getfield(grades, {level}, fieldnames{:}, {10,21:30})
```

---

Using the structure defined in the previous example, find all values in the tenth row of the specified field:

```
getfield(grades, {level}, fieldnames{:}, {10,':'})
```

## See Also

[setfield](#) | [fieldnames](#) | [isfield](#) | [orderfields](#) | [rmfield](#)

## How To

- “Generate Field Names from Variables”
- “Access Data in a Structure Array”

**Purpose** File formats that VideoReader supports

**Syntax** `formats = VideoReader.getFileFormats()`

**Description** `formats = VideoReader.getFileFormats()` returns an array of `audiovideo.FileFormatInfo` objects that indicate which formats VideoReader can read on the current system. Each object has the following properties: `Extension`, `Description`, `ContainsVideo`, and `ContainsAudio`.

- Tips**
- On Windows and UNIX systems, the list of file formats does not always contain all the formats that VideoReader can read on your system. `getFileFormats` returns a platform-dependent, static list of formats that VideoReader can read on most systems.
  - On all systems, VideoReader cannot always read a particular video file even if `getFileFormats` lists its format. For more information, see Supported Video File Formats.

## Output Arguments

### **formats**

Array of `audiovideo.FileFormatInfo` objects, which have the following properties:

<code>Extension</code>	File extension.
<code>Description</code>	Text description of the file format.
<code>ContainsVideo</code>	Whether VideoReader can read video from this format.
<code>ContainsAudio</code>	Whether VideoReader can read audio from this format.

To convert this array to a filter list for dialog boxes generated with `uigetfile`, use the `getFilterSpec` method with the following syntax:

# VideoReader.getFileFormats

---

```
filterSpec = getFilterSpec(formats)
```

The filter list includes 'All Video Files' in the first row of the cell array, and 'All Files (\*.\*)' in the last row.

## Examples

View the list of file formats that VideoReader supports on your system:

```
VideoReader.getFileFormats()
```

On a Windows system, this list appears as follows:

```
Video File Formats:  
  .asf - ASF File  
  .asx - ASX File  
  .avi - AVI File  
  .mj2 - Motion JPEG2000  
  .mpg - MPEG-1  
  .wmv - Windows Media Video
```

---

Create a dialog box to select a video file:

```
% Get the supported file formats.  
formats = VideoReader.getFileFormats();  
  
% Convert to a filter list.  
filterSpec = getFilterSpec(formats);  
  
% Create the dialog box.  
[filename, pathname] = uigetfile(filterSpec);
```

---

Check whether VideoReader can read an .avi file on the current system:

```
fmtList = VideoReader.getFileFormats();
```

```
if any(ismember({fmtList.Extension},'avi'))
    disp('VideoReader can read AVI files on this system.');
```

else

```
    disp('VideoReader cannot read AVI files on this system.');
```

end

## See Also

VideoReader

# getframe

---

**Purpose** Capture movie frame

**Syntax**

```
getframe
F = getframe
F = getframe(h)
F = getframe(h,rect)
```

**Description** `getframe` returns a movie frame. The frame is a snapshot (pixmap) of the current axes or figure.

`F = getframe` gets a frame from the current axes.

`F = getframe(h)` gets a frame from the figure or axes identified by handle `h`.

`F = getframe(h,rect)` specifies a rectangular area from which to copy the pixmap. `rect` is relative to the lower left corner of the figure or axes `h`, in pixel units. `rect` is a four-element vector in the form `[left bottom width height]`, where `width` and `height` define the dimensions of the rectangle.

`getframe` returns a movie frame, which is a structure having two fields:

- `cdata` — The image data stored as a matrix of `uint8` values. The dimensions of `F.cdata` are height-by-width-by-3.
- `colormap` — The colormap stored as an `n-by-3` matrix of doubles. `F.colormap` is empty on true color systems.

To capture an image, use this approach:

```
F = getframe(gcf);
image(F.cdata)
colormap(F.colormap)
```

**Tips** `getframe` is usually used in a `for` loop to assemble an array of movie frames for playback using `movie`. For example,

```
for j = 1:n
    plotting commands
    F(j) = getframe;
```

```
end  
movie(F)
```

If you are capturing frames of a plot that takes a long time to generate or are repeatedly calling `getframe` in a loop, make sure that your computer's screen saver does not activate and that your monitor does not turn off for the duration of the capture; otherwise one or more of the captured frames can contain graphics from your screen saver or nothing at all.

---

**Note** In situations where MATLAB software is running on a virtual desktop that is not currently visible on your monitor, calls to `getframe` will complete, but will capture a region on your monitor that corresponds to the position occupied by the figure or axes on the hidden desktop. Therefore, make sure that the window to be captured by `getframe` exists on the currently active desktop.

---

### Capture Regions

`F = getframe` returns the contents of the current axes, exclusive of the axis labels, title, or tick labels.

`F = getframe(gcf)` captures the entire interior of the current figure window.

To capture the figure window menu, use `F = getframe(h,rect)` with a rectangle sized to include the menu.

### Resolution of Captured Frames

The resolution of the framed image depends on the size of the axes in pixels when `getframe` is called. As the `getframe` command takes a snapshot of the screen, if the axes is small in size (e.g., because you have restricted the view to a window within the axes), `getframe` captures fewer screen pixels, and the captured image might have poor resolution if enlarged for display.

## Capturing UIControls

To capture uicontrols along with the axes and any annotations displayed on the plot, specify the figure handle:

```
F = getframe(figure_handle);
```

To exclude uicontrols outside of the current axes, do not specify the figure handle:

```
F = getframe;
```

## Limitations with Renderer on Windows Systems

Setting the figure `Renderer` property to `zbuffer` or `painters` works around limitations of using `getframe` with the OpenGL renderer on some Windows systems.

## Examples

Make the peaks function vibrate.

```
Z = peaks;
figure('Renderer','zbuffer');
surf(Z);
axis tight;
set(gca,'NextPlot','replaceChildren');
for j = 1:20
    surf(sin(2*pi*j/20)*Z,Z)
    F(j) = getframe;
end
movie(F,20) % Play the movie twenty times
```

The fifth frame of the sequence looks like this.

# GetFullMatrix

---

**Purpose** Matrix from Automation server workspace

**Syntax** **MATLAB Client**  
[xreal ximag] =  
h.GetFullMatrix('varname', 'workspace', zreal,  
zimag)  
[xreal ximag] =  
GetFullMatrix(h, 'varname', 'workspace', zreal,  
zimag)

## IDL Method Signature

```
GetFullMatrix([in] BSTR varname, [in] BSTR  
workspace, [in, out] SAFEARRAY(double) *pr, [in,  
out] SAFEARRAY(double) *pi)
```

## Microsoft Visual Basic Client

```
GetFullMatrix(varname As String, workspace As String,  
[out] XReal As Double, [out] XImag As Double)
```

**Description** [xreal ximag] =  
h.GetFullMatrix('varname', 'workspace', zreal, zimag) gets  
matrix stored in variable varname from the specified workspace of the  
server attached to handle h. The function returns the real  
part in xreal and the imaginary part in ximag. The values  
for *workspace* are base or global.

[xreal ximag] =  
GetFullMatrix(h, 'varname', 'workspace', zreal, zimag) is an  
alternate syntax.

The zreal and zimag arguments are matrices of the same size as the  
real and imaginary matrices (xreal and ximag) returned from the  
server. The zreal and zimag matrices are commonly set to zero.

Use GetFullMatrix for values of type double only. Use GetVariable or  
GetWorkspaceData for other types.

For VBScript clients, use the `GetWorkspaceData` and `PutWorkspaceData` functions to pass numeric data to and from the MATLAB workspace. These functions use the `variant` data type instead of the `safearray` data type used by `GetFullMatrix` and `PutFullMatrix`. VBScript does not support `safearray`.

## Examples

This example uses a MATLAB client to read data from a MATLAB Automation server:

```
%Create the MATLAB server
h = actxserver('matlab.application');
%Create variable M in the base workspace of the server
h.PutFullMatrix('M','base',rand(5),zeros(5));
MReal = h.GetFullMatrix('M','base',zeros(5),zeros(5))
```

---

This example uses a Visual Basic .NET client to read data from a MATLAB Automation server:

- 1 Create the Visual Basic application. Use the `MsgBox` command to control flow between MATLAB and the application.

```
Dim MatLab As Object
Dim Result As String
Dim XReal(4, 4) As Double
Dim XImag(4, 4) As Double
Dim i, j As Integer

MatLab = CreateObject("matlab.application")
Result = MatLab.Execute("M = rand(5);")
MsgBox("In MATLAB, type" & vbCrLf _
    & "M(3,4)")
```

- 2 Open the MATLAB window and type:

```
M(3,4)
```

# GetFullMatrix

---

**3** Click **Ok**.

**4** In the Visual Basic application:

```
MatLab.GetFullMatrix("M", "base", XReal, XImag)
i = 2    %0-based array
j = 3
```

```
MsgBox("XReal(" & i + 1 & ", " & j + 1 & ")") & _
      " = " & XReal(i, j))
```

**5** Click **Ok** to close and terminate MATLAB.

## How To

- “Exchanging Data with the Server”
- “MATLAB COM Automation Server Interface”

**Purpose** Get component position in pixels

**Syntax**

```
position = getpixelposition(handle)
position = getpixelposition(handle,recursive)
```

**Description**

`position = getpixelposition(handle)` gets the position, in pixel units, of the component with handle `handle`. The `position` is returned as a four-element vector that specifies the location and size of the component: [distance from left, distance from bottom, width, height].

`position = getpixelposition(handle,recursive)` gets the position as above. If `recursive` is true, the returned position is relative to the parent figure of `handle`.

Use the `getpixelposition` function only to obtain coordinates for children of figures and container components (uipanel, or uibuttongroups). Results are not reliable for children of axes or other Handle Graphics objects.

**Examples**

This example creates a push button within a panel, and then retrieves its position, in pixels, relative to the panel.

```
f = figure('Position',[300 300 300 200]);
p = uipanel('Position',[.2 .2 .6 .6]);
h1 = uicontrol(p,'Style','PushButton','Units','Normalized',...
              'String','Push Button','Position',[.1 .1 .5 .2]);
pos1 = getpixelposition(h1)
```

```
pos1 =
    18.6000    12.6000    88.0000    23.2000
```

# getpixelposition

---

The following statement retrieves the position of the push button, in pixels, relative to the figure.

```
pos1 = getpixelposition(h1,true)

pos1 =
    79.6000    53.6000    88.0000    23.2000
```

## See Also

[setpixelposition](#) | [uicontrol](#) | [uipanel](#)

**Purpose**

Preference

**Syntax**

```
getpref('group','pref')
getpref('group','pref',default)
getpref('group',{'pref1','pref2',... 'prefn'})
getpref('group',{'pref1',... 'prefn'},{default1,...defaultn})
getpref('group')
getpref
```

**Description**

`getpref('group','pref')` returns the value for the preference specified by `group` and `pref`. It is an error to get a preference that does not exist.

`group` labels a related collection of preferences. You can choose any name that is a legal variable name, and is descriptive enough to be unique, e.g. 'ApplicationOnePrefs'. The input argument `pref` identifies an individual preference in that group, and must be a legal variable name.

`getpref('group','pref',default)` returns the current value if the preference specified by `group` and `pref` exists. Otherwise creates the preference with the specified default value and returns that value.

`getpref('group',{'pref1','pref2',... 'prefn'})` returns a cell array containing the values for the preferences specified by `group` and the cell array of preference names. The return value is the same size as the input cell array. It is an error if any of the preferences do not exist.

`getpref('group',{'pref1',... 'prefn'},{default1,...defaultn})` returns a cell array with the current values of the preferences specified by `group` and the cell array of preference names. Any preference that does not exist is created with the specified default value and returned.

`getpref('group')` returns the names and values of all preferences in the group as a structure.

`getpref` returns all groups and preferences as a structure.

# getpref

---

---

**Note** Preference values are persistent and maintain their values between MATLAB sessions. Where they are stored is system dependent.

---

## Examples

### Example 1

```
addpref('mytoolbox','version','1.0')
getpref('mytoolbox','version')
```

```
ans =
     1.0
```

### Example 2

```
rmpref('mytoolbox','version')
getpref('mytoolbox','version','1.0');
getpref('mytoolbox','version')
```

```
ans =
     1.0
```

**Purpose** List profiles and file formats supported by VideoWriter

**Syntax** `profiles = VideoWriter.getProfiles()`

**Description** `profiles = VideoWriter.getProfiles()` returns an array of `audiovideo.writer.ProfileInfo` objects that indicate the types of files VideoWriter can create.

**Output Arguments**

**profiles**

An array of `audiovideo.writer.ProfileInfo` objects, which have the following read-only properties:

<code>Name</code>	String profile name, such as 'Uncompressed AVI'.
<code>Description</code>	String description of the profile.
<code>FileExtensions</code>	Cell array of strings containing file extensions supported by the file format.
<code>ColorChannels</code>	Number of color channels in each output video frame.
<code>CompressionRatio</code>	Number greater than 1 that specifies the target ratio between the number of bytes in the input image and the number of bytes in the compressed image. Only applies to objects associated with Motion JPEG 2000 files. Default: 10.
<code>FrameRate</code>	Rate of playback for the video in frames per second. Default: 30.

# VideoWriter.getProfiles

---

LosslessCompression	Boolean value (logical true or false) that specifies whether to use reversible mode, so that the decompressed data is identical to the input data. When true, VideoWriter ignores values for CompressionRatio. Only applies to objects associated with Motion JPEG 2000 files.
MJ2BitDepth	Number of least significant bits in the input image data, from 1 to 16. Only applies to objects associated with Motion JPEG 2000 files.
Quality	Number from 0 through 100. Higher values correspond to higher quality video and larger files. Only applies to objects associated with the MPEG-4 or Motion JPEG AVI profile. Default: 75.
VideoBitsPerPixel	Number of bits per pixel in each output video frame.
VideoCompressionMethod	String indicating the type of video compression, such as 'None' or 'Motion JPEG'.
VideoFormat	String indicating the MATLAB representation of the video format, such as 'RGB24'.

## Examples

### Profile Information

View the list of available profiles and specific information about the 'Uncompressed AVI' profile.

```
profiles = VideoWriter.getProfiles()

uncompAVI = find(ismember({profiles.Name}, 'Uncompressed AVI'));
profiles(uncompAVI)
```

`profiles(uncompAVI).FileExtensions`

`VideoWriter`

# getReport (MException)

---

**Purpose** Get error message for exception

**Syntax**

```
msgString = getReport(exception)
msgString = getReport(exception, type)
msgString = getReport(exception, type, 'hyperlinks', value)
```

**Description** `msgString = getReport(exception)` returns a formatted message string, `msgString`, from an exception. This exception is represented by the `exception` input which is a scalar object of the `MException` class. The message string returned by `getReport` is the same as the error message displayed by MATLAB when it throws this exception.

`msgString = getReport(exception, type)` returns a message string that either describes just the error (**basic** type), or shows the error and the stack as well (**extended** type). The `type` argument, when used, must be the second argument in the input argument list. See “Examples” on page 2-1909 , below.

type Option	Displayed Text
'extended'	Display line number, error message, and cause and stack summary (default)
'basic'	Display line number and error message

`msgString = getReport(exception, type, 'hyperlinks', value)` returns a message string that either does or does not include active hyperlinks to the failing lines in the code. See the table below for the valid choices for `value`. The **hyperlinks** and `value` arguments, when used, must be the third and fourth arguments in the input argument list.

value Option	Action
'on'	Display hyperlinks to failing lines (default)
'off'	Do not display hyperlinks to failing lines
'default'	Use the default for the Command Window to determine whether or not to use hyperlinks in the error message

### Examples

This function attempts to read from a file that does not exist. When you call it, pass either 'basic' or 'extended' to specify the type of report you want to see displayed:

```
function line = test_getreport(file, rpttype)
try
    line = read_file(file);
catch exc
    getReport(exc, rpttype)
end

function line = read_file(file)
    fid = fopen(file, 'r');
    line = fread(fid);
```

The basic option displays only the error message:

```
test_getreport('filethatdoesnotexist.txt', 'basic')
ans =
```

Error using fread

Invalid file identifier. Use fopen to generate a valid file identifier

The extended option displays the error message and error call stack:

```
test_getreport('filethatdoesnotexist.txt', 'extended')
ans =
```

## getReport (MException)

---

Error using fread

Invalid file identifier. Use fopen to generate a valid file identifier.

Error in test\_getreport>read\_file (line 10)

```
line = fread(fid);
```

Error in test\_getreport (line 3)

```
line = read_file(file);
```

### See Also

```
try | catch | error | assert | MException | throw(MException)  
| rethrow(MException) | throwAsCaller(MException) |  
addCause(MException) | last(MException)
```

# getsampleusingtime (tscollection)

---

**Purpose**

Extract data samples into new tscollection object

**Syntax**

```
tsc2 = getsampleusingtime(tsc1,Time)
tsc2 = getsampleusingtime(tsc1,StartTime,EndTime)
```

**Description**

tsc2 = getsampleusingtime(tsc1,Time) returns a new tscollection tsc2 with a single sample corresponding to Time in tsc1.

tsc2 = getsampleusingtime(tsc1,StartTime,EndTime) returns a new tscollection tsc2 with samples between the times StartTime and EndTime in tsc1.

**Tips**

When the time vector in ts1 is numeric, StartTime and EndTime must also be numeric. When the times in ts1 are date strings and the StartTime and EndTime values are numeric, then the StartTime and EndTime values are treated as datenum values.

**See Also**

tscollection

# Tiff.getTag

---

**Purpose** Value of specified tag

**Syntax** `tagValue = getTag(tagId)`

**Description** `tagValue = getTag(tagId)` retrieves the value of the TIFF tag specified by `tagId`. You can specify `tagId` as a character string ('ImageWidth') or using the numeric tag identifier defined by the TIFF specification (256). To see a list of all the tags with their numeric identifiers, view the value of the Tiff object `TagID` property. Use the `TagID` property to specify the value of a tag. For example, `Tiff.TagID.ImageWidth` is equivalent to the tag's numeric identifier.

**Examples** Open a Tiff object, and get the value of a tag. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path:

```
t = Tiff('myfile.tif', 'r');
% Specify tag by name.
tagval = t.getTag('ImageWidth');
%
% Specify tag by numeric identifier.
tagval1 = t.getTag(256);
%
% Specify tag by name.
tagval2 = t.getTag('t.TagID.ImageWidth');
```

**References** This method corresponds to the `TIFFGetField` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at `LibTiff - TIFF Library and Utilities`.

**See Also** `Tiff.setTag`

**Tutorials**

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

**Purpose** List of recognized TIFF tags

**Syntax** `tagNames = Tiff.getTagNames()`

**Description** `tagNames = Tiff.getTagNames()` returns a cell array of TIFF tags recognized by the `Tiff` object.

**Examples** Retrieve a list of TIFF tags recognized by the `Tiff` object.

```
Tiff.getTagNames

ans =

    'SubFileType'
    'ImageWidth'
    'ImageLength'
    'BitsPerSample'
    'Compression'
    'Photometric'
    'Thresholding'
    'FillOrder'
    'DocumentName'
    'ImageDescription'
    .
    .
    .
```

**See Also** `Tiff.getTag`

# gettimeseriesnames

---

<b>Purpose</b>	Cell array of names of timeseries objects in tscollection object
<b>Syntax</b>	<code>names = gettimeseriesnames(tsc)</code>
<b>Description</b>	<code>names = gettimeseriesnames(tsc)</code> returns names of timeseries objects in a tscollection object <code>tsc</code> . <code>names</code> is a cell array of strings.
<b>Examples</b>	<p><b>1</b> Create timeseries objects <code>a</code> and <code>b</code>.</p> <pre>a = timeseries(rand(1000,1),'name','position'); b = timeseries(rand(1000,1),'name','response');</pre> <p><b>2</b> Create a tscollection object that includes these two time series.</p> <pre>tsc = tscollection({a,b});</pre> <p><b>3</b> Get the names of the timeseries objects in <code>tsc</code>.</p> <pre>names = gettimeseriesnames(tsc)  names =      'position'    'response'</pre>
<b>See Also</b>	<code>timeseries</code>   <code>tscollection</code>

**Purpose** New `timeseries` object with samples occurring at or after event

**Syntax**

```
ts1 = gettsafteratevent(ts,event)
ts1 = gettsafteratevent(ts,event,n)
```

**Description**

`ts1 = gettsafteratevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring at and after an event in `ts`, where `event` can be either a `tsdata.event` object or a string. When `event` is a `tsdata.event` object, the time defined by `event` is used. When `event` is a string, the first `tsdata.event` object in the `Events` property of the time series `ts` that matches the event name specifies the time.

`ts1 = gettsafteratevent(ts,event,n)` returns a new `timeseries` object `ts1` with samples at and after an event in `ts`, where `n` is the number of the event occurrence with a matching event name.

**Tips**

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the event is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the event is treated as a numeric value that is not associated with a calendar date.

**See Also** `gettsafterevent` | `gettsbeforeevent` | `gettsbetweenevents` | `tsdata.event` | `timeseries`

# gettsafterevent

---

**Purpose** New timeseries object with samples occurring after event

**Syntax**  
`ts1 = gettsafterevent(ts,event)`  
`ts1 = tttsafterevent(ts,event,n)`

**Description** `ts1 = gettsafterevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring after an event in `ts`, where `event` can be either a `tsdata.event` object or a string. When `event` is a `tsdata.event` object, the time defined by `event` is used. When `event` is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = tttsafterevent(ts,event,n)` returns a new `timeseries` object `ts1` with samples occurring after an event in time series `ts`, where `n` is the number of the event occurrence with a matching event name.

**Tips** When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

**See Also** `gettsafteratevent` | `gettsbeforeevent` | `gettsbetweenevents` | `timeseries` | `tsdata.event`

**Purpose** New timeseries object with samples occurring at event

**Syntax**

```
ts1 = gettsatevent(ts,event)
ts1 = gettsatevent(ts,event,n)
```

**Description** `ts1 = gettsatevent(ts,event)` returns a new timeseries object `ts1` with samples occurring at an event in `ts`, where `event` can be either a `tsdata.event` object or a string. When `event` is a `tsdata.event` object, the time defined by `event` is used. When `event` is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = gettsatevent(ts,event,n)` returns a new time series `ts1` with samples occurring at an event in time series `ts`, where `n` is the number of the event occurrence with a matching event name.

**Tips** When the timeseries object `ts` contains date strings and `event` uses numeric time, the time selected by the event is treated as a date that is calculated relative to the `StartDate` property in the `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the event is treated as a numeric value that is not associated with a calendar date.

**See Also** `gettsafterevent` | `gettsafteratevent` | `gettsbeforeevent` | `gettsbetweenevents` | `timeseries`

# gettsbeforeatevent

---

**Purpose** New timeseries object with samples occurring before or at event

**Syntax**  
`ts1 = gettsbeforeatevent(ts,event)`  
`ts1 = gettsbeforeatevent(ts,event,n)`

**Description** `ts1 = gettsbeforeatevent(ts,event)` returns a new timeseries object `ts1` with samples occurring at and before an event in `ts`, where `event` can be either a `tsdata.event` object or a string. When `event` is a `tsdata.event` object, the time defined by `event` is used. When `event` is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = gettsbeforeatevent(ts,event,n)` returns a new timeseries object `ts1` with samples occurring at and before an event in time series `ts`, where `n` is the number of the event occurrence with a matching event name.

**Tips** When the timeseries object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

**See Also** `gettsafterevent` | `gettsbeforeevent` | `gettsbetweenevents` | `tsdata.event`

**Purpose** New `timeseries` object with samples occurring before event

**Syntax**

```
ts1 = gettsbeforeevent(ts,event)
ts1 = gettsbeforeevent(ts,event,n)
```

**Description** `ts1 = gettsbeforeevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring before an event in `ts`, where event can be either a `tsdata.event` object or a string. When event is a `tsdata.event` object, the time defined by event is used. When event is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = gettsbeforeevent(ts,event,n)` returns a new `timeseries` object `ts1` with samples occurring before an event in `ts`, where `n` is the number of the event occurrence with a matching event name.

**Tips** When the `timeseries` object `ts` contains date strings and event uses numeric time, the time selected by the event is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and event uses calendar dates, the time selected by the event is treated as a numeric value that is not associated with a calendar date.

**See Also** `gettsafterevent` | `gettsbeforeatevent` | `gettsbetweenevents` | `tsdata.event`

# gettsbetweenevents

---

**Purpose** New timeseries object with samples occurring between events

**Syntax**  
`ts1 = gettsbetweenevents(ts,event1,event2)`  
`ts1 = gettsbetweenevents(ts,event1,event2,n1,n2)`

**Description** `ts1 = gettsbetweenevents(ts,event1,event2)` returns a new timeseries object `ts1` with samples occurring between events in `ts`, where `event1` and `event2` can be either a `tsdata.event` object or a string. When `event1` and `event2` are `tsdata.event` objects, the time defined by the events is used. When `event1` and `event2` are strings, the first `tsdata.event` object in the `Events` property of `ts` that matches the event names specifies the time.

`ts1 = gettsbetweenevents(ts,event1,event2,n1,n2)` returns a new timeseries object `ts1` with samples occurring between events in `ts`, where `n1` and `n2` are the `n`th occurrences of the events with matching event names.

**Tips** When the timeseries object `ts` contains date strings and `event` uses numeric time, the time selected by the event is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the event is treated as a numeric value that is not associated with a calendar date.

**Purpose** Data from variable in Automation server workspace

**Syntax**

**MATLAB Client**

```
D = h.GetVariable('varname','workspace')
D = GetVariable(h,'varname','workspace')
```

### IDL Method Signature

```
HRESULT GetVariable([in] BSTR varname, [in] BSTR
workspace, [out, retval] VARIANT* pdata)
```

### Microsoft Visual Basic Client

```
GetVariable(varname As String, workspace As
String) As Object
```

**Description** `D = h.GetVariable('varname','workspace')` gets data stored in variable `varname` from the specified workspace of the server attached to handle `h` and returns it in output argument `D`. The values for *workspace* are *base* or *global*.

`D = GetVariable(h,'varname','workspace')` is an alternate syntax.

Do *not* use `GetVariable` on sparse arrays, structures, or function handles.

If your scripting language requires a result be returned explicitly, use the `GetVariable` function in place of `GetWorkspaceData`, `GetFullMatrix` or `GetCharArray`.

**Examples** This example uses a MATLAB client to read data from a MATLAB Automation server:

```
%Create the MATLAB server
h = actxserver('matlab.application');
%Create variable C1 in the base workspace of the server
h.PutWorkspaceData('C1', 'base', {25.72, 'hello', rand(4)});
%The client reads the data
C2 = h.GetVariable('C1','base')
```

# GetVariable

---

This example uses a Visual Basic .NET client to read data from a MATLAB Automation server:

```
Dim Matlab As Object
Dim Result As String
Dim C2 As Variant
Matlab = CreateObject("matlab.application")
Result = Matlab.Execute("C1 = {25.72, 'hello', rand(4)};")
C2 = Matlab.GetVariable("C1", "base")
MsgBox("Second item in cell array: " & C2(0, 1))
```

## How To

- “MATLAB COM Automation Server Interface”
- “Exchanging Data with the Server”

**Purpose** LibTIFF library version

**Syntax** `versionString = Tiff.getVersion()`

**Description** `versionString = Tiff.getVersion()` returns the version number and other information about the LibTIFF library.

**Examples** Display version of LibTIFF library:

```
Tiff.getVersion
```

```
ans =
```

```
LIBTIFF, Version 3.9.5
```

```
Copyright (c) 1988-1996 Sam Leffler
```

```
Copyright (c) 1991-1996 Silicon Graphics, Inc.
```

**References** This method corresponds to the `TIFFGetVersion` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

# GetWorkspaceData

---

**Purpose** Data from Automation server workspace

**Syntax** **MATLAB Client**  
D = h.GetWorkspaceData('varname','workspace')  
D = GetWorkspaceData(h,'varname','workspace')

## IDL Method Signature

```
HRESULT GetWorkspaceData([in] BSTR varname, [in] BSTR workspace, [out] VARIANT* pdata)
```

## Microsoft Visual Basic Client

```
GetWorkspaceData(varname As String, workspace As String) As Object
```

**Description** D = h.GetWorkspaceData('varname','workspace') gets data stored in variable varname from the specified workspace of the server attached to handle h and returns it in output argument D. The values for *workspace* are base or global.

D = GetWorkspaceData(h,'varname','workspace') is an alternate syntax.

Use GetWorkspaceData instead of GetFullMatrix and GetCharArray to get numeric and character array data, respectively. Do *not* use GetWorkspaceData on sparse arrays, structures, or function handles.

For VBScript clients, use the GetWorkspaceData and PutWorkspaceData functions to pass numeric data to and from the MATLAB workspace. These functions use the variant data type instead of the safearray data type used by GetFullMatrix and PutFullMatrix. VBScript does not support safearray.

**Examples** This example uses a MATLAB client to read data from a MATLAB Automation server:

```
%Create the MATLAB server  
h = actxserver('matlab.application');  
%Create cell array C1 in the base workspace of the server
```

```
h.PutWorkspaceData('C1', 'base', ...  
    {25.72, 'hello', rand(4)});  
C2 = h.GetWorkspaceData('C1', 'base')
```

---

This example uses a Visual Basic .NET client to read data from a MATLAB Automation server:

```
Dim Matlab As Object  
Dim C2 As Variant  
Dim Result As String  
Matlab = CreateObject("matlab.application")  
Result = MatLab.Execute("C1 = {25.72, 'hello', rand(4)};")  
MsgBox("In MATLAB, type" & vbCrLf & "C1")  
Matlab.GetWorkspaceData("C1", "base", C2)  
MsgBox("second value of C1 = " & C2(0, 1))
```

| [Execute](#)

## How To

- “MATLAB COM Automation Server Interface”
- “Exchanging Data with the Server”

# ginput

---

**Purpose** Graphical input from mouse or cursor

**Syntax**

```
[x,y] = ginput(n)
[x,y] = ginput
[x,y,button] = ginput(...)
```

**Description** `ginput` raises crosshairs in the current axes to for you to identify points in the figure, positioning the cursor with the mouse. The figure must have focus before `ginput` can receive input. If it has no axes, one is created upon the first click or keypress.

`[x,y] = ginput(n)` enables you to identify  $n$  points from the current axes and returns their  $x$ - and  $y$ -coordinates in the  $x$  and  $y$  column vectors. Press the **Return** key to terminate the input before entering  $n$  points.

`[x,y] = ginput` gathers an unlimited number of points until you press the **Return** key.

`[x,y,button] = ginput(...)` returns the  $x$ -coordinates, the  $y$ -coordinates, and the button or key designation. `button` is a vector of integers indicating which mouse buttons you pressed (1 for left, 2 for middle, 3 for right), or ASCII numbers indicating which keys on the keyboard you pressed.

Clicking an axes makes that axes the current axes. Even if you set the current axes before calling `ginput`, whichever axes you click becomes the current axes and `ginput` returns points relative to that axes. If you select points from multiple axes, the results returned are relative to the coordinate system of the axes they come from.

**Definitions** Coordinates returned by `ginput` are scaled to the `XLim` and `YLim` bounds of the axes you click (data units). Setting the axes or figure `Units` property has no effect on the output from `ginput`. You can click anywhere within the figure canvas to obtain coordinates. If you click outside the axes limits, `ginput` extrapolates coordinate values so they are still relative to the axes origin.

The figure `CurrentPoint` property, by contrast, is always returned in figure `Units`, irrespective of axes `Units` or limits.

## Examples

Pick 4 two-dimensional points from the figure window.

```
[x,y] = ginput(4)
```

Position the cursor with the mouse. Enter data points by pressing a mouse button or a key on the keyboard. To terminate input before entering 4 points, press the **Return** key.

```
x =  
    0.2362  
    0.5749  
    0.5680  
    0.2707
```

```
y =  
    0.6711  
    0.6769  
    0.4313  
    0.4401
```

```
plot(x,y)
```

In this example, `plot` rescaled the axes  $x$ -limits and  $y$ -limits from `[0 1]` and `[0 1]` to `[0.20 0.65]` and `[0.40 0.75]`. The rescaling occurred because the axes `XLimMode` and `YLimMode` are set to `'auto'` (the default). Consider setting `XLimMode` and `YLimMode` to `'manual'` if you want to maintain consistency when you gather results from `ginput` and plot them together.

**Purpose** Declare global variables

**Syntax** `global X Y Z`

**Description** `global X Y Z` defines X, Y, and Z as global in scope.

Ordinarily, each MATLAB function has its own local variables, which are separate from those of other functions, and from those of the base workspace. However, if several functions, and possibly the base workspace, all declare a particular name as global, they all share a single copy of that variable. Any assignment to that variable, in any function, is available to all the functions declaring it global.

If the global variable does not exist the first time you issue the `global` statement, it is initialized to the empty matrix.

If a variable with the same name as the global variable already exists in the current workspace, MATLAB issues a warning and changes the value of that variable to match the global.

## Tips

Use `clear global variable` to clear a global variable from the global workspace. Use `clear variable` to clear the global link from the current workspace without affecting the value of the global.

To use a global within a callback, declare the global, use it, then clear the global link from the workspace. This avoids declaring the global after it has been referenced. For example,

```
cbstr = sprintf('%s, %s, %s, %s, %s', ...
    'global MY_GLOBAL', ...
    'MY_GLOBAL = 100', ...
    'disp(MY_GLOBAL)', ...
    'MY_GLOBAL = MY_GLOBAL+1', ...
    'clear MY_GLOBAL');

uicontrol('style', 'pushbutton', 'CallBack', cbstr, ...
    'string', 'count')
```

There is no function form of the `global` command (i.e., you cannot use parentheses and quote the variable names).

## Examples

### Example 1

Type `edit global_demo1` at the command line and enter the following function definition in the file that opens. This function declares a global variable named `globalvar`. If you pass a value when calling the function, the function stores the value in `globalvar` and then displays it. If you call the function with no arguments, the function just displays the value last written to the global workspace:

```
function global_demo1(num)
    global globalvar

    if nargin > 0
        globalvar = num;
    end

    fprintf('Global variable in function %s is %d\n', ...
           mfilename, globalvar);
```

Create another function `global_demo2` just like it. These two functions have separate function workspaces, but share a common global workspace:

```
copyfile global_demo1 global_demo2
```

Call `global_demo1`, passing a numeric value. Then call `global_demo2` with no value. You can see that the latter function has global access to the value that was passed to `global_demo1`.

```
global_demo1(1357);
Global variable in function global_demo1 is 1357

global_demo2
Global variable in function global_demo2 is 1357
```

Now set the value in `global_demo2` and read it in `global_demo1`:

```
global_demo2(2468)
Global variable in function global_demo2 is 2468

global_demo1
Global variable in function global_demo1 is 2468
```

## **Example 2**

Call the function `global_demo1` that was defined in the previous example to assign a value to variable `globalvar` in the global workspace. Even though the variable is global, it is not accessible outside of the function workspace:

```
clear all
global_demo1(1357);
Global variable in function global_demo1 is 1357

if exist('globalvar', 'var')
    fprintf('Global variable is set to %d\n', globalvar);
else
    fprintf('Global variable is not available at the command line.\n');
end
```

Global variable is not available at the command line.

Now declare `globalvar` as a global variable at the MATLAB command line. Run the same statements to display the variable and this time you can see that the value assigned by the function is also available as a global variable in the base workspace:

```
global globalvar

if exist('globalvar', 'var')
    fprintf('Global variable is set to %d\n', globalvar);
else
    fprintf('Global variable is not available at the command line.\n');
```

```
end
```

```
Global variable is set to 1357
```

### Example 3

Here is the code for the functions `tic` and `toc` (some comments abridged). These functions manipulate a stopwatch-like timer. The global variable `TICTOC` is shared by the two functions, but it is invisible in the base workspace or in any other functions that do not declare it.

```
function tic
%   TIC Start a stopwatch timer.
%       TIC; any stuff; TOC
%   prints the time required.
%   See also: TOC, CLOCK.
global TICTOC
TICTOC = clock;

function t = toc
%   TOC Read the stopwatch timer.
%   TOC prints the elapsed time since TIC was used.
%   t = TOC; saves elapsed time in t, does not print.
%   See also: TIC, ETIME.
global TICTOC
if nargin < 1
    elapsed_time = etime(clock, TICTOC)
else
    t = etime(clock, TICTOC);
end
```

```

**Purpose** Generalized minimum residual method (with restarts)

**Syntax**

```
x = gmres(A,b)
gmres(A,b,restart)
gmres(A,b,restart,tol)
gmres(A,b,restart,tol,maxit)
gmres(A,b,restart,tol,maxit,M)
gmres(A,b,restart,tol,maxit,M1,M2)
gmres(A,b,restart,tol,maxit,M1,M2,x0)
[x,flag] = gmres(A,b,...)
[x,flag,relres] = gmres(A,b,...)
[x,flag,relres,iter] = gmres(A,b,...)
[x,flag,relres,iter,resvec] = gmres(A,b,...)
```

**Description** `x = gmres(A,b)` attempts to solve the system of linear equations  $A*x = b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and should be large and sparse. The column vector  $b$  must have length  $n$ .  $A$  can be a function handle, `afun`, such that `afun(x)` returns  $A*x$ . For this syntax, `gmres` does not restart; the maximum number of iterations is `min(n,10)`.

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `gmres` converges, a message to that effect is displayed. If `gmres` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`gmres(A,b,restart)` restarts the method every `restart` inner iterations. The maximum number of outer iterations is `min(n/restart,10)`. The maximum number of total iterations is `restart*min(n/restart,10)`. If `restart` is `n` or `[]`, then `gmres` does not restart and the maximum number of total iterations is `min(n,10)`.

`gmres(A,b,restart,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `gmres` uses the default, `1e-6`.

`gmres(A,b,restart,tol,maxit)` specifies the maximum number of outer iterations, i.e., the total number of iterations does not exceed `restart*maxit`. If `maxit` is `[]` then `gmres` uses the default, `min(n/restart,10)`. If `restart` is `n` or `[]`, then the maximum number of total iterations is `maxit` (instead of `restart*maxit`).

`gmres(A,b,restart,tol,maxit,M)` and `gmres(A,b,restart,tol,maxit,M1,M2)` use preconditioner `M` or `M = M1*M2` and effectively solve the system  $\text{inv}(M)*A*x = \text{inv}(M)*b$  for `x`. If `M` is `[]` then `gmres` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x)` returns `M\x`.

`gmres(A,b,restart,tol,maxit,M1,M2,x0)` specifies the first initial guess. If `x0` is `[]`, then `gmres` uses the default, an all-zero vector.

`[x,flag] = gmres(A,b,...)` also returns a convergence flag:

- `flag = 0`    `gmres` converged to the desired tolerance `tol` within `maxit` outer iterations.
- `flag = 1`    `gmres` iterated `maxit` times but did not converge.
- `flag = 2`    Preconditioner `M` was ill-conditioned.
- `flag = 3`    `gmres` stagnated. (Two consecutive iterates were the same.)

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = gmres(A,b,...)` also returns the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = gmres(A,b,...)` also returns both the outer and inner iteration numbers at which `x` was computed, where  $0 \leq \text{iter}(1) \leq \text{maxit}$  and  $0 \leq \text{iter}(2) \leq \text{restart}$ .

`[x,flag,relres,iter,resvec] = gmres(A,b,...)` also returns a vector of the residual norms at each inner iteration, including  $\text{norm}(b-A*x0)$ .

## Examples

### Using gmres with a Matrix Input

```
A = gallery('wilk',21);
b = sum(A,2);
tol = 1e-12;
maxit = 15;
M1 = diag([10:-1:1 1 1:10]);

x = gmres(A,b,10,tol,maxit,M1);
```

displays the following message:

```
gmres(10) converged at outer iteration 2 (inner iteration 9) to
a solution with relative residual 3.3e-013
```

### Using gmres with a Function Handle

This example replaces the matrix *A* in the previous example with a handle to a matrix-vector product function *afun*, and the preconditioner *M1* with a handle to a backsolve function *mfun*. The example is contained in a function *run\_gmres* that

- Calls *gmres* with the function handle *@afun* as its first argument.
- Contains *afun* and *mfun* as nested functions, so that all variables in *run\_gmres* are available to *afun* and *mfun*.

The following shows the code for *run\_gmres*:

```
function x1 = run_gmres
n = 21;
b = afun(ones(n,1));
tol = 1e-12; maxit = 15;
x1 = gmres(@afun,b,10,tol,maxit,@mfun);

function y = afun(x)
    y = [0; x(1:n-1)] + ...
        [((n-1)/2:-1:0)'; (1:(n-1)/2)'] .* x + ...
        [x(2:n); 0];
end
```

```
function y = mfun(r)
    y = r ./ [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];
end
end
```

When you enter

```
x1 = run_gmres;
```

MATLAB software displays the message

```
gmres(10) converged at outer iteration 2 (inner iteration 10)
to a solution with relative residual 1.1e-013.
```

## Using a Preconditioner without Restart

This example demonstrates the use of a preconditioner without restarting gmres.

### 1

Load west0479, a real 479-by-479 nonsymmetric sparse matrix:

```
load west0479;
A = west0479;
```

### 2

Set the tolerance and maximum number of iterations:

```
tol = 1e-12; maxit = 20;
```

### 3

Define b so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
[x0,f10,rr0,it0,rv0] = gmres(A,b,[],tol,maxit);
```

`fl0` is 1 because `gmres` does not converge to the requested tolerance  $1e-12$  within the requested 20 iterations. The best approximate solution that `gmres` returns is the last one (as indicated by `it0(2) = 20`). MATLAB stores the residual history in `rv0`.

#### 4

Plot the behavior of `gmres`:

```
semilogy(0:maxit,rv0/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

The plot shows that the solution converges slowly. A preconditioner may improve the outcome.

## 5

Use `ilu` to form the preconditioner, since  $A$  is nonsymmetric :

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));  
Error using ilu  
There is a pivot equal to zero. Consider decreasing  
the drop tolerance or consider using the 'udiag' option.
```

Note MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

## 6

As indicated by the error message, try again with a reduced drop tolerance:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));  
[x1,f11,rr1,it1,rv1] = gmres(A,b,[],tol,maxit,L,U);
```

`f11` is 0 because `gmres` drives the relative residual to  $1.1196e-013$  (the value of `rr1`). The relative residual is less than the prescribed tolerance of  $1e-12$  at the sixth iteration (the value of `it1(2)`) when preconditioned by the incomplete LU factorization with a drop tolerance of  $1e-6$ . The output `rv1(1)` is `norm(b)`, and the output `rv1(7)` is `norm(b-A*x2)`.

## 7

Follow the progress of `gmres` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0):

```
semilogy(0:it1(2),rv1/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

### Using a Preconditioner with Restart

This example demonstrates the use of a preconditioner with restarted gmres.

#### 1

Load west0479, a real 479-by-479 nonsymmetric sparse matrix:

```
load west0479;  
A = west0479;
```

#### 2

Define **b** so that the true solution is a vector of all ones:

```
b = full(sum(A,2));
```

### 3

Construct an incomplete LU preconditioner as in the previous example:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
```

The benefit to using restarted gmres is to limit the amount of memory required to execute the method. Without restart, gmres requires `maxit` vectors of storage to keep the basis of the Krylov subspace. Also, gmres must orthogonalize against all of the previous vectors at each step. Restarting limits the amount of workspace used and the amount of work done per outer iteration. Note that even though preconditioned gmres converged in six iterations above, the algorithm allowed for as many as twenty basis vectors and therefore, allocated all of that space up front.

### 4

Execute `gmres(3)`, `gmres(4)`, and `gmres(5)`:

```
tol = 1e-12; maxit = 20;
re3 = 3;
[x3,f13,rr3,it3,rv3] = gmres(A,b,re3,tol,maxit,L,U);
re4 = 4;
[x4,f14,rr4,it4,rv4] = gmres(A,b,re4,tol,maxit,L,U);
re5 = 5;
[x5,f15,rr5,it5,rv5] = gmres(A,b,re5,tol,maxit,L,U);
```

`f13`, `f14`, and `f15` are all 0 because in each case restarted gmres drives the relative residual to less than the prescribed tolerance of  $1e-12$ . The following plots show the convergence histories of each restarted gmres method. `gmres(3)` converges at outer iteration 5, inner iteration 3 (`it3 = [5, 3]`) which would be the same as outer iteration 6, inner iteration 0, hence the marking of 6 on the final tick mark.

# gplot

---

## Purpose

Plot nodes and links representing adjacency matrix

## Syntax

```
gplot(A,Coordinates)
gplot(A,Coordinates,LineStyle)
```

## Description

The `gplot` function graphs a set of coordinates using an adjacency matrix.

`gplot(A,Coordinates)` plots a graph of the nodes defined in `Coordinates` according to the  $n$ -by- $n$  adjacency matrix `A`, where  $n$  is the number of nodes. `Coordinates` is an  $n$ -by-2 matrix, where  $n$  is the number of nodes and each coordinate pair represents one node.

`gplot(A,Coordinates,LineStyle)` plots the nodes using the line type, marker symbol, and color specified by `LineStyle`.

## Tips

For two-dimensional data, `Coordinates(i,:) = [x(i) y(i)]` denotes node  $i$ , and `Coordinates(j,:) = [x(j) y(j)]` denotes node  $j$ . If node  $i$  and node  $j$  are connected, `A(i,j)` or `A(j,i)` is nonzero; otherwise, `A(i,j)` and `A(j,i)` are zero.

## Examples

Plot half of a “Bucky ball” carbon molecule, placing asterisks at each node:

```
k = 1:30;
[B,XY] = bucky;
gplot(B(k,k),XY(k,:), '-*')
axis square
```

# grabcode

---

**Purpose** Extract MATLAB code from file published to HTML

**Syntax**

```
grabcode('name.html')
grabcode('urlname')
codeString = grabcode('name.html')
```

**Description** `grabcode('name.html')` copies MATLAB code from the file `name.html` and pastes it into an untitled document in the Editor. Use `grabcode` to get MATLAB code from published files when the source code is not readily available. The file `name.html` was created by publishing `name.m`, a MATLAB code file containing cells. The MATLAB code from `name.m` is included at the end of `name.html` as HTML comments.

`grabcode('urlname')` copies MATLAB code from the `urlname` location and pastes it into an untitled document in the Editor.

`codeString = grabcode('name.html')` gets MATLAB code from the file `name.html` and assigns it the variable `codeString`.

**Examples** This example illustrates how to use `grabcode` to get MATLAB code from an existing HTML file:

```
% Copy sine_wave_f.html and the images it includes
% from the MATLAB examples directory to your
% current folder:

copyfile(fullfile(matlabroot,'help','techdoc','matlab_env',...
    'examples','sine_wave_f.html'), 'my_sine_wave.html')

copyfile(fullfile(matlabroot,'help','techdoc','matlab_env',...
    'examples','sine_wave_f_01.png'), 'sine_wave_f_01.png')

copyfile(fullfile(matlabroot,'help','techdoc','matlab_env',...
    'examples','sine_wave_f_02.png'), 'sine_wave_f_02.png')

% If you want to view the file, double-click my_sine_wave.html
5 in your current folder.
```

```
% Extract the MATLAB code from sine_wave_f.html:  
code = grabcode('my_sine_wave.html')
```

MATLAB returns:

```
code =
```

```
%% Plot Sine Wave  
% Calculate and plot a sine wave.  
  
%% Calculate and Plot Sine Wave  
% Calculate and plot  $y = \sin(x)$  |.
```

```
function sine_wave_f(x)
```

```
y = sin(x);  
plot(x,y)
```

```
%% Modify Plot Properties
```

```
title('Sine Wave', 'FontWeight','bold')  
xlabel('x')  
ylabel('sin(x)')  
set(gca, 'Color', 'w')  
set(gcf, 'MenuBar', 'none')
```

```
publish
```

# gradient

---

**Purpose** Numerical gradient

**Syntax**  
FX = gradient(F)  
[FX,FY] = gradient(F)  
[FX,FY,FZ,...] = gradient(F)  
[...] = gradient(F,h)  
[...] = gradient(F,h1,h2,...)

**Definitions** The *gradient* of a function of two variables,  $F(x,y)$ , is defined as

$$\nabla F = \frac{\partial F}{\partial x} \hat{i} + \frac{\partial F}{\partial y} \hat{j}$$

and can be thought of as a collection of vectors pointing in the direction of increasing values of  $F$ . In MATLAB software, numerical gradients (differences) can be computed for functions with any number of variables. For a function of  $N$  variables,  $F(x,y,z, \dots)$ ,

$$\nabla F = \frac{\partial F}{\partial x} \hat{i} + \frac{\partial F}{\partial y} \hat{j} + \frac{\partial F}{\partial z} \hat{k} + \dots$$

**Description** FX = gradient(F) where F is a vector returns the one-dimensional numerical gradient of F. FX corresponds to  $\partial F/\partial x$ , the differences in  $x$  (horizontal) direction.

[FX,FY] = gradient(F) where F is a matrix returns the  $x$  and  $y$  components of the two-dimensional numerical gradient. FX corresponds to  $\partial F/\partial x$ , the differences in  $x$  (horizontal) direction. FY corresponds to  $\partial F/\partial y$ , the differences in the  $y$  (vertical) direction. The spacing between points in each direction is assumed to be one.

[FX,FY,FZ,...] = gradient(F) where F has  $N$  dimensions returns the  $N$  components of the gradient of F. There are two ways to control the spacing between values in F:

- A single spacing value,  $h$ , specifies the spacing between points in every direction.

- N spacing values ( $h_1, h_2, \dots$ ) specifies the spacing for each dimension of F. Scalar spacing parameters specify a constant spacing for each dimension. Vector parameters specify the coordinates of the values along corresponding dimensions of F. In this case, the length of the vector must match the size of the corresponding dimension.

---

**Note** The first output FX is always the gradient along the 2nd dimension of F, going across columns. The second output FY is always the gradient along the 1st dimension of F, going across rows. For the third output FZ and the outputs that follow, the Nth output is the gradient along the Nth dimension of F.

---

[...] = gradient(F,h) where h is a scalar uses h as the spacing between points in each direction.

[...] = gradient(F,h1,h2,...) with N spacing parameters specifies the spacing for each dimension of F.

## Examples

The statements

```
v = -2:0.2:2;
[x,y] = meshgrid(v);
z = x .* exp(-x.^2 - y.^2);
[px,py] = gradient(z,.2,.2);
contour(v,v,z), hold on, quiver(v,v,px,py), hold off
```

produce

# gradient

Given,

```
F(:,:,1) = magic(3); F(:,:,2) = pascal(3);  
gradient(F)
```

takes  $dx = dy = dz = 1$ .

```
[PX,PY,PZ] = gradient(F,0.2,0.1,0.2)
```

takes  $dx = 0.2$ ,  $dy = 0.1$ , and  $dz = 0.2$ .

# grid

---

**Purpose** Grid lines for 2-D and 3-D plots

**Syntax**

```
grid on
grid off
grid minor
grid
grid(axes_handle,...)
grid minor
```

**Description**

`grid on` adds major grid lines to the current axes.

`grid off` removes major and minor grid lines from the current axes.

`grid minor` toggles the visibility of minor grid lines of the current axes.

`grid` toggles the major grid visibility state.

`grid(axes_handle,...)` uses the axes specified by `axes_handle` instead of the current axes.

**Algorithms**

`grid` sets the `XGrid`, `YGrid`, and `ZGrid` properties of the axes.

`grid minor` sets the `XMinorGrid`, `YMinorGrid`, and `ZMinorGrid` properties of the axes. Reissuing `grid minor` toggles minor grid visibility.

You can set the grid lines for just one axis using the `set` command and the individual property. For example,

```
set(axes_handle,'XGrid','on')
```

turns on only *x*-axis grid lines.

You can set grid line width with the axes `LineWidth` property.

By default, the number of grid lines changes when you resize a figure. To prevent this and keep grids the same at any size, set the `XTickMode` or `YTickMode` axes properties to `'manual'`:

```
set(axes_handle,'XTickMode','manual')
set(axes_handle,'YTickMode','manual')
```

To customize the locations of ticks along an axis, set the axes `XTick`, `YTick`, and `ZTick` properties. For minor ticks, use the `XMinorTick`, `YMinorTick`, and `ZTick` properties.

## Examples

Create multiple plots within a single figure and manipulate their grid visibility using the `grid` function:

```
figure
subplot(2,2,1)
plot(rand(1,20))
title('grid off')
subplot(2,2,2)
plot(rand(1,20))
grid on
title('grid on')
subplot(2,2,[3 4])
plot(rand(1,20))
grid on
set(gca, 'GridLineStyle', '-');
grid(gca, 'minor')
title('grid minor')
```

# grid

You can also use the following code to control grids on a per-axis basis:

```
set(axh, 'XGrid', 'on', 'YGrid', 'on', 'ZGrid', 'on')
```

## Alternatives

To control the presence and appearance of grid lines on a graph, use the Property Editor, one of the plotting tools . For details, see The Property Editor.

