers at the output from each section of the filter. The quantizers apply to the output data leaving each filter section. Note that the quantizers for each section are the same. To set the fraction length for interpreting the output values, use the property value in `SectionOutputFracLength`.

In combination with `CoeffWordLength`, `SectionOutputFracLength` determines how the filter interprets and uses the state values stored in the property `States`. As with all fraction length properties, `SectionOutputFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers. 15 bits is the default value when you create the filter object.

SectionOutputWordLength

SOS filters are composed of sections, each one a second-order filter. Filtering data input to the filter involves passing the data through each filter section. `SectionOutputWordLength` specifies the word length applied to data as it leaves one filter section to go to the next. Only second-order implementations direct-form I transposed and direct-form II transposed filters include this property.

The following diagram shows an SOS filter composed of sections (the bottom part of the diagram) and a possible internal structure of each Section (the top portion of the diagram), in this case — a direct form I transposed second order sections filter structure. Note that the output of each section is fed through a multiplier. If the gain of the multiplier =1, then the last Cast block of the Section is ignored, and the format of the output is NumSumQ.
SectionOutputWordLength defaults to 16 bits.

StateAutoScale

Although all filters use states, some do not allow you to choose whether the filter automatically scales the state values to prevent overruns or bad arithmetic errors. You select either of the following settings:

- StateAutoScale = true means the filter chooses the fraction length to maintain the value of the states as close to the double-precision values as possible. When you change the word length applied to the states (where allowed by the filter structure), the filter object changes the fraction length to try to accommodate the change. true is the default setting.

- StateAutoScale = false removes the automatic scaling of the fraction length for the states and exposes the property that controls the coefficient fraction length so you can change it. For example, in a direct form I transposed SOS FIR filter, setting StateAutoScale = false exposes the NumStateFracLength and DenStateFracLength properties that specify the fraction length applied to states.

Each of the following filter structures provides the StateAutoScale property:

- df1t
- df1tsos
- df2t
- df2tsos
- dffirt

Other filter structures do not include this property.

StateFracLength

Filter states stored in the property States have both word length and fraction length. To set the fraction length for interpreting the stored filter object state values, use the property value in StateFracLength.

In combination with `CoeffWordLength`, `StateFracLength` fully determines how the filter interprets and uses the state values stored in the property `States`.

As with all fraction length properties, `StateFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers. 15 bits is the default value when you create the filter object.

States

Digital filters are dynamic systems. The behavior of dynamic systems (their response) depends on the input (stimulus) to the system and the current or previous *state* of the system. You can say the system has memory or inertia. All fixed- or floating-point digital filters (as well as analog filters) have states.

Filters use the states to compute the filter output for each input sample, as well using them while filtering in loops to maintain the filter state between loop iterations. This toolbox assumes zero-valued initial conditions (the dynamic system is at rest) by default when you filter the first input sample. Assuming the states are zero initially does not mean the states are not used; they are, but arithmetically they do not have any effect.

Filter objects store the state values in the property `States`. The number of stored states depends on the filter implementation, since the states represent the delays in the filter implementation.

When you review the display for a filter object with fixed arithmetic, notice that the states return an embedded `fi` object, as you see here.

```
b = ellip(6,3,50,300/500);
hd=dfilt.dffir(b)

hd =

       FilterStructure: 'Direct-Form FIR'
             Arithmetic: 'double'
              Numerator: [0.0773 0.2938 0.5858 0.7239 0.5858 0.2938 0.0773]
         PersistentMemory: false
                 States: [6x1 double]
```

```
hd.arithmetic='fixed'

hd =

         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'fixed'
               Numerator: [0.0773 0.2938 0.5858 0.7239 0.5858 0.2938 0.0773]
        PersistentMemory: false
                  States: [1x1 embedded.fi]

          CoeffWordLength: 16
           CoeffAutoScale: 'on'
                   Signed: 'on'

          InputWordLength: 16
           InputFracLength: 15

         OutputWordLength: 16
               OutputMode: 'AvoidOverflow'

              ProductMode: 'FullPrecision'

          AccumWordLength: 40
             CastBeforeSum: 'on'

                RoundMode: 'convergent'
             OverflowMode: 'wrap'

          InheritSettings: 'off'
```

fi objects provide fixed-point support for the filters. To learn more about the details about fi objects, refer to your Fixed-Point Toolbox documentation.

The property States lets you use a fi object to define how the filter interprets the filter states. For example, you can create a fi object in MATLAB, then assign the object to States, as follows:

```
statefi=fi([],16,12)
```

```
statefi =

[]
    DataTypeMode = Fixed-point: binary point scaling
           Signed = true
      Wordlength = 16
Fractionlength = 12
```

This `fi` object does not have a value associated (notice the `[]` input argument to `fi` for the value), and it has word length of 16 bits and fraction length of 12 bit. Now you can apply `statefi` to the `States` property of the filter `hd`.

```
set(hd,'States',statefi);
Warning: The 'States' property will be reset to the value
specified at construction before filtering.
Set the 'PersistentMemory' flag to 'True'
to avoid changing this property value.
hd

hd =

         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'fixed'
               Numerator: [0.0773 0.2938 0.5858 0.7239 0.5858
                           0.2938 0.0773]
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 16
          CoeffAutoScale: 'on'
                  Signed: 'on'

         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

             ProductMode: 'FullPrecision'
         AccumWordLength: 40
```

```
            CastBeforeSum: 'on'

                RoundMode: 'convergent'
             OverflowMode: 'wrap'
```

StateWordLength

While all filters use states, some do not allow you to directly change the state representation — the word length and fraction lengths — independently. For the others, `StateWordLength` specifies the word length, in bits, the filter uses to represent the states. Filters that do not provide direct state word length control include:

- `df1`

- `dfasymfir`

- `dffir`

- `dfsymfir`

For these structures, the filter derives the state format from the input format you choose for the filter — except for the `df1` IIR filter. In this case, the numerator state format comes from the input format and the denominator state format comes from the output format. All other filter structures provide control of the state format directly.

TapSumFracLength

Direct-form FIR filter objects, both symmetric and antisymmetric, use this property. To set the fraction length for output from the sum operations that involve the filter tap weights, use the property value in `TapSumFracLength`. To enable this property, set the `TapSumMode` to `SpecifyPrecision` in your filter.