## See Also

box | axes | set

**Purpose** Interpolate scattered data

---

**Note** Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `griddata`.

In a future release, the following syntaxes will be removed:

```
[Xq,Yq,Vq] = griddata(x,y,v,xq,yq)
[Xq,Yq,Vq] = griddata(x,y,v,xq,yq, method)
```

In addition, `griddata` will not accept any input vectors of mixed orientation in a future release. To specify a grid of query points, construct a full grid with `ndgrid` or `meshgrid` before calling `griddata`.

---

**Syntax**

```
vq = griddata(x,y,v,xq,yq)
vq = griddata(x,y,z,v,xq,yq,zq)
vq = griddata(..., method)
```

**Description** `vq = griddata(x,y,v,xq,yq)` fits a surface of the form  $v = f(x,y)$  to the scattered data in the vectors  $(x,y,v)$ . The `griddata` function interpolates the surface at the query points specified by  $(xq,yq)$  and returns the interpolated values, `vq`. The surface always passes through the data points defined by `x` and `y`.

`vq = griddata(x,y,z,v,xq,yq,zq)` fits a hypersurface of the form  $v = f(x,y,z)$ .

`vq = griddata(..., method)` uses a specified interpolation method to compute `vq`.

**Input Arguments**

**x**

Vector specifying the  $x$ - coordinates of the sample points.

**y**

Vector specifying the  $y$ - coordinates of the sample points.

**z**

Vector specifying the  $z$ - coordinates of the sample points.

**v**

Vector of sample values that correspond to the sample coordinates  $x$ ,  $y$  (and  $z$  for 3-D interpolation).

**xq**

Vector or array that specifies  $x$ - coordinates of the query points to be evaluated.  $xq$  must be the same size as  $yq$  (and  $zq$  for 3-D interpolation).

- Specify an array if you want to pass a grid of query points. Use `ndgrid` or `meshgrid` to construct the array.
- Specify a vector if you want to pass a collection of scattered points.

**yq**

Vector or array that specifies  $y$ - coordinates of the query points to be evaluated.  $yq$  must be the same size as  $xq$  (and  $zq$  for 3-D interpolation).

- Specify an array if you want to pass a grid of query points. Use `ndgrid` or `meshgrid` to construct the array.
- Specify a vector if you want to pass a collection of scattered points.

**zq**

Vector or array that specifies  $z$ - coordinates of the query points to be evaluated.  $zq$  must be the same size as  $xq$  and  $yq$ .

- Specify an array if you want to pass a grid of query points. Use `ndgrid` or `meshgrid` to construct the array.
- Specify a vector if you want to pass a collection of scattered points.

**method**

Keyword that specifies the interpolation method. Use one of the following:

'linear'	Linear interpolation (default)
'cubic'	Cubic interpolation
'natural'	Natural neighbor interpolation
'nearest'	Nearest neighbor interpolation
'v4'	MATLAB 4 griddata method

## Output Arguments

### **vq**

The interpolated values at the query points.

- For 2-D interpolation, where  $xq$  and  $yq$  specify an  $m$ -by- $n$  grid of query points,  $vq$  is an  $m$ -by- $n$  array.
- For 3-D interpolation, where  $xq$ ,  $yq$ , and  $zq$  specify an  $m$ -by- $n$ -by- $p$  grid of query points,  $vq$  is an  $m$ -by- $n$ -by- $p$  array.
- If  $xq$ ,  $yq$ , (and  $zq$  for 3-D interpolation) are vectors that specify scattered points,  $vq$  is a vector of the same length.

## Examples

### **Interpolate Scattered Data Over a Uniform Grid**

Sample a function at 200 random points between -2.5 and 2.5.

```
xy = -2.5 + 5*gallery('uniformdata',[200 2],0);
x = xy(:,1); y = xy(:,2);
v = x.*exp(-x.^2-y.^2);
```

$x$ ,  $y$ , and  $v$  are vectors containing scattered (nonuniform) sample points and data.

Define a regular grid and interpolate the scattered data over the grid.

```
[xq,yq] = meshgrid(-2:.2:2, -2:.2:2);
vq = griddata(x,y,v,xq,yq);
```

Plot the gridded data as a mesh and the scattered data as dots.

```
figure
mesh(xq,yq,vq);
hold on
plot3(x,y,v,'o');
h = gca;
set(h,'XLim',[-2.7 2.7]);
set(h,'YLim',[-2.7 2.7]);
```

## Interpolate 3-D Data Set Over a Grid in the x-y Plane

Sample a function at 5000 random points between -1 and 1.

```
rng(0, 'twister')
x = 2*rand(5000,1)-1;
y = 2*rand(5000,1)-1;
z = 2*rand(5000,1)-1;
v = x.^2 + y.^2 + z.^2;
```

x, y, and z are now vectors containing nonuniformly sampled data. Define a regular grid with points in the range [-0.8, 0.8].

```
d = -0.8:0.05:0.8;
[xq,yq,zq] = meshgrid(d,d,0);
```

Interpolate the scattered data over a rectangular region at z=0. Then, plot the results.

```
vq = griddata(x,y,z,v,xq,yq,zq);
surf(xq,yq,vq);
set(gca, 'XTick', [-1 -0.5 0 0.5 1]);
set(gca, 'YTick', [-1 -0.5 0 0.5 1]);
```

# griddata

---

## See Also

`TriScatteredInterp` | `delaunay` | `griddatan` | `interp` | `interp` | `meshgrid` | `ndgrid`

**Purpose** Data gridding and hypersurface fitting for 3-D data

---

**Note** `griddata3` has been removed. Use `griddata` instead.

---

**Syntax**

```
w = griddata3(x,y,z,v,xi,yi,zi)
w = griddata3(x,y,z,v,xi,yi,zi,method)
```

**Description** `w = griddata3(x,y,z,v,xi,yi,zi)` fits a hypersurface of the form  $w = f(x,y,z)$  to the data in the (usually) nonuniformly spaced vectors  $(x,y,z,v)$ . `griddata3` interpolates this hypersurface at the points specified by  $(xi,yi,zi)$  to produce  $w$ .  $w$  is the same size as  $xi$ ,  $yi$ , and  $zi$ .  $(xi,yi,zi)$  is usually a uniform grid (as produced by `meshgrid`) and is where `griddata3` gets its name.

`w = griddata3(x,y,z,v,xi,yi,zi,method)` defines the type of surface that is fit to the data, where `method` is either:

'linear'	Tessellation-based linear interpolation (default)
'nearest'	Nearest neighbor interpolation

If `method` is `[]`, the default 'linear' method is used.

`w = griddata3(...,options)` specifies a cell array of strings `options` that were previously in `Qhull`. `Qhull`-specific options are no longer required and are currently ignored.

**Examples** Create vectors `x`, `y`, and `z` containing nonuniformly sampled data:

```
x = gallery('uniformdata',[5000 1],0)-1;
y = gallery('uniformdata',[5000 1],1)-1;
z = gallery('uniformdata',[5000 1],2)-1;
v = x.^2 + y.^2 + z.^2;
```

Define a regular grid, and grid the data to it:

## griddata3

---

```
d = -0.8:0.05:0.8;  
[xi,yi,zi] = meshgrid(d,d,d);  
w = griddata3(x,y,z,v,xi,yi,zi);
```

Since it is difficult to visualize 4-D data sets, use isosurface at 0.8:

```
p = patch(isosurface(xi,yi,zi,w,0.8));  
isonormals(xi,yi,zi,w,p);  
set(p,'FaceColor','blue','EdgeColor','none');  
view(3), axis equal, axis off, camlight, lighting phong
```

**Purpose**

Data gridding and hypersurface fitting (dimension  $\geq 2$ )

**Syntax**

```
yi = griddatan(x,y,xi)
yi = griddatan(x,y,xi,method)
yi = griddatan(x,y,xi,method,options)
```

**Description**

`yi = griddatan(x,y,xi)` fits a hyper-surface of the form  $y = f(x)$  to the data in the (usually) nonuniformly-spaced vectors  $(x, y)$ . `griddatan` interpolates this hyper-surface at the points specified by `xi` to produce `yi`. `xi` can be nonuniform.

`X` is of dimension  $m$ -by- $n$ , representing  $m$  points in  $n$ -dimensional space. `y` is of dimension  $m$ -by-1, representing  $m$  values of the hyper-surface  $f(X)$ . `xi` is a vector of size  $p$ -by- $n$ , representing  $p$  points in the  $n$ -dimensional space whose surface value is to be fitted. `yi` is a vector of length  $p$  approximating the values  $f(xi)$ . The hypersurface always goes through the data points  $(X,y)$ . `xi` is usually a uniform grid (as produced by `meshgrid`).

`yi = griddatan(x,y,xi,method)` defines the type of surface fit to the data, where 'method' is one of:

'linear'	Triangulation-based linear interpolation (default)
'nearest'	Nearest neighbor interpolation

All the methods are based on a Delaunay triangulation of the data.

If `method` is `[]`, the default 'linear' method is used.

`yi = griddatan(x,y,xi,method,options)` specifies a cell array of strings `options` to be used in `Qhull` via `delaunayn`.

If `options` is `[]`, the default options are used. If `options` is `{ ' ' }`, no options are used, not even the default.

**Examples**

```
X=2*gallery('uniformdata',[5000 3],0)-1;;
Y = sum(X.^2,2);
d = -0.8:0.05:0.8;
```

# griddatan

---

```
[y0,x0,z0] = ndgrid(d,d,d);  
XI = [x0(:) y0(:) z0(:)];  
YI = griddatan(X,Y,XI);
```

Since it is difficult to visualize 4-D data sets, use `isosurface` at 0.8:

```
YI = reshape(YI, size(x0));  
p = patch(isosurface(x0,y0,z0,YI,0.8));  
isonormals(x0,y0,z0,YI,p);  
set(p,'FaceColor','blue','EdgeColor','none');  
view(3), axis equal, axis off, camlight, lighting phong
```

<b>Purpose</b>	Interpolant for gridded data
<b>Description</b>	The <code>griddedInterpolant</code> class constructs an interpolant $F$ from a gridded data set. The <i>interpolant</i> $F$ is an interpolating function that can be evaluated at query locations.
<b>Construction</b>	<p><code>F = griddedInterpolant(x,v)</code> takes vectors <math>x</math> and <math>v</math> of equal length and creates an interpolant <math>F</math>. The first input argument, <math>x</math>, is a vector of sample points. <math>v</math> is a vector of corresponding values such that <math>v = f(x)</math>. The interpolant <math>F</math> interpolates a vector of query locations <math>xq</math> using <math>vq = F(xq)</math> to return the interpolated values <math>vq</math>.</p> <p><code>F = griddedInterpolant(X1,X2,...,Xn,V)</code> specifies a grid as <math>n</math> <math>n</math>-dimensional arrays <math>Xi</math>. The grid <math>(X1, X2, \dots, Xn)</math> is created from grid vectors <math>xgi</math> by <math>[X1, X2, \dots, Xn] = \text{ndgrid}(xg1, xg2, \dots, xgn)</math>.</p> <p><code>F = griddedInterpolant(V)</code> creates an interpolant <math>F</math> through the <math>n</math>-dimensional array of values <math>V</math> using the default grid formed by grid vectors <math>xgi = 1:\text{size}(V, i)</math>.</p> <p><code>F = griddedInterpolant({xg1,xg2,...,xgn},V)</code> specifies the grid in compact form in terms of grid vectors <math>xgi</math>, where <math>\text{length}(xgi)</math> is <math>\text{size}(V, i)</math>.</p> <p><code>F = griddedInterpolant(...,Method)</code> specifies the interpolation method. The values for 'Method' are nearest, linear (default), spline, pchip, or cubic.</p> <p>The interpolant <math>F</math> can be evaluated on scattered or gridded query locations.</p>

## Input Arguments

**x**

Vector of input coordinates the same size as  $v$ .

**v**

Vector of input values the same size as  $x$ .

**X1, X2, ..., Xn**

# griddedInterpolant

---

n n-dimensional arrays  $X_i$  that specify a grid. `size(Xi)` is `size(V)`.

## **V**

n-dimensional array of values associated with each grid point.

## **{xg1,xg2,...,xgn}**

Cell array of grid vectors  $x_{gi}$  that specify the grid in compact form.

## **Method**

Interpolation method. Possible values are:

`nearest`

Nearest neighbor interpolation.

`linear` (default)

Linear, bilinear, trilinear,... interpolation.

`spline`

Spline interpolation.

`pchip`

Shape-preserving piecewise cubic interpolation (1-D only).

`cubic`

Cubic, bicubic, tricubic,... For uniformly spaced data only.

## **Properties**

### **GridVectors**

Cell array containing grid vectors.

### **Values**

Array of values associated with each grid point.

### **Method**

Method used to interpolate data. Possible values are the same as for the `Method` input: `nearest`, `linear` (default), `spline`, `pchip`, or `cubic`.

## Evaluation

The interpolant  $F$  can be evaluated on scattered or gridded query locations as follows:

- $Vq = F(Xq)$  evaluates  $F$  at the query locations  $Xq$  to produce the corresponding values  $Vq$ . The  $m$ -by- $n$  matrix  $Xq$  represents  $m$  points scattered in  $n$ -dimensional space.  $Vq$  is  $m$ -by-1.
- $Vq = F(xq1, xq2, \dots, xqn)$  specifies the query locations  $xqi$  as column vectors of length  $m$  representing  $m$  points scattered in  $n$ -dimensional space.  $Vq$  is  $m$ -by-1.
- $Vq = F(Xq1, Xq2, \dots, Xqn)$  specifies the query locations as  $n$   $n$ -dimensional arrays  $Xqi$  of equal size specifying the full grid.  $Vq$  is the same size as  $Xqi$ .
- $Vq = F(\{xgq1, xgq2, \dots, xgqn\})$  specifies the query locations as a grid formed by the grid vectors  $xgqi$ .  $Vq$  is the size of grid defined by  $xgqi$ ,  $\text{length}(xgq1)$ -by- $\text{length}(xgq2)$ -by-...-by- $\text{length}(xgqn)$ .

## Definitions

A *gridded data set* is an axis-aligned, ordered set of points.

A *scattered data set* consists of a set of points where the points have no structure among their relative locations.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB Programming Fundamentals documentation.

## Indexing

Index-based editing of the properties of  $F$  are not supported. Instead, wholly replace the `GridVectors` or `Values` arrays as necessary. See “Interpolation with the `griddedInterpolant` Class” in the MATLAB Mathematics documentation for more information.

## Examples

Interpolate to refine a grid-based sampling:

```
[X1, X2] = ndgrid(1:10,1:10);  
V = X1.^2 + X2.^2;  
F = griddedInterpolant(X1,X2,V, 'cubic');  
[Xq1, Xq2] = ndgrid(1:0.5:10,1:0.5:10);
```

# griddedInterpolant

---

```
Vq = F(Xq1,Xq2);  
mesh(Xq1,Xq2,Vq);
```

## See Also

## How To

- [Class Attributes](#)
- [Property Attributes](#)
- [“Interpolating Gridded Data”](#)

**Purpose**

Generalized singular value decomposition

**Syntax**

```
[U,V,X,C,S] = gsvd(A,B)
sigma = gsvd(A,B)
```

**Description**

`[U,V,X,C,S] = gsvd(A,B)` returns unitary matrices  $U$  and  $V$ , a (usually) square matrix  $X$ , and nonnegative diagonal matrices  $C$  and  $S$  so that

$$\begin{aligned} A &= U * C * X' \\ B &= V * S * X' \\ C' * C + S' * S &= I \end{aligned}$$

$A$  and  $B$  must have the same number of columns, but may have different numbers of rows. If  $A$  is  $m$ -by- $p$  and  $B$  is  $n$ -by- $p$ , then  $U$  is  $m$ -by- $m$ ,  $V$  is  $n$ -by- $n$  and  $X$  is  $p$ -by- $q$  where  $q = \min(m+n, p)$ .

`sigma = gsvd(A,B)` returns the vector of generalized singular values,  $\sqrt{\text{diag}(C' * C) ./ \text{diag}(S' * S)}$ .

The nonzero elements of  $S$  are always on its main diagonal. If  $m \geq p$  the nonzero elements of  $C$  are also on its main diagonal. But if  $m < p$ , the nonzero diagonal of  $C$  is  $\text{diag}(C, p-m)$ . This allows the diagonal elements to be ordered so that the generalized singular values are nondecreasing.

`gsvd(A,B,0)`, with three input arguments and either  $m$  or  $n \geq p$ , produces the “economy-sized” decomposition where the resulting  $U$  and  $V$  have at most  $p$  columns, and  $C$  and  $S$  have at most  $p$  rows. The generalized singular values are  $\text{diag}(C) ./ \text{diag}(S)$ .

When  $B$  is square and nonsingular, the generalized singular values, `gsvd(A,B)`, are equal to the ordinary singular values, `svd(A/B)`, but they are sorted in the opposite order. Their reciprocals are `gsvd(B,A)`.

In this formulation of the `gsvd`, no assumptions are made about the individual ranks of  $A$  or  $B$ . The matrix  $X$  has full rank if and only if the matrix  $[A;B]$  has full rank. In fact, `svd(X)` and `cond(X)` are equal to `svd([A;B])` and `cond([A;B])`. Other formulations, eg. G. Golub and

C. Van Loan [1], require that  $\text{null}(A)$  and  $\text{null}(B)$  do not overlap and replace  $X$  by  $\text{inv}(X)$  or  $\text{inv}(X')$ .

Note, however, that when  $\text{null}(A)$  and  $\text{null}(B)$  do overlap, the nonzero elements of  $C$  and  $S$  are not uniquely determined.

## Examples

### Example 1

The matrices have at least as many rows as columns.

```
A = reshape(1:15,5,3)
```

```
B = magic(3)
```

```
A =
```

1	6	11
2	7	12
3	8	13
4	9	14
5	10	15

```
B =
```

8	1	6
3	5	7
4	9	2

The statement

```
[U,V,X,C,S] = gsvd(A,B)
```

produces a 5-by-5 orthogonal  $U$ , a 3-by-3 orthogonal  $V$ , a 3-by-3 nonsingular  $X$ ,

```
X =
```

2.8284	-9.3761	-6.9346
-5.6569	-8.3071	-18.3301
2.8284	-7.2381	-29.7256

and

```
C =
```

0.0000	0	0
--------	---	---

$$S = \begin{bmatrix} 0 & 0.3155 & 0 \\ 0 & 0 & 0.9807 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1.0000 & 0 & 0 \\ 0 & 0.9489 & 0 \\ 0 & 0 & 0.1957 \end{bmatrix}$$

Since A is rank deficient, the first diagonal element of C is zero.

The economy sized decomposition,

$$[U, V, X, C, S] = \text{gsvd}(A, B, 0)$$

produces a 5-by-3 matrix U and a 3-by-3 matrix C.

$$U = \begin{bmatrix} 0.5700 & -0.6457 & -0.4279 \\ -0.7455 & -0.3296 & -0.4375 \\ -0.1702 & -0.0135 & -0.4470 \\ 0.2966 & 0.3026 & -0.4566 \\ 0.0490 & 0.6187 & -0.4661 \end{bmatrix}$$

$$C = \begin{bmatrix} 0.0000 & 0 & 0 \\ 0 & 0.3155 & 0 \\ 0 & 0 & 0.9807 \end{bmatrix}$$

The other three matrices, V, X, and S are the same as those obtained with the full decomposition.

The generalized singular values are the ratios of the diagonal elements of C and S.

$$\begin{aligned} \text{sigma} &= \text{gsvd}(A, B) \\ \text{sigma} &= \begin{bmatrix} 0.0000 \\ 0.3325 \end{bmatrix} \end{aligned}$$

5.0123

These values are a reordering of the ordinary singular values

```
svd(A/B)
ans =
    5.0123
    0.3325
    0.0000
```

## Example 2

The matrices have at least as many columns as rows.

```
A = reshape(1:15,3,5)
B = magic(5)
A =
```

```

    1     4     7    10    13
      2     5     8    11    14
      3     6     9    12    15
B =
    17    24     1     8    15
      23     5     7    14    16
      4     6    13    20    22
      10    12    19    21     3
      11    18    25     2     9
```

The statement

```
[U,V,X,C,S] = gsvd(A,B)
```

produces a 3-by-3 orthogonal U, a 5-by-5 orthogonal V, a 5-by-5 nonsingular X and

```
C =
    0     0    0.0000     0     0
    0     0     0    0.0439     0
    0     0     0     0    0.7432
```

```
S =
      1.0000      0      0      0      0
      0      1.0000      0      0      0
      0      0      1.0000      0      0
      0      0      0      0.9990      0
      0      0      0      0      0.6690
```

In this situation, the nonzero diagonal of C is `diag(C,2)`. The generalized singular values include three zeros.

```
sigma = gsvd(A,B)
sigma =
      0
      0
      0.0000
      0.0439
      1.1109
```

Reversing the roles of A and B reciprocates these values, producing two infinities.

```
gsvd(B,A)
ans =
      1.0e+016 *
      0.0000
      0.0000
      4.4126
      Inf
      Inf
```

## Algorithms

The generalized singular value decomposition uses the C-S decomposition described in [1], as well as the built-in `svd` and `qr` functions. The C-S decomposition is implemented in a local function in the `gsvd` program file.

## Diagnostics

The only warning or error message produced by `gsvd` itself occurs when the two input arguments do not have the same number of columns.

qr | svd

**Purpose**

Test for greater than

**Syntax**

```
A > B  
gt(A, B)
```

**Description**

`A > B` compares each element of array `A` with the corresponding element of array `B`, and returns an array with elements set to logical 1 (**true**) where `A` is greater than `B`, or set to logical 0 (**false**) where `A` is less than or equal to `B`. Each input of the expression can be an array or a scalar value.

If both `A` and `B` are scalar (i.e., 1-by-1 matrices), then the MATLAB software returns a scalar value.

If both `A` and `B` are nonscalar arrays, then these arrays must have the same dimensions, and MATLAB returns an array of the same dimensions as `A` and `B`.

If one input is scalar and the other a nonscalar array, then the scalar input is treated as if it were an array having the same dimensions as the nonscalar input array. In other words, if input `A` is the number 100, and `B` is a 3-by-5 matrix, then `A` is treated as if it were a 3-by-5 matrix of elements, each set to 100. MATLAB returns an array of the same dimensions as the nonscalar input array.

`gt(A, B)` is called for the syntax `A>B` when either `A` or `B` is an object.

**Examples**

Create two 6-by-6 matrices, `A` and `B`, and locate those elements of `A` that are greater than the corresponding elements of `B`:

```
A = magic(6);  
B = repmat(3*magic(3), 2, 2);
```

```
A > B  
ans =  
     1     0     0     1     1     1  
     0     1     0     1     1     1  
     1     0     0     1     0     1  
     0     1     1     0     1     0
```

# gt

## How To

- “Relational Operators”

**Purpose**

Mouse placement of text in 2-D view

**Syntax**

```
gtext('string')
gtext({'string1','string2','string3',...})
gtext({'string1';'string2';'string3';...})
gtext(...,'PropertyName',PropertyValue,...)
h = gtext(...)
```

**Description**

`gtext` displays a text string in the current figure window after you select a location with the mouse.

`gtext('string')` waits for you to press a mouse button or keyboard key while the pointer is within a figure window. Pressing a mouse button or any key places `'string'` on the plot at the selected location.

`gtext({'string1','string2','string3',...})` places all strings with one click, each on a separate line.

`gtext({'string1';'string2';'string3';...})` places one string per click, in the sequence specified.

`gtext(...,'PropertyName',PropertyValue,...)` sets the values of the specified text properties. For a list of properties, see [Text Properties](#).

`h = gtext(...)` returns the handle to a text graphics object that is placed on the plot at the location you select.

**Tips**

As you move the pointer into a figure window, the pointer becomes crosshairs to indicate that `gtext` is waiting for you to select a location. `gtext` uses the functions `ginput` and `text`.

**Examples**

Place a label on the current plot:

```
gtext('Note this divergence!')
```

**See Also**

[ginput](#) | [text](#)

# guidata

---

**Purpose** Store or retrieve GUI data

**Syntax** `guidata(object_handle,data)`  
`data = guidata(object_handle)`

**Description** `guidata(object_handle,data)` stores the variable `data` as GUI data. If `object_handle` is not a figure handle, then the object's parent figure is used. `data` can be any MATLAB variable, but is typically a structure, which enables you to add new fields as required.

`guidata` can manage only one variable at any time. Subsequent calls to `guidata(object_handle,data)` overwrite the previously created version of GUI data.

---

## **GUIDE Uses guidata**

GUIDE uses `guidata` to store and maintain the `handles` structure. In a GUIDE GUI code file, do not overwrite the `handles` structure or your GUI will no longer work. If you need to store data other than `handles` for your GUI, you can add new fields to the `handles` structure and safely place your data there. See GUI Data in the MATLAB documentation.

---

`data = guidata(object_handle)` returns previously stored data, or an empty matrix if nothing is stored.

To change the data managed by `guidata`:

- 1** Get a copy of the data with the command `data = guidata(object_handle)`.
- 2** Make the desired changes to `data`.
- 3** Save the changed version of `data` with the command `guidata(object_handle,data)`.

guidata provides application developers with a convenient interface to a figure's application data:

- You do not need to create and maintain a hard-coded property name for the application data throughout your source code.
- You can access the data from within a local function callback routine using the component's handle (which is returned by `gcb0`), without needing to find the figure's handle.

If you are not using GUIDE, guidata is particularly useful in conjunction with `guihandles`, which creates a structure containing the handles of all the components in a GUI.

## Examples

This example calls `guidata` to save a structure containing a GUI figure's application data from within the initialization section of the application code file. The first section shows how to do this within a GUI you create manually. The second section shows how the code differs when you use GUIDE to create a template code file. GUIDE provides a `handles` structure as an argument to all local function callbacks, so you do not need to call `guidata` to obtain it. You do, however, need to call `guidata` to save changes you make to the structure.

### Using guidata in a Programmed GUI

Calling the `guihandles` function creates the structure into which your code places additional data. It contains all handles used by the figure at the time it is called, generating field names based on each object's `Tag` property.

```
% Create figure to use as GUI in your main function or a local function
figure_handle = figure('Toolbar','none');
% create structure of handles
myhandles = guihandles(figure_handle);
% Add some additional data as a new field called numberOfErrors
myhandles.numberOfErrors = 0;
% Save the structure
guidata(figure_handle,myhandles)
```

You can recall the data from within a local callback function, modify it, and then replace the structure in the figure:

```
function My_Callback()
% ...
% Get the structure using guidata in the local function
myhandles = guidata(gcbo);
% Modify the value of your counter
myhandles.numberOfErrors = myhandles.numberOfErrors + 1;
% Save the change you made to the structure
guidata(gcbo,myhandles)
```

## Using guidata in a GUIDE GUI

If you use GUIDE, you do not need to call `guihandles` to create a structure, because GUIDE generates a `handles` structure that contains the GUI's handles. You can add your own data to it, for example from within the `OpeningFcn` template that GUIDE creates:

```
% --- Executes just before simple_gui_tab is made visible.
function my_GUIDE_GUI_OpeningFcn(hObject, eventdata, handles, varargin)
% This function has no output args, see OutputFcn.
% hObject    handle to figure
% eventdata  reserved - to be defined in a future version of MATLAB
% handles    structure with handles and user data (see GUIDATA)
% varargin   command line arguments to simple_gui_tab (see VARARGIN)
% ...

% add some additional data as a new field called numberOfErrors
handles.numberOfErrors = 0;
% Save the change you made to the structure
guidata(hObject,handles)
```

Notice that you use the input argument `hObject` in place of `gcbo` to refer to the object whose callback is executing.

Suppose you needed to access the `numberOfErrors` field in a push button callback. Your callback code now looks something like this:

```
% --- Executes on button press in pushbutton1.
function my_GUIDE_GUI_pushbutton1_Callback(hObject, eventdata, handles)
% hObject      handle to pushbutton1 (see GCBO)
% eventdata    reserved - to be defined in a future version of MATLAB
% handles      structure with handles and user data (see GUIDATA)
% ...

% No need to call guidata to obtain a structure;
% it is provided by GUIDE via the handles argument
handles.numberofErrors = handles.numberofErrors + 1;
% save the changes to the structure
guidata(hObject,handles)
```

[guide](#) | [guihandles](#) | [getappdata](#) | [setappdata](#)

# guide

---

**Purpose** Open GUI Layout Editor

**Syntax**

```
guide
guide('filename.fig')
guide('fullpath')
guide(HandleList)
```

**Description**

`guide` initiates the GUI design environment (GUIDE) tools that allow you to create or edit GUIs interactively.

`guide` opens the GUIDE Quick Start dialog where you can choose to open a previously created GUI or create a new one using one of the provided templates.

`guide('filename.fig')` opens the FIG-file named `filename.fig` for editing if it is on the MATLAB path.

`guide('fullpath')` opens the FIG-file at `fullpath` even if it is not on the MATLAB path.

`guide(HandleList)` opens the content of each of the figures in `HandleList` in a separate copy of the GUIDE design environment.

**See Also** `inspect`

**How To**

- “Ways to Build MATLAB GUIs”

**Purpose** Create structure of handles

**Syntax** `handles = guihandles(object_handle)`  
`handles = guihandles`

**Description** `handles = guihandles(object_handle)` returns a structure containing the handles of the objects in a figure, using the value of their Tag properties as the fieldnames, with the following caveats:

- Objects are excluded if their Tag properties are empty, or are not legal variable names.
- If several objects have the same Tag, that field in the structure contains a vector of handles.
- Objects with hidden handles are included in the structure.

`handles = guihandles` returns a structure of handles for the current figure.

**See Also** `guidata` | `guide` | `getappdata` | `setappdata`

# gunzip

---

**Purpose** Uncompress GNU zip files

**Syntax**  
`gunzip(files)`  
`gunzip(files,outputdir)`  
`gunzip(url, ...)`  
`filenames = gunzip(...)`

**Description** `gunzip(files)` uncompresses GNU zip files from the list of files specified in `files`. Directories recursively `gunzip` all of their content. The output files have the same name, excluding the extension `.gz`, and are written to the same directory as the input files.

`files` is a string or cell array of strings containing a list of files or directories. Individual files that are on the MATLAB path can be specified as partial path names. Otherwise, an individual file can be specified relative to the current directory or with an absolute path.

Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with `~/` or `~username/`, which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character `*` can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.

`gunzip(files,outputdir)` writes the gunzipped file into the directory `outputdir`. If `outputdir` does not exist, MATLAB creates it.

`gunzip(url, ...)` extracts the GNU zip contents from an Internet universal resource locator (URL). The URL must include the protocol type (for example, `http://`). MATLAB downloads the URL to the temp directory, and then deletes it.

`filenames = gunzip(...)` gunzips the files and returns the relative path names of the gunzipped files in the string cell array `filenames`.

**Examples** To `gunzip` all `.gz` files in the current directory, type:

```
gunzip('*.*gz');
```

To `gunzip` Cleve Moler's "Numerical Computing with MATLAB" examples to the output directory `ncm`, type:

```
url = 'http://www.mathworks.com/moler/ncm.tar.gz';  
gunzip(url, 'ncm')  
untar('ncm/ncm.tar', 'ncm')
```

## See Also

`gzip` | `tar` | `untar` | `unzip` | `zip`

# gzip

---

**Purpose** Compress files into GNU zip files

**Syntax**  
`gzip(files)`  
`gzip(files,outputdir)`  
`filenames = gzip(...)`

**Description** `gzip(files)` creates GNU zip files from the list of files specified in `files`. Directories recursively `gzip` all their contents. Each output gzipped file is written to the same directory as the input file and with the file extension `.gz`.

`files` is a string or cell array of strings containing a list of files or directories to `gzip`. Individual files that are on the MATLAB path can be specified as partial path names. Otherwise, an individual file can be specified relative to the current directory or with an absolute path.

Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with `~/` or `~username/`, which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character `*` can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.

`gzip(files,outputdir)` writes the gzipped files into the directory `outputdir`. If `outputdir` does not exist, MATLAB creates it.

`filenames = gzip(...)` gzips the files and returns the relative path names of all gzipped files in the string cell array `filenames`.

**Examples** To `gzip` all `.m` and `.mat` files in the current directory and store the results in the directory `archive`, type:

```
gzip({'*.m','*.mat'},'archive');
```

**See Also** `gunzip` | `tar` | `untar` | `unzip` | `zip`

<b>Purpose</b>	Create HDF5 data set
<b>Syntax</b>	<code>h5create(filename,datasetname,size,Name,Value)</code>
<b>Description</b>	<code>h5create(filename,datasetname,size,Name,Value)</code> creates an HDF5 data set in the file specified by <code>filename</code> .
<b>Input Arguments</b>	<p><b>filename</b></p> <p>Text string specifying the name of an HDF5 file. If <code>filename</code> does not already exist, <code>h5create</code> creates it, with additional options specified by one or more <code>Name,Value</code> pair arguments.</p> <p><b>datasetname</b></p> <p>Text string specifying the name of the data set you want to create. If <code>datasetname</code> is a full path name, <code>h5create</code> creates all intermediate groups, if they don't already exist.</p> <p><b>size</b></p> <p>Array specifying the extents of the dataset. To specify an unlimited extent, set the corresponding element of <code>size</code> to <code>Inf</code>.</p>
<b>Name-Value Pair Arguments</b>	<p>Specify optional comma-separated pairs of <code>Name,Value</code> arguments, where <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as <code>Name1,Value1,...,NameN,ValueN</code>.</p> <p><b>Datatype</b></p> <p>Any of the following MATLAB datatypes.</p>

double	uint64	uint32	uint16	uint8
single	int64	int32	int16	int8

# h5create

---

**Default:** double

## **ChunkSize**

Defines chunking layout.

**Default:** Not chunked

## **Deflate**

Defines gzip compression level (0-9).

**Default:** 0

## **FillValue**

Defines the fill value for numeric data sets.

## **Fletcher32**

Turns on the Fletcher32 checksum filter.

**Default:** false

## **Shuffle**

Turns on the Shuffle filter.

**Default:** false

## **Examples**

Create a fixed-size 100-by-200 data set.

```
h5create('myfile.h5', '/myDataset1', [100 200]);  
h5disp('myfile.h5');
```

---

Create a single-precision 1000-by-2000 data set with a chunk size of 50-by-80. Apply the highest level of compression.

```
h5create('myfile.h5', '/myDataset2', [1000 2000], 'Datatype', 'single',  
        'ChunkSize', [50 80], 'Deflate', 9);  
h5disp('myfile.h5');
```

---

Create a two-dimensional data set that is unlimited along the second extent.

```
h5create('myfile.h5', '/myDataset3', [200 Inf], 'ChunkSize', [20 20]);  
h5disp('myfile.h5');
```

- “Exporting to Hierarchical Data Format (HDF5) Files”

# h5disp

---

**Purpose** Display contents of HDF5 file

**Syntax**  
h5disp(filename)  
h5disp(filename,location)  
h5disp(filename,location,mode)

**Description** h5disp(filename) displays the structure (metadata) of the entire HDF5 file, filename.  
h5disp(filename,location) displays the metadata for the specified location.  
h5disp(filename,location,mode) displays the file metadata according to the value of mode.

## Input Arguments

### filename

Text string specifying the name of an HDF5 file.

### location

Text string specifying the full path to a location in an HDF5 file. To display the metadata for the entire file, specify '/' as the value of location. If location is a group, h5disp displays all objects below the group.

### mode

Either of the following text strings.

Value	Description
min	Minimal, display only group and data set names.
simple	Display data set metadata and attribute values, if the attribute is an integer, floating point, or a scalar string.

**Default:** simple

## Examples

Display the entire contents of an HDF5 file.

```
h5disp('example.h5')
```

---

Display metadata for one data set in an HDF5 file.

```
h5disp('example.h5', '/g4/world');
```

`h5info`

## Tutorials

- “Using the High-Level HDF5 Functions to Import Data”

# h5info

---

**Purpose** Return information about HDF5 file

**Syntax**  
`info = h5info(filename)`  
`info = h5info(filename,location)`

**Description** `info = h5info(filename)` returns information about the entire HDF5 file, specified by `filename`.

`info = h5info(filename,location)` returns information about the group, data set, or named datatype specified by `location` in the HDF5 file, `filename`.

**Input Arguments**

**filename**  
Text string specifying the name of an HDF5 file.

**location**  
Text string specifying the location of a group, data set, or named datatype in an HDF5 file.

**Output Arguments**

**info**  
A structure containing information about the HDF5 file. The set of fields in the structure depends on the `location` parameter. The first field is always 'Filename'. Other fields that might be present in the `info` structure are as follows.

Location Type	Field	Description
Files and Groups		
	Name	Text string specifying name of the group. If you specify only a file name, this value is '/ '.

<b>Location Type</b>	<b>Field</b>	<b>Description</b>
	Groups	Array of structures describing subgroups.
	Datasets	Array of structures describing data sets.
	Datatypes	Array of structures describing named datatypes.
	Links	Array of structures describing soft, external, user-defined, and certain hard links.
	Attributes	Array of structures describing group attributes.
Data sets		
	Name	Text string specifying the name of the data set.
	Datatype	Structure describing the datatype.
	Dataspace	Structure describing the size of the dataset.
	ChunkSize	Extents of the data set's chunk size, if defined.
	FillValue	Data set's fill value, if defined.
	Filter	Array of structures describing any defined filters such as compression.
	Attributes	Array of structures describing data set attributes.
Named Datatypes		

# h5info

---

Location Type	Field	Description
	Name	Text string specifying the name of the datatype object.
	Class	HDF5 class of the named datatype.
	Type	Text string or struct further describing the datatype.
	Size	Size of the named datatype in bytes.

## Examples

Return all information.

```
info = h5info('example.h5');
```

---

Return information about a group and all data sets contained within the group.

```
info = h5info('example.h5', '/g4');
```

---

Return information about a specific dataset.

```
info = h5info('example.h5', '/g4/time');
```

- “Using the High-Level HDF5 Functions to Import Data”

**Purpose** Read data from HDF5 data set

**Syntax**

```
data = h5read(filename,datasetname)
data = h5read(filename,datasetname,start,count)
data = h5read(filename,datasetname,start,count,stride)
```

**Description** `data = h5read(filename,datasetname)` retrieves all of the data from the HDF5 data set `datasetname` in the file `filename`.

`data = h5read(filename,datasetname,start,count)` reads a subset of data from the data set `datasetname`. `start` is the one-based index of the first element to be read. `count` defines how many elements to read along each dimension. If a particular element of `count` is `Inf`, `h5read` reads data until the end of the corresponding dimension.

`data = h5read(filename,datasetname,start,count,stride)` reads a subset of data, where `stride` specifies the interelement spacing along each data set extent.

## Input Arguments

### **filename**

Text string specifying the name of an HDF5 file.

### **datasetname**

Text string specifying the name of a data set in an HDF5 file.

### **start**

Numeric index value specifying the place to start reading data in the dataset in an HDF5 file. Indices are 1-based.

### **count**

Numeric value specifying the amount of data to read.

### **stride**

# h5read

---

Numeric value specifying the interval spacing during the read operation. For example, a spacing of 2 indicates reading every other value.

## Output Arguments

### **data**

Data read from the data set.

## Examples

Read an entire data set.

```
h5disp('example.h5','/g4/lat');  
data = h5read('example.h5','/g4/lat');
```

---

Read the first 5-by-3 subset of a data set.

```
h5disp('example.h5','/g4/world');  
data = h5read('example.h5','/g4/world',[1 1],[5 3]);
```

---

Read a data set of references to other data sets.

```
h5disp('example.h5','/g3/reference');  
data = h5read('example.h5','/g3/reference');
```

<b>Tutorials</b>	<ul style="list-style-type: none"><li>“Using the High-Level HDF5 Functions to Import Data”</li></ul>

# h5write

---

## Purpose

Write to HDF5 data set

## Syntax

```
h5write(filename,datasetname,data)
h5write(filename,datasetname,data,start,count)
h5write(filename,datasetname,data,start,count,stride)
```

## Description

`h5write(filename,datasetname,data)` writes data to an entire data set, `datasetname`, in the HDF5 file, `filename`.

`h5write(filename,datasetname,data,start,count)` writes a subset of the data to a data set, `datasetname`, in the HDF5 file, `filename`. `start` is a one-based index value that specifies the first element to be written. `count` specifies the number of elements to write along each dimension. `h5write` extends an extendable data set along any unlimited dimensions, if necessary.

`h5write(filename,datasetname,data,start,count,stride)` writes a hyperslab of data, where `stride` specifies the inter-element spacing along each dimension.

## Input Arguments

### **filename**

Text string specifying the name of an HDF5 file.

### **datasetname**

Text string specifying the name of a data set in the HDF5 file.

### **data**

Data to be written to the HDF5 file. You can specify only floating-point and integer data sets.

### **start**

Numeric index value specifying where in the data set to start writing to the file.

### **count**

Numeric value specifying how much data to write to the file.

**stride**

Numeric value specifying the interelement spacing of data to write to the file.

**Default:** Vector of ones.

**Definitions****Hyperslab**

A hyperslab is a collection of points in a data space. The points can be contiguous or form a regular pattern of points or blocks in a data space.

**Examples**

Write to an entire data set.

```
h5create('myfile.h5', '/DS1', [10 20]);  
mydata = rand(10,20);  
h5write('myfile.h5', '/DS1', mydata);
```

---

Write a hyperslab of data to the last 5-by-7 block of a data set.

```
h5create('myfile.h5', '/DS2', [10 20]);  
mydata = rand(5,7);  
h5write('myfile.h5', '/DS2', mydata, [6 14], [5 7]);
```

---

Append data to an unlimited data set.

```
h5create('myfile.h5', '/DS3', [20 Inf], 'ChunkSize', [5 5]);  
for j = 1:10  
    data = j*ones(20,1);  
    start = [1 j];  
    count = [20 1];  
    h5write('myfile.h5', '/DS3', data, start, count);  
end
```

# h5write

---

```
h5disp('myfile.h5');
```

## Tutorials

- “Exporting to Hierarchical Data Format (HDF5) Files”

<b>Purpose</b>	Write HDF5 attribute
<b>Syntax</b>	<code>h5writeatt(filename,location,attname,attvalue)</code>
<b>Description</b>	<code>h5writeatt(filename,location,attname,attvalue)</code> writes the attribute named <code>attname</code> with the value <code>attvalue</code> to the HDF5 file <code>filename</code> . The parent object <code>location</code> can be either a group or variable. <code>location</code> is the complete path name of the group or variable to which you want to associate the attribute.
<b>Input Arguments</b>	<p><b>filename</b> Text string specifying the name of an HDF5 file.</p> <p><b>location</b> Text string specifying the full path identifying a group or variable in an HDF5 file.</p> <p><b>attname</b> Text string specifying the name of an attribute in an HDF5 file. If the attribute does not exist, <code>h5writeatt</code> creates the attribute with the name specified.  If the specified attribute already exists but does not have a datatype or dataspace consistent with <code>attvalue</code>, <code>h5writeatt</code> deletes the attribute and recreates it. String attributes are created with a scalar dataspace.</p> <p><b>attvalue</b> Value to be written to the attribute in an HDF5 file.</p>
<b>Examples</b>	Create a root group attribute whose value is the current time. <pre>srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5'); copyfile(srcFile,'myfile.h5'); fileattrib('myfile.h5','+w'); h5writeatt('myfile.h5','/', 'creation_date',datestr(now));</pre>

# h5writeatt

---

Create a double-precision data set attribute.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
attData = [0 1 2 3];
h5writeatt('myfile.h5','/g4/world','attr',attData);
h5disp('myfile.h5','/g4/world');
```

## Tutorials

- “Exporting to Hierarchical Data Format (HDF5) Files”

**Purpose** Hadamard matrix

**Syntax** `H = hadamard(n)`

**Description** `H = hadamard(n)` returns the Hadamard matrix of order `n`.

**Definitions** Hadamard matrices are matrices of 1's and -1's whose columns are orthogonal,

$$H' * H = n * I$$

where `[n n]=size(H)` and `I = eye(n,n)` .

They have applications in several different areas, including combinatorics, signal processing, and numerical analysis, [1], [2].

An `n`-by-`n` Hadamard matrix with `n > 2` exists only if `rem(n,4) = 0`. This function handles only the cases where `n`, `n/12`, or `n/20` is a power of 2.

**Examples** The command `hadamard(4)` produces the 4-by-4 matrix:

```
1   1   1   1
1  -1   1  -1
1   1  -1  -1
1  -1  -1   1
```

# handle

---

**Purpose** Abstract class for deriving handle classes

**Syntax** `classdef MyHandleClass < handle`

**Description** `classdef MyHandleClass < handle` makes *MyHandleClass* a subclass of the `handle` class.

The `handle` class is the superclass for all classes that follow handle semantics. A *handle* is a reference to an object. If you copy an object's handle, MATLAB copies only the handle and both the original and copy refer to the same object data. If a function modifies a handle object passed as an input argument, the modification affects the original input object.

In contrast, nonhandle objects (that is, value objects) are not references. Functions must return modified value objects to the caller to cause change to the object outside of the function's workspace.

See “Modifying Objects” for information on passing objects to functions.

Handle object behavior is like that of Handle Graphics objects, where the handle of a graphics object always refers to a particular instance regardless of whether you save the handle when you create the object, store it in another variable, or obtain it with convenience functions like `findobj`, `gca`, and so on.

If you want to create a class that defines events, you must derive that class from the `handle` class.

The `handle` class is an abstract class, so you cannot create an instance of this class directly. You use the `handle` class to derive other classes, which can be concrete classes whose instances are handle objects. See “Handle Classes” for information on using handle classes.

## Handle Class Methods

When you derive a class from the `handle` class, your class inherits the following methods.

Method	Purpose
<code>addlistener</code>	Creates a listener for the specified event and assigns a callback function to execute when the event occurs.
<code>notify</code>	Broadcast a notice that a specific event is occurring on a specified handle object or array of handle objects.
<code>delete</code>	Handle object destructor method that is called when the object's lifecycle ends.
<code>findobj</code>	Finds objects matching the specified conditions from the input array of handle objects.
<code>findprop</code>	Returns a <code>meta.property</code> objects associated with the specified property name.
<code>isvalid</code>	Returns a logical array in which elements are true if the corresponding elements in the input array are valid handles. This method is <b>Sealed</b> so you cannot override it in a handle subclass.
<code>eq</code> <code>ne</code> <code>lt</code> <code>le</code> <code>gt</code> <code>ge</code> <code>relationaloperator</code>	Relational functions return a logical array of the same size as the pair of input handle object arrays. Comparisons use a number associated with each handle. You can assume that the same two handles will compare as equal and the repeated comparison of any two handles will yield the same result in the same MATLAB session. Different handles are always not-equal. The order of handles is purely arbitrary, but consistent.

## Handle Class Events

The handle class defines one event:

`ObjectBeingDestroyed`

# handle

---

This event is triggered when the handle object is about to be destroyed. If you define a listener for this event, its callback executes before MATLAB destroys the handle object.

You can add a listener for this event using the `addlistener` method. See “Events and Listeners — Syntax and Techniques” for more information on using events and listeners.

You can define a `delete` method for a handle subclass that MATLAB calls when the object is destroyed. See “Handle Class Destructor”.

## Handle Subclasses

You can use the following abstract `handle` subclasses to derive more specialized `handle` classes:

- `hgsetget` – use when you want to create a handle class that inherits `set` and `get` methods having the same behavior as Handle Graphics `set` and `get` functions.
- `dynamicprops` – use when you want to create a handle class that allows you to add instance data (dynamically defined properties) to objects.
- `matlab.mixin.Copyable` – use to add a `copy` method to a handle subclass.

## Useful Functions

- `properties` — list the class public properties
- `methods` — list the class methods
- `events` — list the events defined by the class

Note that `ishandle` does not test for handle class objects. Use `isa` instead.

**Purpose** Hankel matrix

**Syntax** `H = hankel(c)`  
`H = hankel(c,r)`

**Description** `H = hankel(c)` returns the square Hankel matrix whose first column is `c` and whose elements are zero below the first anti-diagonal.

`H = hankel(c,r)` returns a Hankel matrix whose first column is `c` and whose last row is `r`. If the last element of `c` differs from the first element of `r`, the last element of `c` prevails.

**Definitions** A Hankel matrix is a matrix that is symmetric and constant across the anti-diagonals, and has elements  $h(i,j) = p(i+j-1)$ , where vector  $p = [c \ r(2:end)]$  completely determines the Hankel matrix.

**Examples** A Hankel matrix with anti-diagonal disagreement is

```
c = 1:3; r = 7:10;  
h = hankel(c,r)  
h =  
    1    2    3    8  
    2    3    8    9  
    3    8    9   10
```

```
p = [1 2 3 8 9 10]
```

**Purpose**

Summary of MATLAB HDF4 capabilities

**Description**

The MATLAB software provides a set of low-level functions that enable you to access the HDF4 library developed by the National Center for Supercomputing Applications (NCSA). For information about HDF4, go to the HDF Web page at <http://www.hdfgroup.org>.

---

**Note** For information about MATLAB HDF5 capabilities, which is a completely separate, incompatible format, see `hdf5`.

---

The following table lists all the HDF4 application programming interfaces (APIs) supported by MATLAB with the name of the MATLAB function used to access the API. To use these functions, you must be familiar with the HDF library. For more information about using these MATLAB functions, see “Importing Hierarchical Data Format (HDF4) Files” and “Exporting to Hierarchical Data Format (HDF4) Files”.

Call `help functionname` to display help for any of these functions in the Command Window.

<b>Application Programming Interface</b>	<b>Description</b>	<b>MATLAB Function</b>
Annotations	Stores, manages, and retrieves text used to describe an HDF file or any of the data structures contained in the file.	<code>hdfan</code>
External Files	Manipulates external file elements.	<code>hdfhx</code>

<b>Application Programming Interface</b>	<b>Description</b>	<b>MATLAB Function</b>
General Raster Images	Stores, manages, and retrieves raster images, their dimensions and palettes. It can also manipulate unattached palettes.  Note: Use the MATLAB functions <code>imread</code> and <code>imwrite</code> with HDF raster image formats.	<code>hdfdf24</code> , <code>hdfdfr8</code>
HDF-EOS	Provides functions to read HDF-EOS grid (GD), point (PT), and swath (SW) data.	<code>matlab.io.hdfeos.gd</code> , <code>hdfpt</code> , <code>matlab.io.hdfeos.sw</code>
HDF Utilities	Provides functions to open and close HDF files and handle errors.	<code>hdfh</code> , <code>hdfhd</code> , <code>hdfhe</code>
MATLAB HDF Utilities	Provides utility functions that help you work with HDF files in the MATLAB environment.	<code>hdfml</code>
Scientific Data	Stores, manages, and retrieves multidimensional arrays of character or numeric data, along with their dimensions and attributes.	<code>matlab.io.hdf4.sd</code>
V Groups	Creates and retrieves groups of other HDF data objects, such as raster images or V data.	<code>hdfv</code>
V Data	Stores, manages, and retrieves multivariate data stored as records in a table.	<code>hdfvf</code> , <code>hdfvh</code> , <code>hdfvs</code>

For copyright information, see the `hdf4copyright.txt` file.

# hdf

---

hdfinfo | hdfread | hdf5tool | hdf5

**Purpose**

Summary of MATLAB HDF5 capabilities

**Description**

MATLAB provides both high- and low-level access to Hierarchical Data Format (HDF5) files.

- High-level access functions make it easy to read a data set from an HDF5 file or write a variable from the MATLAB workspace into an HDF5 file.
- Low-level access functions provide direct access to the more than 300 functions in the HDF5 library.

---

**Note** For information about MATLAB HDF4 capabilities, which is a completely separate and incompatible format, see `hdf`.

---

**High-level Access Functions**

These functions provide high-level access to HDF5 files:

- `h5create` — Create HDF5 data set
- `h5disp` — Display contents of HDF5 file
- `h5info` — Return information about HDF5 file
- `h5read` — Read data from HDF5 data set
- `h5readatt` — Read value of attribute from HDF5 group or data set
- `h5write` — Write data to HDF5 data set
- `h5writeatt` — Write data to HDF5 attribute

---

**Note** To create or write to nonnumeric datasets or attributes, you must use the low-level interface.

---

## Low-level Access Functions

MATLAB provides direct access to dozens of functions in the HDF5 library. Using these functions, you can read and write complex datatypes, use HDF5 data subsetting capabilities, and take advantage of other features present in the HDF5 library. To use these MATLAB functions, you must be familiar with HDF5 programming concepts and, when using the low-level functions, details about the functions in the library. To get this information, see <http://www.hdfgroup.org>.

The HDF5 library organizes the routines in the library into collections called *interfaces*. MATLAB organizes the corresponding MATLAB functions into packages that match these HDF5 library interfaces. For example, the MATLAB functions for the HDF5 Attribute Interface are in the H5A package.

The following table lists the HDF5 library interfaces alphabetically with their associated MATLAB package.

<b>HDF5 Library Interface</b>	<b>MATLAB Package Name</b>	<b>Description</b>
Library	H5	General-purpose functions for use with the entire HDF5 library, such as initialization
Attribute	H5A	Manipulate metadata associated with data sets or groups
Dataset	H5D	Manipulate multidimensional arrays of data elements, together with supporting metadata
Dimension Scale	H5DS	Manipulate dimension scale associated with dataset dimensions
Error	H5E	Handle errors
File	H5F	Access files

<b>HDF5 Library Interface</b>	<b>MATLAB Package Name</b>	<b>Description</b>
Group	H5G	Organize objects in a file; analogous to a folder structure
Identifier	H5I	Manipulate HDF5 object identifiers
Link	H5L	Manipulate links in a file
MATLAB	H5ML	MATLAB utility functions that are not part of the HDF5 library itself
Object	H5O	Manipulate objects in a file
Property	H5P	Manipulate object property lists
Reference	H5R	Manipulate HDF5 references, which are like UNIX links or Windows shortcuts
Dataspace	H5S	Define and work with data spaces, which describe the dimensionality of a data set
Datatype	H5T	Define the type of variable that is stored in a dataset
Filters and Compression	H5Z	Create inline data filters and data compression

In most cases, the syntax of the MATLAB function matches the syntax of the HDF5 library function. To get detailed information about the MATLAB syntax of an HDF5 library function, view the help for the individual MATLAB function, as follows:

```
help H5F.open
```

To view a list of all the MATLAB HDF5 functions in a particular interface, type:

```
help H5F
```

# hdf5

---

## **See Also**

`hdf` | `h5create` | `h5disp` | `h5info` | `h5read` | `h5readatt` | `h5write` | `h5writeatt`

**Purpose** Information about HDF5 file

---

**Note** `hdf5info` will be removed in a future version. Use `h5info` instead.

---

**Syntax**

```
fileinfo = hdf5info(filename)
fileinfo = hdf5info(...,'ReadAttributes',BOOL)
[...] = hdf5info(..., 'V71Dimensions', BOOL)
```

**Description** `fileinfo = hdf5info(filename)` returns a structure `fileinfo` whose fields contain information about the contents of the HDF5 file `filename`. `filename` is a string that specifies the name of the HDF5 file.

`fileinfo = hdf5info(...,'ReadAttributes',BOOL)` specifies whether `hdf5info` returns the values of the attributes or just information describing the attributes. By default, `hdf5info` reads in attribute values (`BOOL = true`).

`[...] = hdf5info(..., 'V71Dimensions', BOOL)` specifies whether to report the dimensions of data sets and attributes as they were returned in previous versions of `hdf5info` (MATLAB 7.1 [R14SP3] and earlier). If `BOOL` is true, `hdf5info` swaps the first two dimensions of the data set. This behavior was intended to account for the difference in how HDF5 and MATLAB express array dimensions. HDF5 describes data set dimensions in row-major order; MATLAB stores data in column-major order. However, swapping these dimensions may not correctly reflect the intent of the data in the file and may invalidate metadata. When `BOOL` is false (the default), `hdf5info` returns data dimensions that correctly reflect the data ordering as it is written in the file—each dimension in the output variable matches the same dimension in the file.

# hdf5info

---

---

**Note** If you use the 'V71Dimensions' parameter and intend on passing the `fileinfo` structure returned to the `hdf5read` function, you should also specify the 'V71Dimensions' parameters with `hdf5read`. If you do not, `hdf5read` uses the new behavior when reading the data set and certain metadata returned by `hdf5info` does not match the actual data returned by `hdf5read`.

---

## Examples

```
fileinfo = hdf5info('example.h5');
```

To get more information about the contents of the HDF5 file, look at the `GroupHierarchy` field in the `fileinfo` structure returned by `hdf5info`.