As you can see in this code example that creates a fixed-point asymmetric FIR filter, the `TapSumFracLength` property becomes available after you change the `TapSumMode` property value.

```
hd=dfilt.dfasymfir

hd =
```

```
              FilterStructure: 'Direct-Form Antisymmetric FIR'
                   Arithmetic: 'double'
                    Numerator: 1
             PersistentMemory: false
                       States: [0x1 double]

set(hd,'arithmetic','fixed');
hd

hd =

              FilterStructure: 'Direct-Form Antisymmetric FIR'
                   Arithmetic: 'fixed'
                    Numerator: 1
             PersistentMemory: false
                       States: [1x1 embedded.fi]

               CoeffWordLength: 16
                CoeffAutoScale: true
                       Signed: true

               InputWordLength: 16
               InputFracLength: 15

              OutputWordLength: 16
                    OutputMode: 'AvoidOverflow'

                    TapSumMode: 'KeepMSB'
              TapSumWordLength: 17

                   ProductMode: 'FullPrecision'

               AccumWordLength: 40

                 CastBeforeSum: true
                     RoundMode: 'convergent'
                  OverflowMode: 'wrap'
```

With the filter now in fixed-point mode, you can change the `TapSumMode` property value to `SpecifyPrecision`, which gives you access to the `TapSumFracLength` property.

```
set(hd,'TapSumMode','SpecifyPrecision');
hd

hd =

          FilterStructure: 'Direct-Form Antisymmetric FIR'
               Arithmetic: 'fixed'
                Numerator: 1
         PersistentMemory: false
                   States: [1x1 embedded.fi]

          CoeffWordLength: 16
            CoeffAutoScale: true
                   Signed: true

          InputWordLength: 16
          InputFracLength: 15

         OutputWordLength: 16
               OutputMode: 'AvoidOverflow'

               TapSumMode: 'SpecifyPrecision'
         TapSumWordLength: 17
         TapSumFracLength: 15

              ProductMode: 'FullPrecision'

          AccumWordLength: 40

            CastBeforeSum: true
                RoundMode: 'convergent'
             OverflowMode: 'wrap'
```

In combination with `TapSumWordLength`, `TapSumFracLength` fully determines how the filter interprets and uses the state values stored in the property `States`.

As with all fraction length properties, `TapSumFracLength` can be any integer, including integers larger than `TapSumWordLength`, and positive or negative integers. 15 bits is the default value when you create the filter object.

TapSumMode

This property, available only after your filter is in fixed-point mode, specifies how the filter outputs the results of summation operations that involve the filter tap weights. Only symmetric (`dfilt.dfsymfir`) and antisymmetric (`dfilt.dfasymfir`) FIR filters use this property.

When available, you select from one of the following values:

- `FullPrecision` — means the filter automatically chooses the word length and fraction length to represent the results of the sum operation so they retain all of the precision provided by the inputs (addends).

- `KeepMSB` — means you specify the word length for representing tap sum summation results to keep the higher order bits in the data. The filter sets the fraction length to discard the LSBs from the sum operation. This is the default property value.

- `KeepLSB` — means you specify the word length for representing tap sum summation results to keep the lower order bits in the data. The filter sets the fraction length to discard the MSBs from the sum operation. Compare to the `KeepMSB` option.

- `SpecifyPrecision` — means you specify the word and fraction lengths to apply to data output from the tap sum operations.

TapSumWordLength

Specifies the word length the filter uses to represent the output from tap sum operations. The default value is 17 bits. Only `dfasymfir` and `dfsymfir` filters include this property.

Adaptive Filter Properties

In this section...

Property Summaries

The following table summarizes the adaptive filter properties and provides a brief description of each. Full descriptions of each property, in alphabetical order, are given in the subsequent section.

Property	Description
Algorithm	Reports the algorithm the object uses for adaptation. When you construct your adaptive filter object, this property is set automatically by the constructor, such as adaptfilt.nlms creating an adaptive filter that uses the normalized LMS algorithm. You cannot change the value — it is read only.
AvgFactor	Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. AvgFactor should lie between zero and one. For default filter objects, AvgFactor equals (1 - step). lambda is the input argument that represents AvgFactor
BkwdPredErrorPower	Returns the minimum mean-squared prediction error. Refer to [3] in the bibliography for details about linear prediction.
BkwdPrediction	Returns the predicted samples generated during adaptation. Refer to [3] in the bibliography for details about linear prediction.

Property	Description
Blocklength	Block length for the coefficient updates. This must be a positive integer such that (1/blocklength) is also an integer. For faster execution, blocklength should be a power of two. blocklength defaults to two.
Coefficients	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
ConversionFactor	Conversion factor defaults to the matrix [1 -1] that specifies soft-constrained initialization. This is the gamma input argument for some of the fast transversal algorithms.
Delay	Update delay given in time samples. This scalar should be a positive integer—negative delays do not work. delay defaults to 1 for most algorithms.
DesiredSignalStates	Desired signal states of the adaptive filter. dstates defaults to a zero vector with length equal to (blocklen - 1) or (swblocklen - 1) depending on the algorithm.
EpsilonStates	Vector of the epsilon values of the adaptive filter. EpsilonStates defaults to a vector of zeros with (projectord - 1) elements.
ErrorStates	Vector of the adaptive filter error states. ErrorStates defaults to a zero vector with length equal to (projectord - 1).
FFTCoefficients	Stores the discrete Fourier transform of the filter coefficients in coeffs.
FFTStates	Stores the states of the FFT of the filter coefficients during adaptation.
FilteredInputStates	Vector of filtered input states with length equal to l - 1.

Property	Description
FilterLength	Contains the length of the filter. Note that this is not the filter order. Filter length is 1 greater than filter order. Thus a filter with length equal to 10 has filter order equal to 9.
ForgettingFactor	Determines how the RLS adaptive filter uses past data in each iteration. You use the forgetting factor to specify whether old data carries the same weight in the algorithm as more recent data.
FwdPredErrorPower	Returns the minimum mean-squared prediction error in the forward direction. Refer to [3] in the bibliography for details about linear prediction.
FwdPrediction	Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.
InitFactor	Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. Called delta as an input argument, this defaults to one.
InvCov	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix. Dimensions are l-by-l, where l is the filter length.
KalmanGain	Empty when you construct the object, this gets populated after you run the filter.
KalmanGainStates	Contains the states of the Kalman gain updates during adaptation.

Property	Description
Leakage	Contains the setting for leakage in the adaptive filter algorithm. Using a leakage factor that is not 1 forces the weights to adapt even when they have found the minimum error solution. Forcing the adaptation can improve the numerical performance of the LMS algorithm.
OffsetCov	Contains the offset covariance matrix.
Offset	Specifies an optional offset for the denominator of the step size normalization term. You must specify offset to be a scalar greater than or equal to zero. Nonzero offsets can help avoid a divide-by-near-zero condition that causes errors.
Power	A vector of 2*l elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.
ProjectionOrder	Projection order of the affine projection algorithm. projectord defines the size of the input signal covariance matrix and defaults to two.
ReflectionCoeffs	Coefficients determined for the reflection portion of the filter during adaptation.
ReflectionCoeffsStep	Size of the steps used to determine the reflection coefficients.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states and coefficients from previous filtering runs.
SecondaryPathCoeffs	A vector that contains the coefficient values of your secondary path from the output actuator to the error sensor.
SecondaryPathEstimate	An estimate of the secondary path filter model.

Property	Description
SecondaryPathStates	The states of the secondary path filter, the unknown system.
SqrtCov	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.
SqrtlnvCov	Square root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
States	Vector of the adaptive filter states. states defaults to a vector of zeros whose length depends on the chosen algorithm. Usually the length is a function of the filter length l and another input argument to the filter object, such as projectord.
StepSize	Reports the size of the step taken between iterations of the adaptive filter process. Each adaptfilt object has a default value that best meets the needs of the algorithm.
SwBlockLength	Block length of the sliding window. This integer must be at least as large as the filter length. swblocklen defaults to 16.

Like dfilt objects, adaptfilt objects have properties that govern their behavior and store some of the results of filtering operations. The following pages list, in alphabetical order, the name of every property associated with adaptfilt objects. Note that not all adaptfilt objects have all of these properties. To view the properties of a particular adaptive filter, such as an adaptfilt.bap filter, use get with the object handle, like this:

```
ha = adaptfilt.bap(32,0.5,4,1.0);
get(ha)
        PersistentMemory: false
               Algorithm: 'Block Affine Projection FIR Adaptive Filter'
              FilterLength: 32
              Coefficients: [1x32 double]
```

```
         States: [35x1 double]
       StepSize: 0.5000
ProjectionOrder: 4
      OffsetCov: [4x4 double]
```

get shows you the properties for ha and the values for the properties. Entering the object handle returns the same values and properties without the formatting of the list and the more familiar property names.

Property Details for Adaptive Filter Properties

Algorithm

Reports the algorithm the object uses for adaptation. When you construct you adaptive filter object, this property is set automatically. You cannot change the value—it is read only.

AvgFactor

Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. AvgFactor should lie between zero and one. For default filter objects, AvgFactor equals (1 - step). lambda is the input argument that represent AvgFactor

BkwdPredErrorPower

Returns the minimum mean-squared prediction error in the backward direction. Refer to [3] in the bibliography for details about linear prediction.

BkwdPrediction

When you use an adaptive filter that does backward prediction, such as adaptfilt.ftf, one property of the filter contains the backward prediction coefficients for the adapted filter. With these coefficient, the forward coefficients, and the system under test, you have the full set of knowledge of how the adaptation occurred. Two values stored in properties compose the BkwdPrediction property:

• Coefficients, which contains the coefficients of the system under test, as determined using backward predictions process.

- Error, which is the difference between the filter coefficients determined by backward prediction and the actual coefficients of the sample filter. In this example, `adaptfilt.ftf` identifies the coefficients of an unknown FIR system.

```
x   = randn(1,500);     % Input to the filter
b   = fir1(31,0.5);     % FIR system to be identified
n   = 0.1*randn(1,500); % Observation noise signal
d   = filter(b,1,x)+n;  % Desired signal
N   = 31;               % Adaptive filter order
lam = 0.99;             % RLS forgetting factor
del = 0.1;              % Soft-constrained initialization factor
ha = adaptfilt.ftf(32,lam,del);
[y,e] = filter(ha,x,d);

```

Blocklength

Block length for the coefficient updates. This must be a positive integer such that (1/blocklen) is also an integer. For faster execution, `blocklen` should be a power of two. `blocklen` defaults to two.

Coefficients

Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.

ConversionFactor

Conversion factor defaults to the matrix [1 -1] that specifies soft-constrained initialization. This is the `gamma` input argument for some of the fast transversal algorithms.

Delay

Update delay given in time samples. This scalar should be a positive integer — negative delays do not work. `delay` defaults to 1 for most algorithms.

DesiredSignalStates

Desired signal states of the adaptive filter. `dstates` defaults to a zero vector with length equal to (`blocklen` - 1) or (`swblocklen` - 1) depending on the algorithm.

EpsilonStates

Vector of the epsilon values of the adaptive filter. `EpsilonStates` defaults to a vector of zeros with (`projectord` - 1) elements.

ErrorStates

Vector of the adaptive filter error states. `ErrorStates` defaults to a zero vector with length equal to (`projectord` - 1).

FFTCoefficients

Stores the discrete Fourier transform of the filter coefficients in `coeffs`.

FFTStates

Stores the states of the FFT of the filter coefficients during adaptation.

FilteredInputStates

Vector of filtered input states with length equal to l - 1.

FilterLength

Contains the length of the filter. Note that this is not the filter order. Filter length is 1 greater than filter order. Thus a filter with length equal to 10 has filter order equal to 9.

ForgettingFactor

Determines how the RLS adaptive filter uses past data in each iteration. You use the forgetting factor to specify whether old data carries the same weight in the algorithm as more recent data.

This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting forgetting factor = 1 denotes infinite memory while adapting to find the new filter. Note that this is the lambda input argument.

FwdPredErrorPower

Returns the minimum mean-squared prediction error in the forward direction. Refer to [3] in the bibliography for details about linear prediction.

FwdPrediction

Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.

InitFactor

Returns the soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. delta defaults to one.

InvCov

Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix. Dimensions are l-by-l, where l is the filter length.

KalmanGain

Empty when you construct the object, this gets populated after you run the filter.

KalmanGainStates

Contains the states of the Kalman gain updates during adaptation.

Leakage

Contains the setting for leakage in the adaptive filter algorithm. Using a leakage factor that is not 1 forces the weights to adapt even when they have found the minimum error solution. Forcing the adaptation can improve the numerical performance of the LMS algorithm.

OffsetCov

Contains the offset covariance matrix.

Offset

Specifies an optional offset for the denominator of the step size normalization term. You must specify offset to be a scalar greater than or equal to zero. Nonzero offsets can help avoid a divide-by-near-zero condition that causes errors.

Use this to avoid dividing by zero or by very small numbers when input signal amplitude becomes very small, or dividing by very small numbers when any of the FFT input signal powers become very small. offset defaults to one.

Power

A vector of 2*l elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.

ProjectionOrder

Projection order of the affine projection algorithm. `projectord` defines the size of the input signal covariance matrix and defaults to two.

ReflectionCoeffs

For adaptive filters that use reflection coefficients, this property stores them.