```
toplevel = fileinfo.GroupHierarchy
```

```
toplevel =
```

```
    Filename: [1x64 char]
         Name: '/'
         Groups: [1x2 struct]
        Datasets: []
       Datatypes: []
         Links: []
    Attributes: [1x2 struct]
```

To probe further into the file hierarchy, keep examining the `Groups` field.

## See also

`hdf5read`, `hdf5write`

**Purpose** Read HDF5 file

---

**Note** `hdf5read` will be removed in a future version. Use `h5read` instead.

---

**Syntax**

```
data = hdf5read(filename,datasetname)
attr = hdf5read(filename,attributename)
[data, attr] = hdf5read(...,'ReadAttributes',B00L)
data = hdf5read(hinfo)
[...] = hdf5read(..., 'V71Dimensions', B00L)
```

**Description** `data = hdf5read(filename,datasetname)` reads all the data in the data set `datasetname` that is stored in the HDF5 file `filename` and returns it in the variable `data`. To determine the names of data sets in an HDF5 file, use the `hdf5info` function.

The return value, `data`, is a multidimensional array. `hdf5read` maps HDF5 data types to native MATLAB data types, whenever possible. If it cannot represent the data using MATLAB data types, `hdf5read` uses one of the HDF5 data type objects. For example, if an HDF5 file contains a data set made up of an enumerated data type, `hdf5read` uses the `hdf5.h5enum` object to represent the data in the MATLAB workspace. The `hdf5.h5enum` object has data members that store the enumerations (names), their corresponding values, and the enumerated data. For more information about the HDF5 data type objects, see the `hdf5` reference page.

---

**Note** `hdf5read` performs best when reading numeric datasets. If you need to read string, compound, or variable length datasets, MathWorks strongly recommends that you use the low-level HDF5 interface function, `H5D.read`. To read a subset of a dataset, you must use the low-level interface.

---

# hdf5read

---

`attr = hdf5read(filename,attributename)` reads all the metadata in the attribute `attributename`, stored in the HDF5 file `filename`, and returns it in the variable `attr`. To determine the names of attributes in an HDF5 file, use the `hdf5info` function.

`[data, attr] = hdf5read(..., 'ReadAttributes', BOOL)` reads all the data, as well as all of the associated attribute information contained within that data set. By default, `BOOL` is false.

`data = hdf5read(hinfo)` reads all of the data in the data set specified in the structure `hinfo` and returns it in the variable `data`. The `hinfo` structure is extracted from the output returned by `hdf5info`, which specifies an HDF5 file and a specific data set.

`[...] = hdf5read(..., 'V71Dimensions', BOOL)` specifies whether to change the majority of data sets read from the file. If `BOOL` is true, `hdf5read` permutes the first two dimensions of the data set, as it did in previous releases (MATLAB 7.1 [R14SP3] and earlier). This behavior was intended to account for the difference in how HDF5 and MATLAB express array dimensions. HDF5 describes data set dimensions in row-major order; MATLAB stores data in column-major order. However, permuting these dimensions may not correctly reflect the intent of the data and may invalidate metadata. When `BOOL` is false (the default), the data dimensions correctly reflect the data ordering as it is written in the file — each dimension in the output variable matches the same dimension in the file.

## Examples

Use `hdf5info` to get information about an HDF5 file and then use `hdf5read` to read a data set, using the information structure (`hinfo`) returned by `hdf5info` to specify the data set.

```
hinfo = hdf5info('example.h5');  
dset = hdf5read(hinfo.GroupHierarchy.Groups(2).Datasets(1));
```

## See Also

[hdf5](#) | [hdf5info](#) | [hdf5write](#)

**Purpose** Write data to file in HDF5 format

---

**Note** hdf5write will be removed in a future version. Use h5write instead.

---

**Syntax**

```

hdf5write(filename,location,dataset)
hdf5write(filename,details,dataset)
hdf5write(filename,details,attribute)
hdf5write(filename, details1, dataset1, details2, dataset2,
    ...)
hdf5write(filename,...,'WriteMode',mode,...)
hdf5write(..., 'V71Dimensions', BOOL)

```

**Description** hdf5write(filename,location,dataset) writes the data dataset to the HDF5 file, filename. If filename does not exist, hdf5write creates it. If filename exists, hdf5write overwrites the existing file, by default, but you can also append data to an existing file using an optional syntax.

location defines where to write the data set in the file. HDF5 files are organized in a hierarchical structure similar to a UNIX directory structure. location is a string that resembles a UNIX path.

hdf5write maps the data in dataset to HDF5 data types according to rules outlined below.

hdf5write(filename,details,dataset) writes dataset to filename using the values in the details structure. For a data set, the details structure can contain the following fields.

Field Name	Description	Data Type
Location	Location of the data set in the file	Character array
Name	Name to attach to the data set	Character array

# hdf5write

---

`hdf5write(filename,details,attribute)` writes the metadata attribute to `filename` using the values in the `details` structure. For an attribute, the `details` structure can contain following fields.

Field Name	Description	Data Type
AttachedTo	Location of the object this attribute modifies	Structure array
AttachType	Identifies what kind of object this attribute modifies; possible values are 'group' and 'dataset'	Character array
Name	Name to attach to the data set	Character array

`hdf5write(filename, details1, dataset1, details2, dataset2,...)` writes multiple data sets and associated attributes to `filename` in one operation. Each data set and attribute must have an associated `details` structure.

`hdf5write(filename,...,'WriteMode',mode,...)` specifies whether `hdf5write` overwrites the existing file (the default) or appends data sets and attributes to the file. Possible values for `mode` are 'overwrite' and 'append'.

`hdf5write(..., 'V71Dimensions', BOOL)` specifies whether to change the majority of data sets written to the file. If `BOOL` is true, `hdf5write` permutes the first two dimensions of the data set, as it did in previous releases (MATLAB 7.1 [R14SP3] and earlier). This behavior was intended to account for the difference in how HDF5 and MATLAB express array dimensions. HDF5 describes data set dimensions in row-major order; MATLAB stores data in column-major order. However, permuting these dimensions may not correctly reflect the intent of the data and may invalidate metadata. When `BOOL` is false (the default), the data written to the file correctly reflects the data ordering of the data sets — each dimension in the file's data sets matches the same dimension in the corresponding MATLAB variable.

## Data Type Mappings

The following table lists how `hdf5write` maps the data type from the workspace into an HDF5 file. If the data in the workspace that is being written to the file is a MATLAB data type, `hdf5write` uses the following rules when translating MATLAB data into HDF5 data objects.

MATLAB Data Type	HDF5 Data Set or Attribute
Numeric	Corresponding HDF5 native data type. For example, if the workspace data type is <code>uint8</code> , the <code>hdf5write</code> function writes the data to the file as 8-bit integers. The size of the HDF5 dataspace is the same size as the MATLAB array.
String	Single, null-terminated string
Cell array of strings	Multiple, null-terminated strings, each the same length. Length is determined by the length of the longest string in the cell array. The size of the HDF5 dataspace is the same size as the cell array.
Cell array of numeric data	Numeric array, the same dimensions as the cell array. The elements of the array must all have the same size and type. The data type is determined by the first element in the cell array.
Structure array	HDF5 compound type. Individual fields in the structure employ the same data translation rules for individual data types. For example, a cell array of strings becomes a multiple, null-terminated strings.
HDF5 objects	If the data being written to the file is composed of HDF5 objects, <code>hdf5write</code> uses the same data type when writing to the file. For all HDF5 objects, except <code>HDF5.h5enum</code> objects, the dataspace has the same dimensions as the array of HDF5 objects passed to the function. For <code>HDF5.h5enum</code> objects, the size and dimensions of the data set in the HDF5 file is the same as the object's Data field.

## Examples

Write a 5-by-5 data set of `uint8` values to the root group.

```
hdf5write('myfile.h5', '/dataset1', uint8(magic(5)))
```

# hdf5write

---

Write a 2-by-2 string data set in a subgroup.

```
dataset = {'north', 'south'; 'east', 'west'};
hdf5write('myfile2.h5', '/group1/dataset1.1', dataset);
```

Write a data set and attribute to an existing group.

```
dset = single(rand(10,10));
dset_details.Location = '/group1/dataset1.2';
dset_details.Name = 'Random';

attr = 'Some random data';
attr_details.Name = 'Description';
attr_details.AttachedTo = '/group1/dataset1.2/Random';
attr_details.AttachType = 'dataset';

hdf5write('myfile2.h5', dset_details, dset, ...
          attr_details, attr, 'WriteMode', 'append');
```

Write a data set using objects.

```
dset = hdf5.h5array(magic(5));
hdf5write('myfile3.h5', '/g1/objects', dset);
```

## See Also

[hdf5](#) | [hdf5read](#) | [hdf5info](#)

**Purpose** Information about HDF4 or HDF-EOS file

**Syntax**  
`S = hdfinfo(filename)`  
`S = hdfinfo(filename,mode)`

**Description** `S = hdfinfo(filename)` returns a structure `S` whose fields contain information about the contents of an HDF4 or HDF-EOS file. `filename` is a string that specifies the name of the HDF4 file.

`S = hdfinfo(filename,mode)` reads the file as an HDF4 file, if `mode` is 'hdf', or as an HDF-EOS file, if `mode` is 'eos'. If `mode` is 'eos', only HDF-EOS data objects are queried. To retrieve information on the entire contents of a file containing both HDF4 and HDF-EOS objects, `mode` must be 'hdf'.

---

**Note** `hdfinfo` can be used on Version 4.x HDF files or Version 2.x HDF-EOS files. To get information about an HDF5 file, use `hdf5info`.

---

The set of fields in the returned structure `S` depends on the individual file. Fields that can be present in the `S` structure are shown in the following table.

Mode	Field Name	Description	Return Type
HDF	Attributes	Attributes of the data set	Structure array
	Description	Annotation description	Cell array
	Filename	Name of the file	String
	Label	Annotation label	Cell array
	Raster8	Description of 8-bit raster images	Structure array

Mode	Field Name	Description	Return Type
	Raster24	Description of 24-bit raster images	Structure array
	SDS	Description of scientific data sets	Structure array
	Vdata	Description of Vdata sets	Structure array
	Vgroup	Description of Vgroups	Structure array
EOS	Filename	Name of the file	String
	Grid	Grid data	Structure array
	Point	Point data	Structure array
	Swath	Swath data	Structure array

Those fields in the table above that contain structure arrays are further described in the tables shown below.

## Fields Common to Returned Structure Arrays

Structure arrays returned by `hdfinfo` contain some common fields. These are shown in the table below. Not all structure arrays will contain all of these fields.

Field Name	Description	Data Type
Attributes	Data set attributes. Contains fields Name and Value.	Structure array
Description	Annotation description	Cell array
Filename	Name of the file	String
Label	Annotation label	Cell array

Field Name	Description	Data Type
Name	Name of the data set	String
Rank	Number of dimensions of the data set	Double
Ref	Data set reference number	Double
Type	Type of HDF or HDF-EOS object	String

## Fields Specific to Certain Structures

Structure arrays returned by `hdinfo` also contain fields that are unique to each structure. These are shown in the tables below.

### Fields of the Attribute Structure

Field Name	Description	Data Type
Name	Attribute name	String
Value	Attribute value or description	Numeric or string

### Fields of the Raster8 and Raster24 Structures

Field Name	Description	Data Type
HasPalette	1 (true) if the image has an associated palette, otherwise 0 (false) (8-bit only)	Logical
Height	Height of the image, in pixels	Number
Interlace	Interlace mode of the image (24-bit only)	String
Name	Name of the image	String
Width	Width of the image, in pixels	Number

## Fields of the SDS Structure

Field Name	Description	Data Type
DataType	Data precision	String
Dims	Dimensions of the data set. Contains fields Name, DataType, Size, Scale, and Attributes. Scale is an array of numbers to place along the dimension and demarcate intervals in the data set.	Structure array
Index	Index of the SDS	Number

## Fields of the Vdata Structure

Field Name	Description	Data Type
DataAttributes	Attributes of the entire data set. Contains fields Name and Value.	Structure array
Class	Class name of the data set	String
Fields	Fields of the Vdata. Contains fields Name and Attributes.	Structure array
NumRecords	Number of data set records	Double
IsAttribute	1 (true) if Vdata is an attribute, otherwise 0 (false)	Logical

## Fields of the Vgroup Structure

Field Name	Description	Data Type
Class	Class name of the data set	String
Raster8	Description of the 8-bit raster image	Structure array
Raster24	Description of the 24-bit raster image	Structure array
SDS	Description of the Scientific Data sets	Structure array
Tag	Tag of this Vgroup	Number
Vdata	Description of the Vdata sets	Structure array
Vgroup	Description of the Vgroups	Structure array

## Fields of the Grid Structure

Field Name	Description	Data Type
Columns	Number of columns in the grid	Number
DataFields	Description of the data fields in each Grid field of the grid. Contains fields Name, Rank, Dims, NumberType, FillValue, and TileDims.	Structure array
LowerRight	Lower right corner location, in meters	Number
Origin Code	Origin code for the grid	Number
PixRegCode	Pixel registration code	Number

## Fields of the Grid Structure (Continued)

Field Name	Description	Data Type
Projection	Projection code, zone code, sphere code, and projection parameters of the grid. Contains fields ProjCode, ZoneCode, SphereCode, and ProjParam.	Structure
Rows	Number of rows in the grid	Number
UpperLeft	Upper left corner location, in meters	Number

## Fields of the Point Structure

Field Name	Description	Data Type
Level	Description of each level of the point. Contains fields Name, NumRecords, FieldNames, DataType, and Index.	Structure

## Fields of the Swath Structure

Field Name	Description	Data Type
DataFields	Data fields in the swath. Contains fields Name, Rank, Dims, NumberType, and FillValue.	Structure array
GeolocationFields	Geolocation fields in the swath. Contains fields Name,	Structure array

**Fields of the Swath Structure (Continued)**

Field Name	Description	Data Type
	Rank, Dims, NumberType, and FillValue.	
IdxMapInfo	Relationship between indexed elements of the geolocation mapping. Contains fields Map and Size.	Structure
MapInfo	Relationship between data and geolocation fields. Contains fields Map, Offset, and Increment.	Structure

**Examples**

To retrieve information about the file `example.hdf`,

```
fileinfo = hdfinfo('example.hdf')
```

```
fileinfo =
  Filename: 'example.hdf'
  SDS: [1x1 struct]
  Vdata: [1x1 struct]
```

And to retrieve information from this about the scientific data set in `example.hdf`,

```
sds_info = fileinfo.SDS

sds_info =
  Filename: 'example.hdf'
  Type: 'Scientific Data Set'
  Name: 'Example SDS'
  Rank: 2
  DataType: 'int16'
  Attributes: []
```

# hdfinfo

---

```
    Dims: [2x1 struct]
    Label: {}
    Description: {}
    Index: 0
```

## See Also

[hdfread](#) | [hdf](#)

**Purpose**

Read data from HDF4 or HDF-EOS file

**Syntax**

```
data = hdfread(filename, datasetname)
data = hdfread(hinfo)
data = hdfread(...,param,value,...)
data = hdfread(filename,EOSname,param,value,...)
[data,map] = hdfread(...)
```

**Description**

`data = hdfread(filename, datasetname)` returns all the data in the data set specified by `datasetname` from the HDF4 or HDF-EOS file specified by `filename`. To determine the name of a data set in an HDF4 file, use the `hdfinfo` function.

---

**Note** `hdfread` can be used on Version 4.x HDF files or Version 2.x HDF-EOS files. To read data from an HDF5 file, use `h5read`.

---

`data = hdfread(hinfo)` returns all the data in the data set specified by the `structurehinfo`, returned by the `hdfinfo` function. Specify the field in the `hinfo` structure that relates to a particular type of data set, and use indexing to specify which data set, when there are more than one. See “Example 2” on page 2-2039 for more information.

`data = hdfread(...,param,value,...)` returns subsets of the data according to the specified parameter and value pairs. See the tables below to find the valid parameters and values for different types of data sets.

`data = hdfread(filename,EOSname,param,value,...)` subsets the data field from the HDF-EOS point, grid, or swath specified by `EOSname`.

`[data,map] = hdfread(...)` returns the image data and the colormap map for an 8-bit raster image.

## Subsetting Parameters

The following tables show the subsetting parameters that can be used with the `hdfread` function for certain types of HDF4 data. These data types are

- HDF Scientific Data (SD)
- HDF Vdata (V)
- HDF-EOS Grid Data
- HDF-EOS Point Data
- HDF-EOS Swath Data

Note the following:

- If a parameter requires multiple values, use a cell array to store the values. For example, the 'Index' parameter requires three values: `start`, `stride`, and `edge`. Enclose these values in curly braces as a cell array.

```
hdfread(..., 'Index', {start, stride, edge})
```

- All values that are indices are 1-based.

### Subsetting Parameters for HDF Scientific Data (SD) Data Sets

When you are working with HDF SD files, `hdfread` supports the parameters listed in this table.

Parameter	Description
'Index'	<p>Three-element cell array, {start, stride, edge}, specifying the location, range, and values to be read from the data set</p> <ul style="list-style-type: none"> <li>• <b>start</b> — A 1-based array specifying the position in the file to begin reading Default: 1, start at the first element of each dimension. The values specified must not exceed the size of any dimension of the data set.</li> <li>• <b>stride</b> — A 1-based array specifying the interval between the values to read Default: 1, read every element of the data set.</li> <li>• <b>edge</b> — A 1-based array specifying the length of each dimension to read Default: An array containing the lengths of the corresponding dimensions</li> </ul>

For example, this code reads the data set `Example SDS` from the HDF file `example.hdf`. The 'Index' parameter specifies that `hdfread` start reading data at the beginning of each dimension, read until the end of each dimension, but only read every other data value in the first dimension.

```
data = hdfread('example.hdf', 'Example SDS', 'Index', {[1],[2 1],[1]})
```

## Subsetting Parameters for HDF Vdata Sets

When you are working with HDF Vdata files, `hdfread` supports these parameters.

Parameter	Description
'Fields'	Text string specifying the name of the field to be read. When specifying multiple field names, use a cell array.
'FirstRecord'	1-based number specifying the record from which to begin reading
'NumRecords'	Number specifying the total number of records to read

# hdfread

---

For example, this code reads the Vdata set `Example Vdata` from the HDF file `example.hdf`.

```
data = hdfread('example.hdf','Example Vdata','FirstRecord', 2,'NumRecords', 5)
```

## Subsetting Parameters for HDF-EOS Grid Data

When you are working with HDF-EOS grid data, `hdfread` supports three types of parameters:

- Required parameters
- Optional parameters
- Mutually exclusive parameters — You can only specify one of these parameters in a call to `hdfread`, and you cannot use these parameters in combination with any optional parameter.

Parameter	Description
<b>Required Parameter</b>	
'Fields'	String specifying the field to be read. You can specify only one field name for a Grid data set.
<b>Mutually Exclusive Optional Parameters</b>	
'Index'	Three-element cell array, { <code>start</code> , <code>stride</code> , <code>edge</code> }, specifying the location, range, and values to be read from the data set  <code>start</code> — An array specifying the position in the file to begin reading Default: 1, start at the first element of each dimension. The values must not exceed the size of any dimension of the data set.  <code>stride</code> — An array specifying the interval between the values to read Default: 1, read every element of the data set.  <code>edge</code> — An array specifying the length of each dimension to read Default: An array containing the lengths of the corresponding dimensions

Parameter	Description
'Interpolate'	Two-element cell array, {longitude,latitude}, specifying the longitude and latitude points that define a region for bilinear interpolation. Each element is an N-length vector specifying longitude and latitude coordinates.
'Pixels'	Two-element cell array, {longitude,latitude}, specifying the longitude and latitude coordinates that define a region. Each element is an N-length vector specifying longitude and latitude coordinates. This region is converted into pixel rows and columns with the origin in the upper left corner of the grid.  Note: This is the pixel equivalent of reading a 'Box' region.
'Tile'	Vector specifying the coordinates of the tile to read, for HDF-EOS Grid files that support tiles
<b>Optional Parameters</b>	
'Box'	Two-element cell array, {longitude,latitude}, specifying the longitude and latitude coordinates that define a region. longitude and latitude are each two-element vectors specifying longitude and latitude coordinates.
'Time'	Two-element cell array, [start stop], where start and stop are numbers that specify the start and end-point for a period of time
'Vertical'	Two-element cell array, {dimension, range}  dimension — String specifying the name of the data set field to be read from. You can specify only one field name for a Grid data set.  range — Two-element array specifying the minimum and maximum range for the subset. If dimension is a dimension name, then range specifies the range of elements to extract. If dimension is a field name, then range specifies the range of values to extract.  'Vertical' subsetting can be used alone or in conjunction with 'Box' or 'Time'. To subset a region along multiple dimensions, vertical subsetting can be used up to eight times in one call to hdfread.

# hdfread

For example,

```
data = hdfread('grid.hdf','PolarGrid','Fields','ice_temp','Index', {[5 10],[1],[15 20]})
```

## Subsetting Parameters for HDF-EOS Point Data

When you are working with HDF-EOS Point data, `hdfread` has two required parameters and three optional parameters.

Parameter	Description
<b>Required Parameters</b>	
'Fields'	String naming the data set field to be read. For multiple field names, use a comma-separated list.
'Level'	1-based number specifying which level to read from in an HDF-EOS Point data set
<b>Mutually Exclusive Optional Parameters</b>	
'Box'	Two-element cell array, {longitude,latitude}, specifying the longitude and latitude coordinates that define a region. longitude and latitude are each two-element vectors specifying longitude and latitude coordinates.
'RecordNumbers'	Vector specifying the record numbers to read
'Time'	Two-element cell array, [start stop], where start and stop are numbers that specify the start and endpoint for a period of time

For example,

```
hdfread(...,'Fields',{field1, field2},...  
          'Level',level,'RecordNumbers',[1:50, 200:250])
```

## Subsetting Parameters for HDF-EOS Swath Data

When you are working with HDF-EOS Swath data, `hdfread` supports three types of parameters:

- Required parameters
- Optional parameters

- Mutually exclusive

You can only use one of the mutually exclusive parameters in a call to `hdfread`, and you cannot use these parameters in combination with any optional parameter.

Parameter	Description
<b>Required Parameter</b>	
'Fields'	String naming the data set field to be read. You can specify only one field name for a Swath data set.
<b>Mutually Exclusive Optional Parameters</b>	
'Index'	<p>Three-element cell array, {<code>start</code>, <code>stride</code>, <code>edge</code>}, specifying the location, range, and values to be read from the data set</p> <ul style="list-style-type: none"> <li>• <code>start</code> — An array specifying the position in the file to begin reading            Default: 1, start at the first element of each dimension. The values must not exceed the size of any dimension of the data set.</li> <li>• <code>stride</code> — An array specifying the interval between the values to read            Default: 1, read every element of the data set.</li> <li>• <code>edge</code> — An array specifying the length of each dimension to read            Default: An array containing the lengths of the corresponding dimensions</li> </ul>
'Time'	<p>Three-element cell array, {<code>start</code>, <code>stop</code>, <code>mode</code>}, where <code>start</code> and <code>stop</code> specify the beginning and the endpoint for a period of time, and <code>mode</code> is a string defining the criterion for the inclusion of a cross track in a region. The cross track is within a region if any of these conditions is met:</p> <ul style="list-style-type: none"> <li>• Its midpoint is within the box (<code>mode='midpoint'</code>).</li> <li>• Either endpoint is within the box (<code>mode='endpoint'</code>).</li> </ul>

# hdfread

Parameter	Description
<b>Optional Parameters</b>	
'Box'	<p>Three-element cell array, {longitude, latitude, mode} specifying the longitude and latitude coordinates that define a region. longitude and latitude are two-element vectors that specify longitude and latitude coordinates. mode is a string defining the criterion for the inclusion of a cross track in a region. The cross track is within a region if any of these conditions is met:</p> <ul style="list-style-type: none"><li>• Its midpoint is within the box (mode='midpoint').</li><li>• Either endpoint is within the box (mode='endpoint').</li><li>• Any point is within the box (mode='anypoint').</li></ul>
'Vertical'	<p>Two-element cell array, {dimension, range}</p> <ul style="list-style-type: none"><li>• dimension is a string specifying either a dimension name or field name to subset the data by.</li><li>• range is a two-element vector specifying the minimum and maximum range for the subset. If dimension is a dimension name, then range specifies the range of elements to extract. If dimension is a field name, then range specifies the range of values to extract.</li></ul> <p>'Vertical' subsetting can be used alone or in conjunction with 'Box' or 'Time'. To subset a region along multiple dimensions, vertical subsetting can be used up to eight times in one call to hdfread.</p>

For example,

```
hdfread('swath.hdf', 'Example Swath', 'Fields', 'Temperature', ...  
        'Time', {5000, 6000, 'midpoint'})
```

## Examples

### Example 1

Specify the name of the HDF file and the name of the data set. This example reads a data set named 'Example SDS' from a sample HDF file.

```
data = hdfread('sd.hdf','temperature')
```

### Example 2

Use data returned by `hdfinfo` to specify the data set to read.

- 1 Call `hdfinfo` to retrieve information about the contents of the HDF file.

```
fileinfo = hdfinfo('sd.hdf')  
fileinfo =
```

```
    Filename: 'C:\Program Files\matlab\toolbox\matlab\imagesci\sd.hdf'  
    Attributes: [1x1 struct]  
           SDS: [1x2 struct]  
           Vdata: [1x1 struct]
```

- 2 Extract the structure containing information about the particular data set you want to import from the data returned by `hdfinfo`. The example uses the structure in the SDS field to retrieve a scientific data set.

```
sds_info = fileinfo.SDS(2)
```

```
sds_info =
```

```
    Filename: [1x73 char]  
           Type: 'Scientific Data Set'  
           Name: 'temperature'  
           Rank: 2  
           DataType: 'double'  
    Attributes: [1x11 struct]  
           Dims: [2x1 struct]  
           Label: {}
```

# hdfread

---

```
Description: {}  
Index: 1
```

**3** Pass this structure to `hdfread` to import the data in the data set.

```
data = hdfread(sds_info)
```

## Example 3

You can use the information returned by `hdfinfo` to check the size of the data set.

```
sds_info.Dims.Size  
ans =  
    16  
ans =  
    5
```

Using the 'index' parameter with `hdfread`, you can read a subset of the data in the data set. This example specifies a starting index of [3 3], an interval of 1 between values ([]) meaning the default value of 1), and a length of 10 rows and 2 columns.

```
data = hdfread(sds_info, 'Index', {[3 3],[],[10 2]});
```

```
data(:,1)  
ans =  
    7  
    8  
    9  
   10  
   11  
   12  
   13  
   14  
   15  
   16
```

```
data(:,2)
```

```
ans =  
     8  
     9  
    10  
    11  
    12  
    13  
    14  
    15  
    16  
    17
```

## Example 4

This example uses the Vdata field from the information returned by `hdfinfo` to read two fields of the data, `Idx` and `Temp`.

```
s = hdfinfo('example.hdf');  
data1 = hdfread(s.Vdata(1), 'Fields', {'Idx', 'Temp', 'Dewpt'})  
  
data1 =  
  
     [1x10 int16]  
     [1x10 int16]  
     [1x10 int16]
```

## See Also

[hdfinfo](#) | [hdf](#)

# hdftool

---

**Purpose** Browse and import data from HDF4 or HDF-EOS files

**Syntax**

```
hdftool
hdftool(filename)
h = hdftool(...)
```

**Description** `hdftool` starts the HDF Import Tool, a graphical user interface used to browse the contents of HDF4 and HDF-EOS files and import data and subsets of data from these files. To open an HDF4 or HDF-EOS file, select **Open** from the **Home** tab. You can open multiple files in the HDF Import Tool by selecting **Open** from the **Home** tab.

`hdftool(filename)` opens the HDF4 or HDF-EOS file specified by `filename` in the HDF Import Tool.

`h = hdftool(...)` returns a handle `h` to the HDF Import Tool. To close the tool from the command line, use `close(h)`.

**Examples** `hdftool('example.hdf');`

**See Also** `hdf` | `hdftool` | `hdfinfo` | `hdfread` | `uiimport`

**Purpose** Help for functions in Command Window

**Syntax** help  
help name

**Description** help lists all primary help topics in the Command Window. Each main help topic corresponds to a folder name on the MATLAB search path.

help name displays the help text for the functionality specified by name, such as a function, method, class, or toolbox.

- Tips**
- Some help text displays the names of functions in uppercase characters to make them stand out from the rest of the text. When typing these function names, use lowercase. For function names that appear in mixed case (such as javaObject), type the names as shown.
  - To prevent long descriptions from scrolling off the screen before you have time to read them, enter more on, and then enter the help statement.
  - Some classes require that you specify the package name to display the help text. To identify the package name, create an instance of the class, and then call class(obj).

**Input Arguments**

**name**

String that specifies an operator symbol (such as +) or the name of a function, class, method, package, toolbox folder, or other functionality.

Some classes require that you specify the package name. Events, properties, and some methods require that you specify the class name. Separate the components of the name with periods, using one of the following forms:

```
help className.name  
help packageName.className  
help packageName.className.name
```

If `name` is overloaded, that is, appears in multiple folders on the search path, `help` displays the help text for the first instance of `name` found on the search path, and displays a hyperlinked list of the overloaded functions and their folders.

When `name` specifies the name or partial path of a toolbox folder:

- If the folder contains a nonempty `Contents.m` file, the `help` function displays the file. `Contents.m` contains a list of MATLAB program files in the folder and their descriptions. If `Contents.m` exists, but is empty, MATLAB responds with `No help found for name.`
- If the folder does not contain a `Contents.m` file, the `help` function lists the first line of help text for each program file in the folder.
- If `name` is the name of both a function and a toolbox, `help` displays the associated text for both the toolbox and the function.

## Examples

### Functions and Overloaded Methods

Display help for the MATLAB `close` function.

```
help close
```

Because `close` refers to the name of a function and to the name of several methods, the help text includes hyperlinks to the overloaded methods.

Request help for the Database Toolbox™ `close` method.

```
help database.close
```

### Package, Class, and Method Help

Display help for the `containers` package, `Map` class, and the `isKey` method.

```
help containers
help containers.Map
help containers.Map.isKey
```

Not all packages, classes, and associated methods or events require complete specification. For example, display the help for the `throwAsCaller` method of the `MException` class.

```
help throwAsCaller
```

## Functions in Folder

List all of the functions in the folder `matlabroot/toolbox/matlab/general` by specifying a partial path.

```
help general
```

## Alternatives

View more extensive help using the `doc` command or the Function Browser. To open the Function Browser, click its icon, .

# helpdlg

---

**Purpose** Create and open help dialog box

**Syntax**

```
helpdlg  
helpdlg('helpstring')  
helpdlg('helpstring','dlgname')  
h = helpdlg(...)
```

**Description** helpdlg creates a nonmodal help dialog box or brings the named help dialog box to the front.

---

**Note** A nonmodal dialog box enables the user to interact with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

---

helpdlg displays a dialog box named 'Help Dialog' containing the string 'This is the default help string.'

helpdlg('helpstring') displays a dialog box named 'Help Dialog' containing the string specified by 'helpstring'.

helpdlg('helpstring','dlgname') displays a dialog box named 'dlgname' containing the string 'helpstring'.

h = helpdlg(...) returns the handle of the dialog box.

**Tips** MATLAB wraps the text in 'helpstring' to fit the width of the dialog box. The dialog box remains on your screen until you press the **OK** button or the **Enter** key. After either of these actions, the help dialog box disappears.

**Examples** The statement

```
helpdlg('Choose 10 points from the figure','Point Selection');
```

displays this dialog box:

# helpwin

---

**Purpose** Provide access to help comments for all functions

---

**Note** helpwin will be removed in a future release. Use doc instead.

---

**Syntax** helpwin  
helpwin topic

**Description** helpwin lists topics for groups of functions in the MATLAB Web browser. It shows brief descriptions of the topics and provides links to display help comments for the functions. You cannot follow links in the helpwin list of functions if the MATLAB software is busy (for example, running a program).

helpwin topic displays help information for the topic. If topic is a folder, it displays all functions in the folder. If topic is a function, helpwin displays help for that function. From the page, you can access a list of folders (**Default Topics** link) as well as the reference page help for the function (**Go to online doc** link). You cannot follow links in the helpwin list of functions if MATLAB is busy (for example, running a program).

**Examples** Typing  
helpwin datafun  
displays the functions in the datafun folder and a brief description of each.

Typing  
helpwin fft  
displays the help for the fft function.

**See Also** doc | help

**Purpose** Hessenberg form of matrix

**Syntax**  
 $H = \text{hess}(A)$   
 $[P, H] = \text{hess}(A)$   
 $[AA, BB, Q, Z] = \text{hess}(A, B)$

**Description**  $H = \text{hess}(A)$  finds H, the Hessenberg form of matrix A.  
 $[P, H] = \text{hess}(A)$  produces a Hessenberg matrix H and a unitary matrix P so that  $A = P*H*P'$  and  $P'*P = \text{eye}(\text{size}(A))$ .  
 $[AA, BB, Q, Z] = \text{hess}(A, B)$  for square matrices A and B, produces an upper Hessenberg matrix AA, an upper triangular matrix BB, and unitary matrices Q and Z such that  $Q*A*Z = AA$  and  $Q*B*Z = BB$ .

**Definitions** A Hessenberg matrix is zero below the first subdiagonal. If the matrix is symmetric or Hermitian, the form is tridiagonal. This matrix has the same eigenvalues as the original, but less computation is needed to reveal them.

**Examples** H is a 3-by-3 eigenvalue test matrix:

```
H =
  -149    -50   -154
    537    180    546
    -27     -9    -25
```

Its Hessenberg form introduces a single zero in the (3,1) position:

```
hess(H) =
  -149.0000    42.2037   -156.3165
  -537.6783   152.5511   -554.9272
           0         0.0728    2.4489
```

**See Also** eig | qz | schur

# matlab.mixin.Heterogeneous

---

**Purpose** Superclass for heterogeneous array formation

**Description** `matlab.mixin.Heterogeneous` is an abstract class that provides support for the formation of heterogeneous arrays. A heterogeneous array is an array of objects that differ in their specific class, but are all derived from or are instances of a root class. The root class derives directly from `matlab.mixin.Heterogeneous`.

## Heterogeneous Hierarchy

Use `matlab.mixin.Heterogeneous` to define hierarchies of classes whose instances you can combine into heterogeneous arrays.

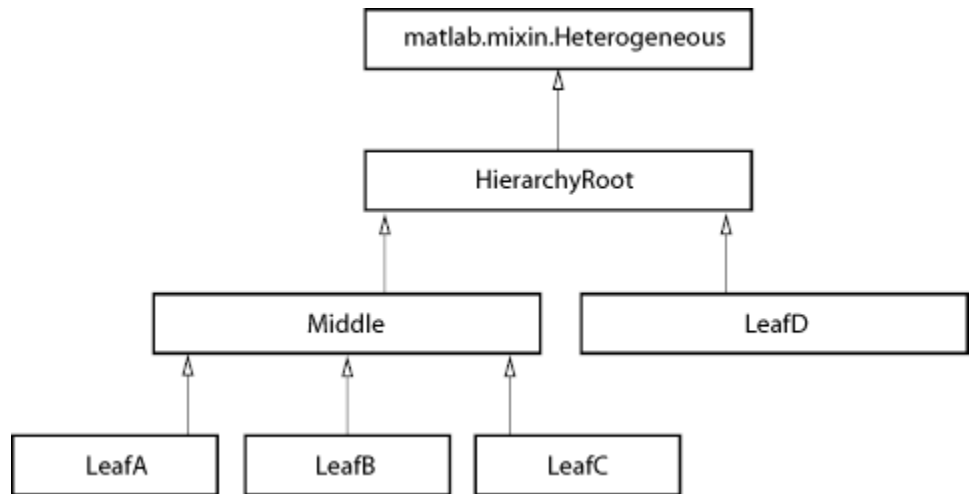

The following class definition enables the formation of heterogeneous arrays that combine instances of any classes derived from `HierarchyRoot`.

```
classdef HierarchyRoot < matlab.mixin.Heterogeneous
% HierarchyRoot is a direct subclass of matlab.mixin.Heterogeneous
% HierarchyRoot is the root of this heterogeneous hierarchy
```

Deriving the `HierarchyRoot` class directly from `matlab.mixin.Heterogeneous` enables the `HierarchyRoot` class to become the root of a hierarchy of classes. You can combine instances of the members of this hierarchy into a heterogeneous array. Only instances of classes derived from the same root class can combine to form a valid heterogeneous array.

## Class of a Heterogeneous Array

The class of a heterogeneous array is always the class of the most specific superclass common to all objects in the array. For example, suppose you define the following class hierarchy:

Forming an array (`harray`) of an instance of `LeafA` with an instance of `LeafB` creates an array of class `Middle`:

```
harray = [LeafA,LeafB];  
class(harray)  
ans =  
Middle
```

Forming an array (`harray`) of an instance of `LeafC` with an instance of `LeafD` creates an array of class `HierarchyRoot`:

```
harray = [LeafC,LeafD];  
class(harray)  
ans =  
HierarchyRoot
```

Forming an array (`harray`) of an instance of `LeafA` with another instance of `LeafA` creates a homogeneous array of class `LeafA`:

```
harray = [LeafA,LeafA];  
class(harray)  
ans =
```

LeafA

---

**Note** You cannot form heterogeneous arrays that include instances of classes that are not derived from the same hierarchy root (that is, the HierarchyRoot class in the hierarchy shown previously).

---

### Forming a Heterogeneous Array

Heterogeneous arrays are the result of operations that produces arrays containing instances of two or more classes from the heterogeneous hierarchy. Usually, concatenation or indexed assignment form these arrays. For example, these statements form harray using indexed assignment:

```
harray(1) = LeafA;  
harray(2) = LeafC;  
class(harray)  
ans =  
Middle
```

### Growing the Array Can Change Its Class

Assigning new objects into an array containing objects derived from matlab.mixin.Heterogeneous can change the class of the array. For example, given a homogeneous array containing objects only of the LeafA class:

```
harray = [LeafA,LeafA,LeafA];  
class(harray)  
ans =  
LeafA
```

Adding an object of another class derived from the same root to harray converts the array's class to the most specific superclass:

```
harray(4) = LeafB;  
class(harray)  
ans =
```

Middle

## Method Dispatching

When MATLAB invokes a method for which the dominant argument is a heterogeneous array, the method:

- Must be defined for the class of the heterogeneous array, either directly by the class of the array or inherited from a superclass.
- Must be `Sealed = true` (cannot be overridden by a subclass).

The class of the heterogeneous array determines which class method executes for any given method invocation, as is the case with a homogeneous array. MATLAB does not consider the class of individual elements in the array when dispatching to methods.

## Sealing Inherited Methods

The requirement that methods called on a heterogeneous array be `Sealed = true` ensures correct and predictable behavior with all array elements.

You must override methods that are inherited from outside the heterogeneous hierarchy if these methods are not `Sealed = true` and you want to call these methods on heterogeneous arrays.

For example, suppose you define a heterogeneous array by subclassing `hgsetget`, in addition to `matlab.mixin.Heterogeneous`. Override the `set` method to call the `hgsetget` superclass method as required by your class design:

```
methods(Sealed)
function varargout = set(obj,varargin)
    if nargin == 0
        set@hgsetget(obj, varargin{:}); % Call superclass set method
    else
        varargout{:} = set@hgsetget(obj,varargin{:});
    end
end
end
```

Method implementations can take advantage of the fact that, given a heterogeneous array `harray`, and a scalar index `n`, the expression

```
harray(n)
```

is not a heterogeneous array. Therefore, when invoking a method on a single element of a heterogeneous array, special requirements for heterogeneous arrays do not apply.

## Defining the Default Object

When working with object arrays (both heterogeneous and homogeneous), MATLAB creates default objects to fill in missing array elements by calling the class constructor with no arguments. Filling in missing array elements becomes necessary in cases such as:

- Indexed assignment creates an array with gaps. For example, if `harray` is not previously defined:

```
harray(5) = LeafA;
```

- Loading a heterogeneous array from a MAT-file when MATLAB cannot find the class definition of a specific object.

The `matlab.mixin.Heterogeneous` class provides a default implementation of a method called `getDefaultScalarElement`. This method returns an instance of the root class of the heterogeneous hierarchy, unless the root class is abstract.

If the root class is abstract or is not an appropriate default object for the classes in the heterogeneous hierarchy, you can override the `getDefaultScalarElement` method to return an instance of a class derived from the root class.

## Defining the `getDefaultScalarElement` Method

Specify the class of the default object by overriding the `matlab.mixin.Heterogeneous` method called `getDefaultScalarElement` in the root class of the heterogeneous

hierarchy. You can override `getDefaultScalarElement` only in the root class (direct subclasses of `matlab.mixin.Heterogeneous`).

`getDefaultScalarElement` has the following signature:

```
methods (Static, Sealed, Access = protected)
    function default_object = getDefaultScalarElement
        ...
    end
end
```

The `getDefaultScalarElement` method must satisfy these criteria:

- Static — MATLAB calls this method without an object.
- Protected — MATLAB calls this method, object users do not.
- Sealed (not required) — Seal this method to ensure users of the heterogeneous hierarchy do not change the intended behavior of the class.
- It must return a scalar object
- It must pass the `isa` test for the root class, that is:

```
(isa(getDefaultScalarElement, 'HierarchyRoot')
```

where *HierarchyRoot* is the name of the heterogeneous hierarchy root class. This means the default object can be an instance of any class derived from the root class.

## Cannot Redefine Indexing or Concatenation

The use of heterogeneous arrays requires consistent indexing and concatenation behaviors. Therefore, subclasses of `matlab.mixin.Heterogeneous` cannot change their default indexed reference, indexed assignment, or concatenation behavior.

You cannot override the following methods in your subclasses:

- `cat`

- horzcat
- vertcat
- subref
- subsasign

In cases involving multiple inheritance in which your subclass inherits from superclasses in addition to `matlab.mixin.Heterogeneous`, the superclasses cannot define any of these methods.

### **Default Concatenation Behavior**

Statements of the form:

```
a = [obj1,obj2,...];
```

create an array, `a`, containing the objects listed in brackets.

Concatenating `Heterogeneous` objects of the same specific class retains the class of the objects and does not form a heterogeneous array.

Concatenating `Heterogeneous` objects derived from the same root superclass, but that are of different specific classes, yields a heterogeneous array. MATLAB does not attempt to convert the class of any array members if all are part of the same root hierarchy.

### **Indexed Assignment Behavior**

Statements of the form:

```
a(m:n) = [objm,...objn];
```

assign the right-hand side objects to the array elements (`m:n`), specified on the left side of the assignment.

Indexed assignment to a heterogeneous array can:

- Increase or decrease the size of the array
- Overwrite existing array elements
- Change property values of objects within the array

- Change the class of the array
- Change whether the array is heterogeneous

## Indexed Reference Behavior

Statements of the form:

```
a = harray(m:n);
```

assign the elements of `harray` referenced by indices `m:n`, to array `a`.

Indexed reference on a heterogeneous array returns a sub-range of the original array. Depending on the specific elements within that sub-range (`m:n`), the result might have a different class than the original array, and might not be heterogeneous.

## Converting Nonmember Objects

If you attempt to form a heterogeneous array with objects that are not derived from the same root class, MATLAB calls the `convertObject` method, if it exists, to convert objects to the dominant class. Implementing a `convertObject` method enables the formation of heterogeneous arrays containing objects that are not part of the heterogeneous hierarchy.

## When Is Conversion Necessary

Suppose there are two classes `A` and `B`, where `B` is not derived from `matlab.mixin.Heterogeneous`, or where `A` and `B` are derived from different root classes that are derived from `matlab.mixin.Heterogeneous`.

MATLAB attempts to call the `convertObject` method implemented by the class of `A` in the following cases:

- The indexed assignment:

```
A(k) = B
```

- Horizontal and vertical concatenations:

```
[A,B] and [A;B]
```

# matlab.mixin.Heterogeneous

---

Implement a `convertObject` method if you want to support conversion of objects whose class is not defined in your heterogeneous hierarchy. You do not need to implement this method if your class design does not require this conversion.

## Implementing `convertObject`

The `convertObject` method must have the following signature:

```
Method (Static, Protected, Sealed)
    function converted_object = convertObject('DominantClassName',objectToC
    ...
    end
end
```

For indexed assignment  $A(k) = B$  and concatenation  $[A,B]$ :

- *DominantClassName* — Name of the class of the array A
- `objectToConvert` — Object to be converted, B in this case
- `converted_object` — Legal member of the heterogeneous hierarchy to which A belongs

You must implement `convertObject` to return a valid object of class A or MATLAB issues an error.

## Handle Compatibility

The `matlab.mixin.Heterogeneous` class is handle compatible. It can be combined with either handle or value classes when defining a subclass using multiple superclasses. See “Supporting Both Handle and Value Subclasses” for information on handle compatibility.

The `matlab.mixin.Heterogeneous` class is a value class. To learn how value classes affect copy operations, see Copying Objects in the MATLAB Programming Fundamentals documentation

## How To

- Class Attributes
- Property Attributes
- “Creating Subclasses — Syntax and Techniques”

# matlab.mixin.Heterogeneous.cat

---

**Purpose** Concatenation for heterogeneous arrays

**Syntax** `C = cat(dim,A,B)`

**Description** `C = cat(dim,A,B)` concatenates objects `A` and `B` along the dimension `dim`. The class of object arrays `A` and `B` must be derived from the same root class of a `matlab.mixin.Heterogeneous` hierarchy.

- If `A` and `B` are of the same class, the class of the resulting array is unchanged.
- If `A` and `B` are of different subclasses of a common superclass that is derived from `matlab.mixin.Heterogeneous`, then the result is a heterogeneous array and the array's class is that of the most specific superclass shared by `A` and `B`.

The `cat` method is sealed in the class `matlab.mixin.Heterogeneous` and, therefore, you cannot override it in subclasses.

## Input Arguments

**dim**

Scalar dimension along which to concatenate arrays

**A**

Object array derived from the same root subclass of `matlab.mixin.Heterogeneous` as `B`

**B**

Object array derived from the same root subclass of `matlab.mixin.Heterogeneous` as `A`

## Output Arguments

**C**

Array resulting from the specified concatenation. The class of this array is that of the most specific superclass shared by `A` and `B`.

## Attributes

Sealed true

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

## See Also

`matlab.mixin.Heterogeneous` | `cat`

# matlab.mixin.Heterogeneous.getDefaultScalarElement

---

**Purpose** Return default object for heterogeneous array operations

**Syntax** `defaultObject = getDefaultScalarElement`

**Description** `defaultObject = getDefaultScalarElement` returns the default object for a heterogeneous hierarchy. Override this method if the “Root Class” on page 2-2065 is abstract or is not an appropriate default object for the classes in the heterogeneous hierarchy. `getDefaultScalarElement` must return an instance of another member of the heterogeneous hierarchy.

The `matlab.mixin.Heterogeneous` class provided a default implementation of this method that returns an instance of the “Root Class” on page 2-2065.

MATLAB calls the `getDefaultScalarElement` method when requiring a default object. See `matlab.mixin.Heterogeneous` for more information on heterogeneous arrays and default objects.

- Tips**
- Override `getDefaultScalarElement` only if the “Root Class” on page 2-2065 is not suitable as a default object.
  - Override `getDefaultScalarElement` only in the “Root Class” on page 2-2065 of the heterogeneous hierarchy.
  - `getDefaultScalarElement` must return a scalar object.
  - `getDefaultScalarElement` must be a static method with protected access. While not required by MATLAB, you can seal this method to prevent overriding by other classes.
  - MATLAB returns an error if the value returned by `getDefaultScalarElement` is not scalar or is not an instance of a class that is a valid member of the hierarchy.

**Output Arguments**

**defaultObject**

The default object for heterogeneous array operations.

# matlab.mixin.Heterogeneous.getDefaultScalarElement

---

## Definitions

### Root Class

Root class – The direct subclass of `matlab.mixin.Heterogeneous` that forms the root of a heterogeneous hierarchy. Classes of objects that you can combine into heterogeneous arrays must derive from this root class.

## Attributes

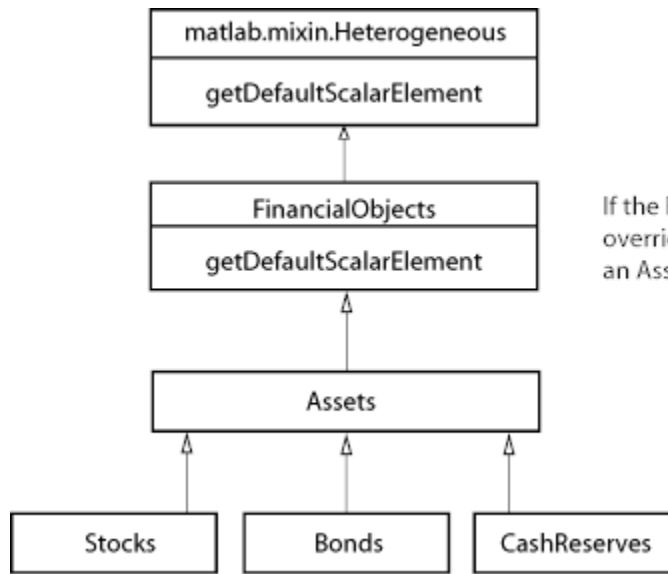

Static	true
Access	Protected
Sealed	true not required

To learn about attributes of methods, see [Method Attributes](#) in the [MATLAB Object-Oriented Programming](#) documentation.

## Examples

This example describes a heterogeneous hierarchy with a root class (`FinancialObjects`) that is an abstract class and cannot, therefore, be used for the default object. The `FinancialObjects` class definition includes an override of the `getDefaultScalarElement` method which returns an instance of the `Assets` class as the default object.

# matlab.mixin.Heterogeneous.getDefaultScalarElement

If the FinancialObjects class is abstract, override getDefaultScalarElement to return an Assets object as the default object.

The root class can override the getDefaultScalarElement method that is defined in matlab.mixin.Heterogeneous class and return an Assets object as the default object.