ReflectionCoeffsStep

As the adaptive filter changes coefficient values during adaptation, the step size used between runs is stored here.

PersistentMemory

Determines whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter.

`PersistentMemory` returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to `false`.

SecondaryPathCoeffs

A vector that contains the coefficient values of your secondary path from the output actuator to the error sensor.

SecondaryPathEstimate

An estimate of the secondary path filter model.

SecondaryPathStates

The states of the secondary path filter, the unknown system.

SqrtCov

Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.

SqrtInvCov

Square root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.

States

Vector of the adaptive filter states. `states` defaults to a vector of zeros whose length depends on the chosen algorithm. Usually the length is a function of the filter length `l` and another input argument to the filter object, such as projectord.

StepSize

Reports the size of the step taken between iterations of the adaptive filter process. Each `adaptfilt` object has a default value that best meets the needs of the algorithm.

SwBlockLength

Block length of the sliding window. This integer must be at least as large as the filter length. `swblocklength` defaults to `16`.

Multirate Filter Properties

In this section...
"Property Summaries" on page 8-115
"Property Details for Multirate Filter Properties" on page 8-120
"References for Multirate Filters" on page 8-130

Property Summaries

The following table summarizes the multirate filter properties and provides a brief description of each. Full descriptions of each property are given in the subsequent section.

Name	Values	Default	Description
BlockLength	Positive integers	100	Length of each block of data input to the FFT used in the filtering. fftfirinterp multirate filters include this property.
DecimationFactor	Any positive integer	2	Amount to reduce the input sampling rate.
DifferentialDelay	Any integer	1	Sets the differential delay for the filter. Usually a value of one or two is appropriate.

Name	Values	Default	Description
FilterInternals	FullPrecision, MinWordlengths, SpecifyWordLengths, SpecifyPrecision	FullPrecision	Controls whether the filter sets the output word and fraction lengths, and the accumulator word and fraction lengths automatically to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision exposes the output and accumulator related properties so you can set your own word and fraction lengths for them.
FilterStructure	mfilt structure string	None	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output. You cannot set this property — it is always read only and results from your choice of mfilt object.

Name	Values	Default	Description
InputOffset	Integers	0	Contains the number of input data samples processed without generating an output sample. InputOffset = mod(length(nx),m) where nx is the number of input samples that have been processed so far and m is the decimation factor.
InterpolationFactor	Positive integers	2	Interpolation factor for the filter. 1 specifies the amount to increase the input sampling rate.
NumberOfSections	Any positive integer	2	Number of sections used in the decimator, or in the comb and integrator portions of CIC filters.
Numerator	Array of double values	No default values	Vector containing the coefficients of the FIR lowpass filter used for interpolation.
OverflowMode	saturate, [wrap]	wrap	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic. The choice you make affects only the accumulator and output

Name	Values	Default	Description
			arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
PolyphaseAccum	Values depend on filter type. Either double, single, or fixed-point object	0	Stores the value remaining in the accumulator after the filter processes the last input sample. The stored value for `PolyphaseAccum` affects the next output when `PersistentMemory` is `true` and `InputOffset` is not equal to 0. Always provides full precision values. Compare the `AccumWordLength` and `AccumFracLength`.
PersistentMemory	`false` or `true`	`false`	Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.

Name	Values	Default	Description
RateChangeFactors	[l,m]	[2,3] or [3,2]	Reports the decimation (m) and interpolation (l) factors for the filter object. Combining these factors results in the final rate change for the signal. The default changes depending on whether the filter decimates or interpolates.
States	Any m+1-by-n matrix of double values	2-by-2 matrix, int32	Stored conditions for the filter, including values for the integrator and comb sections. n is the number of filter sections and m is the differential delay. Stored in a filtstates object.
SpecifyWordLengths	Vector of integers	[16 16 16 16] bits	
WordLengthPerSection	Any integer or a vector of length 2*n	16	Defines the word length used in each section while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter WordLengthPerSection as a scalar or vector of length 2*n, where n is the number of sections. When WordLengthPerSection is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the decimator.

The following sections provide details about the properties that govern the way multirate filter work. Creating any multirate filter object puts in place a number of these properties. The following pages list the `mfilt` object properties in alphabetical order.

Property Details for Multirate Filter Properties

BitsPerSection
Any integer or a vector of length 2*n.

Defines the bits per section used while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using `wrap` arithmetic). Enter `bps` as a scalar or vector of length 2*n, where `n` is the number of sections. When `bps` is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the decimator.

BlockLength
Length of each block of input data used in the filtering.

`mfilt.fftfirinterp` objects process data in blocks whose length is determined by the value you set for the `BlockLength` property. By default the property value is 100. When you set the `BlockLength` value, try choosing a value so that [`BlockLength` + `length`(filter order)] is a power of two.

Larger block lengths generally reduce the computation time.

DecimationFactor
Decimation factor for the filter. `m` specifies the amount to reduce the sampling rate of the input signal. It must be an integer. You can enter any integer value. The default value is 2.

DifferentialDelay
Sets the differential delay for the filter. Usually a value of one or two is appropriate. While you can set any value, the default is one and the maximum is usually two.

FilterInternals

Similar to the FilterInternals pane in FDATool, this property controls whether the filter sets the output word and fraction lengths automatically, and the accumulator word and fraction lengths automatically as well, to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. Setting FilterInternals to SpecifyPrecision exposes the output and accumulator related properties so you can set your own word and fraction lengths for them.

About FilterInternals Mode. There are four usage modes for this that you set using the FilterInternals property in multirate filters.

- FullPrecision — All word and fraction lengths set to B_{max} + 1, called B_{accum} by Fred Harris in [2]. Full precision is the default setting.

- MinWordLengths — Minimum Word Lengths

- SpecifyWordLengths — Specify Word Lengths

- SpecifyPrecision — Specify Precision

Full Precision

In full precision mode, the word lengths of all sections and the output are set to B_{accum} as defined by

$$B_{accum} = ceil(N_{sec\,s}(Log_2(D \times M)) + InputWordLength)$$

where N_{secs} is the number of filter sections.

Section fraction lengths and the fraction length of the output are set to the input fraction length.

Here is the display looks for this mode.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false
```

```
InputWordLength: 16
InputFracLength: 15

FilterInternals: 'FullPrecision'
```

Minimum Word Lengths

In minimum word length mode, you control the output word length explicitly. When the output word length is less than B_{accum}, roundoff noise is introduced at the output of the filter. Hogenauer's bit pruning theory (refer to [3] in the following References section) states that one valid design criterion is to make the word lengths of the different sections of the filter smaller than B_{accum} as well, so that the roundoff noise introduced by all sections does not exceed the roundoff noise introduced at the output.

In this mode, the design calculates the word lengths of each section to meet the Hogenauer criterion. The algorithm subtracts the number of bits computed using eq. 21 in Hogenauer's paper from B_{accum} to determine the word length each section.

To compute the fraction lengths of the different sections, the algorithm notes that the bits thrown out for this word length criterion are least significant bits (LSB), therefore each bit thrown out at a particular section decrements the fraction length of that section by one bit compared to the input fraction length. Setting the output word length for the filter automatically sets the output fraction length as well.

Here is the display for this mode:

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15
```

```
FilterInternals: 'MinWordLengths'
```

```
OutputWordLength: 16
```

Specify Word Lengths

In this mode, the design algorithm discards the LSBs, adjusting the fraction length so that unrecoverable overflow does not occur, always producing a reasonable output.

You can specify the word lengths for all sections and the output, but you cannot control the fraction lengths for those quantities.

To specify the word lengths, you enter a vector of length 2*(`NumberOfSections`), where each vector element represents the word length for a section. If you specify a calar, such as B_{accum}, the full-precision output word length, the algorithm expands that scalar to a vector of the appropriate size, applying the scalar value to each section.

The CIC design does not check that the specified word lengths are monotonically decreasing. There are some cases where the word lengths are not necessarily monotonically decreasing, for example

```
hcic=mfilt.cicdecim;
hcic.FilterInternals='minwordlengths';
hcic.Outputwordlength=14;
```

which are valid CIC filters but the word lengths do not decrease monotonically across the sections.

Here is the display looks like for the `SpecifyWordLengths` mode.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15
```

```
FilterInternals: 'SpecifyWordLengths'

SectionWordLengths: [19 18 18 17]

OutputWordLength: 16
```

Specify Precision

In this mode, you have full control over the word length and fraction lengths of all sections and the filter output.

When you elect the `SpecifyPrecision` mode, you must enter a vector of length 2*(`NumberOfSections`) with elements that represent the word length for each section. When you enter a scalar such as B_{accum}, the CIC algorithm expands that scalar to a vector of the appropriate size and applies the scalar value to each section and the output. The design does not check that this vector is monotonically decreasing.

Also, you must enter a vector of length 2*(`NumberOfSections`) with elements that represent the fraction length for each section as well. When you enter a calar such as B_{accum}, the design applies scalar expansion as done for the word lengths.

Here is the `SpecifyPrecision` display.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'SpecifyPrecision'

SectionWordLengths: [19 18 18 17]
SectionFracLengths: [14 13 13 12]
```

```
OutputWordLength: 16
OutputFracLength: 11
```

FilterStructure

Reports the type of filter object, such as a decimator or fractional integrator. You cannot set this property — it is always read only and results from your choice of `mfilt` object. Because of the length of the names of multirate filters, `FilterStructure` often returns a vector specification for the string. For example, when you use `mfilt.firfracinterp` to design a filter, `FilterStructure` returns as [1x49 char].

```
hm=mfilt.firfracinterp

hm =

         FilterStructure: [1x49 char]
               Numerator: [1x72 double]
        RateChangeFactors: [3 2]
         PersistentMemory: false
                   States: [24x1 double]
```

InputOffset

When you decimate signals whose length is not a multiple of the decimation factor M, the last samples — (nM +1) to [(n+1)(M) -1], where *n* is an integer — are processed and used to track where the filter stopped processing input data and when to expect the next output sample. If you think of the filtering process as generating an output for a block of input data, `InputOffset` contains a count of the number of samples in the last incomplete block of input data.

Note `InputOffset` applies only when you set `PersistentMemory` to `true`. Otherwise, `InputOffset` is not available for you to use.

Two different cases can arise when you decimate a signal:

1 The input signal is a multiple of the filter decimation factor. In this case, the filter processes the input samples and generates output samples for all inputs as determined by the decimation factor. For example, processing 99 input samples with a filter that decimates by three returns 33 output samples.

2 The input signal is not a multiple of the decimation factor. When this occurs, the filter processes all of the input samples, generates output samples as determined by the decimation factor, and has one or more input samples that were processed but did not generate an output sample.

For example, when you filter 100 input samples with a filter which has decimation factor of 3, you get 33 output samples, and 1 sample that did not generate an output. In this case, `InputOffset` stores the value 1 after the filter run.

`InputOffset` equal to 1 indicates that, if you divide your input signal into blocks of data with length equal to your filter decimation factor, the filter processed one sample from a new (incomplete) block of data. Subsequent inputs to the filter are concatenated with this single sample to form the next block of length m.

One way to define the value stored in `InputOffset` is

`InputOffset = mod(length(nx),m)`

where `nx` is the number of input samples in the data set and `m` is the decimation factor.

Storing `InputOffset` in the filter allows you to stop filtering a signal at any point and start over from there, provided that the `PersistentMemory` property is set to `true`. Being able to resume filtering after stopping a signal lets you break large data sets in to smaller pieces for filtering. With `PersistentMemory` set to `true` and the `InputOffset` property in the filter, breaking a signal into sections of arbitrary length and filtering the sections is equivalent to filtering the entire signal at once.

```
xtot=[x,x];
ytot=filter(hm1,xtot)
ytot =
```

```
          0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
reset(hm1);  % Clear history of the filter
hm1.PersistentMemory='true';
ysec=[filter(hm1,x) filter(hm1,x)]

ysec =

          0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
```

This test verifies that `ysec` (the signal filtered by sections) is equal to `ytot` (the entire signal filtered at once).

InterpolationFactor

Amount to increase the sampling rate. Interpolation factor for the filter. It specifies the amount to increase the input sampling rate. It must be an integer. Two is the default value. You may use any positive value.

NumberOfSections

Number of sections used in the multirate filter. By default multirate filters use two sections, but any positive integer works.

OverflowMode

The `OverflowMode` property is specified as one of the following two strings indicating how to respond to overflows in fixed-point arithmetic:

- `'saturate'` — saturate overflows.

  When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the applicable word length and fraction length properties), these values are quantized to the value of either the largest or smallest representable value, depending on which is closest.

- `'wrap'` — wrap all overflows to the range of representable values.

  When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the data format properties), these values are wrapped back into that range using modular

arithmetic relative to the smallest representable number. You can learn more about modular arithmetic in Fixed-Point Toolbox documentation.

These rules apply to the `OverflowMode` property.

- Applies to the accumulator and output data only.

- Does not apply to coefficients or input data. These always saturate the results.

- Does not apply to products. Products maintain full precision at all times. Your filters do not lose precision in the products.

Default value: `'saturate'`

Note Numbers in floating-point filters that extend beyond the dynamic range overflow to ±`inf`.