```
classdef FinancialObjects < matlab.mixin.Heterogeneous
    methods (Abstract)
        val = determineCurrentValue(obj)
    end
    methods (Static, Sealed, Access = protected)
        function default_object = getDefaultScalarElement
            default_object = Assets;
        end
    end
end
```

## See Also

matlab.mixin.Heterogeneous

**Purpose**

Horizontal concatenation for heterogeneous arrays

**Syntax**

```
C = horzcat(A1,A2,...)
```

**Description**

`C = horzcat(A1,A2,...)` concatenates the `matlab.mixin.Heterogeneous` objects `A1`, `A2`, and so on, to form the array `C`. All input arrays must have the same number of rows.

The class of object arrays `A1,A2,...` must be derived from the same root class of a `matlab.mixin.Heterogeneous` hierarchy.

MATLAB calls:

```
C = horzcat(A1,A2,...)
```

for the expressions:

```
C = [A1,A2,...]
```

```
C = [A1 A2 ...]
```

when `A1` is an array of `matlab.mixin.Heterogeneous` objects.

If all input arguments are of the same specific class, the class of the resulting array is unchanged. If all input arguments are of different subclasses of a common superclass that is derived from `matlab.mixin.Heterogeneous`, then the result is a heterogeneous array. The array's class is that of the most specific superclass shared by all input arguments.

If all input arguments are not members of the same heterogeneous hierarchy, MATLAB calls the `convertObjects` method, if defined by the dominant root class (the first argument or the left-most element in the concatenation if no other class is dominant).

The `horzcat` method is sealed in the class `matlab.mixin.Heterogeneous` and, therefore, you cannot override it in subclasses.

# matlab.mixin.Heterogeneous.horzcat

---

## Input Arguments

**A1**

Object array of class `matlab.mixin.Heterogeneous`

**A2**

Object array of class `matlab.mixin.Heterogeneous`

## Output Arguments

**C**

Array resulting from the specified concatenation. The class of this array is that of the most specific superclass shared by the input arguments.

## Attributes

Sealed

true

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

## See Also

`matlab.mixin.Heterogeneous` | `horzcat`

**Purpose**

Vertical concatenation for heterogeneous arrays

**Syntax**

```
C = vertcat(A1,A2,...)
```

**Description**

`C = vertcat(A1,A2,...)` concatenates the `matlab.mixin.Heterogeneous` objects `A1`, `A2`, and so on, to form the array `C`. All input arrays must have the same number of columns.

The class of object arrays `A1,A2,...` must be derived from the same root class of a `matlab.mixin.Heterogeneous` hierarchy.

MATLAB calls:

```
C = vertcat(A1,A2,...)
```

for the expression:

```
C = [A1;A2;...]
```

when `A1` and `A2`, and so on are arrays of `matlab.mixin.Heterogeneous` objects.

If all input arguments are of the same specific class, the class of the resulting array is unchanged. If all input arguments are of different subclasses of a common superclass that is derived from `matlab.mixin.Heterogeneous`, then the result is a heterogeneous array. The array's class is that of the most specific superclass shared by all input arguments.

If all input arguments are not members of the same heterogeneous hierarchy, MATLAB calls the `convertObjects` method, if defined by the dominant root class (the first argument or the left-most element in the concatenation if no other class is dominant).

The `horzcat` method is sealed in the class `matlab.mixin.Heterogeneous` and, therefore, you cannot override it in subclasses.

# matlab.mixin.Heterogeneous.vertcat

---

## Input Arguments

**A1**

Object array of class `matlab.mixin.Heterogeneous`

**A2**

Object array of class `matlab.mixin.Heterogeneous`

## Output Arguments

**C**

Array resulting from the specified vertical concatenation. The class of this array is that of the most specific superclass shared by the input arguments.

## Attributes

Sealed

true

To learn about attributes of methods, see [Method Attributes](#) in the [MATLAB Object-Oriented Programming](#) documentation.

## See Also

`matlab.mixin.Heterogeneous` | `vertcat`

**Purpose** Convert hexadecimal number string to decimal number

**Syntax** `d = hex2dec('hex_value')`

**Description** `d = hex2dec('hex_value')` converts *hex\_value* to its floating-point integer representation. The argument *hex\_value* is a hexadecimal integer stored in a MATLAB string. The value of *hex\_value* must be smaller than hexadecimal 10,000,000,000,000.

If *hex\_value* is a character array, each row is interpreted as a hexadecimal string.

**Examples** `hex2dec('3ff')`

```
ans =
```

```
1023
```

For a character array S,

```
S =
```

```
0FF
```

```
2DE
```

```
123
```

```
hex2dec(S)
```

```
ans =
```

```
255
```

```
734
```

```
291
```

**See Also** `dec2hex` | `format` | `hex2num` | `sprintf`

# hex2num

---

**Purpose** Convert hexadecimal number string to double-precision number

**Syntax** `n = hex2num(S)`

**Description** `n = hex2num(S)`, where `S` is a 16 character string representing a hexadecimal number, returns the IEEE double-precision floating-point number `n` that it represents. Fewer than 16 characters are padded on the right with zeros. If `S` is a character array, each row is interpreted as a double-precision number.

NaNs, infinities and denorms are handled correctly.

**Examples** `hex2num('400921fb54442d18')`

returns `Pi`.

`hex2num('bff')`

returns

`ans =`

`-1`

**See Also** `num2hex` | `hex2dec` | `sprintf` | `format`

**Purpose** Export figure

**Syntax** hgexport(h,filename)  
hgexport(h,'-clipboard')

**Description** hgexport(h,filename) writes figure h to the file filename.  
hgexport(h,'-clipboard') writes figure h to the Microsoft Windows clipboard.

The format in which the figure is exported is determined by which renderer you use. The Painters renderer generates a metafile. The ZBuffer and OpenGL renderers generate a bitmap.

**Alternatives** Use the **File > Export Setup** dialog. Use **Edit > Copy Figure** to copy the figure's content to the system clipboard. For details, see [How to Print or Export](#).

**See Also** print

# hggroup

---

## Purpose

Create hggroup object

## Syntax

```
h = hggroup
h = hggroup(..., 'PropertyName', propertyvalue, ...)
```

## Properties

For a list of properties, see [Hggroup Properties](#).

## Description

`h = hggroup` creates an hggroup object as a child of the current axes and returns its handle, `h`.

`h = hggroup(..., 'PropertyName', propertyvalue, ...)` creates an hggroup object with the property values specified in the argument list. For a description of the properties, see [Hggroup Properties](#).

An hggroup object can be the parent of any axes children except light objects, as well as other hggroup objects. You can use hggroup objects to form a group of objects that can be treated as a single object with respect to the following cases:

- **Visible** — Setting the hggroup object's `Visible` property also sets each child object's `Visible` property to the same value.
- **Selectable** — Setting each hggroup child object's `HitTest` property to `off` enables you to select all children by clicking any child object.
- **Current object** — Setting each hggroup child object's `HitTest` property to `off` enables the hggroup object to become the current object when any child object is picked. See the next section for an example.

## Examples

This example defines a callback for the `ButtonDownFcn` property of an hggroup object. In order for the hggroup to receive the mouse button down event that executes the `ButtonDownFcn` callback, the `HitTest` properties of all the line objects must be set to `off`. The event is then passed up the hierarchy to the hggroup.

The following function creates a random set of lines that are parented to an hggroup object. The local function `set_lines` defines a callback that executes when the mouse button is pressed over any of the lines.

The callback simply increases the widths of all the lines by 1 with each button press.

---

**Note** If you are using the MATLAB help browser, you can run this example or open it in the MATLAB editor.

---

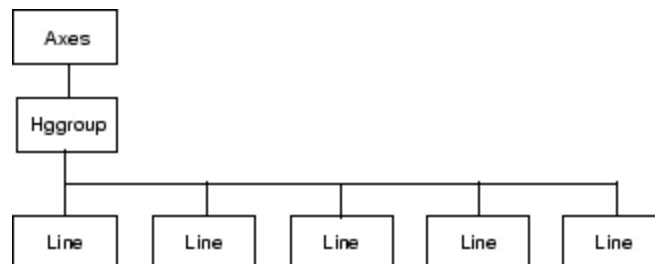

```
function doc_hgroup
hg = hgroup('ButtonDownFcn',@set_lines);
hl = line(randn(5),randn(5),'HitTest','off','Parent',hg);

function set_lines(cb,eventdata)
hl = get(cb,'Children');% cb is handle of hgroup object
lw = get(hl,'LineWidth');% get current line widths
set(hl,{'LineWidth'},num2cell([lw{:}]+1,[5,1]))
```

Note that selecting any one of the lines selects all the lines. (To select an object, enable plot edit mode by selecting **Plot Edit** from the **Tools** menu.)

### Instance Diagram for This Example

The following diagram shows the object hierarchy created by this example.

# hggroup

---

## Setting Default Properties

You can set default hggroup properties on the axes, figure, and root object levels:

```
set(0, 'DefaultHggroupProperty', PropertyValue...)  
set(gcf, 'DefaultHggroupProperty', PropertyValue...)  
set(gca, 'DefaultHggroupProperty', PropertyValue...)
```

where *Property* is the name of the hggroup property whose default value you want to set and *PropertyValue* is the value you are specifying. Use `set` and `get` to access the hggroup properties.

## See Also

[hgtransform](#) | [Hggroup Properties](#)

## How To

- “Group Objects”
- “Function Handle Callbacks”

## Purpose

Hgggroup properties

## Creating Hgggroup Objects

Use `hggroup` to create hgggroup objects.

## Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands.

To change the default values of properties, see “Setting Default Property Values”.

See “Group Objects” for general information on this type of object.

## Hgggroup Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

### Annotation

`hg.Annotation` object (read-only)

*Control the display of hgggroup objects in legends.* Specifies whether this hgggroup object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the hgggroup object is displayed in a figure legend.

# Hgroup Properties

---

<b>IconDisplayStyle Value</b>	<b>Purpose</b>
on	Include the hgroup object in a legend as one entry, but not its children objects
off	Do not include the hgroup or its children in a legend (default)
children	Include only the children of the hgroup as separate entries in the legend

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Controlling Legends” for more information and examples.

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-to-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

**BusyAction**  
cancel | {queue}

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The **BusyAction** property of the *interrupting* callback determines how MATLAB handles its execution. When the **BusyAction** property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the **Interruptible** property of the callback controls whether other callbacks can interrupt the *running* callback, see the **Interruptible** property description.

**ButtonDownFcn**  
function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over the children of the hgggroup object. Define the **ButtonDownFcn** as a function handle. The function must define at least two input arguments (handle of figure associated with the mouse button press and an empty event structure).

See **Function Handle Callbacks** for information on how to use function handles to define the callback function.

# Hgroup Properties

---

## Children

array of graphics object handles

*Children of the hgroup object.* An array containing the handles of all objects parented to the hgroup object (whether visible or not).

Note that if a child object's `HandleVisibility` property is `callback` or `off`, its handle does not appear in the hgroup `Children` property unless you set the `Root ShowHiddenHandles` property to `on`:

```
set(0, 'ShowHiddenHandles', 'on')
```

## Clipping

{on} | off

*Clipping mode.* MATLAB clips stairs plots to the axes plot box by default. If you set `Clipping` to `off`, lines might be displayed outside the axes plot box.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object creation.* Executes when MATLAB creates an hgroup object. You must define this property as a default value for hgroup objects or in a call to the hgroup function to create a new hgroup object. For example, the statement:

```
set(0, 'DefaultHgroupCreateFcn', @myCreateFcn)
```

defines a default value on the root level that applies to every hgroup object created in that MATLAB session. Whenever you create an hgroup object, the function associated with the function handle `@myCreateFcn` executes.

MATLAB executes the callback after setting all the hgggroup object's properties. Setting the `CreateFcn` property on an existing hgggroup object has no effect.

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## `DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when the hgggroup object is deleted (for example, this might happen when you issue a `delete` command on the hgggroup object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values.

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See ["Function Handle Callbacks"](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

## `DisplayName`

string

# Hgggroup Properties

---

*String used by legend.* The `legend` function uses the `DisplayName` property to label the `hgggroup` object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

## EraseMode

{normal} | none | xor | background

*Erase mode.* This property controls the technique MATLAB uses to draw and erase `hgggroup` child objects. Alternative erase modes are useful for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.

- **none** — Do not erase objects when they are moved or destroyed. While the objects are still visible on the screen after erasing with `EraseMode none`, you cannot print these objects because MATLAB stores no information about their former locations.
- **xor** — Draw and erase the object by performing an exclusive OR (XOR) with each pixel index of the screen behind it. Erasing the object does not damage the color of the objects behind it. However, the color of the erased object depends on the color of the screen behind it and it is correctly colored only when it is over the axes background color (or the figure background color if the axes `Color` property is `none`). That is, it isn't erased correctly if there are objects behind it.
- **background** — Erase the graphics objects by redrawing them in the axes background color, (or the figure background color if the axes `Color` property is `none`). This damages other graphics objects that are behind the erased object, but the erased object is always properly colored.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

# Hgroup Properties

---

HandleVisibility  
{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing the hgroup object.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties). See also `findall`.

## Handle Validity

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* `HitTest` determines whether the hggroup object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the hggroup child objects. Note that to pick the hggroup object, its children must have their `HitTest` property set to `off`.

If the hggroup object's `HitTest` is `off`, clicking it picks the object behind it.

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

# Hgroup Properties

---

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

Parent  
axes handle

*Parent of hgroup object.* This property contains the handle of the hgroup object's parent object. The parent of an hgroup object is the axes, hgroup, or hgtransform object that contains it.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

**Selected**  
on | {off}

*Is object selected?* When you set this property to on, MATLAB displays selection handles at the corners and midpoints of hgroup child objects if the SelectionHighlight property is also on (the default).

**SelectionHighlight**  
{on} | off

*Objects are highlighted when selected.* When the Selected property is on, MATLAB indicates the selected state by drawing selection handles on the hgroup child objects. When SelectionHighlight is off, MATLAB does not draw the handles.

**Tag**  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the Tag property and the findobj function to manipulate specific objects within a plotting hierarchy.

For example, create an hgroup object and set the Tag property:

```
t = hgroup('Tag', 'group1')
```

When you want to access the object, use findobj to find its handle. For example:

# Hgroup Properties

---

```
h = findobj('Tag','group1');
```

## Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For hgroup objects, Type is 'hgroup'. The following statement finds all the hgroup objects in the current axes.

```
t = findobj(gca,'Type','hgroup');
```

## UIContextMenu

handle of uicontextmenu object

*Associate a context menu with the hgroup object.* Assign this property the handle of a uicontextmenu object created in the hgroup object's figure. Use the uicontextmenu function to create the context menu. MATLAB displays the context menu whenever you right-click the hgroup object.

## UserData

array

*User-specified data.* Data you want to associate with the hgroup object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the set and get commands.

## Visible

{on} | off

*Visibility of hgroup object and its children.* By default, hgroup object visibility is on. This means all children of the hgroup are visible unless the child object's Visible property is off. Setting an hgroup object's Visible property to off also makes its children invisible.

**See Also**      `hgroup`

# hgload

---

## Purpose

Load Handle Graphics object hierarchy from file

## Syntax

```
h = hgload('filename')  
[h,old_prop_values] = hgload(...,property_structure)  
hgload(...,'all')
```

## Description

`h = hgload('filename')` loads Handle Graphics objects and its children (if any) from the FIG-file specified by `filename` and returns handles to the top-level objects. If `filename` contains no extension, then the MATLAB software adds the `.fig` extension.

`[h,old_prop_values] = hgload(...,property_structure)` overrides the properties on the top-level objects stored in the FIG-file with the values in `property_structure`, and returns their previous values in `old_prop_values`.

`property_structure` must be a structure having field names that correspond to property names and values that are the new property values.

`old_prop_values` is a cell array equal in length to `h`, containing the old values of the overridden properties for each object. Each cell contains a structure having field names that are property names, each of which contains the original value of each property that has been changed. Any property specified in `property_structure` that is not a property of a top-level object in the FIG-file is not included in `old_prop_values`.

`hgload(...,'all')` overrides the default behavior, which does not reload nonserializable objects saved in the file. These objects include the default toolbars and default menus. This option is obsolete and will be removed in a future release.

Nonserializable objects (such as the default toolbars and the default menus) are normally not reloaded because they are loaded from different files at figure creation time. This allows revisions of the default menus and toolbars to occur without affecting existing FIG-files. Passing the string `all` to `hgload` ensures that any nonserializable objects contained in the file are also reloaded.

Note that, by default, `hgsave` excludes nonserializable objects from the FIG-file unless you use the `all` flag.

## **Alternatives**

Use the **File > Open** on the figure window menu to access figure files with the **Open** dialog.

## **See Also**

`hgsave` | `open`

# hgsave

---

**Purpose** Save Handle Graphics object hierarchy to file

**Syntax**

```
hgsave('filename')
hgsave(h,'filename')
hgsave(...,'all')
hgsave(...,'-v6')
hgsave(...,'-v7.3')
```

**Description** `hgsave('filename')` saves the current figure to a file named `filename`.

`hgsave(h,'filename')` saves the objects identified by the array of handles `h` to a file named `filename`. If you do not specify an extension for `filename`, then the extension `.fig` is appended. If `h` is a vector, none of the handles in `h` may be ancestors or descendents of any other handles in `h`.

`hgsave(...,'all')` overrides the default behavior, which does not save nonserializable objects. Nonserializable objects include the default toolbars and default menus. This allows revisions of the default menus and toolbars to occur without affecting existing FIG-files and also reduces the size of FIG-files. Passing the string `all` to `hgsave` ensures that nonserializable objects are also saved. This option is obsolete and will be removed in a future release.

The default behavior of `hgload` is to ignore nonserializable objects in the file at load time. You can override this behavior using the `all` argument with `hgload`.

`hgsave(...,'-v6')` saves the FIG-file in a format that can be loaded by versions prior to MATLAB 7.

`hgsave(...,'-v7.3')` saves the FIG-file in a format that can be loaded only by MATLAB versions 7.3 and above. This format, based on HDF5 files, is intended for saving FIG-files larger than 2 GB.

You can make `-v6` or `-v7.3` your default format for saving MAT-files and FIG-files by setting a preference, which will eliminate the need to specify the flag each time you save. See “MAT-Files Preferences” in the MATLAB Desktop Tools and Development Environment documentation.

## Full Backward Compatibility

When creating a figure you want to save and use in a MATLAB version prior to MATLAB 7, use the 'v6' option with the plotting function and the '-v6' option for hgsave. Check the reference page for the plotting function you are using for more information.

See “Plot Objects and Backward Compatibility” for more information.

## Alternatives

Use the **File > Export Setup** dialog. Use **Edit > Copy Figure** to copy the figure's content to the system clipboard. For details, see [How to Print or Export](#).

## See Also

[hgload](#) | [open](#) | [save](#)

# hgsetget

---

**Purpose** Abstract class used to derive handle class with set and get methods

**Syntax** `classdef myclass < hgsetget`

**Description** `classdef myclass < hgsetget` makes *myclass* a subclass of the `hgsetget` class, which is a subclass of the `handle` class.

Use the `hgsetget` class to derive classes that inherit `set` and `get` methods that behave like Handle Graphics `set` and `get` functions.

## Methods

When you derive a class from the `hgsetget` class, your class inherits the following methods.

Method	Purpose
<code>set</code>	Assigns values to the specified properties or returns a cell array of possible values for writable properties.
<code>get</code>	Returns value of specified property or a struct with all property values.
<code>setdisp</code>	Called when <code>set</code> is called with no output arguments and a handle array, but no property name. Override this method to change what set displays.
<code>getdisp</code>	Called when <code>get</code> is called with no output arguments and handle array, but no property name. Override this method to change what get displays.

**See Also** `handle` | `set (hgsetget)` | `get (hgsetget)` | `set` | `get`

**How To** • “Implementing a Set/Get Interface for Properties”

<b>Purpose</b>	Create hgtransform graphics object
<b>Syntax</b>	<pre>h = hgtransform h = hgtransform('PropertyName',propertyvalue,...)</pre>
<b>Properties</b>	For a list of properties, see Hgtransform Properties.
<b>Description</b>	<p><code>h = hgtransform</code> creates an hgtransform object and returns its handle.</p> <p><code>h = hgtransform('PropertyName',propertyvalue,...)</code> creates an hgtransform object with the property value settings specified in the argument list. For a description of the properties, see Hgtransform Properties.</p> <p>hgtransform objects can contain other objects, which lets you treat the hgtransform and its children as a single entity with respect to visibility, size, orientation, etc. You can group objects by parenting them to a single hgtransform object (i.e., setting the object's Parent property to the hgtransform object's handle):</p> <pre>h = hgtransform; surface('Parent',h,...)</pre> <p>The primary advantage of parenting objects to an hgtransform object is that you can perform <i>transforms</i> (for example, translation, scaling, rotation, etc.) on the child objects in unison.</p> <p>The parent of an hgtransform object is either an axes object or another hgtransform.</p> <p>Although you cannot see an hgtransform object, setting its Visible property to off makes all its children invisible as well.</p>
<b>Exceptions and Limitations</b>	<ul style="list-style-type: none"><li>• An hgtransform object can be the parent of any number of axes child objects belonging to the same axes, except for light objects.</li><li>• hgtransform objects can never be the parent of axes objects and therefore can contain objects only from a single axes.</li></ul>

- hgtransform objects can be the parent of other hgtransform objects within the same axes.
- You cannot transform image objects because images are not true 3-D objects. Texture mapping the image data to a surface CData enables you to produce the effect of transforming an image in 3-D space.

---

**Note** Many plotting functions clear the axes (i.e., remove axes children) before drawing the graph. Clearing the axes also deletes any hgtransform objects in the axes.

---

## Examples

### Transforming a Group of Objects

This example shows how to create a 3-D star with a group of surface objects parented to a single hgtransform object. The hgtransform then rotates the object about the z-axis while scaling its size.

---

**Tip** If you are using the MATLAB Help browser, you can run this example or open it in the MATLAB Editor.

---

- 1 Create an axes and adjust the view. Set the axes limits to prevent auto limit selection during scaling.

```
ax = axes('XLim',[-1.5 1.5],'YLim',[-1.5 1.5],...  
        'ZLim',[-1.5 1.5]);  
view(3); grid on; axis equal
```

**2** Create the objects you want to parent to the hgtransform object.

```
[x y z] = cylinder([.2 0]);  
h(1) = surface(x,y,z,'FaceColor','red');  
h(2) = surface(x,y,-z,'FaceColor','green');  
h(3) = surface(z,x,y,'FaceColor','blue');  
h(4) = surface(-z,x,y,'FaceColor','cyan');  
h(5) = surface(y,z,x,'FaceColor','magenta');  
h(6) = surface(y,-z,x,'FaceColor','yellow');
```

# hgtransform

---

- 3** Create an hgtransform object and parent the surface objects to it. The figure should not change from the image above.

```
t = hgtransform('Parent',ax);  
set(h,'Parent',t)
```

- 4** Select a renderer and show the objects.

```
set(gcf,'Renderer','opengl')  
drawnow
```

- 5 Initialize the rotation and scaling matrix to the identity matrix (`eye`). Again, the image should not change.

```
Rz = eye(4);  
Sxy = Rz;
```

- 6 Form the  $z$ -axis rotation matrix and the scaling matrix. Rotate 360 degrees ( $2\pi$  radians) and scale by using the increasing values of  $r$ .

```
for r = 1:.1:2*pi  
    % Z-axis rotation matrix  
    Rz = makehgtform('zrotate',r);  
    % Scaling matrix  
    Sxy = makehgtform('scale',r/4);
```

# hgtransform

---

```
% Concatenate the transforms and  
% set the hgtransform Matrix property  
    set(t,'Matrix',Rz*Sxy)  
    drawnow  
end  
pause(1)
```

**7** Reset to the original orientation and size using the identity matrix.

```
set(t,'Matrix',eye(4))
```

## Transforming Objects Independently

This example creates two `hgtransform` objects to illustrate how to transform each independently within the same axes. A translation transformation moves one `hgtransform` object away from the origin.

---

**Tip** If you are using the MATLAB Help browser, you can run this example or open it in the MATLAB Editor.

---

- 1 Create and set up the axes object that will be the parent of both `hgtransform` objects. Set the limits to accommodate the translated object.

# hgtransform

---

```
ax = axes('XLim',[-2 1],'YLim',[-2 1],'ZLim',[-1 1]);  
view(3); grid on; axis equal
```

**2** Create the surface objects to group.

```
[x y z] = cylinder([.3 0]);  
h(1) = surface(x,y,z,'FaceColor','red');  
h(2) = surface(x,y,-z,'FaceColor','green');  
h(3) = surface(z,x,y,'FaceColor','blue');  
h(4) = surface(-z,x,y,'FaceColor','cyan');  
h(5) = surface(y,z,x,'FaceColor','magenta');  
h(6) = surface(y,-z,x,'FaceColor','yellow');
```

- 3** Create the hgtransform objects and parent them to the same axes. The figure should not change.

```
t1 = hgtransform('Parent',ax);  
t2 = hgtransform('Parent',ax);
```

- 4** Set the renderer to use OpenGL.

```
set(gcf,'Renderer','opengl')
```

# hgtransform

---

- 5** Parent the surfaces to hgtransform t1, then copy the surface objects and parent the copies to hgtransform t2. This figure should not change.

```
set(h, 'Parent', t1)
h2 = copyobj(h, t2);
```

- 6** Translate the second hgtransform object away from the first hgtransform object and display the result.

```
Txy = makehgtform('translate', [-1.5 -1.5 0]);
set(t2, 'Matrix', Txy)
drawnow
```

- 7 Rotate both hgtransform objects in opposite directions. The final image for this step is the same as for step 6. However, you should run the code to see the rotations.

```
% Rotate 10 times (2pi radians = 1 rotation)
for r = 1:.1:20*pi
    % Form z-axis rotation matrix
    Rz = makehgtform('zrotate',r);
    % Set transforms for both hgtransform objects
    set(t1,'Matrix',Rz)
    set(t2,'Matrix',Txy*inv(Rz))
    drawnow
end
```

# hgtransform

---

## Setting Default Properties

You can set default hgtransform properties on the axes, figure, and root object levels:

```
set(0, 'DefaultHgtransformPropertyName', propertyvalue, ...)  
set(gcf, 'DefaultHgtransformPropertyName', propertyvalue, ...)  
set(gca, 'DefaultHgtransformPropertyName', propertyvalue, ...)
```

*PropertyName* is the name of the hgtransform property and *propertyvalue* is the specified value. Use `set` and `get` to access hgtransform properties.

## See Also

hggroup | makehgtform | Hgtransform Properties

## How To

- “Group Objects”

## Purpose

Hgtransform properties

## Creating Hgtransform Objects

Use `hgtransform` to create hgtransform objects.

## Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands.

To change the default values of properties, see “Setting Default Property Values”.

See “Group Objects” for general information on this type of object.

## Hgtransform Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

### Annotation

`hg.Annotation` object (read-only)

*Control the display of hgtransform objects in legends.* Specifies whether this hgtransform object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the hgtransform object is displayed in a figure legend.

# Hgtransform Properties

---

<b>IconDisplayStyle Value</b>	<b>Purpose</b>
on	Include the hgtransform object in a legend as one entry, but not its children objects
off	Do not include the hgtransform or its children in a legend (default)
children	Include only the children of the hgtransform as separate entries in the legend

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Controlling Legends” for more information and examples.

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

**BusyAction**  
cancel | {queue}

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The **BusyAction** property of the *interrupting* callback determines how MATLAB handles its execution. When the **BusyAction** property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the **Interruptible** property of the callback controls whether other callbacks can interrupt the *running* callback, see the **Interruptible** property description.

**ButtonDownFcn**  
function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is within the extent of the hgtransform object, but not over another graphics object. The extent of an hgtransform object is the smallest rectangle that encloses all the children. Note that you cannot execute the hgtransform object's button down function if it has no children.

Define the **ButtonDownFcn** as a function handle. The function must define at least two input arguments (handle of figure

# Hgtransform Properties

---

associated with the mouse button press and an empty event structure).

See Function Handle Callbacks for information on how to use function handles to define the callback function.

## Children

array of graphics object handles

*Children of the hgtransform object.* An array containing the handles of all graphics objects parented to the hgtransform object (whether visible or not).

The graphics objects that can be children of an hgtransform are images, lights, lines, patches, rectangles, surfaces, and text. You can change the order of the handles and thereby change the stacking of the objects on the display.

Note that if a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in the hgtransform `Children` property unless you set the `Root ShowHiddenHandles` property to `on`.

## Clipping

{on} | off

*Clipping mode.* This property has no effect on hgtransform objects.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object creation.* Executes when MATLAB creates an hgtransform object. You must define this property as a default value for hgtransform objects. For example, the statement:

```
set(0, 'DefaultHgtransformCreateFcn', @myCreateFcn)
```

defines a default value on the root level that applies to every hgtransform object created in a MATLAB session. Whenever you create an hgtransform object, the function associated with the function handle `@myCreateFcn` executes.

MATLAB executes the callback after setting all the hgtransform object's properties. Setting the `CreateFcn` property on an existing hgtransform object has no effect.

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function and is accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when the hgtransform object is deleted (for example, this might happen when you issue a `delete` command on the hgtransform object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values.

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is accessible through the root `CallbackObject` property, which can be queried using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

# Hgtransform Properties

---

DisplayName  
string

*String used by legend.* The legend function uses the DisplayName property to label the hgtransform object in the legend. The default is an empty string.

- If you specify string arguments with the legend function, MATLAB set DisplayName to the corresponding string and uses that string for the legend.
- If DisplayName is empty, legend creates a string of the form, [ 'data' *n* ], where *n* is the number assigned to the object based on its location in the list of legend entries. However, legend does not set DisplayName to this string.
- If you edit the string directly in an existing legend, MATLAB set DisplayName to the edited string.
- If you specify a string for the DisplayName property and create the legend using the figure toolbar, then MATLAB uses the string defined by DisplayName.
- To add a legend programmatically that uses the DisplayName string, call legend with the toggle or show option.

See “Controlling Legends” for more information and examples.

EraseMode  
{normal} | none | xor | background

*Erase mode.* This property controls the technique MATLAB uses to draw and erase hgtransform child objects (light objects have no erase mode). Alternative erase modes are useful for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- normal — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all

objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.

- **none** — Do not erase objects when they are moved or destroyed. While the objects are still visible on the screen after erasing with `EraseMode none`, you cannot print these objects because MATLAB stores no information about their former locations.
- **xor**— Draw and erase the object by performing an exclusive OR (XOR) with each pixel index of the screen behind it. Erasing the object does not damage the color of the objects behind it. However, the color of the erased object depends on the color of the screen behind it and it is correctly colored only when it is over the axes background color (or the figure background color if the axes `Color` property is `none`). That is, it isn't erased correctly if there are objects behind it.
- **background** — Erase the graphics objects by redrawing them in the axes background color, (or the figure background color if the axes `Color` property is `none`). This damages other graphics objects that are behind the erased object, but the erased object is always properly colored.

Set the axes background color with the axes `Color` property.

Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

# Hgtransform Properties

---

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing the hgtransform object.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in

the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties). See also `findall`.

## Handle Validity

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* `HitTest` determines whether the `hgtransform` object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click within the limits of the `hgtransform` object. If `HitTest` is `off`, clicking the `hgtransform` picks the object behind it.

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB

# Hgtransform Properties

---

handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

## Matrix

4-by-4 matrix

*Transformation matrix applied to hgtransform object and its children.* The hgtransform object applies the transformation matrix to all its children.

See “Group Objects” for more information and examples.

## Parent

figure handle

*Parent of hgtransform object.* This property contains the handle of the hgtransform object’s parent object. The parent of an hgtransform object is the axes, hgroup, or hgtransform object that contains it.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## Selected

on | {off}

*Is object selected?* When you set this property to on, MATLAB displays selection handles on all child objects of the hgtransform if the SelectionHighlight property is also on (the default).

## SelectionHighlight

{on} | off

*Objects are highlighted when selected.* When the Selected property is on, MATLAB indicates the selected state by drawing selection handles on the objects parented to the hgtransform. When SelectionHighlight is off, MATLAB does not draw the handles.

## Tag

string

# Hgtransform Properties

---

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an `hgtransform` object and set the `Tag` property:

```
t = hgtransform('Tag','subgroup1')
```

When you want to access the `hgtransform` object to add another object, use `findobj` to find the `hgtransform` object's handle. The following statement adds a line to `subgroup1` (assuming `x` and `y` are defined).

```
line('XData',x,'YData',y,'Parent',findobj('Tag','subgroup1'))
```

## Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For `hgtransform` objects, `Type` is `'hgtransform'`. The following statement finds all the `hgtransform` objects in the current axes.

```
t = findobj(gca,'Type','hgtransform');
```

## UIContextMenu

handle of `uicontextmenu` object

*Associate a context menu with the hgtransform object.* Assign this property the handle of a `uicontextmenu` object created in the `hgtransform` object's figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the extent of the `hgtransform` object.

UserData

array

*User-specified data.* Data you want to associate with the hgtransform object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

Visible

{on} | off

*Visibility of hgtransform object and its children.* By default, hgtransform object visibility is on. This means all children of the hgtransform are visible unless the child object's `Visible` property is off. Setting an hgtransform object's `Visible` property to off also makes its children invisible.

## See Also

hgtransform

# hidden

---

**Purpose** Remove hidden lines from mesh plot

**Syntax** `hidden on`  
`hidden off`  
`hidden`

**Description** Hidden line removal draws only those lines that are not obscured by other objects in a 3-D view. The `hidden` function only applies to surface plot objects that have a uniform `FaceColor`.

`hidden on` turns on hidden line removal for the current mesh plot so lines in the back of a mesh are hidden by those in front. This is the default behavior.

`hidden off` turns off hidden line removal for the current mesh plot.

`hidden` toggles the hidden line removal state.

**Algorithms** When a surface graphics object has a uniform `FaceColor` matching the `Color` property of the axes, `hidden off` sets the `FaceColor` of the surface object to 'none'.

`hidden on` sets the `FaceColor` property of such surface objects to match the axes `Color` property (or to match that of the figure, if axes `Color` is 'none').

**Examples** By default hidden lines are removed (`hidden on`) for mesh plots, such as this one of the `peaks` function.

```
mesh(peaks)
colormap hsv
```

Set hidden line removal off to show the obscured parts of the mesh.

```
hidden off
```

# hidden

# hist

---

## Purpose

Histogram plot

## Syntax

```
n = hist(Y)
n = hist(Y,x)
n = hist(Y,nbins)
[n,xout] = hist(...)
hist(...)
hist(axes_handle,...)
```

## Description

A histogram shows the distribution of data values.

`n = hist(Y)` bins the elements in vector `Y` into 10 equally spaced containers and returns the number of elements in each container as a row vector. If `Y` is an `m`-by-`p` matrix, `hist` treats the columns of `Y` as vectors and returns a 10-by-`p` matrix `n`. Each column of `n` contains the results for the corresponding column of `Y`. No elements of `Y` can be complex or of type `integer`.

`n = hist(Y,x)` where `x` is a vector, returns the distribution of `Y` among `length(x)` bins with centers specified by `x`. For example, if `x` is a 5-element vector, `hist` distributes the elements of `Y` into five bins centered on the `x`-axis at the elements in `x`, none of which can be complex. Note: use `histc` if it is more natural to specify bin edges instead of centers.

`n = hist(Y,nbins)` where `nbins` is a scalar, uses `nbins` number of bins.

`[n,xout] = hist(...)` returns vectors `n` and `xout` containing the frequency counts and the bin locations. You can use `bar(xout,n)` to plot the histogram.

`hist(...)` without output arguments produces a histogram plot of the output described above. `hist` distributes the bins along the `x`-axis between the minimum and maximum values of `Y`.

---

`hist(axes_handle, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

## Tips

All elements in vector `Y` or in one column of matrix `Y` are grouped according to their numeric range. Each group is shown as one bin. If `Y` is a matrix, `hist` scales the current colormap and uses each column number (`1:n`) to assign each a unique color.

The histogram's *x*-axis reflects the range of values in `Y`. The histogram's *y*-axis shows the number of elements that fall within the groups; therefore, the *y*-axis ranges from 0 to the greatest number of elements deposited in any bin. The *x*-range of the leftmost and rightmost bins extends to include the entire data range in the case when the user-specified range does not cover the data range; this often results in "boxes" at either or both edges of the distribution. If you want a plot in which this does not happen (that is, all bins have equal width), you can create a histogram-like display using the `bar` command.

Histograms bins are created as patch objects and always plotted with a face color that maps to the first color in the current colormap (by default, blue) and with black edges. To change colors or other patch properties, use code similar to that given in the example.

The `hist` function accepts data that contains `inf` values, but does not consider them while populating the bins because the bin centers are all finite values. So, you should filter non-finite values before passing them to `hist`.

## Examples

Generate a bell-curve histogram from Gaussian data.

```
x = -4:0.1:4;  
y = randn(10000,1);  
hist(y,x)
```

# hist

---

Change the color of the graph so that the bins are red and the edges of the bins are white.

```
h = findobj(gca,'Type','patch');  
set(h,'FaceColor','r','EdgeColor','w')
```

**See Also**

bar | ColorSpec | histc | mode | patch | rose | stairs

**How To**

- “Histograms”

# histc

---

**Purpose** Histogram count

**Syntax**

```
n = histc(x,edges)
n = histc(x,edges,dim)
[n,bin] = histc(...)
```

**Description** `n = histc(x,edges)` counts the number of values in vector `x` that fall between the elements in the `edges` vector (which must contain monotonically nondecreasing values). `n` is a `length(edges)` vector containing these counts. No elements of `x` can be complex.

`n(k)` counts the value `x(i)` if `edges(k) <= x(i) < edges(k+1)`. The last bin counts any values of `x` that match `edges(end)`. Values outside the values in `edges` are not counted. Use `-inf` and `inf` in `edges` to include all non-NaN values.

For matrices, `histc(x,edges)` returns a matrix of column histogram counts. For N-D arrays, `histc(x,edges)` operates along the first nonsingleton dimension.

`n = histc(x,edges,dim)` operates along the dimension `dim`.

`[n,bin] = histc(...)` also returns an index matrix `bin`. If `x` is a vector, `n(k) = sum(bin==k)`. `bin` is zero for out of range values. If `x` is an M-by-N matrix, then

```
for j=1:N,
n(k,j) = sum(bin(:,j)==k);
end
```

To plot the histogram, use the `bar` command.

**Examples** Generate a cumulative histogram of a distribution.

Consider the following distribution:

```
x = -2.9:0.1:2.9;
y = randn(10000,1);
figure(1)
hist(y,x)
```

Calculate number of elements in each bin

```
n_elements = histc(y,x);
```

Calculate the cumulative sum of these elements using cumsum

```
c_elements = cumsum(n_elements)
```

Plot the cumulative distribution like a histogram using bar:

# histc

---

```
figure(2)  
bar(x,c_elements,'BarWidth',1)
```

<b>Purpose</b>	Retain current graph when adding new graphs
<b>Syntax</b>	<code>hold on</code> <code>hold off</code> <code>hold all</code> <code>hold</code> <code>hold(axes_handle,...)</code>
<b>Description</b>	<p>The <code>hold</code> function controls whether MATLAB clears the current graph when you make subsequent calls to plotting functions (the default), or adds a new graph to the current graph.</p> <p><code>hold on</code> retains the current graph and adds another graph to it. MATLAB adjusts the axes limits, tick marks, and tick labels as necessary to display the full range of the added graph.</p> <p><code>hold off</code> resets hold state to the default behavior, in which MATLAB clears the existing graph and resets axes properties to their defaults before drawing new plots.</p> <p><code>hold all</code> holds the graph and the current line color and line style so that subsequent plotting commands do not reset the <code>ColorOrder</code> and <code>LineStyleOrder</code> property values to the beginning of the list. Plotting commands continue cycling through the predefined colors and line styles from where the last graph stopped in the list.</p> <p><code>hold</code> toggles the hold state between adding to the graph and replacing the graph.</p> <p><code>hold(axes_handle,...)</code> applies the hold to the axes identified by the handle <code>axes_handle</code>. If several axes objects exist in a figure window, each axes has its own hold state. <code>hold</code> also creates an axes if one does not exist.</p> <p>Test the hold state using the <code>ishold</code> function.</p>
<b>Examples</b>	<p>Create a graph, set <code>hold</code> to on, then create another graph in the same axes:</p> <pre>x = -pi:pi/20:pi;</pre>

# hold

---

```
plot(sin(x))  
hold on  
plot(cos(x))  
hold off
```

If the range of subsequently added data is much greater than the original data, the original graph can become difficult to see in one axes. In these cases, it is usually better to use two separate axes. See `subplot` to create multiple axes in one figure.

## Algorithm

`hold` toggles the `NextPlot` axes property between the `add` and `replace`.

`hold on` sets the `NextPlot` property of the current figure and axes to `add`. `hold off` sets the `NextPlot` property of the current axes to `replace`.

## See Also

`axis` | `cla` | `ishold` | `newplot`

## How To

- `NextPlot`
- “Controlling Graphics Output”

**Purpose** Send cursor home

**Syntax** home

**Description** home moves the cursor to the upper-left corner of the window. When using the MATLAB desktop, home also scrolls the visible text in the window up and out of view. You can use the scroll bar to see what was previously on the screen.

**Examples** Execute a MATLAB command that displays something in the Command Window and then run the home function. home moves the cursor to the upper-left corner of the screen and clears the screen.

```
magic(5)
```

```
ans =
```

```
    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22
    10    12    19    21     3

```

```
home
```

**See Also** clc

# horzcat

---

**Purpose** Concatenate arrays horizontally

**Syntax** `C = horzcat(A1, A2, ...)`

**Description** `C = horzcat(A1, A2, ...)` horizontally concatenates matrices `A1`, `A2`, and so on. All matrices in the argument list must have the same number of rows.

`horzcat` concatenates N-dimensional arrays along the second dimension. The first and remaining dimensions must match.

MATLAB calls `C = horzcat(A1, A2, ...)` for the syntax `C = [A1 A2 ...]` when any of `A1`, `A2`, etc., is an object.

**Tips** For information on combining unlike integer types, integers with nonintegers, cell arrays with non-cell arrays, or empty matrices with other elements, see “Valid Combinations of Unlike Classes”.

**Examples** Create a 3-by-5 matrix, `A`, and a 3-by-3 matrix, `B`. Then horizontally concatenate `A` and `B`.

```
A = magic(5);           % Create 3-by-5 matrix, A
A(4:5,:) = []
```

```
A =
```

```
    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22
```

```
B = magic(3)*100       % Create 3-by-3 matrix, B
```

```
B =
```

```
   800   100   600
   300   500   700
```

```
400  900  200
```

```
C = horzcat(A, B)      % Horizontally concatenate A and B
```

```
C =
```

```
17    24     1     8    15   800   100   600
23     5     7    14    16   300   500   700
 4     6    13    20    22   400   900   200
```

## How To

- “Redefining Concatenation for Your Class”

# horzcat (tscollection)

---

**Purpose** Horizontal concatenation for `tscollection` objects

**Syntax** `tsc = horzcat(tsc1,tsc2,...)`

**Description** `tsc = horzcat(tsc1,tsc2,...)` performs horizontal concatenation for `tscollection` objects:

```
tsc = [tsc1 tsc2 ...]
```

This operation combines multiple `tscollection` objects, which must have the same time vectors, into one `tscollection` containing `timeseries` objects from all concatenated collections.

**See Also** `tscollection` | `vertcat` (`tscollection`)

**Purpose** Server host identification number

**Syntax** `id = hostid`

# hostid

---

## Description

`id = hostid` usually returns a single element cell array containing the MATLAB server host identifier as a string. On UNIX<sup>5</sup> platforms, there can be more than one identifier. In that case, `hostid` returns a cell array with an identifier in each cell.

5. UNIX is a registered trademark of The Open Group in the United States and other countries.

**Purpose** Convert HSV colormap to RGB colormap

**Syntax** `M = hsv2rgb(H)`  
`rgb_image = hsv2rgb(hsv_image)`

**Description** `M = hsv2rgb(H)` converts a hue-saturation-value (HSV) colormap to a red-green-blue (RGB) colormap. `H` is an  $m$ -by-3 matrix, where  $m$  is the number of colors in the colormap. The columns of `H` represent hue, saturation, and value, respectively. `M` is an  $m$ -by-3 matrix. Its columns are intensities of red, green, and blue, respectively.

`rgb_image = hsv2rgb(hsv_image)` converts the HSV image to the equivalent RGB image. HSV is an  $m$ -by- $n$ -by-3 image array whose three planes contain the hue, saturation, and value components for the image. RGB is returned as an  $m$ -by- $n$ -by-3 image array whose three planes contain the red, green, and blue components for the image.

**Tips** As `H(:,1)` varies from 0 to 1, the resulting color varies from red through yellow, green, cyan, blue, and magenta, and returns to red. When `H(:,2)` is 0, the colors are unsaturated (i.e., shades of gray). When `H(:,2)` is 1, the colors are fully saturated (i.e., they contain no white component). As `H(:,3)` varies from 0 to 1, the brightness increases.

The MATLAB hsv colormap uses `hsv2rgb([huesaturationvalue])` where hue is a linear ramp from 0 to 1, and saturation and value are all 1's.

**See Also** `brighten` | `colormap` | `rgb2hsv`

# hypot

---

**Purpose** Square root of sum of squares

**Syntax** `c = hypot(a,b)`

**Description** `c = hypot(a,b)` returns the element-wise result of the following equation, computed to avoid underflow and overflow:

$$c = \text{sqrt}(\text{abs}(a).^2 + \text{abs}(b).^2)$$

Inputs `a` and `b` must follow these rules:

- Both `a` and `b` must be single- or double-precision, floating-point arrays.
- The sizes of the `a` and `b` arrays must either be equal, or one a scalar and the other nonscalar. In the latter case, `hypot` expands the scalar input to match the size of the nonscalar input.
- If `a` or `b` is an empty array (0-by-N or N-by-0), the other must be the same size or a scalar. The result `c` is an empty array having the same size as the empty input(s).

`hypot` returns the following in output `c`, depending upon the types of inputs:

- If the inputs to `hypot` are complex (`w+xi` and `y+zi`), then the statement `c = hypot(w+xi,y+zi)` returns the *positive real* result

$$c = \text{sqrt}(\text{abs}(w).^2 + \text{abs}(x).^2 + \text{abs}(y).^2 + \text{abs}(z).^2)$$

- If `a` or `b` is `-Inf`, `hypot` returns `Inf`.
- If neither `a` nor `b` is `Inf`, but one or both inputs is `NaN`, `hypot` returns `NaN`.
- If all inputs are finite, the result is finite. The one exception is when both inputs are very near the value of the MATLAB constant `realmax`. The reason for this is that the equation `c = hypot(realmax,realmax)` is theoretically `sqrt(2)*realmax`, which overflows to `Inf`.

## Examples

### Example 1

To illustrate the difference between using the `hypot` function and coding the basic hypot equation in M-code, create an anonymous function that performs the same function as `hypot`, but without the consideration to underflow and overflow that `hypot` offers:

```
myhypot = @(a,b) sqrt(abs(a).^2+abs(b).^2);
```

Find the upper limit at which your coded function returns a useful value. You can see that this test function reaches its maximum at about  $1e154$ , returning an infinite result at that point:

```
myhypot(1e153,1e153)
ans =
    1.4142e+153
```

```
myhypot(1e154,1e154)
ans =
    Inf
```

Do the same using the `hypot` function, and observe that `hypot` operates on values up to about  $1e308$ , which is approximately equal to the value for `realmax` on your computer (the largest double-precision floating-point number you can represent on a particular computer):

```
hypot(1e308,1e308)
ans =
    1.4142e+308
```

```
hypot(1e309,1e309)
ans =
    Inf
```

### Example 2

`hypot(a,a)` theoretically returns  $\sqrt{2} * \text{abs}(a)$ , as shown in this example:

```
x = 1.271161e308;
```

# hypot

---

```
y = x * sqrt(2)
y =
  1.7977e+308
```

```
y = hypot(x,x)
y =
  1.7977e+308
```

# ichol

---

**Purpose** Incomplete Cholesky factorization

**Syntax**  
L = ichol(A)  
L = ichol(A,opts)

**Description** L = ichol(A) performs the incomplete Cholesky factorization of A with zero-fill.

L = ichol(A,opts) performs the incomplete Cholesky factorization of A with options specified by opts.

By default, ichol references the lower triangle of A and produces lower triangular factors.

## Input Arguments

**A**  
Sparse matrix

**opts**  
Structure with up to five fields:

Field Name	Summary	Description
type	Type of factorization	String indicating which flavor of incomplete Cholesky to perform. Valid values of this field are 'nofill' and 'ict'. The 'nofill' variant performs <i>incomplete Cholesky with zero-fill</i> (IC(0)). The 'ict' variant performs <i>incomplete Cholesky with threshold</i>

Field Name	Summary	Description
droptol	Drop tolerance when type is 'ict'	<p><i>dropping</i> (ICT). The default value is 'nofill'.</p> <p>Nonnegative scalar used as a drop tolerance when performing ICT. Elements which are smaller in magnitude than a local drop tolerance are dropped from the resulting factor except for the diagonal element which is never dropped. The local drop tolerance at step <math>j</math> of the factorization is <math>\text{norm}(A(j:\text{end}, j), 1) * \text{droptol}</math>. 'droptol' is ignored if 'type' is 'nofill'. The default value is 0.</p>
michol	Indicates whether to perform modified incomplete Cholesky	<p>Indicates whether or not <i>modified incomplete Cholesky</i> (MIC) is performed. The field may be 'on' or 'off'. When performing MIC, the diagonal is compensated for dropped elements to enforce the relationship <math>A * e = L * L' * e</math> where <math>e = \text{ones}(\text{size}(A, 2), 1)</math>. The default value is 'off'.</p>

<b>Field Name</b>	<b>Summary</b>	<b>Description</b>
diagcomp	Perform compensated incomplete Cholesky with the specified coefficient	Real nonnegative scalar used as a global diagonal shift $\alpha$ in forming the incomplete Cholesky factor. That is, instead of performing incomplete Cholesky on $A$ , the factorization of $A + \alpha \cdot \text{diag}(\text{diag}(A))$ is formed. The default value is 0.
shape	Determines which triangle is referenced and returned	Valid values are 'upper' and 'lower'. If 'upper' is specified, only the upper triangle of $A$ is referenced and $R$ is constructed such that $A$ is approximated by $R' * R$ . If 'lower' is specified, only the lower triangle of $A$ is referenced and $L$ is constructed such that $A$ is approximated by $L * L'$ . The default value is 'lower'.

## Tips

- The factor given by this routine may be useful as a preconditioner for a system of linear equations being solved by iterative methods such as pcg or minres.
- ichol works only for sparse square matrices

## Examples

### Incomplete Cholesky Factorization

This example generates an incomplete Cholesky factorization.

Start with a symmetric positive definite matrix,  $A$ :

```
N = 100;  
A = delsq(numgrid('S',N));
```

A is the two-dimensional, five-point discrete negative Laplacian on a 100-by-100 square grid with Dirichlet boundary conditions. The size of A is  $98 \times 98 = 9604$  (not 10000 as the borders of the grid are used to impose the Dirichlet conditions).

The no-fill incomplete Cholesky factorization is a factorization which contains only nonzeros in the same position as A contains nonzeros. This factorization is extremely cheap to compute. Although the product  $L^*L'$  is typically very different from A, the product  $L^*L'$  will match A on its pattern up to round-off.