PolyphaseAccum

The idea behind `PolyphaseAccum` and `AccumWordLength/AccumFracLength` is to distinguish between the adders that always work in full precision (`PolyphaseAccum`) from the others [the adders that are controlled by the user (through `AccumWordLength` and `AccumFracLength`) and that may introduce quantization effects when you set property `FilterInternals` to `SpecifyPrecision`].

Given a product format determined by the input word and fraction lengths, and the coefficients word and fraction lengths, doing full precision accumulation means allowing enough guard bits to avoid overflows and underflows.

Property `PolyphaseAccum` stores the value that was in the accumulator the last time your filter ran out of input samples to process. The default value for `PolyphaseAccum` affects the next output only if `PersistentMemory` is `true` and `InputOffset` is not equal to 0.

`PolyphaseAccum` stores data in the format for the filter arithmetic. Double-precision filters store doubles in `PolyphaseAccum`. Single-precision

filter store singles in `PolyphaseAccum`. Fixed-point filters store `fi` objects in `PolyphaseAccum`.

PersistentMemory

Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.

Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter object. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `true` — the filter retains memory about filtering operations from one to the next. Maintaining memory lets you filter large data sets as collections of smaller subsets and get the same result.

```
xtot=[x,x];
ytot=filter(hm1,xtot)
ytot =

        0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
reset(hm1);  % Clear history of the filter
hm1.PersistentMemory='true';
ysec=[filter(hm1,x) filter(hm1,x)]

ysec =

        0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
```

This test verifies that `ysec` (the signal filtered by sections) is equal to `ytot` (the entire signal filtered at once).

RateChangeFactors

Reports the decimation (m) and interpolation (l) factors for the filter object when you create fractional integrators and decimators, although m and l are used as arguments to both decimators and integrators, applying the

same meaning. Combining these factors as input arguments to the fractional decimator or integrator results in the final rate change for the signal.

For decimating filters, the default is [2,3]. For integrators, [3,2].

States

Stored conditions for the filter, including values for the integrator and comb sections. m is the differential delay and n is the number of sections in the filter.

About the States of Multirate Filters. In the states property you find the states for both the integrator and comb portions of the filter, stored in a filtstates object. states is a matrix of dimensions m+1-by-n, with the states in CIC filters apportioned as follows:

- States for the integrator portion of the filter are stored in the first row of the state matrix.

- States for the comb portion fill the remaining rows in the state matrix.

In the state matrix, state values are specified and stored in double format.

States stores conditions for the delays between each interpolator phase, the filter states, and the states at the output of each phase in the filter, including values for the interpolator and comb states.

The number of states is (lh-1)*m+(l-1)*(lo+mo) where lh is the length of each subfilter, and l and m are the interpolation and decimation factors. lo and mo, the input and output delays between each interpolation phase, are integers from Euclid's theorem such that lo*l-mo*m = -1 (refer to the reference for more details). Use euclidfactors to get lo and mo for an mfilt.firfracdecim object.

States defaults to a vector of zeros that has length equal to nstates(hm)

Glossary

This glossary defines terms related to fixed-point data types and numbers. These terms may appear in some or all of the documents that describe MathWorks® products that have fixed-point support.

arithmetic shift

Shift of the bits of a binary word for which the sign bit is recycled for each bit shift to the right. A zero is incorporated into the least significant bit of the word for each bit shift to the left. In the absence of overflows, each arithmetic shift to the right is equivalent to a division by 2, and each arithmetic shift to the left is equivalent to a multiplication by 2.

See also binary point, binary word, bit, logical shift, most significant bit

bias

Part of the numerical representation used to interpret a fixed-point number. Along with the slope, the bias forms the scaling of the number. Fixed-point numbers can be represented as

$$real\text{-}world\ value = (slope \times stored\ integer) + bias$$

where the slope can be expressed as

$$slope = fractional\ slope \times 2^{exponent}$$

See also fixed-point representation, fractional slope, integer, scaling, slope, [Slope Bias]

binary number

Value represented in a system of numbers that has two as its base and that uses 1's and 0's (bits) for its notation.

See also bit

binary point

Symbol in the shape of a period that separates the integer and fractional parts of a binary number. Bits to the left of the binary point are integer bits and/or sign bits, and bits to the right of the binary point are fractional bits.

See also binary number, bit, fraction, integer, radix point

binary point-only scaling

Scaling of a binary number that results from shifting the binary point of the number right or left, and which therefore can only occur by powers of two.

See also binary number, binary point, scaling

binary word

Fixed-length sequence of bits (1's and 0's). In digital hardware, numbers are stored in binary words. The way in which hardware components or software functions interpret this sequence of 1's and 0's is described by a data type.

See also bit, data type, word

bit

Smallest unit of information in computer software or hardware. A bit can have the value 0 or 1.

ceiling (round toward)

Rounding mode that rounds to the closest representable number in the direction of positive infinity. This is equivalent to the `ceil` mode in Fixed-Point Toolbox software.

See also convergent rounding, floor (round toward), nearest (round toward), rounding, truncation, zero (round toward)

contiguous binary point

Binary point that occurs within the word length of a data type. For example, if a data type has four bits, its contiguous binary point must be understood to occur at one of the following five positions:

.0000

0.000

00.00

000.0

0000.

See also data type, noncontiguous binary point, word length

convergent rounding

Rounding mode that rounds to the nearest allowable quantized value. Numbers that are exactly halfway between the two nearest allowable quantized values are rounded up only if the least significant bit (after rounding) would be set to 0.

See also ceiling (round toward), floor (round toward), nearest (round toward), rounding, truncation, zero (round toward)

data type

Set of characteristics that define a group of values. A fixed-point data type is defined by its word length, its fraction length, and whether it is signed or unsigned. A floating-point data type is defined by its word length and whether it is signed or unsigned.

See also fixed-point representation, floating-point representation, fraction length, signedness, word length

data type override

Parameter in the Fixed-Point Tool that allows you to set the output data type and scaling of fixed-point blocks on a system or subsystem level.

See also data type, scaling

exponent

Part of the numerical representation used to express a floating-point or fixed-point number.

1. Floating-point numbers are typically represented as

$$real\text{-}world\ value = mantissa \times 2^{exponent}$$

2. Fixed-point numbers can be represented as

$$real\text{-}world\ value = (slope \times stored\ integer) + bias$$

where the slope can be expressed as

$$slope = fractional\ slope \times 2^{exponent}$$

The exponent of a fixed-point number is equal to the negative of the fraction length:

$$exponent = -1 \times fraction\ length$$

See also bias, fixed-point representation, floating-point representation, fraction length, fractional slope, integer, mantissa, slope

fixed-point representation

Method for representing numerical values and data types that have a set range and precision.