```
L = ichol(A);  
norm(A-L*L', 'fro') ./ norm(A, 'fro');  
ans =  
    9.1599e-002
```

```
norm(A-(L*L') .* spones(A), 'fro') ./ norm(A, 'fro');  
ans =  
    4.9606e-017
```

`ichol` may also be used to generate incomplete Cholesky factorizations with threshold dropping. As the drop tolerance decreases, the factor tends to get more dense and the product  $L^*L'$  tends to be a better approximation of A. The following plots show the relative error of the incomplete factorization plotted against the drop tolerance as well as the ratio of the density of the incomplete factors to the density of the complete Cholesky factor.

The relative error is typically on the same order as the drop tolerance, although this is not guaranteed.

## Using a Preconditioner

Use the same matrix A as in the previous example:

```
N = 100;  
A = delsq(numgrid('S',N));
```

Create an incomplete Cholesky factorization as a preconditioner for `pcg`. Use a constant vector as the right hand side. As a baseline, execute `pcg` without a preconditioner:

```
b = ones(size(A,1),1);
tol = 1e-6; maxit = 100;
[x0,f10,rr0,it0,rv0] = pcg(A,b,tol,maxit);
```

Note that `f10 = 1` indicating that `pcg` did not drive the relative residual to the requested tolerance in the maximum allowed iterations. Try the no-fill incomplete Cholesky factorization as a preconditioner:

```
L1 = ichol(A);
[x1,f11,rr1,it1,rv1] = pcg(A,b,tol,maxit,L1,L1');
```

`f11 = 0`, indicating that `pcg` converged to the requested tolerance and did so in 59 iterations (the value of `it1`). Since this matrix is a discretized Laplacian, however, using modified incomplete Cholesky can create a better preconditioner. A modified incomplete Cholesky factorization constructs an approximate factorization that preserves the action of the operator on the constant vector. That is,  $\text{norm}(A*e - L*(L'*e))$  will be approximately zero for  $e = \text{ones}(\text{size}(A,2),1)$  even though  $\text{norm}(A-L*L', 'fro')/\text{norm}(A, 'fro')$  is not close to zero.

---

**Note** It is not necessary to specify `type` for this syntax since `nofill` is the default, but it is good practice.

---

```
opts.type = 'nofill'; opts.michol = 'on';
L2 = ichol(A,opts);
e = ones(size(A,2),1);
norm(A*e-L2*(L2'*e))
ans =
    3.7983e-014

[x2,f12,rr2,it2,rv2] = pcg(A,b,tol,maxit,L2,L2');
```

pcg converges ( $f12 = 0$ ) but in only 38 iterations. Plotting all three convergence histories shows the convergence:

```
semilogy(0:maxit,rv0./norm(b),'b. ');
hold on;
semilogy(0:it1,rv1./norm(b),'r. ');
semilogy(0:it2,rv2./norm(b),'k. ');
legend('No Preconditioner','IC(0)','MIC(0)');
```

The plot shows that the modified incomplete Cholesky preconditioner creates a much faster convergence.

You can also try incomplete Cholesky factorizations with threshold dropping. The following plot shows convergence of pcg with preconditioners constructed with various drop tolerances.

```
L3 = ichol(A, struct('type','ict','droptol',1e-1));
[x3,f13,rr3,it3,rv3] = pcg(A,b,tol,maxit,L3,L3');
```

```

L4 = ichol(A, struct('type','ict','droptol',1e-2));
[x4,fl4,rr4,it4,rv4] = pcg(A,b,tol,maxit,L4,L4');
L5 = ichol(A, struct('type','ict','droptol',1e-3));
[x5,fl5,rr5,it5,rv5] = pcg(A,b,tol,maxit,L5,L5');
figure; semilogy(0:maxit,rv0./norm(b),'b-', 'linewidth',2);
hold on;
semilogy(0:it3,rv3./norm(b),'b-.', 'linewidth',2);
semilogy(0:it4,rv4./norm(b),'b--', 'linewidth',2);
semilogy(0:it5,rv5./norm(b),'b:', 'linewidth',2);
legend('No Preconditioner', 'ICT(1e-1)', 'ICT(1e-2)', ...
      'ICT(1e-3)', 'Location', 'SouthEast');

```

Note the incomplete Cholesky preconditioner constructed with drop tolerance  $1e-2$  is denoted as `ICT(1e-2)`.

As with the zero-fill incomplete Cholesky, the threshold dropping factorization can benefit from modification (i.e. `opts.michol = 'on'`) since the matrix arises from an elliptic partial differential equation.

As with `MIC(0)`, the modified threshold based dropping incomplete Cholesky will preserve the action of the preconditioner on constant vectors, that is  $\text{norm}(A \cdot e - L \cdot (L' \cdot e))$  will be approximately zero.

## Using the `diagcomp` Option

This example illustrates using the `diagcomp` option of `ichol`. Incomplete Cholesky factorizations of positive definite matrices do not always exist. The following code constructs a random symmetric positive definite matrix and attempts to solve a linear system using `pcg`.

```
S = rng('default');
A = sprandsym(1000,1e-2,1e-4,1);
rng(S);
b = full(sum(A,2));
[x0,f10,rr0,it0,rv0] = pcg(A,b,1e-6,100);
```

Since convergence is not attained, try to construct an incomplete Cholesky preconditioner:

```
L = ichol(A,struct('type','ict','droptol',1e-3));
Error using ichol
Encountered nonpositive pivot.
```

If `ichol` breaks down as above, you can use the `diagcomp` option to construct a shifted incomplete Cholesky factorization. That is, instead of constructing  $L$  such that  $L \cdot L'$  approximates  $A$ , `ichol` with diagonal compensation constructs  $L$  such that  $L \cdot L'$  approximates  $M = A + \alpha \cdot \text{diag}(\text{diag}(A))$  without explicitly forming  $M$ . As incomplete factorizations always exist for diagonally dominant matrices,  $\alpha$  can be found to make  $M$  diagonally dominant:

```
alpha = max(sum(abs(A),2)./diag(A))-2
alpha =
    62.9341
```

```
L1 = ichol(A, struct('type','ict','droptol',1e-3,'diagcomp',alpha));
[x1,f11,rr1,it1,rv1] = pcg(A,b,1e-6,100,L1,L1');
```

Here, `pcg` still fails to converge to the desired tolerance within the desired number of iterations, but as the plot below shows, convergence is better for `pcg` with this preconditioner than with no preconditioner. Choosing a smaller `alpha` may help. With some experimentation, we can settle on an appropriate value for `alpha`:

```
alpha = .1;
L2 = ichol(A, struct('type','ict','droptol',1e-3,'diagcomp',alpha));
[x2,f12,rr2,it2,rv2] = pcg(A,b,1e-6,100,L2,L2');
```

Now, `pcg` converges and a plot can show the convergence histories with each preconditioner:

```
semilogy(0:100,rv0./norm(b),'b. ');
hold on;
semilogy(0:100,rv1./norm(b),'r. ');
semilogy(0:it2,rv2./norm(b),'k. ');
legend('No Preconditioner','\alpha \approx 63','\alpha = .1');
xlabel('Iteration Number');
ylabel('Relative Residual');
```

**Purpose** Integer division with rounding option

**Syntax**

```
C = idivide(A, B, opt)
C = idivide(A, B)
C = idivide(A, B, 'fix')
C = idivide(A, B, 'round')
C = idivide(A, B, 'floor')
C = idivide(A, B, 'ceil')
```

**Description** `C = idivide(A, B, opt)` is the same as `A./B` for integer classes except that fractional quotients are rounded to integers using the optional rounding mode specified by `opt`. The default rounding mode is `'fix'`. Inputs `A` and `B` must be real and must have the same dimensions unless one is a scalar. At least one of the arguments `A` and `B` must belong to an integer class, and the other must belong to the same integer class or be a scalar double. The result `C` belongs to the integer class.

`C = idivide(A, B)` is the same as `A./B` except that fractional quotients are rounded toward zero to the nearest integers.

`C = idivide(A, B, 'fix')` is the same as the syntax shown immediately above.

`C = idivide(A, B, 'round')` is the same as `A./B` for integer classes. Fractional quotients are rounded to the nearest integers.

`C = idivide(A, B, 'floor')` is the same as `A./B` except that fractional quotients are rounded toward negative infinity to the nearest integers.

`C = idivide(A, B, 'ceil')` is the same as `A./B` except that the fractional quotients are rounded toward infinity to the nearest integers.

**Examples**

```
a = int32([-2 2]);
b = int32(3);
```

```
idivide(a,b)           % Returns [0 0]
idivide(a,b,'floor')  % Returns [-1 0]
idivide(a,b,'ceil')   % Returns [0 1]
```

# idivide

---

```
idivide(a,b,'round')    % Returns [-1 1]
```

## Purpose

Execute statements if condition is true

## Syntax

```
if expression
    statements
elseif expression
    statements
else
    statements
end
```

## Description

`if expression, statements, end` evaluates an expression, and executes a group of statements when the expression is true.

`elseif` and `else` are optional, and execute statements only when previous expressions in the `if` block are false. An `if` block can include multiple `elseif` statements.

An evaluated expression is true when the result is nonempty and contains all nonzero elements (logical or real numeric). Otherwise, the expression is false.

Expressions can include relational operators (such as `<` or `==`) and logical operators (such as `&&`, `||`, or `~`). MATLAB evaluates compound expressions from left to right, adhering to operator precedence rules.

## Tips

- You can nest any number of `if` statements. Each `if` statement requires an `end` keyword.
- Avoid adding a space within the `elseif` keyword (`else if`). The space creates a nested `if` statement that requires its own `end` keyword.
- Within an `if` or `while` expression, all logical operators, including `|` and `&`, short-circuit. That is, if the first part of the expression determines a true or false result, MATLAB does not evaluate the second part of the expression.

# if/elseif/else

---

## Examples

Assign to a matrix values that depend on their indices:

```
% Preallocate a matrix
nrows = 10;
ncols = 10;
myData = ones(nrows, ncols);

% Loop through the matrix
for r = 1:nrows
    for c = 1:ncols

        if r == c
            myData(r,c) = 2;
        elseif abs(r - c) == 1
            myData(r,c) = -1;
        else
            myData(r,c) = 0;
        end

    end
end
```

---

Respond to command-line input. Because the input string could be more than one character, use `strcmp` rather than `==` to test for equality:

```
reply = input('Would you like to see an echo? (y/n): ', 's');
if strcmp(reply, 'y')
    disp(reply)
end
```

Find the indices of values in a vector that are greater than a specified limit:

```
A = rand(1,10);
limit = .75;

B = (A > limit); % B is a vector of logical values
```

```
if any(B)
    fprintf('Indices of values > %4.2f: \n', limit);
    disp(find(B))
else
    disp('All values are below the limit.')
end
```

---

Concatenate two variables when they are the same size. To avoid an error when the variables have different dimensions, compare the sizes using `isequal` rather than the `==` operator:

```
A = ones(2,3);           % Two-dimensional array
B = rand(3,4,5);        % Three-dimensional array

if isequal(size(A), size(B))
    C = [A; B];
else
    warning('A and B are not the same size.');
```

```
    C = [];
end
```

---

Take advantage of short-circuiting to avoid error or warning messages:

```
x = 42;
if exist('myfunction.m') && (myfunction(x) >= pi)
    disp('Condition is true')
end
```

- “Logical Operators”

**Purpose** Inverse fast Fourier transform

**Syntax**

```
y = ifft(X)
y = ifft(X,n)
y = ifft(X,[],dim)
y = ifft(X,n,dim)
y = ifft(..., 'symmetric')
y = ifft(..., 'nonsymmetric')
```

**Description** `y = ifft(X)` returns the inverse discrete Fourier transform (DFT) of vector `X`, computed with a fast Fourier transform (FFT) algorithm. If `X` is a matrix, `ifft` returns the inverse DFT of each column of the matrix.

`ifft` tests `X` to see whether vectors in `X` along the active dimension are *conjugate symmetric*. If so, the computation is faster and the output is real. An `N`-element vector `x` is conjugate symmetric if  $x(i) = \text{conj}(x(\text{mod}(N-i+1,N)+1))$  for each element of `x`.

If `X` is a multidimensional array, `ifft` operates on the first non-singleton dimension.

`y = ifft(X,n)` returns the `n`-point inverse DFT of vector `X`.

`y = ifft(X,[],dim)` and `y = ifft(X,n,dim)` return the inverse DFT of `X` across the dimension `dim`.

`y = ifft(..., 'symmetric')` causes `ifft` to treat `X` as conjugate symmetric along the active dimension. This option is useful when `X` is not exactly conjugate symmetric, merely because of round-off error.

`y = ifft(..., 'nonsymmetric')` is the same as calling `ifft(...)` without the argument `'nonsymmetric'`.

For any `X`, `ifft(fft(X))` equals `X` to within roundoff error.

**Algorithms** The algorithm for `ifft(X)` is the same as the algorithm for `fft(X)`, except for a sign change and a scale factor of `n = length(X)`. As for `fft`, the execution time for `ifft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have

---

only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

---

**Note** You might be able to increase the speed of `ifft` using the utility function `fftw`, which controls how MATLAB software optimizes the algorithm used to compute an FFT of a particular size and dimension.

---

### Data Type Support

`ifft` supports inputs of data types `double` and `single`. If you call `ifft` with the syntax `y = ifft(X, ...)`, the output `y` has the same data type as the input `X`.

### See Also

**Purpose** 2-D inverse fast Fourier transform

**Syntax**

```
Y = ifft2(X)
Y = ifft2(X,m,n)
y = ifft2(..., 'symmetric')
y = ifft2(..., 'nonsymmetric')
```

**Description** `Y = ifft2(X)` returns the two-dimensional inverse discrete Fourier transform (DFT) of `X`, computed with a fast Fourier transform (FFT) algorithm. The result `Y` is the same size as `X`.

`ifft2` tests `X` to see whether it is *conjugate symmetric*. If so, the computation is faster and the output is real. An `M`-by-`N` matrix `X` is conjugate symmetric if  $X(i,j) = \text{conj}(X(\text{mod}(M-i+1, M) + 1, \text{mod}(N-j+1, N) + 1))$  for each element of `X`.

`Y = ifft2(X,m,n)` returns the `m`-by-`n` inverse fast Fourier transform of matrix `X`.

`y = ifft2(..., 'symmetric')` causes `ifft2` to treat `X` as conjugate symmetric. This option is useful when `X` is not exactly conjugate symmetric, merely because of round-off error.

`y = ifft2(..., 'nonsymmetric')` is the same as calling `ifft2(...)` without the argument `'nonsymmetric'`.

For any `X`, `ifft2(fft2(X))` equals `X` to within roundoff error.

**Algorithms** The algorithm for `ifft2(X)` is the same as the algorithm for `fft2(X)`, except for a sign change and scale factors of `[m,n] = size(X)`. The execution time for `ifft2` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

---

**Note** You might be able to increase the speed of `iff2` using the utility function `fftw`, which controls how MATLAB software optimizes the algorithm used to compute an FFT of a particular size and dimension.

---

### Data Type Support

`iff2` supports inputs of data types `double` and `single`. If you call `iff2` with the syntax `y = iff2(X, ...)`, the output `y` has the same data type as the input `X`.

**Purpose** N-D inverse fast Fourier transform

**Syntax**

```
Y = ifftn(X)
Y = ifftn(X,siz)
y = ifftn(..., 'symmetric')
y = ifftn(..., 'nonsymmetric')
```

**Description** `Y = ifftn(X)` returns the n-dimensional inverse discrete Fourier transform (DFT) of `X`, computed with a multidimensional fast Fourier transform (FFT) algorithm. The result `Y` is the same size as `X`.

`ifftn` tests `X` to see whether it is *conjugate symmetric*. If so, the computation is faster and the output is real. An `N1`-by-`N2`-by- ... `Nk` array `X` is conjugate symmetric if

$$X(i_1, i_2, \dots, i_k) = \text{conj}(X(\text{mod}(N_1 - i_1 + 1, N_1) + 1, \text{mod}(N_2 - i_2 + 1, N_2) + 1, \dots, \text{mod}(N_k - i_k + 1, N_k) + 1))$$

for each element of `X`.

`Y = ifftn(X,siz)` pads `X` with zeros, or truncates `X`, to create a multidimensional array of size `siz` before performing the inverse transform. The size of the result `Y` is `siz`.

`y = ifftn(..., 'symmetric')` causes `ifftn` to treat `X` as conjugate symmetric. This option is useful when `X` is not exactly conjugate symmetric, merely because of round-off error.

`y = ifftn(..., 'nonsymmetric')` is the same as calling `ifftn(...)` without the argument `'nonsymmetric'`.

**Tips** For any `X`, `ifftn(fftn(X))` equals `X` within roundoff error.

**Algorithms** `ifftn(X)` is equivalent to

```
Y = X;
for p = 1:length(size(X))
    Y = ifft(Y,[],p);
end
```

This computes in-place the one-dimensional inverse DFT along each dimension of  $X$ .

The execution time for `ifftn` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

---

**Note** You might be able to increase the speed of `ifftn` using the utility function `fftw`, which controls how MATLAB software optimizes the algorithm used to compute an FFT of a particular size and dimension.

---

## Data Type Support

`ifftn` supports inputs of data types `double` and `single`. If you call `ifftn` with the syntax `y = ifftn(X, ...)`, the output `y` has the same data type as the input `X`.

## See Also

`fftn` | `fftw` | `ifft` | `ifft2` | `ifftshift`

# ifftshift

---

**Purpose** Inverse FFT shift

**Syntax** `ifftshift(X)`  
`ifftshift(X,dim)`

**Description** `ifftshift(X)` swaps the left and right halves of the vector  $X$ . For matrices, `ifftshift(X)` swaps the first quadrant with the third and the second quadrant with the fourth. If  $X$  is a multidimensional array, `ifftshift(X)` swaps “half-spaces” of  $X$  along each dimension.

`ifftshift(X,dim)` applies the `ifftshift` operation along the dimension `dim`.

---

**Note** `ifftshift` undoes the results of `fftshift`. If the matrix  $X$  contains an odd number of elements, `ifftshift(fftshift(X))` must be done to obtain the original  $X$ . Simply performing `fftshift(X)` twice will not produce  $X$ .

---

**See Also** `fft` | `fft2` | `fftn` | `fftshift`

**Purpose** Sparse incomplete LU factorization

**Syntax**

```
ilu(A,setup)
[L,U] = ilu(A,setup)
[L,U,P] = ilu(A,setup)
```

**Description** `ilu` produces a unit lower triangular matrix, an upper triangular matrix, and a permutation matrix.

`ilu(A,setup)` computes the incomplete LU factorization of `A`. `setup` is an input structure with up to five setup options. The fields must be named exactly as shown in the table below. You can include any number of these fields in the structure and define them in any order. Any additional fields are ignored.

Field Name	Description
<code>type</code>	<p>Type of factorization. Values for <code>type</code> include:</p> <ul style="list-style-type: none"> <li>'nofill'—Performs ILU factorization with 0 level of fill in, known as ILU(0). With <code>type</code> set to 'nofill', only the <code>milu</code> setup option is used; all other fields are ignored.</li> <li>'crout'—Performs the Crout version of ILU factorization, known as ILUC. With <code>type</code> set to 'crout', only the <code>droptol</code> and <code>milu</code> setup options are used; all other fields are ignored.</li> <li>'ilutp' (default)—Performs ILU factorization with threshold and pivoting.</li> </ul> <p>If <code>type</code> is not specified, the ILU factorization with pivoting ILUTP is performed. Pivoting is never performed with <code>type</code> set to 'nofill' or 'crout'.</p>
<code>droptol</code>	<p>Drop tolerance of the incomplete LU factorization. <code>droptol</code> is a non-negative scalar. The default value is 0, which produces the complete LU factorization.</p>

Field Name	Description
	<p>The nonzero entries of U satisfy</p> $\text{abs}(U(i,j)) \geq \text{droptol} * \text{norm}(A(:,j)),$ <p>with the exception of the diagonal entries, which are retained regardless of satisfying the criterion. The entries of L are tested against the local drop tolerance before being scaled by the pivot, so for nonzeros in L</p> $\text{abs}(L(i,j)) \geq \text{droptol} * \text{norm}(A(:,j)) / U(j,j).$
milu	<p>Modified incomplete LU factorization. Values for milu include:</p> <ul style="list-style-type: none"> <li>• 'row'—Produces the row-sum modified incomplete LU factorization. Entries from the newly-formed column of the factors are subtracted from the diagonal of the upper triangular factor, U, preserving column sums. That is, <math>A * e = L * U * e</math>, where e is the vector of ones.</li> <li>• 'col'—Produces the column-sum modified incomplete LU factorization. Entries from the newly-formed column of the factors are subtracted from the diagonal of the upper triangular factor, U, preserving column sums. That is, <math>e' * A = e' * L * U</math>.</li> <li>• 'off' (default)—No modified incomplete LU factorization is produced.</li> </ul>
udiag	<p>If udiag is 1, any zeros on the diagonal of the upper triangular factor are replaced by the local drop tolerance. The default is 0.</p>
thresh	<p>Pivot threshold between 0 (forces diagonal pivoting) and 1, the default, which always chooses the maximum magnitude entry in the column to be the pivot.</p>

`ilu(A,setup)` returns `L+U-speye(size(A))`, where `L` is a unit lower triangular matrix and `U` is an upper triangular matrix.

`[L,U] = ilu(A,setup)` returns a unit lower triangular matrix in `L` and an upper triangular matrix in `U`.

`[L,U,P] = ilu(A,setup)` returns a unit lower triangular matrix in `L`, an upper triangular matrix in `U`, and a permutation matrix in `P`.

## Tips

These incomplete factorizations may be useful as preconditioners for a system of linear equations being solved by iterative methods such as BICG (BiConjugate Gradients), GMRES (Generalized Minimum Residual Method).

## Limitations

`ilu` works on sparse square matrices only.

## Examples

Start with a sparse matrix and compute the LU factorization.

```
A = gallery('neumann', 1600) + speye(1600);
setup.type = 'crout';
setup.milu = 'row';
setup.droptol = 0.1;
[L,U] = ilu(A,setup);
e = ones(size(A,2),1);
norm(A*e-L*U*e)
```

ans =

```
1.4251e-014
```

This shows that `A` and `L*U`, where `L` and `U` are given by the modified Crout ILU, have the same row-sum.

Start with a sparse matrix and compute the LU factorization.

```
A = gallery('neumann', 1600) + speye(1600);
setup.type = 'nofill';
nnz(A)
```

```
ans =  
  
      7840  
  
nnz(lu(A))  
ans =  
  
    126478  
  
nnz(ilu(A,setup))  
ans =  
  
      7840
```

This shows that A has 7840 nonzeros, the complete LU factorization has 126478 nonzeros, and the incomplete LU factorization, with 0 level of fill-in, has 7840 nonzeros, the same amount as A.

**Purpose** Convert image to movie frame

**Syntax** `f = im2frame(X,map)`  
`f = im2frame(X)`

**Description** `f = im2frame(X,map)` converts the indexed image `X` and associated colormap `map` into a movie frame `f`. If `X` is a truecolor (m-by-n-by-3) image, then `map` is optional and has no effect.

Typical usage:

```
M(1) = im2frame(X1,map);  
M(2) = im2frame(X2,map);  
...  
M(n) = im2frame(Xn,map);  
movie(M)
```

`f = im2frame(X)` converts the indexed image `X` into a movie frame `f` using the current colormap if `X` contains an indexed image.

**See Also** `frame2im` | `movie`

# im2java

---

**Purpose** Convert image to Java image

**Syntax**

```
jimage = im2java(I)
jimage = im2java(X,MAP)
jimage = im2java(RGB)
```

**Description** To work with a MATLAB image in the Java environment, you must convert the image from its MATLAB representation into an instance of the Java image class, `java.awt.Image`.

`jimage = im2java(I)` converts the intensity image `I` to an instance of the Java image class, `java.awt.Image`.

`jimage = im2java(X,MAP)` converts the indexed image `X`, with colormap `MAP`, to an instance of the Java image class, `java.awt.Image`.

`jimage = im2java(RGB)` converts the RGB image `RGB` to an instance of the Java image class, `java.awt.Image`.

**Class Support** The input image can be of class `uint8`, `uint16`, or `double`.

---

**Note** Java requires `uint8` data to create an instance of the Java image class, `java.awt.Image`. If the input image is of class `uint8`, `jimage` contains the same `uint8` data. If the input image is of class `double` or `uint16`, `im2java` makes an equivalent image of class `uint8`, rescaling or offsetting the data as necessary, and then converts this `uint8` representation to an instance of the Java image class, `java.awt.Image`.

---

**Examples** This example reads an image into the MATLAB workspace and then uses `im2java` to convert it into an instance of the Java image class.

```
I = imread('ngc6543a.jpg');
javaImage = im2java(I);
frame = javax.swing.JFrame;
icon = javax.swing.ImageIcon(javaImage);
label = javax.swing.JLabel(icon);
```

```
frame.getContentPane.add(label);  
frame.pack  
frame.show
```

# imag

---

**Purpose**            Imaginary part of complex number

**Syntax**             $Y = \text{imag}(Z)$

**Description**        $Y = \text{imag}(Z)$  returns the imaginary part of the elements of array  $Z$ .

**Examples**            $\text{imag}(2+3i)$

ans =

3

**See Also**           `conj` | `i` | `j` | `real`

**Purpose**

Display image object

**Syntax**

```
image(C)
image(x,y,C)
image(x,y,C, 'PropertyName',PropertyValue,...)
image('PropertyName',PropertyValue,...)
handle = image(...)
```

**Properties**

For a list of properties, see Image Properties.

**Description**

`image` creates an image graphics object by interpreting each element in a matrix as an index into the figure's colormap or directly as RGB values, depending on the data specified.

The `image` function has two forms:

- A high-level function that calls `newplot` to determine where to draw the graphics objects and sets the following axes properties:
  - `XLim` and `YLim` to enclose the image
  - Layer to top to place the image in front of the tick marks and grid lines
  - `YDir` to reverse
  - `View` to `[0 90]`
- A low-level function that adds the image to the current axes without calling `newplot`. The low-level function argument list can contain only property name/property value pairs.

You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see `set` and `get` for examples of how to specify these data types).

# image

---

`image(C)` displays matrix `C` as an image. Each element of `C` specifies the color of a rectangular segment in the image.

`image(x,y,C)`, where `x` and `y` are two-element vectors, specifies the range of the `x`- and `y`-axis labels, but produces the same image as `image(C)`. This can be useful, for example, if you want the axis tick labels to correspond to real physical dimensions represented by the image. If `x(1) > x(2)` or `y(1) > y(2)`, the image is flipped left-right or up-down, respectively. It can also be useful when you want to place the image within a set of axes already created. In this case, use `hold on` with the current figure and enter `x` and `y` values corresponding to the corners of the desired image location. The image is stretched and oriented as applicable.

`image(x,y,C,'PropertyName',PropertyValue,...)` is a high-level function that also specifies property name/property value pairs. For a description of the properties, see [Image Properties](#). This syntax calls `newplot` before drawing the image.

`image('PropertyName',PropertyValue,...)` is the low-level syntax of the `image` function. It specifies only property name/property value pairs as input arguments.

`handle = image(...)` returns the handle of the image object it creates. You can obtain the handle with all forms of the `image` function.

## Tips

Image data can be either indexed or true color. An indexed image stores colors as an array of indices into the figure colormap. A true color image does not use a colormap; instead, the color values for each pixel are stored directly as RGB triplets. In MATLAB graphics, the `CData` property of a truecolor image object is a three-dimensional (`m`-by-`n`-by-3) array. This array consists of three `m`-by-`n` matrices (representing the red, green, and blue color planes) concatenated along the third dimension.

The `imread` function reads image data into MATLAB arrays from graphics files in various standard formats, such as TIFF. You can write MATLAB image data to graphics files using the `imwrite` function. `imread` and `imwrite` both support a variety of graphics file formats and compression schemes.

When you read image data into the MATLAB workspace using `imread`, the data is usually stored as an array of 8-bit integers. However, `imread` also supports reading 16-bit-per-pixel data from TIFF and PNG files. These are more efficient storage methods than the double-precision (64-bit) floating-point numbers that MATLAB typically uses. However, it is necessary to interpret 8-bit and 16-bit image data differently from 64-bit data. This table summarizes these differences.

You cannot interactively pan or zoom outside the  $x$ -limits or  $y$ -limits of an image, unless the axes limits are already been set outside the bounds of the image, in which case there is no such restriction. If other objects (such as lineseries) occupy the axes and extend beyond the bounds of the image, you can pan or zoom to the bounds of the other objects, but no further.

<b>Image Type</b>	<b>Double-Precision Data (double Array)</b>	<b>8-Bit Data (uint8 Array) 16-Bit Data (uint16 Array)</b>
Indexed (colormap)	Image is stored as a two-dimensional (m-by-n) array of integers in the range [1, length(colormap)]; colormap is an m-by-3 array of floating-point values in the range [0, 1].	Image is stored as a two-dimensional (m-by-n) array of integers in the range [0, 255] (uint8) or [0, 65535] (uint16); colormap is an m-by-3 array of floating-point values in the range [0, 1].
True color (RGB)	Image is stored as a three-dimensional (m-by-n-by-3) array of floating-point values in the range [0, 1].	Image is stored as a three-dimensional (m-by-n-by-3) array of integers in the range [0, 255] (uint8) or [0, 65535] (uint16).

By default, `image` plots the  $y$ -axis from lowest to highest value, top to bottom. To reverse this, type `set(gca, 'YDir', 'normal')`. This will reverse both the  $y$ -axis and the image.

## Indexed Images

In an indexed image of class `double`, the value 1 points to the first row in the colormap, the value 2 points to the second row, and so on. In a `uint8` or `uint16` indexed image, there is an offset; the value 0 points to the first row in the colormap, the value 1 points to the second row, and so on.

If you want to convert a `uint8` or `uint16` indexed image to `double`, you need to add 1 to the result. For example,

```
X64 = double(X8) + 1;
```

or

```
X64 = double(X16) + 1;
```

To convert from `double` to `uint8` or `uint16`, you need to first subtract 1, and then use `round` to ensure all the values are integers.

```
X8 = uint8(round(X64 - 1));
```

or

```
X16 = uint16(round(X64 - 1));
```

When you write an indexed image using `imwrite`, values are automatically converted if necessary.

## Colormaps

MATLAB colormaps are always `m`-by-3 arrays of double-precision floating-point numbers in the range [0, 1]. In most graphics file formats, colormaps are stored as integers, but MATLAB colormaps cannot have integer values. `imread` and `imwrite` automatically convert colormap values when reading and writing files.

## True Color Images

In a true color image of class `double`, the data values are floating-point numbers in the range [0, 1]. In a true color image of class `uint8`, the

data values are integers in the range [0, 255], and for true color images of class `uint16` the data values are integers in the range [0, 65535].

If you want to convert a true color image from one data type to the other, you must rescale the data. For example, this statement converts a `uint8` true color image to `double`.

```
RGB64 = double(RGB8)/255;
```

or for `uint16` images,

```
RGB64 = double(RGB16)/65535;
```

This statement converts a `double` true color image to `uint8`:

```
RGB8 = uint8(round(RGB64*255));
```

or to obtain `uint16` images, type

```
RGB16 = uint16(round(RGB64*65535));
```

When you write a true color image using `imwrite`, values are automatically converted if necessary.

## Examples

Load a mat-file containing a photograph of a colorful primate. Display the indexed image using its associated colormap.

```
load mandrill
figure('color','k')
image(X)
colormap(map)
axis off           % Remove axis ticks and numbers
axis image       % Set aspect ratio to obtain
square pixels
```

## image

---

---

Load a JPEG image file of the Cat's Eye Nebula from the Hubble Space Telescope (image courtesy NASA). Display the original image using its RGB color values (left) as a subplot. Create a linked subplot (same size and scale) to display the transformed intensity image as a heat map (right).

```
figure
ax(1) = subplot(1,2,1);
rgb = imread('ngc6543a.jpg');
```

```
image(rgb); title('RGB image')
ax(2) = subplot(1,2,2);
im = mean(rgb,3);
image(im); title('Intensity Heat Map')
colormap(hot(256))
linkaxes(ax,'xy')
axis(ax,'image')
```

# image

---

## Setting Default Properties

You can set default image properties on the axes, figure, and root object levels:

```
set(0,'DefaultImageProperty',PropertyValue...)  
set(gcf,'DefaultImageProperty',PropertyValue...)  
set(gca,'DefaultImageProperty',PropertyValue...)
```

where *Property* is the name of the image property and *PropertyValue* is the value you are specifying. Use `set` and `get` to access image properties.

## Tutorials

For more information, see “Working with Images in MATLAB Graphics”  
.

## See Also

`colormap` | `imagesc` | `imfinfo` | `imread` | `imwrite` | `newplot` | `pcolor`  
| `surface` | Image Properties

## Purpose

Define image properties

## Creating Image Objects

Use `image` to create image objects.

## Modifying Properties

You can set and query graphics object properties in two ways:

- “The Property Editor” is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see “Setting Default Property Values”.

See “Core Graphics Objects” for general information about this type of object.

## Image Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

`AlphaData`

m-by-n matrix of `double` or `uint8`

*Transparency data.* A matrix of non-NaN values specifying the transparency of each face or vertex of the object. The `AlphaData` can be of class `double` or `uint8`.

MATLAB software determines the transparency in one of the following ways:

- Using the elements of `AlphaData` as transparency values (`AlphaDataMapping` set to `none`)
- Using the elements of `AlphaData` as indices into the current `alphamap` (`AlphaDataMapping` set to `direct`)

# Image Properties

---

- Scaling the elements of `AlphaData` to range between the minimum and maximum values of the axes `ALim` property (`AlphaDataMapping` set to `scaled`, the default)

## `AlphaDataMapping`

`none` | `direct` | `{scaled}`

*Transparency mapping method.* Determines how MATLAB interprets indexed alpha data. Values for this property are:

- `none` — The transparency values of `AlphaData` are between 0 and 1 or are clamped to this range.
- `scaled` — Transform the `AlphaData` to span the portion of the `alphamap` indicated by the axes `ALim` property, linearly mapping data values to alpha values (the default).
- `direct` — Use the `AlphaData` as indices directly into the `alphamap`. When not scaled, the data are usually integer values ranging from 1 to `length(alphamap)`. MATLAB maps values less than 1 to the first alpha value in the `alphamap`, and values greater than `length(alphamap)` to the last alpha value in the `alphamap`. Values with a decimal portion are fixed to the nearest, lower integer. If `AlphaData` is an array of `uint8` integers, then the indexing begins at 0 (that is, MATLAB maps a value of 0 to the first alpha value in the `alphamap`).

## `Annotation`

`hg.Annotation` object (read-only)

*Handle of Annotation object.* The `Annotation` property enables you to specify whether this image object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the image object is displayed in a figure legend:

<b>IconDisplayStyle Value</b>	<b>Purpose</b>
on	Represent this image object in a legend (default)
off	Do not include this image object in a legend
children	Same as on because image objects do not have children

## Setting the `IconDisplayStyle` property

Set the `IconDisplayStyle` of a graphics object with handle `hobj` to `off`:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'off')
```

## Using the `IconDisplayStyle` property

See “Controlling Legends” for more information and examples.

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to

# Image Properties

---

perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`  
cancel | {queue}

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`  
string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## CData

matrix | m-by-n-by-3 array

*The image data.* A matrix or 3-D array of values specifying the color of each rectangular area defining the image. `image(C)` assigns the values of `C` to `CData`. MATLAB determines the coloring of the image in one of three ways:

- Using the elements of `CData` as indices into the current colormap (the default) (`CDataMapping` set to `direct`)
- Scaling the elements of `CData` to range between the values `min(get(gca,'CLim'))` and `max(get(gca,'CLim'))` (`CDataMapping` set to `scaled`)
- Interpreting the elements of `CData` directly as RGB values (true color specification)

Note that the behavior of NaNs in image `CData` is not defined. See the image `AlphaData` property for information on using transparency with images.

A true color specification for `CData` requires an m-by-n-by-3 array of RGB values. The first page contains the red component, the second page the green component, and the third page the blue component of each element in the image. RGB values range from 0 to 1. The following picture illustrates the relative dimensions of `CData` for the two color models.

# Image Properties

---

Indexed Colors

True Colors

If CData has only one row or column, the height or width respectively is always one data unit and is centered about the first YData or XData element respectively. For example, using a 4-by-1 matrix of random data:

```
C = rand(4,1);  
image(C, 'CDataMapping', 'scaled')  
axis image
```

produces

CDataMapping  
scaled | {direct}

*Direct or scaled indexed colors.* Determines whether MATLAB interprets the values in CData as indices into the figure colormap (the default) or scales the values according to the values of the axes CLim property.

When CDataMapping is direct, the values of CData should be in the range 1 to `length(get(gcf, 'Colormap'))`. If you use true color specification for CData, this property has no effect. If CData is of type `logical`, values of 0 index the first color of the colormap and values of 1 index the second color.

# Image Properties

---

Children  
handle

The empty matrix; image objects have no children.

Clipping  
{on} | off

*Clipping mode.* By default, MATLAB clips images to the axes rectangle. If you set `Clipping` to `off`, the image can be displayed outside the axes rectangle. For example, if you create an image, set `hold` to `on`, freeze axis scaling (with `axis manual`), and then create a larger image, it extends beyond the axis limits.

CreateFcn  
string | function handle

*Callback routine executed during object creation.* This property defines a callback routine that executes when MATLAB creates an image object. You must define this property as a default value for images or in a call to the `image` function to create a new image object. For example, the statement:

```
set(0, 'DefaultImageCreateFcn', 'axis image')
```

defines a default value on the root level that sets the aspect ratio and the axis limits so the image has square pixels. MATLAB executes this routine after setting all image properties. Setting this property on an existing image object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

## DisplayName

string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the image object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.

# Image Properties

---

- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

## EraseMode

{normal} | none | xor | background

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object’s color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

### `HandleVisibility`

`{on} | callback | off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

# Image Properties

---

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## HitTest

{on} | off

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the objects that compose the area graph. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

## Interruptible

off | {on}

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.

# Image Properties

---

- If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

BusyAction property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting Interruptible property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

## Parent

handle of parent axes, hgroup, or hgtransform

*Parent of object.* Handle of the object’s parent. The parent is normally the axes, hgroup, or hgtransform object that contains the object.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## Selected

on | {off}

*Object selection state.* When you set this property to on, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also on (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to on, thereby indicating that this particular object is selected. This property is also set to on when an object is manually selected in plot edit mode.

`SelectionHighlight`  
{on} | off

*Object highlighted when selected.*

- on — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- off — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

`Tag`  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an `areaseries` object and set the `Tag` property.

```
t = area(Y, 'Tag', 'area1')
```

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag', 'area1'), 'FaceColor', 'red')
```

`Type`  
string (read-only)

# Image Properties

---

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For image objects, `Type` is always `'image'`.

## UIContextMenu

handle of `uicontextmenu` object

*Associate context menu with object.* Handle of a `uicontextmenu` object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

## UserData

array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## Visible

{on} | off

*Visibility of object and its children.*

- `on` — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- `off` — Object not displayed. However, the object still exists and you can set and query its properties.

## XData

[1 size(CData,2)] by default

*Control placement of image along x-axis.* A vector specifying the locations of the centers of the elements `CData(1,1)` and `CData(m,n)`, where `CData` has a size of `m`-by-`n`. Element `CData(1,1)` is centered over the coordinate defined by the first

elements in `XData` and `YData`. Element `CData(m,n)` is centered over the coordinate defined by the last elements in `XData` and `YData`. The centers of the remaining elements of `CData` are evenly distributed between those two points.

The width of each `CData` element is determined by the expression:

$$(XData(2) - XData(1)) / (\text{size}(CData, 2) - 1)$$

You can also specify a single value for `XData`. In this case, `image` centers the first element at this coordinate and centers each following element one unit apart.

`YData`

`[1 size(CData,1)]` by default

*Control placement of image along y-axis.* A vector specifying the locations of the centers of the elements `CData(1,1)` and `CData(m,n)`, where `CData` has a size of `m`-by-`n`. Element `CData(1,1)` is centered over the coordinate defined by the first elements in `XData` and `YData`. Element `CData(m,n)` is centered over the coordinate defined by the last elements in `XData` and `YData`. The centers of the remaining elements of `CData` are evenly distributed between those two points.

The height of each `CData` element is determined by the expression:

$$(YData(2) - YData(1)) / (\text{size}(CData, 1) - 1)$$

You can also specify a single value for `YData`. In this case, `image` centers the first element at this coordinate and centers each following element one unit apart.

## See Also

`image`

# imagesc

---

**Purpose** Scale data and display image object

**Syntax**

```
imagesc(C)
imagesc(x,y,C)
imagesc(...,clims)
imagesc('PropertyName',PropertyValue,...)
h = imagesc(...)
```

**Description** The `imagesc` function scales image data to the full range of the current colormap and displays the image. (See “Examples” on page 2-2201 for an illustration.)

`imagesc(C)` displays `C` as an image. Each element of `C` corresponds to a rectangular area in the image. The values of the elements of `C` are indices into the current colormap that determine the color of each patch.

`imagesc(x,y,C)` displays `C` as an image and specifies the bounds of the  $x$ - and  $y$ -axis with vectors `x` and `y`. If `x(1) > x(2)` or `y(1) > y(2)`, the image is flipped left-right or up-down, respectively. If `x` and `y` are scalars, the image is translated to the specified location `(x,y)` such that the upper left corner of the image starts at `(x,y)`.

`imagesc(...,clims)` normalizes the values in `C` to the range specified by `clims` and displays `C` as an image. `clims` is a two-element vector that limits the range of data values in `C`. These values map to the full range of values in the current colormap.

`imagesc('PropertyName',PropertyValue,...)` is the low-level syntax of the `imagesc` function. It specifies only property name/property value pairs as input arguments. See Image Properties for a list of the property names and their values.

`h = imagesc(...)` returns the handle for an image graphics object.

## Tips

$x$  and  $y$  do not affect the elements in  $C$ ; they only affect the annotation of the axes. If  $\text{length}(x) > 2$  or  $\text{length}(y) > 2$ , `imagesc` ignores all except the first and last elements of the respective vector.

`imagesc` creates an image with `CDataMapping` set to `scaled`, and sets the axes `CLim` property to the value passed in `clims`.

You cannot interactively pan or zoom outside the  $x$ -limits or  $y$ -limits of an image.

By default, `imagesc` plots the  $y$ -axis from lowest to highest value, top to bottom. To reverse this, type `set(gca, 'YDir', 'normal')`. This will reverse both the  $y$ -axis and the image.

## Examples

You can expand midrange color resolution by mapping low values to the first color and high values to the last color in the colormap by specifying color value limits (`clims`). If the size of the current colormap is 81-by-3, the statements

```
clims = [ 10 60 ]
imagesc(C,clims)
```

map the data values in  $C$  to the colormap as shown in this illustration and the code that follows:

# imagesc

---

In this example, the left image maps to the gray colormap using the statements

```
load clown
figure
subplot(1,2,1)
imagesc(X)
colormap(gray)
axis image
title('Default CLim (= [1 81])')
```

The right image has values between 10 and 60 scaled to the full range of the gray colormap using the statements

```
subplot(1,2,2)
clims = [10 60];
imagesc(X,clims)
colormap(gray)
axis image
title('CLim = [10 60]')
```

This example shows how to shift the image starting from origin to a position (100, 100),

```
i = imread('eight.tif');
```

```
figure; subplot(2,2,1); imagesc(i);  
axis([0 400 0 400]);  
colormap(gray);  
subplot(2,2,2); imagesc(100,100,i);  
axis([0 400 0 400]);  
colormap(gray);
```

The figure output is as:

The top right corner of the image is now starting from (100,100) instead of the origin.

Passing vector values with the image scales the image to the specified size of 400-by-400.

```
figure; imagesc(1:400,1:400,i);  
colormap(gray);
```

# imagesc

---

## See Also

`image` | `imfinfo` | `imread` | `imwrite` | `colorbar` | `colormap` | `pcolor`  
| `surface` | `surf`

**Purpose** Approximate indexed image by reducing number of colors

**Syntax**

```
[Y,newmap] = imapprox(X,map,n)
[Y,newmap] = imapprox(X,map,tol)
Y = imapprox(X,map,newmap)
Y = imapprox(...,dither_option)
```

**Description** [Y,newmap] = imapprox(X,map,n) approximates the colors in the indexed image X and associated colormap map by using minimum variance quantization. imapprox returns the indexed image Y with colormap newmap, which has at most n colors.

[Y,newmap] = imapprox(X,map,tol) approximates the colors in X and map through uniform quantization. newmap contains at most  $(\text{floor}(1/\text{tol})+1)^3$  colors. tol must be between 0 and 1.0.

Y = imapprox(X,map,newmap) approximates the colors in map by using colormap mapping to find the colors in newmap that best match the colors in map.

Y = imapprox(...,dither\_option) enables or disables dithering. dither\_option is a string that can have one of these values.

Value	Description
{'dither'}(default)	Dithers, if necessary, to achieve better color resolution at the expense of spatial resolution.
'nodither'	Maps each color in the original image to the closest color in the new map. No dithering is performed.

**Class Support** The input image X can be of class uint8, uint16, or double. The output image Y is of class uint8 if the length of newmap is less than or equal to 256. If the length of newmap is greater than 256, Y is of class double.

**Algorithms** imapprox uses rgb2ind to create a new colormap that uses fewer colors.

## Examples

Load an indexed image of a mandrill's face. Display image  $X$  using its associated colormap,  $map$ , which has 220 colors.

```
load mandrill
figure('color','k')
image(X)
colormap(map)
size(map)           % See that the color map has 220 entries

ans =
    220     3

axis off           % Remove axis ticks and numbers
axis image        % Set aspect ratio to obtain square pixels
```

Reduce the number of colors in the indexed image from 220 to only 16 colors by producing a new image, `Y`, and its associated colormap, `newmap`:

```
figure('color','k')
[Y, newmap] = imapprox(X, map, 16);
size(newmap)      % See that the new color map has 16 entries
```

```
ans =
    16     3
```

# imapprox

---

```
image(Y)
colormap(newmap)
axis off           % Remove axis ticks and numbers
axis image        % Set aspect ratio to obtain square pixels
```

[cmunique](#) | [dither](#) | [rgb2ind](#)

**Purpose** Information about graphics file

**Syntax**

```
info = imfinfo(filename,fmt)
info = imfinfo(filename)
info = imfinfo(URL,...)
```

**Description** `info = imfinfo(filename,fmt)` returns a structure whose fields contain information about an image in a graphics file. `filename` is a string that specifies the name of the graphics file, and `fmt` is a string that specifies the format of the file. The file must be in the current folder or in a folder on the MATLAB path. If `imfinfo` cannot find a file named `filename`, it looks for a file named `filename.fmt`. The possible values for `fmt` are contained in the MATLAB file format registry. To view a list of these formats, run the `imformats` command.

If `filename` is a TIFF, HDF, ICO, GIF, or CUR file containing more than one image, `info` is a structure array with one element for each image in the file. For example, `info(3)` would contain information about the third image in the file.

`info = imfinfo(filename)` attempts to infer the format of the file from its contents.

`info = imfinfo(URL,...)` reads the image from the specified Internet URL. The URL must include the protocol type (e.g., `http://`)

### Information Returned

The set of fields in `info` depends on the individual file and its format. However, the first nine fields are always the same. This table lists these common fields, in the order they appear in the structure, and describes their values. “Format-Specific Notes” on page 2-2210 contains information about some fields returned by certain formats.

Field	Value
Filename	A string containing the name of the file or the Internet URL specified; if the file is not in the current folder, the string contains the full pathname of the file
FileModDate	A string containing the date when the file was last modified
FileSize	An integer indicating the size of the file in bytes
Format	A string containing the file format, as specified by <i>fmt</i> ; for formats with more than one possible extension (e.g. JPEG and TIFF files), <code>imfinfo</code> returns the first variant in the file format registry.
FormatVersion	A string or number describing the file format version
Width	An integer indicating the width of the image in pixels
Height	An integer indicating the height of the image in pixels
BitDepth	An integer indicating the number of bits per pixel
ColorType	A string indicating the type of image; this can include, but is not limited to, 'truecolor' for a truecolor (RGB) image, 'grayscale' for a grayscale intensity image, or 'indexed' for an indexed image

## Format-Specific Notes

- **JPEG and TIFF only** — If `filename` contains Exchangeable Image File Format (EXIF) tags, the `info` structure returned by `imfinfo` might also contain 'DigitalCamera' or 'GPSInfo' (global positioning system information) fields.
- **GIF only** — `imfinfo` returns the value of the 'DelayTime' field in hundredths of seconds.

**Examples**

```
info = imfinfo('ngc6543a.jpg')

info =

    Filename: [1x95 char]
  FileModDate: '01-Oct-1996 17:19:44'
    FileSize: 27387
      Format: 'jpg'
  FormatVersion: ''
        Width: 600
        Height: 650
    BitDepth: 24
    ColorType: 'truecolor'
  FormatSignature: ''
  NumberOfSamples: 3
    CodingMethod: 'Huffman'
  CodingProcess: 'Sequential'
        Comment: {[1x69 char]}
```

**See Also**

```
imformats | imread | imwrite
```

# imformats

---

**Purpose** Manage image file format registry

**Syntax**

```
imformats
formats = imformats
formats = imformats('fmt')
formats = imformats(format_struct)
formats = imformats('factory')
```

**Description** `imformats` displays a table of information listing all the values in the MATLAB file format registry. This registry determines which file formats are supported by the `imfinfo`, `imread`, and `imwrite` functions. `formats = imformats` returns a structure containing all the values in the MATLAB file format registry. The following tables lists the fields in the order they appear in the structure.

Field	Value
<code>ext</code>	A cell array of strings that specify filename extensions that are valid for this format
<code>isa</code>	A string specifying the name of the function that determines if a file is a certain format. This can also be a function handle.
<code>info</code>	A string specifying the name of the function that reads information about a file. This can also be a function handle.
<code>read</code>	A string specifying the name of the function that reads image data in a file. This can also be a function handle.
<code>write</code>	A string specifying the name of the function that writes MATLAB data to a file. This can also be a function handle.
<code>alpha</code>	Returns 1 if the format has an alpha channel, 0 otherwise
<code>description</code>	A text description of the file format

---

**Note** The values for the `isa`, `info`, `read`, and `write` fields must be functions on the MATLAB search path or function handles.

---

`formats = imformats('fmt')` searches the known formats in the MATLAB file format registry for the format associated with the filename extension `'fmt'`. If found, `imformats` returns a structure containing the characteristics and function names associated with the format. Otherwise, it returns an empty structure.

`formats = imformats(format_struct)` sets the MATLAB file format registry to the values in `format_struct`. The output structure, `formats`, contains the new registry settings.

---

**Caution** Using `imformats` to specify values in the MATLAB file format registry can result in the inability to load any image files. To return the file format registry to a working state, use `imformats` with the `'factory'` setting.

---

`formats = imformats('factory')` resets the MATLAB file format registry to the default format registry values. This removes any user-specified settings.

Changes to the format registry do not persist between MATLAB sessions. To have a format always available when you start MATLAB, add the appropriate `imformats` command to the MATLAB startup file, `startup.m`, located in `$MATLAB/toolbox/local` on UNIX systems, or `$MATLAB\toolbox\local` on Windows systems.

## Examples

```
formats = imformats;
formats(1)

ans =

        ext: {'bmp'}
```

# imformats

---

```
isa: @isbmp
info: @imbmpinfo
read: @readbmp
write: @writebmp
alpha: 0
description: 'Windows Bitmap (BMP)'
```

## See Also

[imfinfo](#) | [imread](#) | [imwrite](#) | [path](#)

**Purpose** Add package or class to current import list

**Syntax**

```
import package_name.class_name
import package_name.function_name
import package_name.*
import package_name.class_name1 package_name.class_name2...
import package_name1.* package_name2.*...
L = import
import
```

**Description**

`import package_name.class_name` adds the fully qualified class name to the current import list.

`import package_name.function_name` adds the specified package-based function.

`import package_name.*` adds the specified package name. Note that `package_name` must be followed by `.*`.

`import package_name.class_name1 package_name.class_name2...` adds multiple fully qualified class names.

`import package_name1.* package_name2.*...` adds multiple package names.

`L = import` with no input arguments returns a cell array of strings containing the current import list, without adding to it.

`import` with no input arguments displays the current import list, without adding to it.

The `import` function allows your code to refer to an imported class or function using fewer or no package prefixes.

The `import` function only affects the import list of the function within which it is used. When invoked at the command prompt, `import` uses the import list for the MATLAB command environment. If `import` is used in a script invoked from a function, it affects the import list of the function. If `import` is used in a script that is invoked from the command prompt, it affects the import list for the command environment.

# import

---

The `import` list of a function is persistent across calls to that function and is only cleared when the function is cleared.

To clear the current import list, use the following command.