1. Fixed-point numbers can be represented as

$$real\text{-}world\ value = (slope \times stored\ integer) + bias$$

where the slope can be expressed as

$$slope = fractional\ slope \times 2^{exponent}$$

The slope and the bias together represent the scaling of the fixed-point number.

2. Fixed-point data types can be defined by their word length, their fraction length, and whether they are signed or unsigned.

See also bias, data type, exponent, fraction length, fractional slope, integer, precision, range, scaling, slope, word length

floating-point representation

Method for representing numerical values and data types that can have changing range and precision.

1. Floating-point numbers can be represented as

$$real\text{-}world\ value = mantissa \times 2^{exponent}$$

2. Floating-point data types are defined by their word length.

See also data type, exponent, mantissa, precision, range, word length

floor (round toward)

Rounding mode that rounds to the closest representable number in the direction of negative infinity.

See also ceiling (round toward), convergent rounding, nearest (round toward), rounding, truncation, zero (round toward)

fraction

Part of a fixed-point number represented by the bits to the right of the binary point. The fraction represents numbers that are less than one.

See also binary point, bit, fixed-point representation

fraction length

Number of bits to the right of the binary point in a fixed-point representation of a number.

See also binary point, bit, fixed-point representation, fraction

fractional slope

Part of the numerical representation used to express a fixed-point number. Fixed-point numbers can be represented as

$$real\text{-}world\ value = (slope \times stored\ integer) + bias$$

where the slope can be expressed as

$$slope = fractional\ slope \times 2^{exponent}$$

The term *slope adjustment* is sometimes used as a synonym for fractional slope.

See also bias, exponent, fixed-point representation, integer, slope

full range

The broadest range available for a data type. From $-\infty$ to ∞ for floating-point types. For integer types, the representable range is the range from the smallest to largest integer value (finite) the type can represent. For example, from -128 to 127 for a signed 8–bit integer. Also known as representable range.

guard bits

Extra bits in either a hardware register or software simulation that are added to the high end of a binary word to ensure that no information is lost in case of overflow.

See also binary word, bit, overflow

incorrect range

A range that is too restrictive and does not include values that can actually occur in the model element. A range that is too broad is not considered incorrect because it will not lead to overflow.

See also range analysis

integer

1. Part of a fixed-point number represented by the bits to the left of the binary point. The integer represents numbers that are greater than or equal to one.

2. Also called the "stored integer." The raw binary number, in which the binary point is assumed to be at the far right of the word. The integer is part of the numerical representation used to express a fixed-point number. Fixed-point numbers can be represented as

$$real\text{-}world\ value = 2^{-fraction\ length} \times stored\ integer$$

or

$$real\text{-}world\ value = (slope \times stored\ integer) + bias$$

where the slope can be expressed as

$$slope = fractional\ slope \times 2^{exponent}$$

See also bias, fixed-point representation, fractional slope, integer, real-world value, slope

integer length

Number of bits to the left of the binary point in a fixed-point representation of a number.

See also binary point, bit, fixed-point representation, fraction length, integer

least significant bit (LSB)

Bit in a binary word that can represent the smallest value. The LSB is the rightmost bit in a big-endian-ordered binary word. The weight of the LSB is related to the fraction length according to

$$weight\ of\ LSB = 2^{-fraction\ length}$$

See also big-endian, binary word, bit, most significant bit

logical shift

Shift of the bits of a binary word, for which a zero is incorporated into the most significant bit for each bit shift to the right and into the least significant bit for each bit shift to the left.

See also arithmetic shift, binary point, binary word, bit, most significant bit

mantissa

Part of the numerical representation used to express a floating-point number. Floating-point numbers are typically represented as

$$real\text{-}world\ value = mantissa \times 2^{exponent}$$

See also exponent, floating-point representation

model element

Entities in a model that range analysis software tracks, for example, blocks, signals, parameters, block internal data (such as accumulators, products).

See also range analysis

most significant bit (MSB)

Bit in a binary word that can represent the largest value. The MSB is the leftmost bit in a big-endian-ordered binary word.

See also binary word, bit, least significant bit

nearest (round toward)

Rounding mode that rounds to the closest representable number, with the exact midpoint rounded to the closest representable number in the direction of positive infinity. This is equivalent to the `nearest` mode in Fixed-Point Toolbox software.

See also ceiling (round toward), convergent rounding, floor (round toward), rounding, truncation, zero (round toward)

noncontiguous binary point

Binary point that is understood to fall outside the word length of a data type. For example, the binary point for the following 4-bit word is understood to occur two bits to the right of the word length,

0000__.

thereby giving the bits of the word the following potential values:

$2^5 2^4 2^3 2^2$ __.

See also binary point, data type, word length

one's complement representation

Representation of signed fixed-point numbers. Negating a binary number in one's complement requires a bitwise complement. That is, all 0's are flipped to 1's and all 1's are flipped to 0's. In one's complement notation there are two ways to represent zero. A binary word of all 0's represents "positive" zero, while a binary word of all 1's represents "negative" zero.

See also binary number, binary word, sign/magnitude representation, signed fixed-point, two's complement representation

overflow

Situation that occurs when the magnitude of a calculation result is too large for the range of the data type being used. In many cases you can choose to either saturate or wrap overflows.

See also saturation, wrapping

padding

Extending the least significant bit of a binary word with one or more zeros.

See also least significant bit

precision

1. Measure of the smallest numerical interval that a fixed-point data type and scaling can represent, determined by the value of the number's least significant bit. The precision is given by the slope, or the number

of fractional bits. The term *resolution* is sometimes used as a synonym for this definition.

2. Measure of the difference between a real-world numerical value and the value of its quantized representation. This is sometimes called quantization error or quantization noise.

See also data type, fraction, least significant bit, quantization, quantization error, range, slope

Q format

Representation used by Texas Instruments™ to encode signed two's complement fixed-point data types. This fixed-point notation takes the form

$Qm.n$

where

- *Q* indicates that the number is in Q format.

- *m* is the number of bits used to designate the two's complement integer part of the number.

- *n* is the number of bits used to designate the two's complement fractional part of the number, or the number of bits to the right of the binary point.

In Q format notation, the most significant bit is assumed to be the sign bit.

See also binary point, bit, data type, fixed-point representation, fraction, integer, two's complement

quantization

Representation of a value by a data type that has too few bits to represent it exactly.

See also bit, data type, quantization error

quantization error

Error introduced when a value is represented by a data type that has too few bits to represent it exactly, or when a value is converted from

one data type to a shorter data type. Quantization error is also called
quantization noise.

See also bit, data type, quantization

radix point

Symbol in the shape of a period that separates the integer and fractional
parts of a number in any base system. Bits to the left of the radix point
are integer and/or sign bits, and bits to the right of the radix point are
fraction bits.

See also binary point, bit, fraction, integer, sign bit

range

Span of numbers that a certain data type can represent.

See also data type, full range, precision, representable range

range analysis

Static analysis of model to derive minimum and maximum range values for elements in the model. The software statically analyzes the ranges of the individual computations in the model based on specified design ranges, inputs, and the semantics of the calculation.

real-world value

Stored integer value with fixed-point scaling applied. Fixed-point numbers can be represented as

$$real\text{-}world\ value = 2^{-fraction\ length} \times stored\ integer$$

or

$$real\text{-}world\ value = (slope \times stored\ integer) + bias$$

where the slope can be expressed as

$$slope = fractional\ slope \times 2^{exponent}$$

See also integer

representable range

The broadest range available for a data type. From $-\infty$ to ∞ for floating-point types. For integer types, the representable range is the range from the smallest to largest integer value (finite) the type can represent. For example, from -128 to 127 for a signed 8–bit integer. Also known as full range.

resolution

See **precision**

rounding

Limiting the number of bits required to express a number. One or more least significant bits are dropped, resulting in a loss of precision. Rounding is necessary when a value cannot be expressed exactly by the number of bits designated to represent it.

See also bit, ceiling (round toward), convergent rounding, floor (round toward), least significant bit, nearest (round toward), precision, truncation, zero (round toward)

saturation

Method of handling numeric overflow that represents positive overflows as the largest positive number in the range of the data type being used, and negative overflows as the largest negative number in the range.

See also overflow, wrapping

scaled double

A double data type that retains fixed-point scaling information. For example, in Simulink and Fixed-Point Toolbox software you can use data type override to convert your fixed-point data types to scaled doubles. You can then simulate to determine the ideal floating-point behavior of your system. After you gather that information you can turn data type override off to return to fixed-point data types, and your quantities still have their original scaling information because it was held in the scaled double data types.

scaling

1. Format used for a fixed-point number of a given word length and signedness. The slope and bias together form the scaling of a fixed-point number.

2. Changing the slope and/or bias of a fixed-point number without changing the stored integer.

See also bias, fixed-point representation, integer, slope

shift

Movement of the bits of a binary word either toward the most significant bit ("to the left") or toward the least significant bit ("to the right"). Shifts to the right can be either logical, where the spaces emptied at the front of the word with each shift are filled in with zeros, or arithmetic, where the word is sign extended as it is shifted to the right.

See also arithmetic shift, logical shift, sign extension

sign bit

Bit (or bits) in a signed binary number that indicates whether the number is positive or negative.

See also binary number, bit

sign extension

Addition of bits that have the value of the most significant bit to the high end of a two's complement number. Sign extension does not change the value of the binary number.

See also binary number, guard bits, most significant bit, two's complement representation, word

sign/magnitude representation

Representation of signed fixed-point or floating-point numbers. In sign/magnitude representation, one bit of a binary word is always the dedicated sign bit, while the remaining bits of the word encode the magnitude of the number. Negation using sign/magnitude representation consists of flipping the sign bit from 0 (positive) to 1 (negative), or from 1 to 0.

See also binary word, bit, fixed-point representation, floating-point representation, one's complement representation, sign bit, signed fixed-point, signedness, two's complement representation

signed fixed-point

Fixed-point number or data type that can represent both positive and negative numbers.

See also data type, fixed-point representation, signedness, unsigned fixed-point

signedness

The signedness of a number or data type can be signed or unsigned. Signed numbers and data types can represent both positive and negative values, whereas unsigned numbers and data types can only represent values that are greater than or equal to zero.

See also data type, sign bit, sign/magnitude representation, signed fixed-point, unsigned fixed-point

slope

Part of the numerical representation used to express a fixed-point number. Along with the bias, the slope forms the scaling of a fixed-point number. Fixed-point numbers can be represented as

$$real\text{-}world\ value = (slope \times stored\ integer) + bias$$

where the slope can be expressed as

$$slope = fractional\ slope \times 2^{exponent}$$

See also bias, fixed-point representation, fractional slope, integer, scaling, [Slope Bias]

slope adjustment

See **fractional slope**

[Slope Bias]

Representation used to define the scaling of a fixed-point number.

See also bias, scaling, slope

stored integer

See **integer**

trivial scaling

Scaling that results in the real-world value of a number being simply equal to its stored integer value:

$$real\text{-}world\ value = stored\ integer$$

In [Slope Bias] representation, fixed-point numbers can be represented as

$$real\text{-}world\ value = (slope \times stored\ integer) + bias$$

In the trivial case, slope = 1 and bias = 0.

In terms of binary point-only scaling, the binary point is to the right of the least significant bit for trivial scaling, meaning that the fraction length is zero:

$$real\text{-}world\ value = stored\ integer \times 2^{-fraction\ length} = stored\ integer \times 2^0$$

Scaling is always trivial for pure integers, such as `int8`, and also for the true floating-point types `single` and `double`.

See also bias, binary point, binary point-only scaling, fixed-point representation, fraction length, integer, least significant bit, scaling, slope, [Slope Bias]

truncation

Rounding mode that drops one or more least significant bits from a number.

See also ceiling (round toward), convergent rounding, floor (round toward), nearest (round toward), rounding, zero (round toward)

two's complement representation

Common representation of signed fixed-point numbers. Negation using signed two's complement representation consists of a translation into one's complement followed by the binary addition of a one.

See also binary word, one's complement representation, sign/magnitude representation, signed fixed-point

unsigned fixed-point

Fixed-point number or data type that can only represent numbers greater than or equal to zero.

See also data type, fixed-point representation, signed fixed-point, signedness

word

Fixed-length sequence of binary digits (1's and 0's). In digital hardware, numbers are stored in words. The way hardware components or software functions interpret this sequence of 1's and 0's is described by a data type.

See also binary word, data type

word length

Number of bits in a binary word or data type.

See also binary word, bit, data type

wrapping

Method of handling overflow. Wrapping uses modulo arithmetic to cast a number that falls outside of the representable range the data type being used back into the representable range.

See also data type, overflow, range, saturation

zero (round toward)

Rounding mode that rounds to the closest representable number in the direction of zero. This is equivalent to the `fix` mode in Fixed-Point Toolbox software.

See also ceiling (round toward), convergent rounding, floor (round toward), nearest (round toward), rounding, truncation

Index