```
clear import
```

This command may only be invoked at the command prompt. Attempting to use `clear import` within a function results in an error.

## Importing MATLAB Packages and Classes

You can `import` packages and classes into a MATLAB workspace (from the command line or in a function definition). For example:

```
import packagename.*
```

`import` imports all classes and package functions so that you can reference those classes and functions by their simple names, without the package qualifier.

You can `import` just a single class from a package:

```
import packagename.ClassName  
import Classname
```

You must still use the class name to call static methods:

```
ClassName.staticMethod()
```

For more information on how `import` works with MATLAB classes and packages, see “Importing Classes”.

## Tips

The `import` function allows your code to refer to an imported class by class name only, rather than with the fully qualified class name. `import` is particularly useful in streamlining calls to constructors, where most references to Java classes occur.

If you use the `import` function in a control statement, for example, `if` or `switch`, or in a function, MATLAB limits the scope of the variables

to that block of code. If you use the variables outside the function or control block, MATLAB displays an error message.

## Limitations

- `import` cannot load a Java JAR package created by the MATLAB Builder™ JA product.

## Examples

To add the `containers.Map` class to the current import list:

```
import containers.Map
myMap = Map('KeyType', 'char', 'ValueType', 'double');
```

---

To import two Java packages:

```
import java.util.Enumeration java.lang.String
s = String('hello'); % Create java.lang.String object
methods Enumeration % List java.util.Enumeration methods
```

---

To add the `java.awt` package:

```
import java.awt.*
f = Frame; % Create java.awt.Frame object
```

---

This example uses `import` in a function to call members of a .NET class in the `System.Drawing` namespace. Create the `getPrinterInfo` function:

```
function ptr = getPrinterInfo
import System.Drawing.Printing.*;
ptr = PrinterSettings;
end
```

To call the function, type:

```
NET.addAssembly('System.Drawing');
```

# import

---

```
printer = getPrinterInfo;
```

## **See Also**

`clear` | `load` | `importdata`

## Purpose

Load data from file

## Syntax

```
A = importdata(filename)
A = importdata('-pastespecial')
A = importdata(___,delimiterIn)
A = importdata(___,delimiterIn,headerlinesIn)
[A,delimiterOut,headerlinesOut] = importdata(___)
```

## Description

`A = importdata(filename)` loads data into array `A`.

`A = importdata('-pastespecial')` loads data from the system clipboard rather than from a file.

`A = importdata(___,delimiterIn)` interprets `delimiterIn` as the column separator in ASCII file, `filename`, or the clipboard data. You can use `delimiterIn` with any of the input arguments in the above syntaxes.

`A = importdata(___,delimiterIn,headerlinesIn)` loads data from ASCII file, `filename`, or the clipboard, reading numeric data starting from line `headerlinesIn+1`.

`[A,delimiterOut,headerlinesOut] = importdata(___)` additionally returns the detected delimiter character for the input ASCII file in `delimiterOut` and the detected number of header lines in `headerlinesOut`, using any of the input arguments in the previous syntaxes.

## Input Arguments

### **filename** - Name and extension of file to import

string

Name and extension of the file to import, specified as a string. If `importdata` recognizes the file extension, it calls the MATLAB helper function designed to import the associated file format (such as `load`

# importdata

---

for MAT-files or `xlsread` for spreadsheets). Otherwise, `importdata` interprets the file as a delimited ASCII file.

For ASCII files and spreadsheets, `importdata` expects to find numeric data in a rectangular form (that is, like a matrix). Text headers can appear above or to the left of the numeric data, as follows:

- Column headers or file description text at the top of the file, above the numeric data.
- Row headers to the left of the numeric data.

**Example:** `'myFile.jpg'`

## **delimiterIn - Column separator character**

string

Column separator character, specified as a string. The default character is interpreted from the file. Use `'\t'` for tab.

**Example:** `','`

**Example:** `' '`

## **headerlinesIn - Number of text header lines in ASCII file**

nonnegative scalar integer

Number of text header lines in the ASCII file, specified as a nonnegative scalar integer. If you do not specify `headerlinesIn`, the `importdata` function detects this value in the file.

## **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32  
| uint64

## **Output Arguments**

### **A - Data from the file**

matrix | multidimensional array | scalar structure array

Data from the file, returned as a matrix, multidimensional array, or scalar structure array, depending on the characteristics of the file. Based on the file format of the input file, `importdata` calls a helper function to read the data. When the helper function returns more than

one nonempty output, `importdata` combines the outputs into a struct array.

This table lists the file formats associated with helper functions that can return more than one output, and the possible fields in the structure array, `A`.

File Format	Possible Fields	Class
MAT-files	One field for each variable	Associated with each variable.
ASCII files and Spreadsheets	<code>data</code> <code>textdata</code> <code>colheaders</code> <code>rowheaders</code>	For ASCII files, <code>data</code> contains a double array. Other fields contain cell arrays of strings. <code>textdata</code> includes row and column headers. For spreadsheets, each field contains a struct, with one field for each worksheet.
Images	<code>cdata</code> <code>colormap</code> <code>alpha</code>	See <code>imread</code> .
Audio files	<code>data</code> <code>fs</code>	See <code>auread</code> or <code>wavread</code> .

The MATLAB helper functions for all other supported file formats return one output. For more information about the class of each output, see the functions listed in “Supported File Formats”.

If the ASCII file or spreadsheet contains either column or row headers, but not both, `importdata` returns a `colheaders` or `rowheaders` field in the output structure, where:

- `colheaders` contains only the last line of column header text. `importdata` stores all text in the `textdata` field.

- `rowheaders` is created only when the file or worksheet contains a single column of row headers.

## **delimiterOut - Detected column separator in the input ASCII file**

string

Detected column separator in the input ASCII file, returned as a string.

## **headerlinesOut - Detected number of text header lines in the input ASCII file**

integer

Detected number of text header lines in the input ASCII file, returned as an integer.

## **Examples**

### **Import and Display an Image**

Import and display the image `ngc6543a.jpg`.

```
filename = 'ngc6543a.jpg';  
A = importdata(filename);  
image(A);
```

The output, `A`, is class `uint8` because the helper function, `imread`, returns empty results for `colormap` and `alpha`.

### **Import a Text File and Specify Delimiter and Column Header**

Using a text editor, create a space-delimited ASCII file with column headers called `myfile01.txt`.

```
Day1 Day2 Day3 Day4 Day5 Day6 Day7  
95.01 76.21 61.54 40.57 5.79 20.28 1.53  
23.11 45.65 79.19 93.55 35.29 19.87 74.68  
60.68 1.85 92.18 91.69 81.32 60.38 44.51  
48.60 82.14 73.82 41.03 0.99 27.22 93.18  
89.13 44.47 17.63 89.36 13.89 19.88 46.60
```

Import the file, specifying the space delimiter and the single column header.

```
filename = 'myfile01.txt';  
delimiterIn = ' ';  
headerlinesIn = 1;  
A = importdata(filename,delimiterIn,headerlinesIn);
```

View columns 3 and 5.

```
for k = [3, 5]  
    disp(A.colheaders{1, k})  
    disp(A.data(:, k))  
    disp(' ' )  
end
```

```
Day3  
    61.5400  
    79.1900  
    92.1800  
    73.8200  
    17.6300
```

```
Day5  
    5.7900  
    35.2900  
    81.3200  
    0.9900  
    13.8900
```

## **Import a Text File and Return Detected Delimiter**

Using a text editor, create a comma-delimited ASCII file called myfile02.txt.

```
1,2,3
```

# importdata

---

```
4,5,6  
7,8,9
```

Import the file, and display the output data and detected delimiter character.

```
filename = 'myfile02.txt';  
[A,delimiterOut]=importdata(filename)
```

```
A =
```

```
     1     2     3  
     4     5     6  
     7     8     9
```

```
delimiterOut =
```

```
,
```

## Import Data from Clipboard

Copy the following lines to the clipboard. Select the text, right-click, and then select **Copy**.

```
1,2,3  
4,5,6  
7,8,9
```

Import the clipboard data into MATLAB by typing the following.

```
A = importdata('-pastespecial')
```

```
A =
```

```
     1     2     3  
     4     5     6  
     7     8     9
```

## Tips

- To import ASCII files with nonnumeric characters outside of column or row headers, including columns of character data or formatted dates or times, use `textscan` instead of `importdata`.

# imread

---

**Purpose** Read image from graphics file

**Syntax**

```
A = imread(filename, fmt)
[X, map] = imread(...)
[...] = imread(filename)
[...] = imread(URL,...)
[...] = imread(...,Param1,Val1,Param2,Val2...)
```

**Description** `A = imread(filename, fmt)` reads a grayscale or color image from the file specified by the string `filename`. If the file is not in the current folder, or in a folder on the MATLAB path, specify the full pathname.

The text string `fmt` specifies the format of the file by its standard file extension. For example, specify 'gif' for Graphics Interchange Format files. To see a list of supported formats, with their file extensions, use the `imformats` function. If `imread` cannot find a file named `filename`, it looks for a file named `filename.fmt`.

The return value `A` is an array containing the image data. If the file contains a grayscale image, `A` is an M-by-N array. If the file contains a truecolor image, `A` is an M-by-N-by-3 array. For TIFF files containing color images that use the CMYK color space, `A` is an M-by-N-by-4 array. See TIFF in the Format-Specific Information section for more information.

The class of `A` depends on the bits-per-sample of the image data, rounded to the next byte boundary. For example, `imread` returns 24-bit color data as an array of `uint8` data because the sample size for each color component is 8 bits. See “Tips” on page 2-2227 for a discussion of bitdepths, and see “Format-Specific Information” on page 2-2227 for more detail about supported bitdepths and sample sizes for a particular format.

`[X, map] = imread(...)` reads the indexed image in `filename` into `X` and its associated colormap into `map`. Colormap values in the image file are automatically rescaled into the range `[0,1]`.

`[...] = imread(filename)` attempts to infer the format of the file from its content.

[...] = imread(URL,...) reads the image from an Internet URL. The URL must include the protocol type (e.g., http://).

[...] = imread(...,Param1,Val1,Param2,Val2...) specifies parameters that control various characteristics of the operations for specific formats. For more information, see “Format-Specific Information” on page 2-2227.

## Tips

- Bitdepth is the number of bits used to represent each image pixel. Bitdepth is calculated by multiplying the bits-per-sample with the samples-per-pixel. Thus, a format that uses 8-bits for each color component (or sample) and three samples per pixel has a bitdepth of 24. Sometimes the sample size associated with a bitdepth can be ambiguous: does a 48-bit bitdepth represent six 8-bit samples, four 12-bit samples, or three 16-bit samples? The following format-specific sections provide sample size information to avoid this ambiguity.

**Format-Specific Information** The following sections provide information about the support for specific formats, listed in alphabetical order by format name. These sections include information about format-specific syntaxes, if they exist.

“BMP — Windows Bitmap” on page 2-2228	“JPEG — Joint Photographic Experts Group” on page 2-2230	“PNG — Portable Network Graphics” on page 2-2233
“CUR — Cursor File” on page 2-2228	“JPEG 2000 — Joint Photographic Experts Group 2000” on page 2-2231	“PPM — Portable Pixmap” on page 2-2234
“GIF — Graphics Interchange Format” on page 2-2229	“PBM — Portable Bitmap” on page 2-2232	“RAS — Sun Raster” on page 2-2234

“HDF4 — Hierarchical Data Format” on page 2-2230	“PCX — Windows Paintbrush” on page 2-2232	“TIFF — Tagged Image File Format” on page 2-2234
“ICO — Icon File” on page 2-2230	“PGM — Portable Graymap” on page 2-2232	“XWD — X Window Dump” on page 2-2237

## BMP — Windows Bitmap

Supported Bitdepths	No Compression	RLE Compression	Output Class	Notes
1-bit	y	—	logical	
4-bit	y	y	uint8	
8-bit	y	y	uint8	
16-bit	y	—	uint8	1 sample/pixel
24-bit	y	—	uint8	3 samples/pixel
32-bit	y	—	uint8	3 samples/pixel (1 byte padding)

## CUR — Cursor File

Supported Bitdepths	No Compression	Compression	Output Class
1-bit	y	—	logical
4-bit	y	—	uint8
8-bit	y	—	uint8

Format-specific syntaxes:

`[...] = imread(..., idx)` reads in one image from a multi-image icon or cursor file. `idx` is an integer value that specifies the order that the image appears in the file. For example, if `idx` is 3, `imread` reads

the third image in the file. If you omit this argument, `imread` reads the first image in the file.

`[A, map, alpha] = imread(...)` returns the AND mask for the resource, which can be used to determine the transparency information. For cursor files, this mask may contain the only useful data.

---

**Note** By default, Microsoft Windows cursors are 32-by-32 pixels. MATLAB pointers must be 16-by-16. You will probably need to scale your image. If you have Image Processing Toolbox™, you can use its `imresize` function.

---

## GIF – Graphics Interchange Format

Supported Bitdepths	No Compression	Compression	Output Class
1-bit	y	–	logical
2-bit to 8-bit	y	–	uint8

Format-specific syntaxes:

`[...] = imread(..., idx)` reads in one or more frames from a multiframe (i.e., animated) GIF file. `idx` must be an integer scalar or vector of integer values. For example, if `idx` is 3, `imread` reads the third image in the file. If `idx` is 1:5, `imread` returns only the first five frames.

`[...] = imread(..., 'frames', idx)` is the same as the syntax above except that `idx` can be 'all'. In this case, all the frames are read and returned in the order that they appear in the file.

---

**Note** Because of the way that GIF files are structured, all the frames must be read when a particular frame is requested. Consequently, it is much faster to specify a vector of frames or 'all' for `idx` than to call `imread` in a loop when reading multiple frames from the same GIF file.

---

## HDF4 – Hierarchical Data Format

Supported Bitdepths	Raster Image with colormap	Raster image without colormap	Output Class	Notes
8-bit	y	y	uint8	
24-bit	–	y	uint8	3 samples/pixel

Format-specific syntaxes:

[...] = `imread(..., ref)` reads in one image from a multi-image HDF4 file. `ref` is an integer value that specifies the reference number used to identify the image. For example, if `ref` is 12, `imread` reads the image whose reference number is 12. (Note that in an HDF4 file the reference numbers do not necessarily correspond to the order of the images in the file. You can use `imfinfo` to match image order with reference number.) If you omit this argument, `imread` reads the first image in the file.

## ICO – Icon File

See “CUR — Cursor File” on page 2-2228

## JPEG – Joint Photographic Experts Group

`imread` can read any baseline JPEG image as well as JPEG images with some commonly used extensions. For information about support for JPEG 2000 files, see JPEG 2000.

Supported Bitdepths (Bits-per-sample)	Lossy Compression	Lossless Compression	Output Class	Notes
8-bit	y	y	uint8	Grayscale or RGB
12-bit	y	y	uint16	Grayscale or RGB
16-bit	–	y	uint16	Grayscale

## JPEG 2000 – Joint Photographic Experts Group 2000

For information about JPEG files, see JPEG.

**Note** Only 1- and 3-sample images are supported. Indexed JPEG 2000 images are not supported.

Supported Bitdepths (Bits-per-sample)	Lossy Compression	Lossless Compression	Output Class	Notes
1-bit	y	y	logical	Grayscale only
2- to 8-bit	y	y	uint8	Grayscale or RGB
9- to 16-bit	y	y	uint16	Grayscale or RGB

Format-specific syntaxes:

`[...] = imread(..., 'Param1', value1, 'Param2', value2, ...)` uses parameter-value pairs to control the read operation, described in the following table.

Parameter	Value
'ReductionLevel'	A non-negative integer specifying the reduction in the resolution of the image. For a reduction level $L$ , the image resolution is reduced by a factor of $2^L$ . Its default value is 0 implying no reduction. The reduction level is limited by the total number of decomposition levels as specified by the 'WaveletDecompositionLevels' field in the structure returned by the <code>imfinfo</code> function.
'PixelRegion'	{ROWS, COLS} — The <code>imread</code> function returns the sub-image specified by the boundaries in ROWS and

# imread

Parameter	Value
	COLS. ROWS and COLS must both be two-element vectors that denote the 1-based indices [START STOP]. If 'ReductionLevel' is greater than 0, then ROWS and COLS are coordinates in the reduced-sized image.

## PBM – Portable Bitmap

Supported Bitdepths	Raw Binary	ASCII (Plain) Encoded	Output Class
1-bit	y	y	logical

## PCX – Windows Paintbrush

Supported Bitdepths	Output Class	Notes
1-bit	logical	Grayscale only
8-bit	uint8	Grayscale or indexed
24-bit	uint8	RGB Three 8-bit samples/pixel

## PGM – Portable Graymap

Supported Bitdepths	Raw Binary	ASCII (Plain) Encoded	Output Class	Notes
8-bit	y	–	uint8	
16-bit	y	–	uint16	
Arbitrary	–	y	1-bit to 8-bit: uint8 9-bit to 16-bit: uint16	Values are scaled

## PNG – Portable Network Graphics

Supported Bitdepths	Output Class	Notes
1-bit	logical	Grayscale
2-bit	uint8	Grayscale
4-bit	uint8	Grayscale
8-bit	uint8	Grayscale or Indexed
16-bit	uint16	Grayscale or Indexed
24-bit	uint8	RGB Three 8-bit samples/pixel.
48-bit	uint16	RGB Three 16-bit samples/pixel.

Format-specific syntaxes:

`[...] = imread(..., 'BackgroundColor', BG)` composites any transparent pixels in the input image against the color specified in BG. If BG is 'none', then no compositing is performed. If the input image is indexed, BG must be an integer in the range  $[1, P]$  where P is the colormap length. If the input image is grayscale, BG should be an integer in the range  $[0, 1]$ . If the input image is RGB, BG should be a three-element vector whose values are in the range  $[0, 1]$ . The string 'BackgroundColor' may be abbreviated.

`[A, map, alpha] = imread(...)` returns the alpha channel if one is present; otherwise alpha is `[]`. Note that map may be empty if the file contains a grayscale or truecolor image.

If you specify the `alpha` output argument, BG defaults to 'none', if not specified. Otherwise, if the PNG file contains a background color chunk, that color is used as the default value for BG. If `alpha` is not used and the file does not contain a background color chunk, then the default value for BG is 1 for indexed images; 0 for grayscale images; and `[0 0 0]` for truecolor (RGB) images.

## PPM – Portable Pixmap

Supported Bitdepths	Raw Binary	ASCII (Plain) Encoded	Output Class
Up to 16-bit	y	–	uint8
Arbitrary	–	y	

## RAS – Sun™ Raster

The following table lists the supported bitdepths, compression, and output classes for RAS files.

Supported Bitdepths	Output Class	Notes
1-bit	logical	Bitmap
8-bit	uint8	Indexed
24-bit	uint8	RGB Three 8-bit samples/pixel
32-bit	uint8	RGB with Alpha Four 8-bit samples/pixel

## TIFF – Tagged Image File Format

imread supports the following TIFF capabilities:

- Any number of samples-per-pixel
- CCITT group 3 and 4 FAX, Packbits, JPEG, LZW, Deflate, ThunderScan compression, and uncompressed images
- Logical, grayscale, indexed color, truecolor and hyperspectral images
- RGB, CMYK, CIELAB, ICCLAB color spaces. If the color image uses the CMYK color space, A is an M-by-N-by-4 array. To determine which color space is used, use `imfinfo` to get information about the graphics file and look at the value of the `PhotometricInterpretation` field. If a file contains CIELAB color

data, `imread` converts it to ICCLAB before bringing it into the MATLAB workspace because 8- or 16-bit TIFF CIELAB-encoded values use a mixture of signed and unsigned data types that cannot be represented as a single MATLAB array.

- Data organized into tiles or scanlines

The following table lists the supported bit/sample and corresponding output classes for TIFF files.

Supported Bitdepths	Compression							Output Class	Notes
	None	Packbits	CCITT	RGB	ICCLAB	CIELAB	CMYK		
1-bit	y	y	y	-	-	-	-	logical	
8-bit	y	y	-	-	-	-	-	uint8	
12-bit	-	-	-	-	-	-	-	uint16	Grayscale or Indexed
16-bit	-	-	-	-	-	-	-	uint16	Grayscale or Indexed
24-bit	y	y	-	y	y	y	-	uint8	3 samples
32-bit	-	-	-	-	-	-	y	uint8	4 samples
36-bit	-	-	-	y	-	-	-	uint16	3 samples
48-bit	-	-	-	y	y	y	-	uint16	3 samples
64-bit	-	-	-	-	-	-	y	double	4 samples

---

**Note** `imread` supports 8-bit integral and 32-bit floating point tiled TIFF images, with any compression and color space combination listed above, and 32-bit IEEE floating point images.

---

The following are format-specific syntaxes for TIFF files.

`A = imread(...)` returns color data that uses the RGB, CIELAB, ICCLAB, or CMYK color spaces. If the color image uses the CMYK color space, `A` is an M-by-N-by-4 array.

`[...] = imread(..., 'Param1', value1, 'Param2', value2, ...)` uses parameter/value pairs to control the read operation. The following table lists the parameters you can use.

Parameter	Value
'Index'	Positive integer specifying which image to read. For example, if you specify the value 3, <code>imread</code> reads the third image in the file. If you omit this argument, <code>imread</code> reads the first image in the file.
'Info'	Structure array returned by <code>imfinfo</code> .  Note: When reading images from a multi-image TIFF file, passing the output of <code>imfinfo</code> as the value of the 'Info' argument helps <code>imread</code> locate the images in the file more quickly.
'PixelRegion'	Cell array, {Rows, Cols}, specifying the boundaries of the region. Rows and Cols must be either two- or three-element vectors. If you specify two elements, the values denote the 1-based indices [start stop]. If you specify three elements, the values denote the 1-based indices [start increment stop], to allow image downsampling.

For copyright information, see the `libtiffcopyright.txt` file.

### XWD – X Window Dump

The following table lists the supported bitdepths, compression, and output classes for XWD files.

Supported Bitdepths	ZPixmaps	XYBitmaps	XPixmaps	Output Class
1-bit	y	–	y	logical
8-bit	y	–	–	uint8

### Class Support

For most image file formats, `imread` uses 8 or fewer bits per color plane to store image pixels. The following table lists the class of the returned array for the data types used by the file formats.

Data Type Used in File	Class of Array Returned by <code>imread</code>
1-bit per pixel	logical
2- to 8-bits per color plane	uint8
9- to 16-bit per pixel	uint16 (BMP, JPEG, PNG, and TIFF) For the 16-bit BMP packed format (5-6-5), MATLAB returns uint8

---

**Note** For indexed images, `imread` always reads the colormap into an array of class `double`, even though the image array itself may be of class `uint8` or `uint16`.

---

### Examples

Read sample image.

```
imdata = imread('ngc6543a.jpg');
```

# imread

---

Read indexed image and convert it to an RGB image.

```
[cdata,map] = imread( filename )
if ~isempty( map )
    cdata = ind2rgb( cdata, map );
end
```

Read sixth image in a TIFF file.

```
[X,map] = imread('your_image.tif',6);
```

Read fourth image in an HDF4 file.

```
info = imfinfo('your_hdf_file.hdf');
[X,map] = imread('your_hdf_file.hdf',info(4).Reference);
```

Read a 24-bit PNG image and set any of its fully transparent (alpha channel) pixels to red.

```
bg = [1 0 0];
A = imread('your_image.png','BackgroundColor',bg);
```

Return the alpha channel (if any) of a PNG image.

```
[A,map,alpha] = imread('your_image.png');
```

Read an ICO image, apply a transparency mask, and then display the image.

```
[a,b,c] = imread('your_icon.ico');
% Augment colormap for background color (white).
b2 = [b; 1 1 1];
% Create new image for display.
d = ones(size(a)) * (length(b2) - 1);
% Use the AND mask to mix the background and
% foreground data on the new image
d(c == 0) = a(c == 0);
% Display new image
image(uint8(d), colormap(b2))
```

## See Also

`double` | `fread` | `image` | `imfinfo` | `imformats` | `imwrite` | `ind2rgb` |  
`uint8` | `uint16`

# imwrite

---

## Purpose

Write image to graphics file

## Syntax

```
imwrite(A,filename,fmt)
imwrite(X,map,filename,fmt)
imwrite(...,filename)
imwrite(...,Param1,Val1,Param2,Val2...)
```

## Description

`imwrite(A,filename,fmt)` writes the image *A* to the file specified by *filename* in the format specified by *fmt*.

*A* can be an M-by-N (grayscale image) or M-by-N-by-3 (truecolor image) array, but it cannot be an empty array. For TIFF files, *A* can be an M-by-N-by-4 array containing color data that uses the CMYK color space. For GIF files, *A* can be an M-by-N-by-1-by-P array containing grayscale or indexed images — RGB images are not supported. For information about the class of the input array and the output image, see “Class Support” on page 2-2241.

*filename* is a string that specifies the name of the output file.

*fmt* can be any of the text strings listed in the table in “Supported Image Types” on page 2-2242. This list of supported formats is determined by the MATLAB image file format registry. See `imformats` for more information about this registry.

`imwrite(X,map,filename,fmt)` writes the indexed image in *X* and its associated colormap *map* to *filename* in the format specified by *fmt*. If *X* is of class `uint8` or `uint16`, `imwrite` writes the actual values in the array to the file. If *X* is of class `double`, `imwrite` offsets the values in the array before writing, using `uint8(X-1)`. *map* must be a valid MATLAB colormap. Note that most image file formats do not support colormaps with more than 256 entries.

When writing multiframe GIF images, *X* should be an 4-dimensional M-by-N-by-1-by-P array, where *P* is the number of frames to write.

`imwrite(...,filename)` writes the image to *filename*, inferring the format to use from the *filename*’s extension. The extension must be one of the values for *fmt*, listed in “Supported Image Types” on page 2-2242.

`imwrite(...,Param1,Val1,Param2,Val2...)` specifies parameters that control various characteristics of the output file for HDF, JPEG, PBM, PGM, PNG, PPM, and TIFF files. For example, if you are writing a JPEG file, you can specify the quality of the output image. For the lists of parameters available for each format, see “Format-Specific Parameters” on page 2-2244.

## Class Support

The input array `A` can be of class `logical`, `uint8`, `uint16`, or `double`. Indexed images (`X`) can be of class `uint8`, `uint16`, or `double`; the associated colormap, `map`, must be of class `double`. Input values must be full (non-sparse).

The class of the image written to the file depends on the format specified. For most formats, if the input array is of class `uint8`, `imwrite` outputs the data as 8-bit values. If the input array is of class `uint16` and the format supports 16-bit data (JPEG, PNG, and TIFF), `imwrite` outputs the data as 16-bit values. If the format does not support 16-bit values, `imwrite` issues an error. Several formats, such as JPEG and PNG, support a parameter that lets you specify the bit depth of the output data.

If the input array is of class `double`, and the image is a grayscale or RGB color image, `imwrite` assumes the dynamic range is `[0,1]` and automatically scales the data by 255 before writing it to the file as 8-bit values.

If the input array is of class `double`, and the image is an indexed image, `imwrite` converts the indices to zero-based indices by subtracting 1 from each element, and then writes the data as `uint8`.

If the input array is of class `logical`, `imwrite` assumes the data is a binary image and writes it to the file with a bit depth of 1, if the format allows it. BMP, PNG, or TIFF formats accept binary images as input arrays.

## Supported Image Types

This table summarizes the types of images that `imwrite` can write. The MATLAB file format registry determines which file formats are supported. See `imformats` for more information about this registry. Note that, for certain formats, `imwrite` may take additional parameters, described in “Format-Specific Parameters” on page 2-2244.

Format	Full Name	Variants
'bmp'	Windows Bitmap (BMP)	1-bit, 8-bit, and 24-bit uncompressed images
'gif'	Graphics Interchange Format (GIF)	8-bit images
'hdf'	Hierarchical Data Format (HDF4)	8-bit raster image data sets, with or without associated colormap, 24-bit raster image data sets; uncompressed or with RLE or JPEG compression
'jpg' or 'jpeg'	Joint Photographic Experts Group (JPEG)	8-bit, 12-bit, and 16-bit Baseline JPEG images <hr/> <b>Note</b> <code>imwrite</code> converts indexed images to RGB before writing data to JPEG files, because the JPEG format does not support indexed images. <hr/>

<b>Format</b>	<b>Full Name</b>	<b>Variants</b>
'jp2' or 'jpx'	“JPEG 2000 — Joint Photographic Experts Group 2000” on page 2-2247	1-bit, 8-bit, and 16-bit JPEG 2000 images
pbm	Portable Bitmap (PBM)	Any 1-bit PBM image, ASCII (plain) or raw (binary) encoding
'pcx'	Windows Paintbrush (PCX)	8-bit images
'pgm'	Portable Graymap (PGM)	Any standard PGM image; ASCII (plain) encoded with arbitrary color depth; raw (binary) encoded with up to 16 bits per gray value
'png'	Portable Network Graphics (PNG)	1-bit, 2-bit, 4-bit, 8-bit, and 16-bit grayscale images; 8-bit and 16-bit grayscale images with alpha channels; 1-bit, 2-bit, 4-bit, and 8-bit indexed images; 24-bit and 48-bit truecolor images; 24-bit and 48-bit truecolor images with alpha channels
'pnm'	Portable Anymap (PNM)	Any of the PPM/PGM/PBM formats, chosen automatically
'ppm'	Portable Pixmap (PPM)	Any standard PPM image. ASCII (plain) encoded with arbitrary color depth; raw (binary) encoded with up to 16 bits per color component

Format	Full Name	Variants
'ras'	Sun Raster (RAS)	Any RAS image, including 1-bit bitmap, 8-bit indexed, 24-bit truecolor and 32-bit truecolor with alpha
'tif' or 'tiff'	Tagged Image File Format (TIFF)	Baseline TIFF images, including 1-bit, 8-bit, 16-bit, and 24-bit uncompressed images, images with packbits compression, images with LZW compression, and images with Deflate compression; 1-bit images with CCITT 1D, Group 3, and Group 4 compression; CIELAB, ICCLAB, and CMYK images
'xwd'	X Windows Dump (XWD)	8-bit ZPixmap

## Format-Specific GIF – Graphics Interchange Format Parameters

Format-specific parameters.

Parameter	Values
'BackgroundColor'	A scalar integer that specifies which index in the colormap should be treated as the transparent color for the image and is used for certain disposal methods in animated GIFs. If X is <code>uint8</code> or <code>logical</code> , indexing starts at 0. If X is <code>double</code> , indexing starts at 1.
'Comment'	A string or cell array of strings containing a comment to be added to the image. For a cell array of strings, a carriage return is added after each row.
'DelayTime'	A scalar value between 0 and 655 inclusive, that specifies the delay in seconds before displaying the next image.

Parameter	Values
'DisposalMethod'	One of the following strings, which sets the disposal method of an animated GIF: 'leaveInPlace', 'restoreBG', 'restorePrevious', or 'doNotSpecify'.
'Location'	A two-element vector specifying the offset of the top left corner of the screen relative to the top left corner of the image. The first element is the offset from the top, and the second element is the offset from the left.
'LoopCount'	<p>A finite integer between 0 and 65535 or the value Inf which specifies the number of times to repeat the animation. By default, the animation does not loop. If you specify 0, the animation will be played once. If you specify the value 1, the animation will be played twice, etc.</p> <p>To enable animation within Microsoft PowerPoint®, specify a value for the 'LoopCount' parameter within the range [1 65535]. Some Microsoft applications interpret the value 0 to mean do not loop at all.</p>
'ScreenSize'	A two-element vector specifying the height and width of the frame. When used with 'Location', ScreenSize provides a way to write frames to the image that are smaller than the whole frame. 'DisposalMethod' determines the fill value used for pixels outside the frame.
'TransparentColor'	A scalar integer. This value specifies which index in the colormap should be treated as the transparent color for the image. If X (the image) is uint8 or logical, indexing starts at 0. If X is double, indexing starts at 1.
'WriteMode'	'overwrite' (the default) or 'append'. In append mode, imwrite adds a single frame to the existing file.

## HDF4 – Hierarchical Data Format

Format-specific parameters.

Parameter	Values
'Compression'	'none' (the default)  'jpeg' (valid only for grayscale and RGB images)  'rle' (valid only for grayscale and indexed images)
'Quality'	A number between 0 and 100; this parameter applies only if 'Compression' is 'jpeg'.  Higher numbers mean higher <i>quality</i> (less image degradation due to compression), but the resulting file size is larger. The default value is 75.
'WriteMode'	'overwrite' (the default)  'append'

## JPEG – Joint Photographic Experts Group

Format-specific parameters. For information about support for JPEG 2000 files, see “JPEG 2000 — Joint Photographic Experts Group 2000” on page 2-2247.

Parameter	Values	Default
'Bitdepth'	A scalar value indicating desired bitdepth; for grayscale images this can be 8, 12, or 16; for color images this can be 8 or 12.	8 (grayscale) and 8 bit per plane for color images
'Comment'	A column vector cell array of strings or a character matrix. <code>imwrite</code> writes each row of input as a comment in the JPEG file.	Empty

Parameter	Values	Default
'Mode'	Specifies the type of compression used: 'lossy' or 'lossless'	'lossy'
'Quality'	A number between 0 and 100; higher numbers mean higher quality (less image degradation due to compression), but the resulting file size is larger.	75

### JPEG 2000 – Joint Photographic Experts Group 2000

Format-specific parameters. For information about support for JPEG files, see “JPEG — Joint Photographic Experts Group” on page 2-2246.

Parameter	Values	Default
'Comment'	A column vector cell array of strings or a character matrix. <code>imwrite</code> writes each row of input as a comment in the JPEG file.	Empty
'CompressionRatio'	A real value greater than 1 specifying the target compression ratio which is defined as the ratio of input image size to the output compressed size. For example, a value of 2.0 implies that the output image size will be half of the input image size or less. A higher value implies a smaller file size and reduced image quality. This is valid only with 'lossy' mode.  Note that the compression ratio doesn't take into account the header size, and hence in some cases the output file size can be larger than expected.	
'Mode'	Specifies the type of compression used: 'lossy' or 'lossless'	'lossy'

Parameter	Values	Default
'ProgressionOrder'	One of the following text strings: 'LRCP', 'RLCP', 'RPCL', 'PCRL' or 'CPRL'. The characters in these text strings represent the following: L=layer, R=resolution, C=component and P=position. The first character refers to the index which progresses most slowly, while the last refers to the index which progresses most quickly.	'LRCP'
'QualityLayers'	A positive integer (not exceeding 20) specifying the number of quality layers.	1
'ReductionLevel'	A positive integer (not exceeding 8) specifying the number of reduction levels or the wavelet decomposition levels	
'TileSize'	A 2-element vector specifying tile height and tile width. The minimum tile size that can be specified is [128 128].	tile size is same as the image size

## PBM-, PGM-, and PPM-Specific Parameters

This table describes the available parameters for PBM, PGM, and PPM files.

Parameter	Values	Default
'Encoding'	One of these strings: 'ASCII' for plain encoding 'rawbits' for binary encoding	'rawbits'
'MaxValue'	A scalar indicating the maximum gray or color value. Available only for PGM and PPM files.  For PBM files, this value is always 1.	Default is 65535 if image array is 'uint16'; 255 otherwise.

### PNG-Specific Parameters

The following table lists the available parameters for PNG files, in alphabetical order. In addition to these PNG parameters, you can use any parameter name that satisfies the PNG specification for keywords; that is, uses only printable characters, contains 80 or fewer characters, and no contains no leading or trailing spaces. The value corresponding to these user-specified parameters must be a string that contains no control characters other than linefeed.

Parameter	Values
'Alpha'	A matrix specifying the transparency of each pixel individually. The row and column dimensions must be the same as the data array; they can be <code>uint8</code> , <code>uint16</code> , or <code>double</code> , in which case the values should be in the range <code>[0,1]</code> .
'Author'	A string
'Background'	The value specifies background color to be used when compositing transparent pixels. For indexed images: an integer in the range <code>[1,P]</code> , where <code>P</code> is the colormap length. For grayscale images: a scalar in the range <code>[0,1]</code> . For truecolor images: a three-element vector in the range <code>[0,1]</code> .
'bitdepth'	A scalar value indicating desired bit depth.  For grayscale images this can be 1, 2, 4, 8, or 16. For grayscale images with an alpha channel this can be 8 or 16.  For indexed images this can be 1, 2, 4, or 8. For truecolor images with or without an alpha channel this can be 8 or 16.  By default, <code>imwrite</code> uses 8 bits per pixel, if image is <code>double</code> or <code>uint8</code> ; 16 bits per pixel if image is <code>uint16</code> ; 1 bit per pixel if image is <code>logical</code> .

Parameter	Values
'Chromaticities'	An eight-element vector [wx wy rx ry gx gy bx by] that specifies the reference white point and the primary chromaticities
'Comment'	A string
'Copyright'	A string
'CreationTime'	A string
'Description'	A string
'Disclaimer'	A string
'Gamma'	A nonnegative scalar indicating the file gamma
'ImageModTime'	A MATLAB serial date number (see the <code>datenum</code> function) or a string convertible to a date vector via the <code>datevec</code> function. Values should be in Coordinated Universal Time (UTC).
'InterlaceType'	Either 'none' (the default) or 'adam7'
'ResolutionUnit'	Either 'unknown' or 'meter'
'SignificantBits'	<p>A scalar or vector indicating how many bits in the data array should be regarded as significant; values must be in the range [1,BitDepth].</p> <p>For indexed images: a three-element vector. For grayscale images: a scalar. For grayscale images with an alpha channel: a two-element vector. For truecolor images: a three-element vector. For truecolor images with an alpha channel: a four-element vector.</p>
'Software'	A string
'Source'	A string

Parameter	Values
'Transparency'	<p>This value is used to indicate transparency information only when no alpha channel is used. Set to the value that indicates which pixels should be considered transparent. (If the image uses a colormap, this value represents an index number to the colormap.)</p> <p>For indexed images: a <math>Q</math>-element vector in the range <math>[0,1]</math>, where <math>Q</math> is no larger than the colormap length and each value indicates the transparency associated with the corresponding colormap entry. In most cases, <math>Q = 1</math>.</p> <p>For grayscale images: a scalar in the range <math>[0,1]</math>. The value indicates the grayscale color to be considered transparent.</p> <p>For truecolor images: a three-element vector in the range <math>[0,1]</math>. The value indicates the truecolor color to be considered transparent.</p> <hr/> <p><b>Note</b> You cannot specify 'Transparency' and 'Alpha' at the same time.</p> <hr/>
'Warning'	A string
'XResolution'	A scalar indicating the number of pixels/unit in the horizontal direction
'YResolution'	A scalar indicating the number of pixels/unit in the vertical direction

## RAS-Specific Parameters

This table describes the available parameters for RAS files.

Parameter	Values	Default
'Alpha'	A matrix specifying the transparency of each pixel individually; the row and column dimensions must be the same as the data array; can be <code>uint8</code> , <code>uint16</code> , or <code>double</code> . Can only be used with truecolor images.	Empty matrix ([])
'Type'	One of these strings: 'standard' (uncompressed, b-g-r color order with truecolor images) 'rgb' (like 'standard', but uses r-g-b color order for truecolor images) 'rle' (run-length encoding of 1-bit and 8-bit images)	'standard'

## TIFF-Specific Parameters

This table describes the available parameters for TIFF files.

Parameter	Values
'ColorSpace'	Specifies the color space used to represent the color data. 'rgb' 'cielab' 'icclab' <sup>1</sup> (default is 'rgb').  Note: To use the CMYK color space in a TIFF file, do not use the 'ColorSpace' parameter. It is sufficient to specify an M-by-N-by-4 input array.
'Compression'	'none' 'packbits' (default for non-binary images) 'lzw' 'deflate' 'jpeg' 'ccitt' (binary images only; default) 'fax3' (binary images only) 'fax4' (binary images only)  Note: 'jpeg' is a lossy compression scheme; other compression modes are lossless. Also, if you specify 'jpeg' compression, you

Parameter	Values
	must specify the 'RowsPerStrip' parameter and the value must be a multiple of 8.
'Description'	Any string; fills in the ImageDescription field returned by imfinfo. By default, the field is empty.
'Resolution'	A two-element vector containing the XResolution and YResolution, or a scalar indicating both resolutions. The default value is 72.
'RowsPerStrip'	A scalar value specifying the number of rows to include in each strip. The default will be such that each strip is about 8K bytes.  Note: You must specify the 'RowsPerStrip' parameter if you specify 'jpeg' compression. The value must be a multiple of 8.
'WriteMode'	'overwrite' (default)  'append'

<sup>1</sup>imwrite can write color image data that uses the  $L^*a^*b^*$  color space to TIFF files. The 1976 CIE  $L^*a^*b^*$  specification defines numeric values that represent luminance ( $L^*$ ) and chrominance ( $a^*$  and  $b^*$ ) information. To store  $L^*a^*b^*$  color data in a TIFF file, the values must be encoded to fit into either 8-bit or 16-bit storage. imwrite can store  $L^*a^*b^*$  color data in a TIFF file using 8-bit and 16-bit encodings defined by the TIFF specification, called the CIELAB encodings, or using 8-bit and 16-bit encodings defined by the International Color Consortium, called ICCLAB encodings.

The output class and encoding used by imwrite depends on the class of the input array and the value of the TIFF-specific ColorSpace parameter. The following table explains these options. (The 8-bit and 16-bit CIELAB encodings cannot be input arrays because they use a mixture of signed and unsigned values and cannot be represented as a single MATLAB array.)

Input Class and Encoding	ColorSpace Parameter Value	Output Class and Encoding
8-bit ICCLAB  Represents values as integers in the range [0 255]. $L^*$ values are multiplied by 255/100. 128 is added to both the $a^*$ and $b^*$ values.	'icclab'	8-bit ICCLAB
	'cielab'	8-bit CIELAB
16-bit ICCLAB  Represents the values as integers in the range [0, 65280]. $L^*$ values are multiplied by 65280/100. 32768 is added to both the $a^*$ and $b^*$ values, which are represented as integers in the range [0,65535].	'icclab'	16-bit ICCLAB
	'cielab'	16-bit CIELAB

Input Class and Encoding	ColorSpace Parameter Value	Output Class and Encoding
Double-precision 1976 CIE $L^*a^*b^*$ values  $L^*$ is in the dynamic range [0, 100]. $a^*$ and $b^*$ can take any value. Setting $a^*$ and $b^*$ to 0 (zero) produces a neutral color (gray).	'icclab'	8-bit ICCLAB
	'cielab'	8-bit CIELAB

For copyright information, see the `libtiffcopyright.txt` file.

## Examples

This example appends an indexed image `X` and its colormap `map` to an existing uncompressed multipage HDF4 file.

```
imwrite(X,map,'your_hdf_file.hdf','Compression','none',...
'WriteMode','append')
```

# TriRep.incenters

---

<b>Purpose</b>	Incenters of specified simplices	
<b>Syntax</b>	IC = inceters(TR,SI) [IC RIC] = inceters(TR, SI)	
<b>Description</b>	IC = inceters(TR,SI) returns the coordinates of the incenter of each specified simplex SI.  [IC RIC] = inceters(TR, SI) returns the incenters and the corresponding radius of the inscribed circle/sphere.	
<b>Input Arguments</b>	TR	Triangulation representation.
	SI	Column vector of simplex indices that index into the triangulation matrix TR.Triangulation. If SI is not specified the incenter information for the entire triangulation is returned, where the incenter associated with simplex i is the i'th row of IC.
<b>Output Arguments</b>	IC	m-by-n matrix, where m = length(SI), the number of specified simplices, and n is the dimension of the space where the triangulation resides. Each row IC(i, :) represents the coordinates of the incenter of simplex SI(i).
	RIC	Vector of length length(SI), the number of specified simplices.
<b>Definitions</b>	A simplex is a triangle/tetrahedron or higher-dimensional equivalent.	
<b>Examples</b>	<b>Example 1</b>	
	Load a 3-D triangulation:	
	load tetmesh	

Use TriRep to compute the incenters of the first five tetrahedra.

```
trep = TriRep(tet, X)
ic = incenters(trep, [1:5]')
```

## Example 2

Query a 2-D triangulation created with DelaunayTri.

```
x = [0 1 1 0 0.5]';
y = [0 0 1 1 0.5]';
dt = DelaunayTri(x,y);
```

Compute incenters of the triangles:

```
ic = incenters(dt);
```

Plot the triangles and incenters:

```
triplot(dt);
axis equal;
axis([-0.2 1.2 -0.2 1.2]);
hold on;
plot(ic(:,1),ic(:,2),'*r');
hold off;
```

## See Also

`DelaunayTri` | `circumcenters`

**Purpose** Status of triangles in 2-D constrained Delaunay triangulation

**Syntax** `IN = inOutStatus(DT)`

**Description** `IN = inOutStatus(DT)` returns the in/out status of the triangles in a 2-D constrained Delaunay triangulation of a geometric domain. Given a Delaunay triangulation that has a set of constrained edges that define a bounded geometric domain. The *i*'th triangle in the triangulation is classified as inside the domain if `IN(i) = 1` and outside otherwise.

---

**Note** `inOutStatus` is only relevant for 2-D constrained Delaunay triangulations where the imposed edge constraints bound a closed geometric domain.

---

**Input Arguments**

DT	Delaunay triangulation.
----	-------------------------

**Output Arguments**

IN	Logical array of length equal to the number of triangles in the triangulation. The constrained edges in the triangulation define the boundaries of a valid geometric domain.
----	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**Examples** Create a geometric domain that consists of a square with a square hole:

```
outerprofile = [-5 -5; -3 -5; -1 -5; 1 -5; 3 -5; ...  
5 -5; 5 -3; 5 -1; 5 1; 5 3;...  
5 5; 3 5; 1 5; -1 5; -3 5; ...  
-5 5; -5 3; -5 1; -5 -1; -5 -3; ];  
innerprofile = outerprofile.*0.5;  
profile = [outerprofile; innerprofile];  
outercons = [(1:19)' (2:20)'; 20 1;];  
innercons = [(21:39)' (22:40)'; 40 21];
```

## DelaunayTri.inOutStatus

---

```
edgeconstraints = [outercons; innercons];
```

Create a constrained Delaunay triangulation of the domain:

```
dt = DelaunayTri(profile, edgeconstraints)
subplot(1,2,1);
triplot(dt);
hold on;
plot(dt.X(outercons',1), dt.X(outercons',2), ...
     '-r', 'LineWidth', 2);
plot(dt.X(innercons',1), dt.X(innercons',2), ...
     '-r', 'LineWidth', 2);
axis equal;
% Plot showing interior and exterior
% triangles with respect to the domain.
hold off;
subplot(1,2,2);
inside = inOutStatus(dt);
triplot(dt(inside, :), dt.X(:,1), dt.X(:,2));
hold on;
plot(dt.X(outercons',1), dt.X(outercons',2), ...
     '-r', 'LineWidth', 2);
plot(dt.X(innercons',1), dt.X(innercons',2), ...
     '-r', 'LineWidth', 2);
axis equal;
% Plot showing interior triangles only
hold off;
```

# ind2rgb

---

<b>Purpose</b>	Convert indexed image to RGB image
<b>Syntax</b>	<code>RGB = ind2rgb(X,map)</code>
<b>Description</b>	<code>RGB = ind2rgb(X,map)</code> converts the matrix <code>X</code> and corresponding colormap <code>map</code> to RGB (truecolor) format.
<b>Class Support</b>	<code>X</code> can be of class <code>uint8</code> , <code>uint16</code> , <code>single</code> , or <code>double</code> . <code>RGB</code> is an <code>m-by-n-by-3</code> array of class <code>double</code> .
<b>See Also</b>	<code>image</code>   <code>imread</code>

**Purpose**

Subscripts from linear index

**Syntax**

```
[I,J] = ind2sub(siz,IND)
[I1,I2,I3,...,In] = ind2sub(siz,IND)
```

**Description**

The `ind2sub` command determines the equivalent subscript values corresponding to a single index into an array.

`[I,J] = ind2sub(siz,IND)` returns the matrices `I` and `J` containing the equivalent row and column subscripts corresponding to each linear index in the matrix `IND` for a matrix of size `siz`. `siz` is a vector with `ndim(A)` elements (in this case, 2), where `siz(1)` is the number of rows and `siz(2)` is the number of columns.

---

**Note** For matrices, `[I,J] = ind2sub(size(A),find(A>5))` returns the same values as `[I,J] = find(A>5)`.

---

`[I1,I2,I3,...,In] = ind2sub(siz,IND)` returns `n` subscript arrays `I1,I2,...,In` containing the equivalent multidimensional array subscripts equivalent to `IND` for an array of size `siz`. `siz` is an `n`-element vector that specifies the size of each array dimension.

**Examples****Example 1 – Two-Dimensional Matrices**

The mapping from linear indexes to subscript equivalents for a 3-by-3 matrix is

# ind2sub

---

This code determines the row and column subscripts in a 3-by-3 matrix, of elements with linear indices 3, 4, 5, 6.

```
IND = [3 4 5 6]
s = [3,3];
[I,J] = ind2sub(s,IND)
```

```
I =
     3     1     2     3
```

```
J =
     1     2     2     2
```

## Example 2 – Three-Dimensional Matrices

The mapping from linear indexes to subscript equivalents for a 2-by-2-by-2 array is

This code determines the subscript equivalents in a 2-by-2-by-2 array, of elements whose linear indices 3, 4, 5, 6 are specified in the IND matrix.

```
IND = [3 4;5 6];
s = [2,2,2];
[I,J,K] = ind2sub(s,IND)
```

```
I =
     1     2
     1     2
```

```
J =
     2     2
     1     1
```

```
K =
     1     1
     2     2
```

### Example 3 – Effects of Returning Fewer Outputs

When calling `ind2sub` for an N-dimensional matrix, you would typically supply N output arguments in the call: one for each dimension of the matrix. This example shows what happens when you return three, two, and one output when calling `ind2sub` on a 3-dimensional matrix.

# ind2sub

---

The matrix is 2-by-2-by-2 and the linear indices are 1 through 8:

```
dims = [2 2 2];  
indices = [1 2 3 4 5 6 7 8];
```

The 3-output call to `ind2sub` returns the expected subscripts for the 2-by-2-by-2 matrix:

```
[rowsub colsub pagsub] = ind2sub(dims, indices)  
rowsub =  
     1     2     1     2     1     2     1     2  
colsub =  
     1     1     2     2     1     1     2     2  
pagsub =  
     1     1     1     1     2     2     2     2
```

If you specify only two outputs (row and column), `ind2sub` still returns a subscript for each specified index, but drops the third dimension from the matrix, returning subscripts for a 2-dimensional, 2-by-4 matrix instead:

```
[rowsub colsub] = ind2sub(dims, indices)  
rowsub =  
     1     2     1     2     1     2     1     2  
colsub =  
     1     1     2     2     3     3     4     4
```

If you specify one output (row), `ind2sub` drops both the second and third dimensions from the matrix, and returns subscripts for a 1-dimensional, 1-by-8 matrix instead:

```
[rowsub] = ind2sub(dims, indices)  
rowsub =  
     1     2     3     4     5     6     7     8
```

[find](#) | [size](#) | [sub2ind](#)

**Purpose**

Infinity

**Syntax**

```
Inf
Inf('double')
Inf('single')
Inf(n)
Inf(m,n)
Inf(m,n,p,...)
Inf(...,classname)
```

**Description**

Inf returns the IEEE arithmetic representation for positive infinity. Infinity results from operations like division by zero and overflow, which lead to results too large to represent as conventional floating-point values.

Inf('double') is the same as Inf with no inputs.

Inf('single') is the single precision representation of Inf.

Inf(n) is an n-by-n matrix of Infs.

Inf(m,n) or inf([m,n]) is an m-by-n matrix of Infs.

Inf(m,n,p,...) or Inf([m,n,p,...]) is an m-by-n-by-p-by-... array of Infs.

---

**Note** The size inputs m, n, p, ... should be nonnegative integers. Negative integers are treated as 0.

---

Inf(...,classname) is an array of Infs of class specified by classname. classname must be either 'single' or 'double'.

**Examples**

1/0, 1.e1000, 2^2000, and exp(1000) all produce Inf.

log(0) produces -Inf.

Inf - Inf and Inf/Inf both produce NaN (Not-a-Number).

# Inf

---

## See Also

`isinf` | `NaN`

**Purpose** Specify inferior class relationship

**Syntax** `inferiorto('class1','class2',...)`

**Description** `inferiorto('class1','class2',...)` establishes that the class invoking this function in its constructor has lower precedence than the classes in the argument list. MATLAB uses this precedence to determine which method or function MATLAB calls in any given situation.

Use this function only from a constructor that calls the `class` function to create objects (classes defined before MATLAB 7.6).

**Examples** Specify class precedence.

Suppose `a` is an object of class `class_a`, `b` is an object of class `class_b`, and `c` is an object of class `class_c`. Suppose the constructor method of `class_c` contains the statement:

```
inferiorto('class_a')
```

This function call establishes `class_a` as taking precedence over `class_c` for function dispatching. Therefore, either of the following two statements:

```
e = fun(a,c);  
e = fun(c,a);
```

Invoke `class_a`/fun.

If you call a function with two objects having an unspecified relationship, the two objects have equal precedence. In this case, MATLAB calls the method of the left-most object. So `fun(b, c)` calls `class_b`/fun, while `fun(c, b)` calls `class_c`/fun.

<b>Purpose</b>	Construct inline object
<b>Syntax</b>	<code>inline(expr)</code> <code>inline(expr, arg1, arg2, ...)</code> <code>inline(expr, n)</code>
<b>Description</b>	<p><code>inline(expr)</code> constructs an inline function object from the MATLAB expression contained in the string <code>expr</code>. The input argument to the inline function is automatically determined by searching <code>expr</code> for an isolated lower case alphabetic character, other than <code>i</code> or <code>j</code>, that is not part of a word formed from several alphabetic characters. If no such character exists, <code>x</code> is used. If the character is not unique, the one closest to <code>x</code> is used. If two characters are found, the one later in the alphabet is chosen.</p> <p><code>inline(expr, arg1, arg2, ...)</code> constructs an inline function whose input arguments are specified by the strings <code>arg1, arg2, ...</code>. Multicharacter symbol names may be used.</p> <p><code>inline(expr, n)</code> where <code>n</code> is a scalar, constructs an inline function whose input arguments are <code>x, P1, P2, ...</code>.</p>
<b>Tips</b>	<p>Three commands related to <code>inline</code> allow you to examine an inline function object and determine how it was created.</p> <p><code>char(fun)</code> converts the inline function into a character array. This is identical to <code>formula(fun)</code>.</p> <p><code>argnames(fun)</code> returns the names of the input arguments of the inline object <code>fun</code> as a cell array of strings.</p> <p><code>formula(fun)</code> returns the formula for the inline object <code>fun</code>.</p> <p>A fourth command <code>vectorize(fun)</code> inserts a <code>.</code> before any <code>^</code>, <code>*</code> or <code>/</code> in the formula for <code>fun</code>. The result is a vectorized version of the inline function.</p>
<b>Examples</b>	<b>Example 1</b> This example creates a simple inline function to square a number.

```
g = inline('t^2')
g =
```

```
    Inline function:
    g(t) = t^2
```

You can convert the result to a string using the `char` function.

```
char(g)
```

```
ans =
```

```
t^2
```

## Example 2

This example creates an inline function to represent the formula  $f = 3\sin(2x^2)$ . The resulting inline function can be evaluated with the `argnames` and `formula` functions.

```
f = inline('3*sin(2*x.^2)')
```

```
f =
    Inline function:
    f(x) = 3*sin(2*x.^2)
```

```
argnames(f)
```

```
ans =
    'x'
```

```
formula(f)
ans =
```

```
3*sin(2*x.^2)
```

## Example 3

This call to `inline` defines the function `f` to be dependent on two variables, `alpha` and `x`:

```
f = inline('sin(alpha*x)')
```

```
f =
```

```
    Inline function:
```

```
    f(alpha,x) = sin(alpha*x)
```

If `inline` does not return the desired function variables or if the function variables are in the wrong order, you can specify the desired variables explicitly with the `inline` argument list.

```
g = inline('sin(alpha*x)', 'x', 'alpha')
```

```
g =
```

```
    Inline function:
```

```
    g(x,alpha) = sin(alpha*x)
```

# inmem

---

**Purpose** Names of functions, MEX-files, Java classes in memory

**Syntax**

```
M = inmem
[M, X] = inmem
[M, X, J] = inmem
[...] = inmem('-completenames')
```

**Description**

`M = inmem` returns a cell array of strings containing the names of the functions that are currently loaded.

`[M, X] = inmem` returns an additional cell array `X` containing the names of the MEX-files that are currently loaded.

`[M, X, J] = inmem` also returns a cell array `J` containing the names of the Java classes that are currently loaded.

`[...] = inmem('-completenames')` returns not only the names of the currently loaded function and MEX-files, but the path and filename extension for each as well. No additional information is returned for loaded Java classes.

## Examples

Example 1

This example lists the functions that are required to run `erf`.

```
clear all;           % Clear the workspace
erf(0.5);
```

```
M = inmem
M =
    'erf'
```

### Example 2

Generate a plot, and then find the function and MEX-files that had been loaded to perform this operation:

```
clear all
surf(peaks)
```

```
[m x] = inmem('-completenames');  
  
m{1:5}  
ans =  
    F:\matlab\toolbox\matlab\general\usejava.m  
ans =  
    F:\matlab\toolbox\matlab\graph3d\private\surfchk.m  
ans =  
    F:\matlab\toolbox\matlab\graphics\gcf.m  
ans =  
    F:\matlab\toolbox\matlab\datatypes\@opaque\char.m  
ans =  
    F:\matlab\toolbox\matlab\graphics\findall.m  
  
x  
x =  
    Empty cell array: 0-by-1
```

**See Also**

```
clear
```

# inpolygon

---

**Purpose** Points inside polygonal region

**Syntax**  
`IN = inpolygon(X,Y,xv,yv)`  
`[IN ON] = inpolygon(X,Y,xv,yv)`

**Description** `IN = inpolygon(X,Y,xv,yv)` returns a matrix `IN` the same size as `X` and `Y`. Each element of `IN` is assigned the value 1 or 0 depending on whether the point  $(X(p,q), Y(p,q))$  is inside the polygonal region whose vertices are specified by the vectors `xv` and `yv`. In particular:

$IN(p,q) = 1$  If  $(X(p,q), Y(p,q))$  is inside the polygonal region or on the polygon boundary

$IN(p,q) = 0$  If  $(X(p,q), Y(p,q))$  is outside the polygonal region

`[IN ON] = inpolygon(X,Y,xv,yv)` returns a second matrix `ON` the same size as `X` and `Y`. Each element of `ON` is assigned the value 1 or 0 depending on whether the point  $(X(p,q), Y(p,q))$  is on the boundary of the polygonal region whose vertices are specified by the vectors `xv` and `yv`. In particular:

$ON(p,q) = 1$  If  $(X(p,q), Y(p,q))$  is on the polygon boundary

$ON(p,q) = 0$  If  $(X(p,q), Y(p,q))$  is inside or outside the polygon boundary

## Examples

```
L = linspace(0,2.*pi,6); xv = cos(L)';yv = sin(L)';  
xv = [xv ; xv(1)]; yv = [yv ; yv(1)];  
x = randn(250,1); y = randn(250,1);  
in = inpolygon(x,y,xv,yv);  
plot(xv,yv,x(in),y(in), 'r+',x(~in),y(~in), 'bo')
```

# input

---

**Purpose** Request user input

**Syntax** `evalResponse = input(prompt)`  
`strResponse = input(prompt, 's')`

**Description** `evalResponse = input(prompt)` displays the *prompt* string on the screen, waits for input from the keyboard, evaluates any expressions in the input, and returns the value in *evalResponse*. To evaluate expressions, the `input` function accesses variables in the current workspace.

`strResponse = input(prompt, 's')` returns the entered text as a MATLAB string, without evaluating expressions.

- Tips**
- If you press the **Return** key without entering anything, `input` returns an empty matrix.
  - To create a prompt that spans several lines, use `'\n'` to indicate each new line. To include a backslash (`'\'`) in the prompt, use `'\\'`.
  - If you enter an invalid expression at the prompt, MATLAB displays the relevant error message and then redisplay the prompt.

**Examples** Request a text response. Assign a default value ('Y') by checking for an empty matrix.

```
reply = input('Do you want more? Y/N [Y]: ', 's');  
if isempty(reply)  
    reply = 'Y';  
end
```

**See Also** `keyboard` | `inputdlg` | `menu` | `ginput` | `uicontrol`

## Purpose

Create and open input dialog box

## Syntax

```
answer = inputdlg(prompt)
answer = inputdlg(prompt,dlg_title)
answer = inputdlg(prompt,dlg_title,num_lines)
answer = inputdlg(prompt,dlg_title,num_lines,defAns)
answer = inputdlg(prompt,dlg_title,num_lines,defAns,options)
```

## Description

`answer = inputdlg(prompt)` creates a modal dialog box and returns user input for multiple prompts in the cell array. `prompt` is a cell array containing prompt strings.

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

---

`answer = inputdlg(prompt,dlg_title)` `dlg_title` specifies a title for the dialog box.

`answer = inputdlg(prompt,dlg_title,num_lines)` `num_lines` specifies the number of lines for each user-entered value. `num_lines` can be a scalar, column vector, or matrix.

- If `num_lines` is a scalar, it applies to all prompts.
- If `num_lines` is a column vector, each element specifies the number of lines of input for a prompt.
- If `num_lines` is a matrix, it should be size `m-by-2`, where `m` is the number of prompts on the dialog box. Each row refers to a prompt. The first column specifies the number of lines of input for a prompt. The second column specifies the width of the field in characters.

`answer = inputdlg(prompt,dlg_title,num_lines,defAns)` `defAns` specifies the default value to display for each prompt. `defAns` must contain the same number of elements as `prompt` and all elements must be strings.

# inputdlg

---

```
answer =  
inputdlg(prompt,dlg_title,num_lines,defAns,options) If  
options is the string 'on', the dialog is made resizable in the  
horizontal direction. If options is a structure, the fields shown in  
the following table are recognized:
```

Field	Description
Resize	Can be 'on' or 'off' (default). If 'on', the window is resizable horizontally.
WindowStyle	Can be either 'normal' or 'modal' (default).
Interpreter	Can be either 'none' (default) or 'tex'. If the value is 'tex', the prompt strings are rendered using LaTeX.

If the user clicks the **Cancel** button to close an `inputdlg` box, the dialog returns an empty cell array:

```
answer =  
    {}
```

## Tips

`inputdlg` uses the `uiwait` function to suspend execution until the user responds.

The returned variable `answer` is a cell array containing strings, one string per text entry field, starting from the top of the dialog box.

To convert a member of the cell array to a number, use `str2num`. To do this, you can add the following code to the end of any of the examples below:

```
[val status] = str2num(answer{1}); % Use curly bracket for subscript  
if ~status  
    % Handle empty value returned for unsuccessful conversion  
    % ...  
end  
% val is a scalar or matrix converted from the first input
```

Users can enter scalar or vector values into `inputdlg` fields; `str2num` converts space- and comma-delimited strings into row vectors, and semicolon-delimited strings into column vectors. For example, if `answer{1}` contains `'1 2 3;4 -5 6+7i'`, the conversion produces:

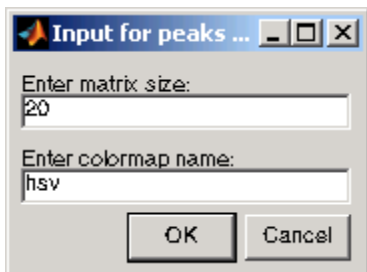

```
val = str2num(answer{1})
val =
    1.0000    2.0000    3.0000
    4.0000   -5.0000    6.0000 + 7.0000i
```

## Examples

### Example 1

Create a dialog box to input an integer and colormap name. Allow one line for each value.

```
prompt = {'Enter matrix size:', 'Enter colormap name:'};
dlg_title = 'Input for peaks function';
num_lines = 1;
def = {'20', 'hsv'};
answer = inputdlg(prompt, dlg_title, num_lines, def);
```

### Example 2

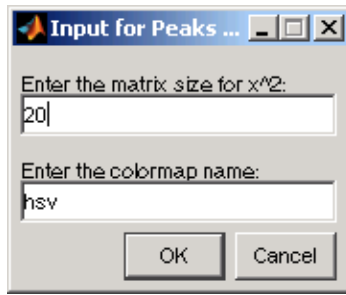

Create a dialog box using the default options. Then use the options to make it resizable and not modal, and to interpret the text using LaTeX.

```
prompt={'Enter the matrix size for x^2:', ...
        'Enter the colormap name:'};
name='Input for Peaks function';
numlines=1;
```

# inputdlg

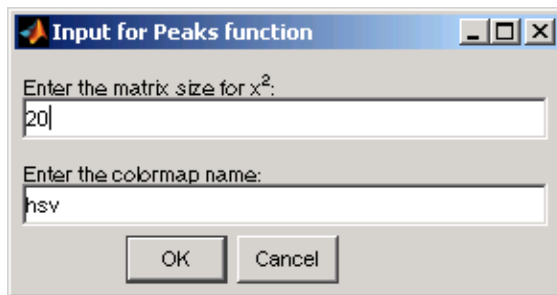

---

```
defaultanswer={'20','hsv'};  
answer=inputdlg(prompt,name,numlines,defaultanswer);
```

```
options.Resize='on';  
options.WindowStyle='normal';  
options.Interpreter='tex';
```

```
answer=inputdlg(prompt,name,numlines,defaultanswer,options);
```

**Purpose** Variable name of function input

**Syntax** `inputname(argnum)`

**Description** This command can be used only inside the body of a function. `inputname(argnum)` returns the workspace variable name corresponding to the argument number *argnum*. If the input argument has no name (for example, if it is an expression instead of a variable), the `inputname` command returns the empty string ('').

**Examples** Suppose the function `myfun.m` is defined as

```
function c = myfun(a,b)
fprintf('First calling variable is "%s"\n.', inputname(1))
```

Then

```
x = 5; y = 3; myfun(x,y)
```

produces

```
First calling variable is "x".
```

But

```
myfun(pi+1, pi-1)
```

produces

```
First calling variable is "".
```

**See Also** `nargin` | `nargout` | `nargchk`

# inputParser

---

**Purpose** Parse function inputs

**Description** Use `inputParser` objects to verify that each input passed to your custom function conforms to the expected type and value.

- 1 Construct an `inputParser` object.
- 2 Add inputs to the input scheme using the `addRequired`, `addOptional`, or `addParamValue` methods. Each method allows you to specify a validation function that checks the input. You can call these methods in any order to add inputs to the scheme. However, when you call your custom function, pass any required inputs first. Then, pass any optional positional inputs, followed by parameter value inputs.
- 3 Optionally, set properties to adjust the parsing behavior, such as handling case sensitivity, structure array inputs, and inputs that are not in the input scheme.
- 4 Call the `parse` method to parse and store inputs in the `Results`, `UsingDefaults`, and `Unmatched` properties of the `inputParser` object.

**Construction** `p = inputParser` creates `inputParser` object `p`.

**Properties** **CaseSensitive**

Logical value that indicates whether to match case when checking argument names.

Possible values:

- |                        |                                                   |
|------------------------|---------------------------------------------------|
| <code>false (0)</code> | Names are not sensitive to case: 'a' matches 'A'. |
| <code>true (1)</code>  | Names are case sensitive: 'a' does not match 'A'. |

**Default:** `false`

## FunctionName

String that specifies the name of the function to include in error messages.

**Default:** If you construct the `inputParser` object within a function, the default value is the name of that function. Otherwise, the default value is an empty string, `''`.

## KeepUnmatched

Logical value that indicates how to handle parameter name and value inputs that are not in the input scheme.

Possible values:

- |                        |                                                                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>false (0)</code> | Throw an error whenever inputs are not in the scheme.                                                                                                           |
| <code>true (1)</code>  | Store the parameter names and values of unmatched inputs in the <code>Unmatched</code> property of the <code>inputParser</code> object, and suppress the error. |

**Default:** `false`

## Parameters

Cell array of strings that contains the names of arguments currently defined in the input scheme. Read-only.

Each method that adds an input argument to the scheme (`addRequired`, `addOptional`, `addParamValue`) updates the `Parameters` property.

## Results

Structure containing names and values of inputs that match the function input scheme, populated by the `parse` method. Read-only.

# inputParser

---

Each field of the `Results` structure corresponds to the name of an input.

## **StructExpand**

Logical value that specifies whether to interpret a structure array as a single input or as a set of parameter name and value pairs.

<code>true</code> (1)	Expand structures into separate inputs. Each field name corresponds to an input parameter name.
<code>false</code> (0)	Regard a structure array as a single input argument.

**Default:** `true`

## **Unmatched**

Structure array containing the names and values of inputs that do not match the function input scheme, populated by the `parse` method. Read-only.

If `KeepUnmatched` is `false` (default) or all inputs match the scheme, then `Unmatched` is a 1-by-1 structure with no fields. Otherwise, each field of the structure corresponds to the name of an input that did not match the scheme.

## **UsingDefaults**

Cell array containing the names of inputs not passed explicitly to the function and assigned default values, populated by the `parse` method. Read-only.

## **Methods**

<code>addOptional</code>	Add optional argument to Input Parser scheme
<code>addParamValue</code>	Add parameter name and value argument to Input Parser scheme

addRequired	Add required argument to Input Parser scheme
createCopy	Create copy of inputParser object
parse	Parse function inputs

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB Programming Fundamentals documentation.

The createCopy method allows you to create another scheme with the same properties as an existing inputParser object.

## Examples

### Input Validation

Check the validity of required and optional function inputs.

Create a custom function with required and optional inputs in the file findArea.m.

```
function a = findArea(width,varargin)
    p = inputParser;
    defaultHeight = 1;
    defaultUnits = 'inches';
    defaultShape = 'rectangle';
    expectedShapes = {'square','rectangle','parallelogram'};

    addRequired(p,'width',@isnumeric);
    addOptional(p,'height',defaultHeight,@isnumeric);
    addParamValue(p,'units',defaultUnits);
    addParamValue(p,'shape',defaultShape,...
        @(x) any(validatestring(x,expectedShapes)));

    parse(p,width,varargin{:});
    a = p.Results.width .* p.Results.height;
```

The input parser checks whether width and height are numeric, and whether the shape matches a string in cell array expectedShapes. @

# inputParser

---

indicates a function handle, and the syntax @(x) creates an anonymous function with input x.

Call the function with inputs that do not match the scheme. For example, specify a nonnumeric value for the width input:

```
findArea('text')
```

```
Error using findArea (line 14)  
Argument 'width' failed validation isnumeric.
```

Specify an unsupported value for shape:

```
findArea(4,'shape','circle')
```

```
Error using findArea (line 14)  
Argument 'shape' failed validation with error:  
Expected input to match one of these strings:
```

```
square, rectangle, parallelogram
```

```
The input, 'circle', did not match any of the valid strings.
```

## Extra Parameter Value Inputs

Store parameter name and value inputs that are not in the input scheme instead of throwing an error.

```
default = 0;  
value = 1;  
  
p = inputParser;  
p.KeepUnmatched = true;  
addOptional(p,'expectedInputName',default);  
parse(p,'extraInput',value);
```

View the unmatched parameter name and value:

```
p.Unmatched
```

```
ans =  
    extraInput: 1
```

## Case Sensitivity

Enforce case sensitivity when checking function inputs.

```
p = inputParser;  
p.CaseSensitive = true;  
defaultValue = 0;  
addParamValue(p, 'InputName', defaultValue);  
  
parse(p, 'inputname', 10)
```

Argument 'inputname' did not match any valid parameter of the parser.

## Structure Array Inputs

Parse structure array inputs with the StructExpand property set to true (default) or false.

Expand a structure array input into parameter name and value pairs using the default true value of the StructExpand property.

```
s.input1 = 10;  
s.input2 = 20;  
default = 0;  
  
p = inputParser;  
addParamValue(p, 'input1', default);  
addParamValue(p, 'input2', default);  
parse(p, s);
```

```
p.Results
```

```
ans =  
    input1: 10  
    input2: 20
```

# inputParser

---

Explicitly specifying a parameter name and value pair overrides values in the structure.

```
parse(p,s,'input2',300);  
p.Results
```

```
ans =  
    input1: 10  
    input2: 300
```

Accept a structure array input as a single argument by setting the StructExpand property to false.

```
s2.first = 1;  
s2.random = rand(3,4,2);  
s2.mytext = 'some text';
```

```
p = inputParser;  
p.StructExpand = false;  
addRequired(p,'structInput');  
parse(p,s2);
```

```
results = p.Results  
fieldList = fieldnames(p.Results.structInput)
```

```
results =  
    structInput: [1x1 struct]
```

```
fieldList =  
    'first'  
    'random'  
    'mytext'
```

## Concepts

- “Input Parser Validation Functions”

**Purpose** Open Property Inspector

**Syntax**  
`inspect`  
`inspect(h)`  
`inspect([h1,h2,...])`

**Description** `inspect` creates a separate Property Inspector window to enable the display and modification of the properties of any object you select in the figure window or Layout Editor. If no object is selected, the Property Inspector is blank.

`inspect(h)` creates a Property Inspector window for the object whose handle is `h`.

`inspect([h1,h2,...])` displays properties that objects `h1` and `h2` have in common, or a blank window if there are no such properties; any number of objects can be inspected and edited in this way (for example, handles returned by the `bar` command).

The Property Inspector has the following behaviors:

- Only one Property Inspector window is active at any given time; when you inspect a new object, its properties replace those of the object last inspected.
- When the Property Inspector is open and plot edit mode is on, clicking any object in the figure window displays the properties of that object (or set of objects) in the Property Inspector.
- When you select and inspect two or more objects of different types, the Property Inspector only shows the properties that all objects have in common.
- To change the value of any property, click on the property name shown at the left side of the window, and then enter the new value in the field at the right.

The Property Inspector provides two different views:

- List view — properties are ordered alphabetically (default); this is the only view available for annotation objects.

- Group view — properties are grouped under classified headings (Handle Graphics objects only)

To view alphabetically, click the “AZ” Icon  in the Property Inspector toolbar. To see properties in groups, click

the “++” icon . When properties are grouped, the “-” and “+” icons are enabled; click  to expand all categories and click  to collapse all categories. You can also expand and collapse individual categories by clicking on the “+” next to the category name. Some properties expand and collapse

---

**Notes** To see a complete description of any property, right-click on its name or value and select **What’s This**; a help window opens that displays the reference page entry for it.

The Property Inspector displays most, but not all, properties of Handle Graphics objects. For example, the `parent` and `children` of HG objects are not shown.

`inspect h` displays a Property Inspector window that enables modification of the string 'h', not the object whose handle is h.

If you modify properties at the MATLAB command line, you must refresh the Property Inspector window to see the change reflected there. Refresh the Property Inspector by reinvoking `inspect` on the object.

---

## Examples

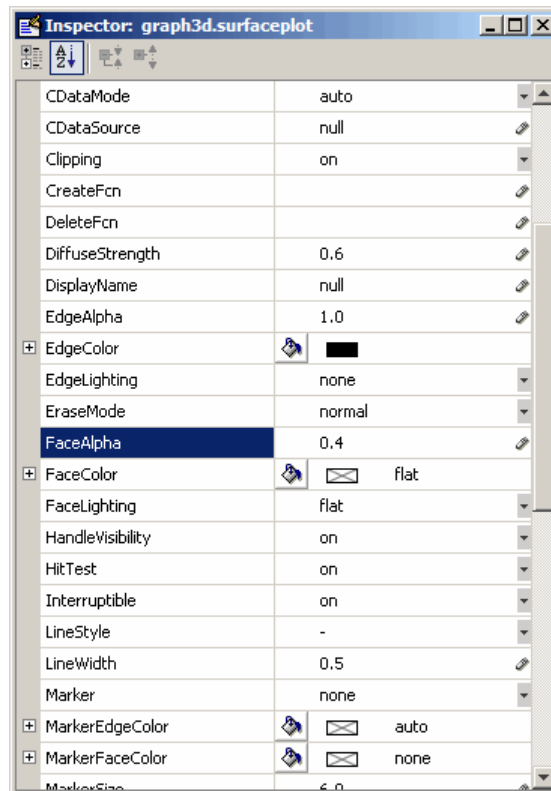

### Example 1

Create a surface mesh plot and view its properties with the Property Inspector:

```
Z = peaks(30);  
h = surf(Z)  
inspect(h)
```

Use the Property Inspector to change the `FaceAlpha` property from 1.0 to 0.4 (equivalent to the command `set(h,'FaceAlpha',0.4)`). `FaceAlpha` controls the transparency of patch faces.

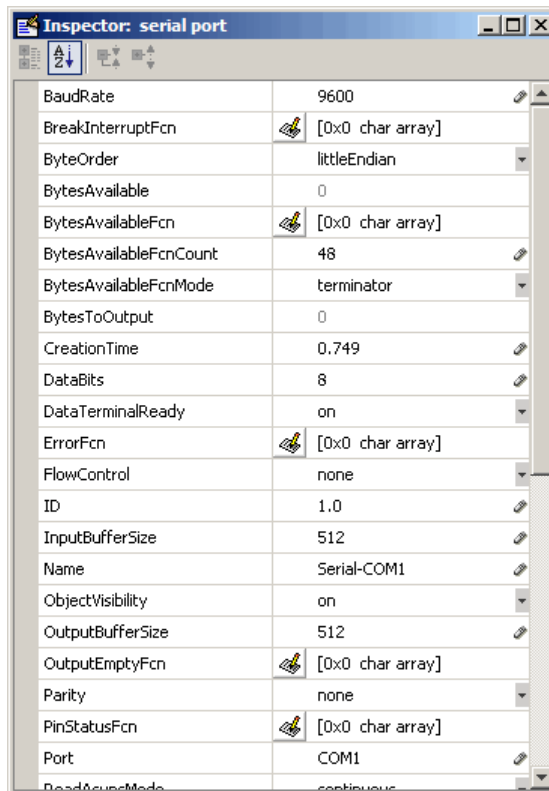

When you press **Enter** or click a different field, the FaceAlpha property of the surface object is updated:

### Example 2

Create a serial port object for COM1 on a Windows platform and use the Property Inspector to peruse its properties:

```
s = serial('COM1');  
inspect(s)
```

Because COM objects do not define property groupings, only the alphabetical list view of their properties is available.

### Example 3

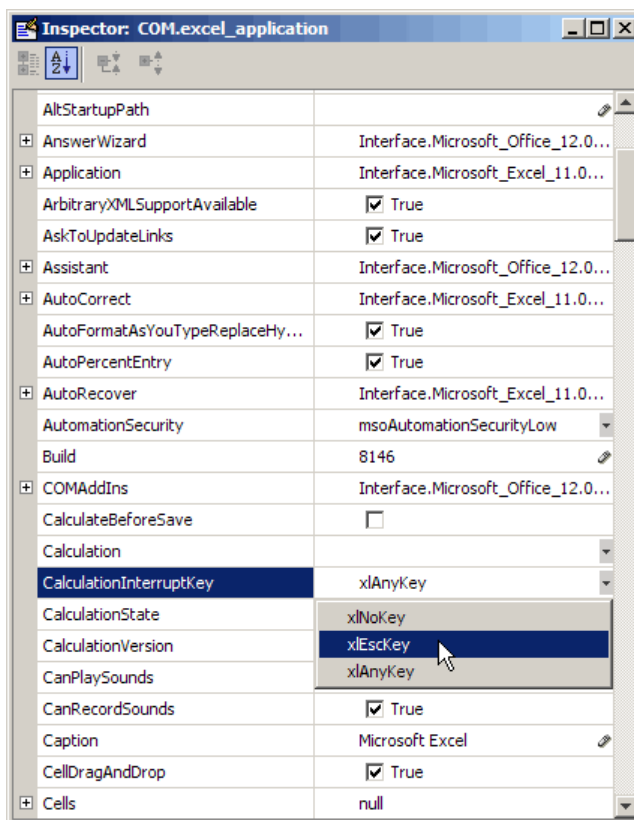

Create a COM Excel server and open a Property Inspector window with `inspect`:

```
h = actxserver('excel.application');  
inspect(h)
```

Scroll down until you see the `CalculationInterruptKey` property, which by default is `x1AnyKey`. Click on the down-arrow in the right

margin of the property inspector and select `xlEscKey` from the drop-down menu, as shown below:

Check this field in the MATLAB Command Window using `get` to confirm that it has changed:

```
get(h, 'CalculationInterruptKey')
```

```
ans =  
xlEscKey
```

# inspect

---

## **See Also**

`get` | `set` | `isprop` | `guide` | `addproperty` | `deletproperty`

<b>Purpose</b>	Event information when event occurs
<b>Syntax</b>	<code>instrcallback(obj,event)</code>
<b>Description</b>	<p><code>instrcallback(obj,event)</code> displays a message that contains the event type, event, the time the event occurred, and the name of the serial port object, <code>obj</code>, that caused the event to occur.</p> <p>For error events, the error message is also displayed. For pin status events, the pin that changed value and its value are also displayed.</p>
<b>Tips</b>	You should use <code>instrcallback</code> as a template from which you create callback functions that suit your specific application needs.
<b>Examples</b>	<p>The following example creates the serial port objects <code>s</code>, on a Windows platform. It configures <code>s</code> to execute <code>instrcallback</code> when an output-empty event occurs. The event occurs after the <code>*IDN?</code> command is written to the instrument.</p> <pre>s = serial('COM1'); set(s, 'OutputEmptyFcn', @instrcallback) fopen(s) fprintf(s, '*IDN?', 'async')</pre> <p>The resulting display from <code>instrcallback</code> is shown below.</p> <pre>OutputEmpty event occurred at 08:37:49 for the object: Serial-COM1.</pre> <p>Read the identification information from the input buffer and end the serial port session.</p> <pre>idn = fscanf(s); fclose(s) delete(s) clear s</pre>

# instrfind

---

**Purpose** Read serial port objects from memory to MATLAB workspace

**Syntax**

```
out = instrfind
out = instrfind('PropertyName',PropertyValue,...)
out = instrfind(S)
out = instrfind(obj,'PropertyName',PropertyValue,...)
```

**Description**

`out = instrfind` returns all valid serial port objects as an array to `out`.

`out = instrfind('PropertyName',PropertyValue,...)` returns an array of serial port objects whose property names and property values match those specified.

`out = instrfind(S)` returns an array of serial port objects whose property names and property values match those defined in the structure `S`. The field names of `S` are the property names, while the field values are the associated property values.

`out = instrfind(obj,'PropertyName',PropertyValue,...)` restricts the search for matching property name/property value pairs to the serial port objects listed in `obj`.

**Tips** Refer to “Displaying Property Names and Property Values” for a list of serial port object properties that you can use with `instrfind`.

You must specify property values using the same format as the `get` function returns. For example, if `get` returns the `Name` property value as `MyObject`, `instrfind` will not find an object with a `Name` property value of `myobject`. However, this is not the case for properties that have a finite set of string values. For example, `instrfind` will find an object with a `Parity` property value of `Even` or `even`.

You can use property name/property value string pairs, structures, and cell array pairs in the same call to `instrfind`.

**Examples** Suppose you create the following two serial port objects on a Windows platform.

```
s1 = serial('COM1');
```

```
s2 = serial('COM2');  
set(s2, 'BaudRate', 4800)  
fopen([s1 s2])
```

You can use `instrfind` to return serial port objects based on property values.

```
out1 = instrfind('Port', 'COM1');  
out2 = instrfind({'Port', 'BaudRate'}, {'COM2', 4800});
```

You can also use `instrfind` to return cleared serial port objects to the MATLAB workspace.

```
clear s1 s2  
newobjs = instrfind
```

```
Instrument Object Array  
Index:   Type:      Status:   Name:  
1        serial     open     Serial-COM1  
2        serial     open     Serial-COM2
```

To close both `s1` and `s2`

```
fclose(newobjs)
```

```
clear | get
```

# instrfindall

---

**Purpose** Find visible and hidden serial port objects

**Syntax**

```
out = instrfindall
out = instrfindall('P1',V1,...)
out = instrfindall(s)
out = instrfindall(objs,'P1',V1,...)
```

**Description** `out = instrfindall` finds all serial port objects, regardless of the value of the objects' `ObjectVisibility` property. The object or objects are returned to `out`.

`out = instrfindall('P1',V1,...)` returns an array, `out`, of serial port objects whose property names and corresponding property values match those specified as arguments.

`out = instrfindall(s)` returns an array, `out`, of serial port objects whose property names and corresponding property values match those specified in the structure `s`, where the field names correspond to property names and the field values correspond to the current value of the respective property.

`out = instrfindall(objs,'P1',V1,...)` restricts the search for objects with matching property name/value pairs to the serial port objects listed in `objs`.

Note that you can use string property name/property value pairs, structures, and cell array property name/property value pairs in the same call to `instrfindall`.

**Tips** `instrfindall` differs from `instrfind` in that it finds objects whose `ObjectVisibility` property is set to `off`.

Property values are case sensitive. You must specify property values using the same format as that returned by the `get` function. For example, if `get` returns the `Name` property value as `'MyObject'`, `instrfindall` will not find an object with a `Name` property value of `'myobject'`. However, this is not the case for properties that have a finite set of string values. For example, `instrfindall` will find an object with a `Parity` property value of `'Even'` or `'even'`.

## Examples

Suppose you create the following serial port objects on a Windows platform:

```
s1 = serial('COM1');  
s2 = serial('COM2');  
set(s2,'ObjectVisibility','off')
```

Because object `s2` has its `ObjectVisibility` set to `'off'`, it is not visible to commands like `instrfind`:

```
instrfind  
  
Serial Port Object : Serial-COM1
```

However, `instrfindall` finds all objects regardless of the value of `ObjectVisibility`:

```
instrfindall  
  
Instrument Object Array  
Index:   Type:           Status:      Name:  
1        serial          closed      Serial-COM1  
2        serial          closed      Serial-COM2
```

The following statements use `instrfindall` to return objects with specific property settings, which are passed as cell arrays:

```
props = {'PrimaryAddress','SecondaryAddress'};  
vals = {2,0};  
obj = instrfindall(props,vals);
```

You can use `instrfindall` as an argument when you want to apply the command to all objects, visible and invisible. For example, the following statement makes all objects visible:

```
set(instrfindall,'ObjectVisibility','on')
```

# int2str

---

**Purpose** Convert integer to string

**Syntax** `str = int2str(N)`

**Description** `str = int2str(N)` converts an integer to a string with integer format. The input `N` can be a single integer or a vector or matrix of integers. Noninteger inputs are rounded before conversion.

**Examples** `int2str(2+3)` is the string '5'.

One way to label a plot is

```
title(['case number ' int2str(n)])
```

For matrix or vector inputs, `int2str` returns a string matrix:

```
int2str(eye(3))
```

```
ans =
```

```
1 0 0
0 1 0
0 0 1
```

<b>Purpose</b>	Convert to 64-bit signed integer
<b>Syntax</b>	<code>intArray = int64(array)</code>
<b>Description</b>	<code>intArray = int64(array)</code> converts the elements of an array into signed 64-bit (8-byte) integers of class <code>int64</code> .
<b>Tips</b>	<p>Double-precision floating-point numbers have only 52 bits in the mantissa. Therefore, <code>double</code> values cannot represent all integers greater than <math>2^{53}</math> correctly. Before performing arithmetic operations on values larger than <math>2^{53}</math> in magnitude, convert the values to 64-bit integers. For example,</p> <pre>x = int64(2^53+1);    % Floating-point arithmetic, loses precision</pre> <p>is not as accurate as the 64-bit integer arithmetic operation:</p> <pre>x = int64(2^53) + 1;    % Preferred</pre>
<b>Input Arguments</b>	<p><b>array</b></p> <p>Array of any numeric class, such as <code>single</code> or <code>double</code>. If <code>array</code> is already of class <code>int64</code>, the <code>int64</code> function has no effect.</p>
<b>Output Arguments</b>	<p><b>intArray</b></p> <p>Array of class <code>int64</code>. Values range from <math>-2^{63}</math> to <math>2^{63} - 1</math>.</p> <p>The <code>int64</code> function maps any values in <code>array</code> that are outside the limit to the nearest endpoint. For example,</p> <pre>int64(2^63)    % 2^63 = 9223372036854775808</pre> <p>returns</p> <pre>ans =     9223372036854775807</pre>

# int64

---

## Examples

Convert a literal value to int64:

```
x = int64(9007199254740993);
```

## Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = int64(zeros(100));    % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'int64'); % Preferred
```

## Tutorials

- “Integers”
- “Arithmetic Operations on Integer Classes”

## Purpose

Numerically evaluate integral

## Syntax

```
q = integral(fun,xmin,xmax)
q = integral(fun,xmin,xmax,Name,Value)
```

## Description

`q = integral(fun,xmin,xmax)` approximates the integral of function `fun` from `xmin` to `xmax` using global adaptive quadrature and default error tolerances.

`q = integral(fun,xmin,xmax,Name,Value)` specifies additional options with one or more `Name, Value` pair arguments.

## Input Arguments

### **fun - Integrand**

function handle

Integrand, specified as a function handle, defines the function to be integrated from `xmin` to `xmax`. For scalar-valued problems, the function `y = fun(x)` must accept a vector argument, `x`, and return a vector result, `y`. If you set the 'ArrayValued' option to true, `fun` must accept a scalar and return an array of fixed size.

### **xmin - Lower limit of x**

real number | complex number

Lower limit of `x`, specified as a real (finite or infinite) scalar value or a complex (finite) scalar value. If either `xmin` or `xmax` are complex, `integral` approximates the path integral from `xmin` to `xmax` over a straight line path.

### **Data Types**

double | single

**Complex Number Support:** Yes

### **xmax - Upper limit of x**

real number | complex number

Upper limit of `x`, specified as a real (finite or infinite) scalar value or a complex (finite) scalar value. If either `xmin` or `xmax` are complex,

`integral` approximates the path integral from `xmin` to `xmax` over a straight line path.

## Data Types

double | single

**Complex Number Support:** Yes

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'AbsTol',1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

## AbsTol - Absolute error tolerance

nonnegative real number

Absolute error tolerance, specified as the comma-separated pair consisting of `'AbsTol'` and a nonnegative real number. `integral` uses the absolute error tolerance to limit an estimate of the absolute error,  $|q - Q|$ , where  $q$  is the computed value of the integral and  $Q$  is the (unknown) exact value. `integral` might provide more decimal places of precision if you decrease the absolute error tolerance. The default value is `1e-10`.

---

**Note** `AbsTol` and `RelTol` work together. `integral` might satisfy the absolute error tolerance or the relative error tolerance, but not necessarily both. For more information on using these tolerances, see the “Tips” on page 2-2316 section.

---

**Example:** `'AbsTol',1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

**Data Types**

single | double

**RelTol - Relative error tolerance**

nonnegative real number

Relative error tolerance, specified as the comma-separated pair consisting of 'RelTol' and a nonnegative real number. `integral` uses the relative error tolerance to limit an estimate of the relative error,  $|q - Q|/|Q|$ , where  $q$  is the computed value of the integral and  $Q$  is the (unknown) exact value. `integral` might provide more significant digits of precision if you decrease the relative error tolerance. The default value is `1e-6`.

---

**Note** `RelTol` and `AbsTol` work together. `integral` might satisfy the relative error tolerance or the absolute error tolerance, but not necessarily both. For more information on using these tolerances, see the Tips section.

---

**Example:** `'RelTol', 1e-9` sets the relative error tolerance to approximately 9 significant digits.

**Data Types**

single | double

**ArrayValued - Array-valued function flag**

false (default) | true

Array-valued function flag, specified as the comma-separated pair consisting of 'ArrayValued' and either `true` or `false`. Set this flag to `true` when you want to integrate over an array-valued function. The shape of `fun(x)` can be a vector, matrix, or N-D array.

**Example:** `'ArrayValued', true` indicates that the integrand is an array-valued function.

## Data Types

logical

## Waypoints - Integration waypoints

vector

Integration waypoints, specified as the comma-separated pair consisting of 'Waypoints' and a vector of real or complex numbers. Use waypoints to indicate any points in the integration interval you would like the integrator to use. You can use waypoints to integrate efficiently across discontinuities of the integrand. Specify the locations of the discontinuities in the vector you supply.

You can specify waypoints when you want to perform complex contour integration. If `xmin`, `xmax`, or any entry of the waypoints vector is complex, the integration is performed over a sequence of straight line paths in the complex plane.

**Example:** 'Waypoints', [1+1i, 1-1i] specifies two complex waypoints along the interval of integration.

## Data Types

single | double

**Complex Number Support:** Yes

## Output Arguments

### q - Computed integral

Computed integral of `fun(x)` between the limits `xmin` and `xmax`, returned as a numeric value or numeric array.

## Tips

- Do not use waypoints to specify singularities. Instead, split the interval and add the results of separate integrations with the singularities at the endpoints.
- The integral function attempts to satisfy:

$$\text{abs}(q - Q) \leq \max(\text{AbsTol}, \text{RelTol} * \text{abs}(q))$$

where `q` is the computed value of the integral and `Q` is the (unknown) exact value. The absolute and relative tolerances provide a way of

trading off accuracy and computation time. Usually, the relative tolerance determines the accuracy of the integration. However if `abs(q)` is sufficiently small, the absolute tolerance determines the accuracy of the integration. You should generally specify both absolute and relative tolerances together.

- If you specify a complex value for `xmin`, `xmax`, or any waypoint, all of your limits and waypoints must be finite.
- If you are specifying single-precision limits of integration, or if `fun` returns single-precision results, you might need to specify larger absolute and relative error tolerances.

## Examples

### Evaluate Improper Integral

Create the anonymous function  $f(x) = e^{-x^2}(\ln x)^2$ .

```
fun = @(x) exp(-x.^2).*log(x).^2;
```

Evaluate the integral from  $x=0$  to  $x=Inf$ .

```
q = integral(fun,0,Inf)
```

```
q =
```

```
1.9475
```

### Integrate Parameterized Function

Create the anonymous function  $f(x) = 1/(x^3 - 2x - c)$  with one parameter,  $c$ .

```
fun = @(x,c) 1./(x.^3-2*x-c);
```

Evaluate the integral from  $x=0$  to  $x=2$  at  $c=5$ .

```
q = integral(@(x)fun(x,5),0,2)
```

```
q =
```

```
-0.4605
```

## Evaluate Integral with Singularity at the Lower Limit of Integration

Create the anonymous function  $f(x) = \ln(x)$ .

```
fun = @(x)log(x);
```

Evaluate the integral from  $x=0$  to  $x=1$  with the default error tolerances.

```
format long  
q1 = integral(fun,0,1)
```

```
q1 =
```

```
-1.000000010959678
```

Evaluate the integral again, specifying approximately 12 decimal places of accuracy.

```
q2 = integral(fun,0,1,'RelTol',0,'AbsTol',1e-12)
```

```
q2 =
```

```
-1.000000000000010
```

## Complex Contour Integration Using Waypoints

Specify waypoints  $[1+1i, 1-1i]$  to integrate over the triangular path: 0 to  $1+1i$  to  $1-1i$  to 0.

Create the anonymous function  $f(z) = 1/(2z - 1)$ .

```
fun = @(z) 1./(2*z-1);
```

Integrate in the complex plane over the triangular path from 0 to  $1+1i$  to  $1-1i$  to 0.

```
q = integral(fun,0,0,'Waypoints',[1+1i,1-1i])
```

```
q =
    0 - 3.1416i
```

### Integrate Vector-Valued Function

Specify 'ArrayValued', true to evaluate the integral of an array-valued or vector-valued function.

Create the anonymous vector-valued function  $f(x) = [\sin x, \sin 2x, \sin 3x, \sin 4x, \sin 5x]$  and integrate from  $x=0$  to  $x=1$ .

```
fun = @(x)sin((1:5)*x);
q = integral(fun,0,1,'ArrayValued',true)
```

```
q =
    0.4597    0.7081    0.6633    0.4134    0.1433
```

### Improper Integral of an Oscillatory Function

Create the anonymous function  $f(x) = x^5 e^{-x} \sin x$ .

```
fun = @(x)x.^5.*exp(-x).*sin(x);
```

Evaluate the integral from  $x=0$  to  $x=Inf$ , adjusting the absolute and relative tolerances.

```
format long
q = integral(fun,0,Inf,'RelTol',1e-8,'AbsTol',1e-13)
```

```
q =
-14.999999999998364
```

- “Parameterizing Functions”

# integral2

---

**Purpose** Numerically evaluate double integral

**Syntax**  
`q = integral2(fun,xmin,xmax,ymin,ymax)`  
`q = integral2(fun,xmin,xmax,ymin,ymax,Name,Value)`

**Description** `q = integral2(fun,xmin,xmax,ymin,ymax)` approximates the integral of the function  $z = \text{fun}(x,y)$  over the planar region  $x_{\min} \leq x \leq x_{\max}$  and  $y_{\min}(x) \leq y \leq y_{\max}(x)$ .

`q = integral2(fun,xmin,xmax,ymin,ymax,Name,Value)` specifies additional options with one or more Name,Value pair arguments.

## Input Arguments

**fun - Integrand**  
function handle

Integrand, specified as a function handle, defines the function to be integrated over the planar region  $x_{\min} \leq x \leq x_{\max}$  and  $y_{\min}(x) \leq y \leq y_{\max}(x)$ . The function `fun` must accept two arrays of the same size and return an array of corresponding values. It must perform element-wise operations.

**Data Types**  
function\_handle

**xmin - Lower limit of x**  
real number

Lower limit of  $x$ , specified as a real scalar value that is either finite or infinite.

**Data Types**  
double | single

**xmax - Upper limit of x**  
real number

Upper limit of  $x$ , specified as a real scalar value that is either finite or infinite.

**Data Types**

double | single

**ymin - Lower limit of y**

real number | function handle

Lower limit of  $y$ , specified as a real scalar value that is either finite or infinite. You can specify `ymin` to be a function handle (a function of  $x$ ) when integrating over a nonrectangular region.

**Data Types**

double | function\_handle | single

**ymax - Upper limit of y**

real number | function handle

Upper limit of  $y$ , specified as a real scalar value that is either finite or infinite. You also can specify `ymax` to be a function handle (a function of  $x$ ) when integrating over a nonrectangular region.

**Data Types**

double | function\_handle | single

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'AbsTol', 1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

**AbsTol - Absolute error tolerance**

nonnegative real number

Absolute error tolerance, specified as the comma-separated pair consisting of `'AbsTol'` and a nonnegative real number. `integral2` uses the absolute error tolerance to limit an estimate of the absolute error,  $|q - Q|$ , where  $q$  is the computed value of the integral and  $Q$  is

the (unknown) exact value. `integral2` might provide more decimal places of precision if you decrease the absolute error tolerance. The default value is  $1e-10$ .

---

**Note** `AbsTol` and `RelTol` work together. `integral2` might satisfy the absolute error tolerance or the relative error tolerance, but not necessarily both. For more information on using these tolerances, see the “Tips” on page 2-2324 section.

---

**Example:** `'AbsTol', 1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

## Data Types

double | single

## RelTol - Relative error tolerance

nonnegative real number

Relative error tolerance, specified as the comma-separated pair consisting of `'RelTol'` and a nonnegative real number. `integral2` uses the relative error tolerance to limit an estimate of the relative error,  $|q - Q|/|Q|$ , where  $q$  is the computed value of the integral and  $Q$  is the (unknown) exact value. `integral2` might provide more significant digits of precision if you decrease the relative error tolerance. The default value is  $1e-6$ .

---

**Note** `RelTol` and `AbsTol` work together. `integral2` might satisfy the relative error tolerance or the absolute error tolerance, but not necessarily both. For more information on using these tolerances, see the “Tips” on page 2-2324 section.

---

**Example:** `'RelTol', 1e-9` sets the relative error tolerance to approximately 9 significant digits.

## Data Types

double | single

## Method - Integration method

'auto' (default) | 'tiled' | 'iterated'

Integration method, specified as the comma-separated pair consisting of 'Method' and one of the methods described below.

Integration Method	Description
'auto'	For most cases, <code>integral2</code> uses the 'tiled' method. It uses the 'iterated' method when any of the integration limits are infinite. This is the default method.
'tiled'	<code>integral2</code> transforms the region of integration to a rectangular shape and subdivides it into smaller rectangular regions as needed. The integration limits must be finite.
'iterated'	<code>integral2</code> calls <code>integral</code> to perform an iterated integral. The outer integral is evaluated over $x_{\min} \leq x \leq x_{\max}$ . The inner integral is evaluated over $y_{\min}(x) \leq y \leq y_{\max}(x)$ . The integration limits can be infinite.

**Example:** 'Method', 'tiled' specifies the tiled integration method.

## Output Arguments

### q - Computed integral

Computed integral of  $\text{fun}(x,y)$  over the specified region, returned as a numeric value.

# integral2

---

## Tips

- The `integral2` function attempts to satisfy:

$$\text{abs}(q - Q) \leq \max(\text{AbsTol}, \text{RelTol} * \text{abs}(q))$$

where  $q$  is the computed value of the integral and  $Q$  is the (unknown) exact value. The absolute and relative tolerances provide a way of trading off accuracy and computation time. Usually, the relative tolerance determines the accuracy of the integration. However if  $\text{abs}(q)$  is sufficiently small, the absolute tolerance determines the accuracy of the integration. You should generally specify both absolute and relative tolerances together.

- The `'iterated'` method can be more effective when your function has discontinuities within the integration region. However, the best performance and accuracy occurs when you split the integrand at the points of discontinuity and sum the results of multiple integrations.
- When integrating over nonrectangular regions, the best performance and accuracy occurs when `ymin`, `ymax`, (or both) are function handles. Avoid setting integrand function values to zero to integrate over a nonrectangular region. If you must do this, specify `'iterated'` method.
- Use the `'iterated'` method when `ymin`, `ymax`, (or both) are unbounded functions.
- When parameterizing anonymous functions, be aware that parameter values persist for the life of the function handle. For example, the function `fun = @(x,y) x + y + a` uses the value of `a` at the time `fun` was created. If you later decide to change the value of `a`, you must redefine the anonymous function with the new value.
- If you are specifying single-precision limits of integration, or if `fun` returns single-precision results, you might need to specify larger absolute and relative error tolerances.

## Examples

### Integrate Triangular Region with Singularity at the Boundary

The function

$$f(x, y) = \frac{1}{(\sqrt{x+y})(1+x+y)}$$

is undefined when  $x$  and  $y$  are zero. `integral2` performs best when singularities are on the integration boundary.

Create the anonymous function.

```
fun = @(x,y) 1./( sqrt(x + y) .* (1 + x + y).^2 )
```

Integrate over the triangular region bounded by  $0 \leq x \leq 1$  and  $0 \leq y \leq 1 - x$ .

```
ymax = @(x) 1 - x
q = integral2(fun,0,1,0,ymax)
```

```
q =
```

```
0.2854
```

## Evaluate Double Integral in Polar Coordinates

Define the function

$$f(\theta, r) = \frac{r}{\sqrt{r \cos \theta + r \sin \theta} (1 + r \cos \theta + r \sin \theta)^2}$$

```
fun = @(x,y) 1./( sqrt(x + y) .* (1 + x + y).^2 );
polarfun = @(theta,r) fun(r.*cos(theta),r.*sin(theta)).*r;
```

Define a function for the upper limit of  $r$ .

```
rmax = @(theta) 1./(sin(theta) + cos(theta));
```

Integrate over the region bounded by  $0 \leq \theta \leq \pi/2$  and  $0 \leq r \leq rmax$ .

```
q = integral2(polarfun,0,pi/2,0,rmax)
```

```
q =
```

0.2854

## Evaluate Double Integral of Parameterized Function with Specific Method and Error Tolerance

Create the anonymous parameterized function  $f(x,y) = ax^2 + by^2$  with parameters  $a=3$  and  $b=5$ .

```
a = 3; b = 5;  
fun = @(x,y) a*x.^2 + b*y.^2;
```

Evaluate the integral over the region  $0 \leq x \leq 5$  and  $-5 \leq y \leq 0$ . Specify the 'iterated' method and approximately 10 significant digits of accuracy.

```
format long  
q = integral2(fun,0,5,-5,0,'Method','iterated',...  
'AbsTol',0,'RelTol',1e-10)
```

q =

1.666666666666666e+03

### Concepts

- “Parameterizing Functions”

## Purpose

Numerically evaluate triple integral

## Syntax

```
q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax)
q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax,Name,Value)
```

## Description

`q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax)` approximates the integral of the function  $z = \text{fun}(x,y,z)$  over the region  $x_{\min} \leq x \leq x_{\max}$ ,  $y_{\min}(x) \leq y \leq y_{\max}(x)$  and  $z_{\min}(x,y) \leq z \leq z_{\max}(x,y)$ .

`q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax,Name,Value)` specifies additional options with one or more `Name,Value` pair arguments.

## Input Arguments

### **fun - Integrand**

function handle

Integrand, specified as a function handle, defines the function to be integrated over the region  $x_{\min} \leq x \leq x_{\max}$ ,  $y_{\min}(x) \leq y \leq y_{\max}(x)$ , and  $z_{\min}(x,y) \leq z \leq z_{\max}(x,y)$ . The function `fun` must accept three arrays of the same size and return an array of corresponding values. It must perform element-wise operations.

### **Data Types**

function\_handle

### **xmin - Lower limit of x**

real number

Lower limit of  $x$ , specified as a real scalar value that is either finite or infinite.

### **Example:**

### **Data Types**

double | single

### **xmax - Upper limit of x**

real number

Upper limit of  $x$ , specified as a real scalar value that is either finite or infinite.

### Data Types

double | single

### **ymin - Lower limit of y**

real number | function handle

Lower limit of  $y$ , specified as a real scalar value that is either finite or infinite. You also can specify `ymin` to be a function handle (a function of  $x$ ) when integrating over a nonrectangular region.

### Example:

### Data Types

double | function\_handle | single

### **ymax - Upper limit of y**

real number | function handle

Upper limit of  $y$ , specified as a real scalar value that is either finite or infinite. You also can specify `ymax` to be a function handle (a function of  $x$ ) when integrating over a nonrectangular region.

### Example:

### Data Types

double | function\_handle | single

### **zmin - Lower limit of z**

real number | function handle

Lower limit of  $z$ , specified as a real scalar value that is either finite or infinite. You also can specify `zmin` to be a function handle (a function of  $x,y$ ) when integrating over a nonrectangular region.

### Data Types

double | function\_handle | single

### **zmax - Upper limit of z**

real number | function handle

Upper limit of  $z$ , specified as a real scalar value that is either finite or infinite. You also can specify `zmax` to be a function handle (a function of  $x,y$ ) when integrating over a nonrectangular region.

### Data Types

double | function\_handle | single

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'AbsTol',1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

### AbsTol - Absolute error tolerance

nonnegative real number

Absolute error tolerance, specified as the comma-separated pair consisting of `'AbsTol'` and a nonnegative real number. `integral3` uses the absolute error tolerance to limit an estimate of the absolute error,  $|q - Q|$ , where  $q$  is the computed value of the integral and  $Q$  is the (unknown) exact value. `integral3` might provide more decimal places of precision if you decrease the absolute error tolerance. The default value is `1e-10`.

---

**Note** `AbsTol` and `RelTol` work together. `integral3` might satisfy the absolute error tolerance or the relative error tolerance, but not necessarily both. For more information on using these tolerances, see the “Tips” on page 2-2331 section.

---

**Example:** `'AbsTol',1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

# integral3

---

## Data Types

double | single

## RelTol - Relative error tolerance

nonnegative real number

Relative error tolerance, specified as the comma-separated pair consisting of 'RelTol' and a nonnegative real number. `integral3` uses the relative error tolerance to limit an estimate of the relative error,  $|q - Q|/|Q|$ , where  $q$  is the computed value of the integral and  $Q$  is the (unknown) exact value. `integral3` might provide more significant digits of precision if you decrease the relative error tolerance. The default value is  $1e-6$ .

---

**Note** `RelTol` and `AbsTol` work together. `integral3` might satisfy the relative error tolerance or the absolute error tolerance, but not necessarily both. For more information on using these tolerances, see the “Tips” on page 2-2331 section.

---

**Example:** `'RelTol', 1e-9` sets the relative error tolerance to approximately 9 significant digits.

## Data Types

double | single

## Method - Integration method

'auto' (default) | 'tiled' | 'iterated'

Integration method, specified as the comma-separated pair consisting of 'Method' and one of the methods described below.

Integration Method	Description
'auto'	For most cases, <code>integral3</code> uses the 'tiled' method. It uses the 'iterated' method when any of the integration limits are infinite. This is the default method.
'tiled'	<code>integral3</code> calls <code>integral</code> to integrate over $x_{\min} \leq x \leq x_{\max}$ . It calls <code>integral2</code> with the 'tiled' method to evaluate the double integral over $y_{\min}(x) \leq y \leq y_{\max}(x)$ and $z_{\min}(x,y) \leq z \leq z_{\max}(x,y)$ .
'iterated'	<code>integral3</code> calls <code>integral</code> to integrate over $x_{\min} \leq x \leq x_{\max}$ . It calls <code>integral2</code> with the 'iterated' method to evaluate the double integral over $y_{\min}(x) \leq y \leq y_{\max}(x)$ and $z_{\min}(x,y) \leq z \leq z_{\max}(x,y)$ . The integration limits can be infinite.

**Example:** 'Method', 'tiled' specifies the tiled integration method.

## Output Arguments

### q - Computed integral

Computed integral of `fun(x,y,z)` over the specified region, returned as a numeric value.

## Tips

- The `integral3` function attempts to satisfy:

$$\text{abs}(q - Q) \leq \max(\text{AbsTol}, \text{RelTol} * \text{abs}(q))$$

where `q` is the computed value of the integral and `Q` is the (unknown) exact value. The absolute and relative tolerances provide a way of trading off accuracy and computation time. Usually, the relative tolerance determines the accuracy of the integration. However if `abs(q)` is sufficiently small, the absolute tolerance determines the accuracy of the integration. You should generally specify both absolute and relative tolerances together.

# integral3

---

- The 'iterated' method can be more effective when your function has discontinuities within the integration region. However, the best performance and accuracy occurs when you split the integrand at the points of discontinuity and sum the results of multiple integrations.
- When integrating over nonrectangular regions, the best performance and accuracy occurs when any or all of the limits: `ymin`, `ymax`, `zmin`, `zmax` are function handles. Avoid setting integrand function values to zero to integrate over a nonrectangular region. If you must do this, specify 'iterated' method.
- Use the 'iterated' method when any or all of the limits: `ymin(x)`, `ymax(x)`, `zmin(x,y)`, `zmax(x,y)` are unbounded functions.
- When parameterizing anonymous functions, be aware that parameter values persist for the life of the function handle. For example, the function `fun = @(x,y,z) x + y + z + a` uses the value of `a` at the time `fun` was created. If you later decide to change the value of `a`, you must redefine the anonymous function with the new value.
- If you are specifying single-precision limits of integration, or if `fun` returns single-precision results, you may need to specify larger absolute and relative error tolerances.

## Examples

### Triple Integral with Finite Limits

Define the anonymous function  $f(x,y,z) = y \sin x + z \cos x$ .

```
fun = @(x,y,z) y.*sin(x)+z.*cos(x)
```

Integrate over the region  $0 \leq x \leq \pi$ ,  $0 \leq y \leq 1$ , and  $-1 \leq z \leq 1$ .

```
q = integral3(fun,0,pi,0,1,-1,1)
```

```
q =
```

```
2.0000
```

## Integral Over the Unit Sphere in Cartesian Coordinates

Define the anonymous function  $f(x,y,z) = x \cos y + x^2 \cos z$ .

```
fun = @(x,y,z) x.*cos(y) + x.^2.*cos(z)
```

Define the limits of integration.

```
xmin = -1;
xmax = 1;
ymin = @(x)-sqrt(1 - x.^2);
ymax = @(x) sqrt(1 - x.^2);
zmin = @(x,y)-sqrt(1 - x.^2 - y.^2);
zmax = @(x,y) sqrt(1 - x.^2 - y.^2);
```

Evaluate the definite integral with the 'tiled' method.

```
q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax,'Method','tiled')
```

```
q =
```

```
0.7796
```

## Evaluate Improper Triple Integral of Parameterized Function

Define the anonymous parameterized function  $f(x,y,z) = 10/(x^2 + y^2 + z^2 + a)$ .

```
a = 2;
f = @(x,y,z) 10./(x.^2 + y.^2 + z.^2 + a);
```

Evaluate the triple integral over the region  $-\infty \leq x \leq 0$ ,  $-100 \leq y \leq 0$ , and  $-100 \leq z \leq 0$ .

```
format long
q1 = integral3(f,-Inf,0,-100,0,-100,0)
```

```
q1 =
```

```
2.734244598320928e+03
```

# integral3

---

Evaluate the integral again and specify accuracy to approximately 9 significant digits.

```
q2 = integral3(f,-Inf,0,-100,0,-100,0,'AbsTol', 0,'RelTol',1e-9)
```

```
q2 =
```

```
2.734244599944285e+03
```

## Concepts

- “Parameterizing Functions”

**Purpose** List custom interfaces exposed by COM server object

**Syntax** `customlist = h.interfaces`  
`customlist = interfaces(h)`

**Description** `customlist = h.interfaces` returns cell array of strings `customlist` listing all custom interfaces implemented by the component in a specific COM server object. The server is designated by input argument `h`, the handle returned by the `actxcontrol` or `actxserver` function when creating that server.

`customlist = interfaces(h)` is an alternate syntax.

The `interfaces` function only lists the custom interfaces exposed by the object; it does not return interfaces. Use the `invoke` function to return a handle to a specific custom interface.

COM functions are available on Microsoft Windows systems only.

**See Also** `actxcontrol` | `actxserver` | `invoke` | `get (COM)`

**How To**

- “Custom Interfaces”

# interp1

---

**Purpose** 1-D data interpolation (table lookup)

---

**Note** If you pass non-uniformly spaced points and specify the 'v5cubic' method, `interp1` will now issue a warning. In addition, the following syntaxes will be removed or changed in a future release:

- `interp1(..., 'cubic')`
- `pp = interp1(..., 'pp')`
- `interp1(X, Y, Xq, [], ...)`
- `interp1(x, Y, ...)` where `x` is a vector and `Y` is an array representing multiple value sets.
- `interp1(..., *METHOD)`

For more information, and recommendations for updating your code, see “Interpolation and Computational Geometry Functionality Being Removed or Changed”.

---

**Syntax**

```
yi = interp1(x, Y, xi)
yi = interp1(Y, xi)
yi = interp1(x, Y, xi, method)
yi = interp1(x, Y, xi, method, 'extrap')
yi = interp1(x, Y, xi, method, extrapval)
pp = interp1(x, Y, method, 'pp')
```

**Description** `yi = interp1(x, Y, xi)` interpolates to find `yi`, the values of the underlying function `Y` at the points in the vector or array `xi`. `x` must be a vector. `Y` can be a scalar, a vector, or an array of any dimension, subject to the following conditions:

- If `Y` is a vector, it must have the same length as `x`. A scalar value for `Y` is expanded to have the same length as `x`. `xi` can be a scalar, a vector, or a multidimensional array, and `yi` has the same size as `xi`.

- If  $Y$  is an array that is not a vector, the size of  $Y$  must have the form  $[n, d1, d2, \dots, dk]$ , where  $n$  is the length of  $x$ . The interpolation is performed for each  $d1$ -by- $d2$ -by-...- $dk$  value in  $Y$ . The sizes of  $x_i$  and  $y_i$  are related as follows:
  - If  $x_i$  is a scalar or vector,  $\text{size}(y_i)$  equals  $[\text{length}(x_i), d1, d2, \dots, dk]$ .
  - If  $x_i$  is an array of size  $[m1, m2, \dots, mj]$ ,  $y_i$  has size  $[m1, m2, \dots, mj, d1, d2, \dots, dk]$ .

$y_i = \text{interp1}(Y, x_i)$  assumes that  $x = 1:N$ , where  $N$  is the length of  $Y$  for vector  $Y$ , or  $\text{size}(Y, 1)$  for matrix  $Y$ .

$y_i = \text{interp1}(x, Y, x_i, \text{method})$  interpolates using alternative methods:

'nearest'	Nearest neighbor interpolation
'linear'	Linear interpolation (default)
'spline'	Cubic spline interpolation
'pchip'	Piecewise cubic Hermite interpolation
'cubic'	(Same as 'pchip')
'v5cubic'	Cubic interpolation used in MATLAB 5. This method does not extrapolate. Also, if $x$ is not equally spaced, 'spline' is used.

For the 'nearest', 'linear', and 'v5cubic' methods,  $\text{interp1}(x, Y, x_i, \text{method})$  returns NaN for any element of  $x_i$  that is outside the interval spanned by  $x$ . For all other methods,  $\text{interp1}$  performs extrapolation for out of range values.

$y_i = \text{interp1}(x, Y, x_i, \text{method}, \text{'extrap'})$  uses the specified interpolation algorithm specified by  $\text{method}$  to perform extrapolation for out of range values.

$y_i = \text{interp1}(x, Y, x_i, \text{method}, \text{extrapval})$  returns the scalar  $\text{extrapval}$  for out of range values. NaN and 0 are often used for  $\text{extrapval}$ .

# interp1

`pp = interp1(x,Y,method,'pp')` uses the interpolation algorithm specified by `method` to generate the piecewise polynomial form (ppform) of `Y`. You can use any of the methods in the preceding table, except for 'v5cubic'. `pp` can then be evaluated via `ppval`. `ppval(pp,xi)` is the same as `interp1(x,Y,xi,method,'extrap')`.

The `interp1` command interpolates between data points. It finds values at intermediate points, of a one-dimensional function  $f(x)$  that underlies the data. This function is shown below, along with the relationship between vectors `x`, `Y`, `xi`, and `yi`.

Interpolation is the same operation as *table lookup*. Described in table lookup terms, the *table* is `[x,Y]` and `interp1` *looks up* the elements of `xi` in `x`, and, based upon their locations, returns values `yi` interpolated within the elements of `Y`.

## Examples

### Example 1

Generate a coarse sine curve and interpolate over a finer abscissa.

```
x = 0:10;  
y = sin(x);  
xi = 0:.25:10;  
yi = interp1(x,y,xi);  
plot(x,y,'o',xi,yi)
```

### Example 2

Here are two vectors representing the census years from 1900 to 1990 and the corresponding United States population in millions of people.

```
t = 1900:10:1990;
p = [75.995 91.972 105.711 123.203 131.669...
     150.697 179.323 203.212 226.505 249.633];
```

The expression `interp1(t,p,1975)` interpolates within the census data to estimate the population in 1975. The result is

```
ans =
    214.8585
```

Now interpolate within the data at every year from 1900 to 2000, and plot the result.

```
x = 1900:1:2000;
```

# interp1

```
y = interp1(t,p,x,'spline');  
plot(t,p,'o',x,y)
```

Sometimes it is more convenient to think of interpolation in table lookup terms, where the data are stored in a single table. If a portion of the census data is stored in a single 5-by-2 table,

```
tab =  
    1950    150.697  
    1960    179.323  
    1970    203.212  
    1980    226.505  
    1990    249.633
```

then the population in 1975, obtained by table lookup within the matrix `tab`, is

```
p = interp1(tab(:,1),tab(:,2),1975)
```

```
p =  
    214.8585
```

## Algorithms

The `interp1` command is written in MATLAB. The 'nearest' and 'linear' methods have straightforward implementations.

For the 'spline' method, `interp1` calls a function `spline` that uses the functions `ppval`, `mkpp`, and `unmkpp`. These routines form a small suite of functions for working with piecewise polynomials. The `spline` function uses them to perform the cubic spline interpolation. For access to more advanced features, see the `spline` reference page, the command-line help for these functions, and the Curve Fitting Toolbox™ spline functions.

For the 'pchip' and 'cubic' methods, `interp1` calls a function `pchip` that performs piecewise cubic interpolation within the vectors `x` and `y`. This method preserves monotonicity and the shape of the data. See the `pchip` reference page for more information.

`interpft` | `interp2` | `interp3` | `interpn` | `pchip` | `spline`

# interp1q

---

**Purpose** Quick 1-D linear interpolation

---

**Note** `interp1q` is not recommended. Use `interp1` instead.

---

**Syntax** `yi = interp1q(x,Y,xi)`

**Description** `yi = interp1q(x,Y,xi)` returns the value of the 1-D function `Y` at the points of column vector `xi` using linear interpolation. The vector `x` specifies the coordinates of the underlying interval. The length of output `yi` is equal to the length of `xi`.

`interp1q` is quicker than `interp1` on non-uniformly spaced data because it does no input checking.

For `interp1q` to work properly,

- `x` must be a monotonically increasing column vector.
- `Y` must be a column vector or matrix with `length(x)` rows.
- `xi` must be a column vector

`interp1q` returns NaN for any values of `xi` that lie outside the coordinates in `x`. If `Y` is a matrix, then the interpolation is performed for each column of `Y`, in which case `yi` is `length(xi)-by-size(Y,2)`.

**Examples** Generate a coarse sine curve and interpolate over a finer abscissa.

```
x = (0:10)';  
y = sin(x);  
xi = (0:.25:10)';  
yi = interp1q(x,y,xi);  
plot(x,y,'o',xi,yi)
```

**See Also**

[interp1](#) | [interp2](#) | [interp3](#) | [interpn](#)

# interp2

---

**Purpose** 2-D data interpolation (table lookup)

---

**Note** In a future release, `interp2` will not accept mixed combinations of row and column vectors for the sample and query grids. In addition, the following syntaxes will be removed or changed in a future release:

- `interp2(..., 'cubic')`
- `interp2(..., *METHOD)`

For more information, and recommendations for updating your code, see “Interpolation and Computational Geometry Functionality Being Removed or Changed”.

---

**Syntax**

```
ZI = interp2(X,Y,Z,XI,YI)
ZI = interp2(Z,XI,YI)
ZI = interp2(Z,ntimes)
ZI = interp2(X,Y,Z,XI,YI,method)
ZI = interp2(...,method, extrapval)
```

**Description** `ZI = interp2(X,Y,Z,XI,YI)` returns matrix `ZI` containing elements corresponding to the elements of `XI` and `YI` and determined by interpolation within the two-dimensional function specified by matrices `X`, `Y`, and `Z`. `X` and `Y` must be monotonic, and have the same format ("plaid") as if they were produced by `meshgrid`. Matrices `X` and `Y` specify the points at which the data `Z` is given. Out of range values are returned as `NaNs`.

`XI` and `YI` can be matrices, in which case `interp2` returns the values of `Z` corresponding to the points  $(XI(i, j), YI(i, j))$ . Alternatively, you can pass in the row and column vectors `xi` and `yi`, respectively. In this case, `interp2` interprets these vectors as if you issued the command `meshgrid(xi,yi)`.

`ZI = interp2(Z,XI,YI)` assumes that `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`.

`ZI = interp2(Z,ntimes)` expands `Z` by interleaving interpolates between every element, working recursively for `ntimes`. `interp2(Z)` is the same as `interp2(Z,1)`.

`ZI = interp2(X,Y,Z,XI,YI,method)` specifies an alternative interpolation method:

'nearest'	Nearest neighbor interpolation
'linear'	Linear interpolation (default)
'spline'	Cubic spline interpolation
'cubic'	Cubic interpolation, as long as data is uniformly-spaced. <code>interp2</code> switches to 'spline' and issues a warning if the data is not equally spaced.

All interpolation methods require that `X` and `Y` be monotonic, and have the same format (“plaid”) as if they were produced by `meshgrid`. If you provide two monotonic vectors, `interp2` changes them to a plaid internally. Variable spacing is handled by mapping the given values in `X`, `Y`, `XI`, and `YI` to an equally spaced domain before interpolating. For faster interpolation when `X` and `Y` are equally spaced and monotonic, use the methods `'*linear'`, `'*cubic'`, `'*spline'`, or `'*nearest'`.

`ZI = interp2(...,method, extrapval)` specifies a method and a scalar value for `ZI` outside of the domain created by `X` and `Y`. Thus, `ZI` equals `extrapval` for any value of `YI` or `XI` that is not spanned by `Y` or `X` respectively. A method must be specified to use `extrapval`. The default method is `'linear'`.

## Tips

The `interp2` command interpolates between data points. It finds values of a two-dimensional function  $f(x,y)$  underlying the data at intermediate points.

# interp2

Interpolation is the same operation as table lookup. Described in table lookup terms, the table is  $\text{tab} = [\text{NaN}, Y; X, Z]$  and `interp2` looks up the elements of  $XI$  in  $X$ ,  $YI$  in  $Y$ , and, based upon their location, returns values  $ZI$  interpolated within the elements of  $Z$ .

## Examples

### Example 1

Interpolate the peaks function over a finer grid.

```
[X,Y] = meshgrid(-3:.25:3);  
Z = peaks(X,Y);  
[XI,YI] = meshgrid(-3:.125:3);  
ZI = interp2(X,Y,Z,XI,YI);  
mesh(X,Y,Z), hold, mesh(XI,YI,ZI+15)  
hold off  
axis([-3 3 -3 3 -5 20])
```

### Example 2

Given this set of employee data,

```
years = 1950:10:1990;
service = 10:10:30;
wage = [150.697 199.592 187.625
179.323 195.072 250.287
203.212 179.092 322.767
226.505 153.706 426.730
249.633 120.281 598.243];
```

it is possible to interpolate to find the wage earned in 1975 by an employee with 15 years' service:

```
[X,Y] = meshgrid(service,years');
w = interp2(X,Y,wage,15,1975)
w =
    190.6288
```

# interp3

---

**Purpose** 3-D data interpolation (table lookup)

---

**Note** In a future release, `interp3` will not accept mixed combinations of row and column vectors for the sample and query grids. In addition, the following syntaxes will be removed or changed in a future release:

- `interp3(..., 'cubic')`
- `interp3(..., *METHOD)`

For more information, and recommendations for updating your code, see “Interpolation and Computational Geometry Functionality Being Removed or Changed”.

---

**Syntax**

```
VI = interp3(X,Y,Z,V,XI,YI,ZI)
VI = interp3(V,XI,YI,ZI)
VI = interp3(V,ntimes)
VI = interp3(...,method)
VI = interp3(...,method,extrapval)
```

**Description** `VI = interp3(X,Y,Z,V,XI,YI,ZI)` interpolates to find `VI`, the values of the underlying three-dimensional function `V` at the points in arrays `XI`, `YI` and `ZI`. `XI`, `YI`, `ZI` must be arrays of the same size, or vectors. Vector arguments that are not the same size, and have mixed orientations (i.e. with both row and column vectors) are passed through `meshgrid` to create the `Y1`, `Y2`, `Y3` arrays. Arrays `X`, `Y`, and `Z` specify the points at which the data `V` is given. Out of range values are returned as `NaN`.

`VI = interp3(V,XI,YI,ZI)` assumes `X=1:N`, `Y=1:M`, `Z=1:P` where `[M,N,P]=size(V)`.

`VI = interp3(V,ntimes)` expands `V` by interleaving interpolates between every element, working recursively for `ntimes` iterations. The command `interp3(V)` is the same as `interp3(V,1)`.

`VI = interp3(...,method)` specifies alternative methods:

'nearest'	Nearest neighbor interpolation
'linear'	Linear interpolation (default)
'spline'	Cubic spline interpolation
'cubic'	Cubic interpolation, as long as data is uniformly-spaced. <code>interp3</code> switches to 'spline' and issues a warning if the data is not equally spaced.

`VI = interp3(...,method,extrapval)` specifies a method and a value for `VI` outside of the domain created by `X`, `Y` and `Z`. Thus, `VI` equals `extrapval` for any value of `XI`, `YI` or `ZI` that is not spanned by `X`, `Y`, and `Z`, respectively. You must specify a method to use `extrapval`. The default method is 'linear'.

## Discussion

All the interpolation methods require that `X`, `Y` and `Z` be monotonic and have the same format ("plaid") as if they were created using `meshgrid`. `X`, `Y`, and `Z` can be non-uniformly spaced. For faster interpolation when `X`, `Y`, and `Z` are equally spaced and monotonic, use the methods '\*linear', '\*cubic', or '\*nearest'.

## Examples

To generate a coarse approximation of flow and interpolate over a finer mesh:

```
[x,y,z,v] = flow(10);
[xi,yi,zi] = meshgrid(.1:.25:10, -3:.25:3, -3:.25:3);
vi = interp3(x,y,z,v,xi,yi,zi); % vi is 25-by-40-by-25
slice(xi,yi,zi,vi,[6 9.5],2,[-2 .2]), shading flat
```

# interp3

---

# interp

---

**Purpose** N-D data interpolation (table lookup)

---

**Note** In a future release, `interp` will not accept mixed combinations of row and column vectors for the sample and query grids. In addition, the following syntaxes will be removed or changed in a future release:

- `interp(..., 'cubic')`
- `interp(..., *METHOD)`

For more information, and recommendations for updating your code, see “Interpolation and Computational Geometry Functionality Being Removed or Changed”.

---

**Syntax**

```
VI = interp(X1,X2,X3,...,V,Y1,Y2,Y3,...)
VI = interp(V,Y1,Y2,Y3,...)
VI = interp(V,ntimes)
VI = interp(...,method)
VI = interp(...,method,extrapval)
```

**Description** `VI = interp(X1,X2,X3,...,V,Y1,Y2,Y3,...)` interpolates to find `VI`, the values of the underlying multidimensional function `V` at the points in the arrays `Y1`, `Y2`, `Y3`, etc. For an `n`-dimensional array `V`, `interp` is called with `2*N+1` arguments. Arrays `X1`, `X2`, `X3`, etc. specify the points at which the data `V` is given. Out of range values are returned as NaNs. `Y1`, `Y2`, `Y3`, etc. must be arrays of the same size, or vectors. Vector arguments that are not the same size, and have mixed orientations (i.e. with both row and column vectors) are passed through `ndgrid` to create the `Y1`, `Y2`, `Y3`, etc. arrays. `interp` works for all `n`-dimensional arrays with 2 or more dimensions.

`VI = interp(V,Y1,Y2,Y3,...)` interpolates as above, assuming `X1 = 1:size(V,1)`, `X2 = 1:size(V,2)`, `X3 = 1:size(V,3)`, etc.

`VI = interp(V,ntimes)` expands `V` by interleaving interpolates between each element, working recursively for `ntimes` iterations. `interp(V)` is the same as `interp(V,1)`.

`VI = interpn(...,method)` specifies alternative methods:

'nearest'	Nearest neighbor interpolation
'linear'	Linear interpolation (default)
'spline'	Cubic spline interpolation
'cubic'	Cubic interpolation, as long as data is uniformly-spaced. <code>interp</code> switches to 'spline' and issues a warning if the data is not equally spaced.

`VI = interpn(...,method,extrapval)` specifies a method and a value for `VI` outside of the domain created by `X1, X2, ...`. Thus, `VI` equals `extrapval` for any value of `Y1, Y2,...` that is not spanned by `X1, X2,...` respectively. You must specify a method to use `extrapval`. The default method is 'linear'.

`interp` requires that `X1, X2, X3, ...` be monotonic and plaid (as if they were created using `ndgrid`). `X1, X2, X3`, and so on can be non-uniformly spaced.

## Discussion

All the interpolation methods require that `X1,X2, X3 ...` be monotonic and have the same format ("plaid") as if they were created using `ndgrid`. `X1,X2,X3,...` and `Y1, Y2, Y3, etc.` can be non-uniformly spaced. For faster interpolation when `X1, X2, X3, etc.` are equally spaced and monotonic, use the methods '\*linear', '\*cubic', or '\*nearest'.

## Examples

Start by defining an anonymous function to compute  $f = te^{-x^2-y^2-z^2}$ :

```
f = @(x,y,z,t) t.*exp(-x.^2 - y.^2 - z.^2);
```

Build the lookup table by evaluating the function `f` on a grid constructed by `ndgrid`:

```
[x,y,z,t] = ndgrid(-1:0.2:1,-1:0.2:1,-1:0.2:1,0:2:10);
v = f(x,y,z,t);
```

# interp

---

Now construct a finer grid:

```
[xi,yi,zi,ti] = ndgrid(-1:0.05:1,-1:0.08:1,-1:0.05:1, ...  
                      0:0.5:10);
```

Compute the spline interpolation at xi, yi, zi, and ti:

```
vi = interp(x,y,z,t,v,xi,yi,zi,ti,'spline');
```

Plot the interpolated function, and then create a movie from the plot:

```
nframes = size(ti, 4);  
for j = 1:nframes  
    slice(yi(:,:,:,j), xi(:,:,:,j), zi(:,:,:,j), ...  
          vi(:,:,:,j),0,0,0);  
    caxis([0 10]);  
    M(j) = getframe;  
end  
movie(M);
```

## See Also

[interp1](#) | [interp2](#) | [interp3](#) | [ndgrid](#)

# interpstreamspeed

---

**Purpose** Interpolate stream-line vertices from flow speed

**Syntax**

```
interpstreamspeed(X,Y,Z,U,V,W,vertices)
interpstreamspeed(U,V,W,vertices)
interpstreamspeed(X,Y,Z,speed,vertices)
interpstreamspeed(speed,vertices)
interpstreamspeed(X,Y,U,V,vertices)
interpstreamspeed(U,V,vertices)
interpstreamspeed(X,Y,speed,vertices)
interpstreamspeed(speed,vertices)
interpstreamspeed(...,sf)
vertsout = interpstreamspeed(...)
```

**Description** `interpstreamspeed(X,Y,Z,U,V,W,vertices)` interpolates streamline vertices based on the magnitude of the vector data `U, V, W`.

The arrays `X, Y, and Z`, which define the coordinates for `U, V, and W`, must be monotonic, but do not need to be uniformly spaced. `X, Y, and Z` must have the same number of elements, as if produced by `meshgrid`.

`interpstreamspeed(U,V,W,vertices)` assumes `X, Y, and Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p] = size(U)`.

`interpstreamspeed(X,Y,Z,speed,vertices)` uses the 3-D array `speed` for the speed of the vector field.

`interpstreamspeed(speed,vertices)` assumes `X, Y, and Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p]=size(speed)`.

`interpstreamspeed(X,Y,U,V,vertices)` interpolates streamline vertices based on the magnitude of the vector data `U, V`.

The arrays `X` and `Y`, which define the coordinates for `U` and `V`, must be monotonic, but do not need to be uniformly spaced. `X` and `Y` must have the same number of elements, as if produced by `meshgrid`.

`interpstreamspeed(U,V,vertices)` assumes `X` and `Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[M N]=size(U)`.

`interpstreamspeed(X,Y,speed,vertices)` uses the 2-D array `speed` for the speed of the vector field.

`interpstreamspeed(speed,vertices)` assumes `X` and `Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[M,N]= size(speed)`.

`interpstreamspeed(...,sf)` uses `sf` to scale the magnitude of the vector data and therefore controls the number of interpolated vertices. For example, if `sf` is 3, then `interpstreamspeed` creates only one-third of the vertices.

`vertsout = interpstreamspeed(...)` returns a cell array of vertex arrays.

## Examples

This example draws streamlines using the vertices returned by `interpstreamspeed`. Dot markers indicate the location of each vertex. This example enables you to visualize the relative speeds of the flow data. Streamlines having widely spaced vertices indicate faster flow; those with closely spaced vertices indicate slower flow.

```
load wind
[sx sy sz] = meshgrid(80,20:1:55,5);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
iverts = interpstreamspeed(x,y,z,u,v,w,verts,.2);
sl = streamline(iverts);
```

# interpstreamspeed

---

```
set(sl,'Marker','.')  
axis tight; view(2); daspect([1 1 1])
```

This example plots streamlines whose vertex spacing indicates the value of the gradient along the streamline.

```
z = membrane(6,30);  
[u v] = gradient(z);  
[verts averts] = streamslice(u,v);  
iverts = interpstreamspeed(u,v,verts,15);  
sl = streamline(iverts);  
set(sl,'Marker','.')  
hold on; pcolor(z); shading interp  
axis tight; view(2); daspect([1 1 1])
```

[stream2](#) | [stream3](#) | [streamline](#) | [streamslice](#) | [streamparticles](#)

# intersect

---

**Purpose** Find set intersection of two arrays

**Compatibility** In a future release, the behavior of `intersect` will change. This change is introduced for adoption in R2012a. For a detailed demonstration that shows how you can preview the future behavior and preserve the current behavior of your existing code, see the example, “Assessing the Impact of Forthcoming Changes to `intersect`” on page 2-2366. For a detailed explanation of all the forthcoming changes, see “Set Functions Changing Behavior in a Future Release”.

**Syntax**

```
C = intersect(A,B)
C = intersect(A,B,'rows')
[C,ia,ib] = intersect(A,B)
[C,ia,ib] = intersect(A,B,'rows')

[C,ia,ib] = intersect(__,'R2012a')

[C,ia,ib] = intersect(__,'legacy')

[C,ia,ib] = intersect(A,B,setOrder)

[C,ia,ib] = intersect(A,B,'rows',setOrder)
```

**Description** `C = intersect(A,B)` returns the values common to both A and B. The values of C are in sorted order.

`C = intersect(A,B,'rows')` returns the rows common to both A and B. The rows of the matrix C are in sorted order.

`[C,ia,ib] = intersect(A,B)` also returns index vectors `ia` and `ib`, such that `C = A(ia)` and `C = B(ib)`.

`[C,ia,ib] = intersect(A,B,'rows')` also returns index vectors `ia` and `ib`, such that `C = A(ia,:)` and `C = B(ib,:)`.

`[C,ia,ib] = intersect( __ , 'R2012a' )` adopts the future behavior of the `intersect` function. `[C,ia,ib] = intersect( __ , 'legacy' )` preserves the current behavior. You can specify either flag, 'R2012a' or 'legacy', as the final input argument in any previous syntax.

`[C,ia,ib] = intersect(A,B,setOrder)` and `[C,ia,ib] = intersect(A,B, 'rows',setOrder)` return `C` in a specific order. `setOrder='sorted'` returns the values (or rows) of `C` in sorted order. `setOrder='stable'` returns the values (or rows) of `C` in the same order as `A`, then `B`.

## Input Arguments

### A,B - Input arrays

vectors | matrices | N-D arrays

Input arrays of which to find the intersection, specified as `logical`, `char`, a cell array of strings, or any numeric class. `A` and `B` also can be any object with the class methods: `sort` (or `sortrows` for the 'rows' option), `eq`, and `ne`. This includes heterogeneous arrays derived from the same root class.

`A` and `B` must be of the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with double arrays.
- Cell arrays of strings can combine with `char` arrays.

If you specify the 'rows' option, `A` and `B` must have the same number of columns.

### Data Types

`double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

**Complex Number Support:** Yes

### 'rows' - Rows flag

Rows flag, specified as 'rows', identifies the rows of `A` and `B` as individual elements. When you specify this flag, `intersect` returns the rows common to both `A` and `B`. This option does not support cell arrays.

# intersect

---

## setOrder - Order flag

'sorted' | 'stable'

Order flag, specified as 'sorted' or 'stable', indicates the order of the values (or rows) in C.

Order Flag	Meaning
'sorted'	The values (or rows) in C, are returned in sorted order. For example: <code>C = intersect([7 0 5],[7 1 5],'sorted')</code> returns <code>C = [5 7]</code> .
'stable'	The values (or rows) in C, are returned in the same order as they appear in A and B. For example: <code>C = intersect([7 0 5],[7 1 5],'stable')</code> returns <code>C = [7 5]</code> .

## 'legacy' - Legacy behavior flag

Legacy behavior flag, when specified, preserves the current behavior. If the new behavior adversely affects your existing code, you can preserve the current behavior by specifying 'legacy' as the final argument.

## 'R2012a' - Future behavior flag

Future behavior flag, when specified, adopts the future behavior change. Specify 'R2012a' as the final argument to see what impact the new behavior has on your existing code.

## Output Arguments

### C - Values common to A and B

vector | matrix

Values common to A and B, returned as a vector or matrix. C is a vector unless you specify the 'rows' flag. If 'rows' is specified, C is a matrix containing the rows common to both A and B.

## ia - Index to A

vector

Index to A, returned as a vector, identifies the elements in A that are common to B. If there is a repeated value (or row) in A, then ia contains the index to the last occurrence of the value (or row).

If you call `intersect` with the `setOrder` or 'R2012a' argument, ia contains the index to the first occurrence of any repeated value (or row) in A.

## ib - Index to B

vector

Index to B, returned as a vector, identifies the elements in B that are common to A. If there is a repeated value (or row) in B, then ib contains the index to the last occurrence of the value (or row).

If you call `intersect` with the `setOrder` or 'R2012a' argument, ib contains the index to the first occurrence of any repeated value (or row) in B.

## Examples

### Intersection of Two Vectors

```
A = [7 1 7 7 4]; B = [7 0 4 4 0];
C = intersect(A,B)
```

```
C =
```

```
4 7
```

### Find the Intersection of Two Vectors and Their Indices

```
A = [7 1 7 7 4]; B = [7 0 4 4 0];
[C,ia,ib] = intersect(A,B)
```

```
C =
```

```
4 7
```

# intersect

---

```
ia =
```

```
5 4
```

```
ib =
```

```
4 1
```

## Intersection of Rows in Two Matrices

```
A = [2 2 2; 0 0 1; 1 2 3; 1 1 1];
```

```
B = [1 2 3; 2 2 2; 2 2 0];
```

```
[C,ia,ib] = intersect(A,B,'rows')
```

```
C =
```

```
1 2 3  
2 2 2
```

```
ia =
```

```
3  
1
```

```
ib =
```

```
1  
2
```

A and B do not need to have the same number of rows, but they must have the same number of columns.

## Intersection with Specified Output Order

Use the `setOrder` argument to specify the ordering of the values in C.

Specify 'stable' if you want the values in **C** to have the same order as in **A**.

```
A = [7 1 7 7 4]; B = [7 0 4 4 0];  
[C,ia,ib] = intersect(A,B,'stable')
```

```
C =
```

```
     7     4
```

```
ia =
```

```
     1  
     5
```

```
ib =
```

```
     1  
     3
```

Alternatively, you can specify 'sorted' order.

```
[C,ia,ib] = intersect(A,B,'sorted')
```

```
C =
```

```
     4     7
```

```
ia =
```

```
     5  
     1
```

```
ib =
```

# intersect

---

```
3  
1
```

`intersect` adopts the forthcoming behavior when you specify the `setOrder` argument. If you omit the `setOrder` argument, the output is sorted, but the size and content of `C`, `ia`, and `ib` conforms to the current behavior.

## Assessing the Impact of Forthcoming Changes to `intersect`

Use the 'R2012a' flag to assess the impact of the forthcoming behavior changes. Use the 'legacy' flag to preserve the current behavior of your existing code.

Find the intersection of A and B with the current default behavior.

```
A = [7 1 7 7 4]; B = [7 0 4 4 0];  
[C1,ia1,ib1] = intersect(A,B)
```

```
C1 =
```

```
4 7
```

```
ia1 =
```

```
5 4
```

```
ib1 =
```

```
4 1
```

Find the intersection of A and B, and opt into the forthcoming behavior. In the future, this behavior will be the default.

```
[C2,ia2,ib2] = intersect(A,B,'R2012a')
```

```
C2 =
     4     7
```

```
ia2 =
     5
     1
```

```
ib2 =
     3
     1
```

Notice that `ia1` and `ia2` have different shapes and content. The same is also true for `ib1` and `ib2`.

Find the unique elements of `A`, and preserve the current behavior.

```
[C3,ia3,ib3] = intersect(A,B,'legacy')
```

```
C3 =
     4     7
```

```
ia3 =
     5     4
```

```
ib3 =
     4     1
```

Notice that `C3`, `ia3`, and `ib3` match `C1`, `ia1`, and `ib1` respectively.

# intersect

---

## Intersection of Vectors Containing NaNs

```
A = [5 NaN NaN]; B = [5 NaN NaN];  
C = intersect(A,B)
```

```
C =
```

```
    5
```

intersect treats NaN values as distinct.

## See Also

[unique](#) | [union](#) | [ismember](#) | [issorted](#) | [setdiff](#) | [setxor](#) | [sort](#)

**Purpose** Largest value of specified integer type

**Syntax**

```
v = intmax
v = intmax('classname')
```

**Description** `v = intmax` is the largest positive value that can be represented in the MATLAB software with a 32-bit integer. Any value larger than the value returned by `intmax` saturates to the `intmax` value when cast to a 32-bit integer.

`v = intmax('classname')` is the largest positive value in the integer class `classname`. Valid values for the string `classname` are

'int8'	'int16'	'int32'	'int64'
'uint8'	'uint16'	'uint32'	'uint64'

`intmax('int32')` is the same as `intmax` with no arguments.

**Examples** Find the maximum value for a 64-bit signed integer:

```
v = intmax('int64')
v =
    9223372036854775807
```

Convert this value to a 32-bit signed integer:

```
x = int32(v)
x =
    2147483647
```

Compare the result with the default value returned by `intmax`:

```
isequal(x, intmax)
ans =
     1
```

**See Also** `intmin` | `realmax` | `realmin` | `int8` | `uint8` | `isa` | `class`

# intmin

---

**Purpose** Smallest value of specified integer type

**Syntax**  
`v = intmin`  
`v = intmin('classname')`

**Description** `v = intmin` is the smallest value that can be represented in the MATLAB software with a 32-bit integer. Any value smaller than the value returned by `intmin` saturates to the `intmin` value when cast to a 32-bit integer.

`v = intmin('classname')` is the smallest positive value in the integer class `classname`. Valid values for the string `classname` are

'int8'	'int16'	'int32'	'int64'
'uint8'	'uint16'	'uint32'	'uint64'

`intmin('int32')` is the same as `intmin` with no arguments.

## Examples

Find the minimum value for a 64-bit signed integer:

```
v = intmin('int64')
v =
-9223372036854775808
```

Convert this value to a 32-bit signed integer:

```
x = int32(v)
x =
2147483647
```

Compare the result with the default value returned by `intmin`:

```
isequal(x, intmin)
ans =
1
```

## See Also

`intmax` | `realmin` | `realmax` | `int8` | `uint8` | `isa` | `class`

**Purpose** Matrix inverse

**Syntax**  $Y = \text{inv}(X)$

**Description**  $Y = \text{inv}(X)$  returns the inverse of the square matrix  $X$ . A warning message is printed if  $X$  is badly scaled or nearly singular.

In practice, it is seldom necessary to form the explicit inverse of a matrix. A frequent misuse of `inv` arises when solving the system of linear equations  $Ax = b$ . One way to solve this is with  $x = \text{inv}(A) * b$ . A better way, from both an execution time and numerical accuracy standpoint, is to use the matrix division operator  $x = A \backslash b$ . This produces the solution using Gaussian elimination, without forming the inverse. See `mldivide (\)` for further information.

## Examples

Here is an example demonstrating the difference between solving a linear system by inverting the matrix with  $\text{inv}(A) * b$  and solving it directly with  $A \backslash b$ . A random matrix  $A$  of order 500 is constructed so that its condition number,  $\text{cond}(A)$ , is  $1.e10$ , and its norm,  $\text{norm}(A)$ , is 1. The exact solution  $x$  is a random vector of length 500 and the right-hand side is  $b = A * x$ . Thus the system of linear equations is badly conditioned, but consistent.

On a 300 MHz, laptop computer the statements

```
n = 500;
Q = orth(randn(n,n));
d = logspace(0, -10, n);
A = Q*diag(d)*Q';
x = randn(n,1);
b = A*x;
tic, y = inv(A)*b; toc
err = norm(y-x)
res = norm(A*y-b)
```

produce

```
elapsed_time =
```

```
1.4320
err =
7.3260e-006
res =
4.7511e-007
```

while the statements

```
tic, z = A\b, toc
err = norm(z-x)
res = norm(A*z-b)
```

produce

```
elapsed_time =
0.6410
err =
7.1209e-006
res =
4.4509e-015
```

It takes almost two and one half times as long to compute the solution with `y = inv(A)*b` as with `z = A\b`. Both produce computed solutions with about the same error,  $1.e-6$ , reflecting the condition number of the matrix. But the size of the residuals, obtained by plugging the computed solution back into the original equations, differs by several orders of magnitude. The direct solution produces residuals on the order of the machine accuracy, even though the system is badly conditioned.

The behavior of this example is typical. Using `A\b` instead of `inv(A)*b` is two to three times as fast and produces residuals on the order of machine accuracy, relative to the magnitude of the data.

# invoke

---

**Purpose** Invoke method on COM object or interface, or display methods

**Syntax**

```
S = h.invoke
S = h.invoke('methodname')
S = h.invoke('methodname',arg1,arg2, ...)
S = h.invoke('custominterfacename')
S = invoke(h,...)
```

**Description** `S = h.invoke` returns structure array `S` containing a list of all methods supported by the object or interface, `h`, along with the prototypes for these methods. If `S` is empty, either there are no properties or methods in the object, or the MATLAB software cannot read the object's type library. Refer to the COM vendor's documentation.

`S = h.invoke('methodname')` invokes the method specified in the string `methodname`, and returns an output value, if any, in `S`. The data type of the return value depends on the invoked method, which is determined by the control or server.

`S = h.invoke('methodname',arg1,arg2, ...)` invokes the method specified in the string `methodname` with input arguments `arg1`, `arg2`, etc.

`S = h.invoke('custominterfacename')` returns an `Interface` object `S`, which is a handle to a custom interface implemented by the COM component. The `h` argument is a handle to the COM object. The `custominterfacename` argument is a string returned by the `interfaces` function.

`S = invoke(h, ...)` is an alternate syntax. For Automation objects, if the vendor provides documentation for specific properties or methods, use the `S = invoke(h, ...)` syntax to call them.

If the method returns a COM interface, then `invoke` returns a new MATLAB COM object that represents the interface returned. For a description of how MATLAB converts COM types, see "Handling COM Data in MATLAB Software".

COM functions are available on Microsoft Windows systems only.

## Examples

Invoke the Redraw method in the mwsamp control:

```
f = figure ('position', [100 200 200 200]);  
h = actxcontrol ('mwsamp.mwsampctrl.1', [0 0 200 200], f);  
h.Radius = 100;  
h.invoke('Redraw');
```

---

Call the method directly:

```
h.Redraw;
```

---

Display all mwsamp methods:

```
h.invoke
```

MATLAB displays (in part):

```
ans =  
  AboutBox = void AboutBox(handle)  
  Beep = void Beep(handle)  
  FireClickEvent = void FireClickEvent(handle)  
  .  
  .
```

## Getting a Custom Interface Example

Once you have created a COM server, you can query the server component to see if any custom interfaces are implemented. Use the `interfaces` function to return a list of all available custom interfaces:

```
h = actxserver('mytestenv.calculator');  
customlist = h.interfaces
```

MATLAB displays:

```
customlist =  
  ICalc1
```

# invoke

---

```
ICalc2  
ICalc3
```

To get a handle to the custom interface you want, use the `invoke` function, specifying the handle returned by `actxcontrol` or `actxserver` and also the name of the custom interface:

```
c1 = h.invoke('ICalc1')
```

MATLAB displays:

```
c1 =  
    Interface.Calc_1.0_Type_Library.ICalc_Interface
```

You can now use this handle with most of the COM client functions to access the properties and methods of the object through the selected custom interface.

## How To

- “Handling COM Data in MATLAB Software”
- “Custom Interfaces”

**Purpose** Inverse permute dimensions of N-D array

**Syntax** `A = ipermute(B,order)`

**Description** `A = ipermute(B,order)` is the inverse of `permute`. `ipermute` rearranges the dimensions of `B` so that `permute(A,order)` will produce `B`. `B` has the same values as `A` but the order of the subscripts needed to access any particular element are rearranged as specified by `order`. All the elements of `order` must be unique.

**Tips** `permute` and `ipermute` are a generalization of transpose (`.'`) for multidimensional arrays.

**Examples** Consider the 2-by-2-by-3 array `a`:

```
a = cat(3,eye(2),2*eye(2),3*eye(2))
```

```
a(:,:,1) =           a(:,:,2) =
     1     0           2     0
     0     1           0     2
```

```
a(:,:,3) =
     3     0
     0     3
```

Permuting and inverse permuting `a` in the same fashion restores the array to its original form:

```
B = permute(a,[3 2 1]);
C = ipermute(B,[3 2 1]);
isequal(a,C)
ans=
```

```
1
```

**See Also** `permute`

**Purpose** Detect state

**Description** These functions detect the state of MATLAB entities:

isa	Detect object of given MATLAB class or Java class
isappdata	Determine if object has specific application-defined data
iscell	Determine if input is cell array
iscellstr	Determine if input is cell array of strings
ischar	Determine if input is character array
iscom	Determine if input is Component Object Model (COM) object
isdir	Determine if input is folder
isempty	Determine if input is empty array
isequal	Determine if arrays are numerically equal
isequaln	Determine if arrays are numerically equal, treating NaNs as equal
isevent	Determine if input is Component Object Model (COM) object event
isfield	Determine if input is MATLAB structure array field
isfinite	Detect finite elements of array
isfloat	Determine if input is floating-point array
isglobal	Determine if input is global variable
ishandle	Detect valid graphics object handles
ishold	Determine if graphics hold state is on
isinf	Detect infinite elements of array
isinteger	Determine if input is integer array

isinterface	Determine if input is Component Object Model (COM) interface
isjava	Determine if input is Java object
iskeyword	Determine if input is MATLAB keyword
isletter	Detect elements that are alphabetic letters
islogical	Determine if input is logical array
ismac	Determine if running MATLAB for Macintosh OS X platform
ismember	Detect members of specific set
ismethod	Determine if input is object method
isnan	Detect elements of array that are not a number (NaN)
isnumeric	Determine if input is numeric array
isobject	Determine if input is MATLAB object
ispc	Determine if running MATLAB for PC (Windows) platform
isprime	Detect prime elements of array
isprop	Determine if input is object property
isreal	Determine if all array elements are real numbers
isscalar	Determine if input is scalar
issorted	Determine if set elements are in sorted order
isspace	Detect space characters in array
issparse	Determine if input is sparse array
isstrprop	Determine if string is of specified category
isstruct	Determine if input is MATLAB structure array
isstudent	Determine if Student Version of MATLAB

## is\*

---

isunix	Determine if running MATLAB for UNIX <sup>6</sup> platform.
isvarname	Determine if input is valid variable name
isvector	Determine if input is vector

### See Also

isa | exist

6. UNIX is a registered trademark of The Open Group in the United States and other countries.

**Purpose** Determine if input is object of specified class

**Syntax**

```
tf = isa(obj, 'ClassName')  
tf = isa(obj, 'classCategory')
```

**Description** `tf = isa(obj, 'ClassName')` returns true if `obj` is an instance of the class specified by `ClassName`, and false otherwise. `isa` also returns true if `obj` is an instance of a class that is derived from `ClassName`.

`obj` can be any MATLAB variable.

`ClassName` can be any of the following:

- Name of any MATLAB class or fundamental type
- Name of a Java, or .NET class

### **MATLAB Fundamental Types**

<code>logical</code>	Logical array of true and false values
<code>char</code>	Character array
<code>single</code>	Single-precision floating-point array
<code>double</code>	Double-precision floating-point array
<code>int8</code>	8-bit signed integer array
<code>uint8</code>	8-bit unsigned integer array
<code>int16</code>	16-bit signed integer array
<code>uint16</code>	16-bit unsigned integer array
<code>int32</code>	32-bit signed integer array
<code>uint32</code>	32-bit unsigned integer array
<code>int64</code>	64-bit signed integer array
<code>uint64</code>	64-bit unsigned integer array
<code>cell</code>	Cell array

`struct`            Structure array  
`function_handle`   Function handle

`tf = isa(obj, 'classCategory')` returns `true` if `obj` is an instance of any of the classes in the specified `classCategory`, and `false` otherwise. `isa` also returns `true` if `obj` is an instance of a class that is derived from any of the classes in `classCategory`.

`classCategory` can be `'numeric'`, `'float'`, or `'integer'`, representing a category of numeric types:

## Categories of Numeric Types

<code>numeric</code>	Integer or floating-point array ( <code>double</code> , <code>single</code> , <code>int8</code> , <code>uint8</code> , <code>int16</code> , <code>uint16</code> , <code>int32</code> , <code>uint32</code> , <code>int64</code> , <code>uint64</code> )
<code>float</code>	Single- or double-precision floating-point array ( <code>double</code> , <code>single</code> )
<code>integer</code>	Signed or unsigned integer array ( <code>int8</code> , <code>uint8</code> , <code>int16</code> , <code>uint16</code> , <code>int32</code> , <code>uint32</code> , <code>int64</code> , <code>uint64</code> )

To test for a sparse array, use `issparse`. To test for a complex array, use `~isreal`.

## Examples

These examples show the values returned by `isa` when passed different types:

Determine if the value returned by the `pi` function is of class `double`:

```
isa(pi, 'double')  
ans =  
     1
```

More generally, determine if the value returned by the `pi` function is a numeric value:

```
isa(pi, 'numeric')
```

```
ans =  
    1
```

`isa` also returns `true` for the `float` category because the class `double` is a floating-point type. However, `pi` does not return an integer type:

```
isa(pi, 'integer')  
ans =  
    0
```

Determine if the 2-by-3 array returned by `true` is of type `logical`:

```
isa(true(2,3), 'logical')  
ans =  
    1
```

Identify an instance of the MATLAB `containers.Map` class:

```
mapObj = containers.Map({'Color', 'RGB'}, ...  
    {'Yellow', uint8([255,255,0])});  
isa(mapObj, 'containers.Map')  
ans =  
    1
```

The map key, `RGB`, references a `uint8` array:

```
isa(mapObj('RGB'), 'integer')  
ans =  
    1
```

Specifying a particular integer class provides more specific testing:

```
if strcmp(mapObj('Color'), 'Yellow') && isa(mapObj('RGB'), 'uint8')  
    % The Color is Yellow and the RGB numbers are uint8 values  
    ...  
end
```

# isappdata

---

<b>Purpose</b>	True if application-defined data exists
<b>Syntax</b>	<code>isappdata(h,name)</code>
<b>Description</b>	<code>isappdata(h,name)</code> returns 1 if application-defined data with the specified name exists on the object specified by handle <code>h</code> , and returns 0 otherwise.
<b>Tips</b>	Application data is data that is meaningful to or defined by your application which you attach to a figure or any GUI component (other than ActiveX controls) through its <code>AppData</code> property. Only Handle Graphics MATLAB objects use this property.
<b>See Also</b>	<code>getappdata</code>   <code>rmappdata</code>   <code>setappdata</code>

**Purpose** Determine whether input is cell array

**Syntax** `tf = iscell(A)`

**Description** `tf = iscell(A)` returns logical 1 (true) if A is a cell array and logical 0 (false) otherwise.

**Examples**

```
A{1,1} = [1 4 3; 0 5 8; 7 2 9];  
A{1,2} = 'Anne Smith';  
A{2,1} = 3+7i;  
A{2,2} = -pi:pi/10:pi;
```

```
iscell(A)
```

```
ans =
```

```
1
```

**See Also** `cell` | `iscellstr` | `isstruct` | `isnumeric` | `islogical` | `isobject`  
| `isa` | `is*`

# iscellstr

---

**Purpose** Determine whether input is cell array of strings

**Syntax** `tf = iscellstr(A)`

**Description** `tf = iscellstr(A)` returns logical 1 (true) if A is a cell array of strings (or an empty cell array), and logical 0 (false) otherwise. A cell array of strings is a cell array where every element is a character array.

**Examples**

```
A{1,1} = 'Thomas Lee';  
A{1,2} = 'Marketing';  
A{2,1} = 'Allison Jones';  
A{2,2} = 'Development';
```

```
iscellstr(A)
```

```
ans =
```

```
1
```

**See Also** `cellstr` | `iscell` | `isstrprop` | `strings` | `char` | `isstruct` | `isa` | `is*`

**Purpose** Determine whether item is character array

**Syntax** `tf = ischar(A)`

**Description** `tf = ischar(A)` returns logical 1 (true) if A is a character array and logical 0 (false) otherwise.

**Examples** Given the following cell array,

```
C{1,1} = magic(3);           % double array
C{1,2} = 'John Doe';       % char array
C{1,3} = 2 + 4i            % complex double
```

C =

```
      [3x3 double]      'John Doe'      [2.0000+ 4.0000i]
```

`ischar` shows that only `C{1,2}` is a character array.

```
for k = 1:3
x(k) = ischar(C{1,k});
end
```

x

x =

```
      0      1      0
```

**See Also** `char` | `strings` | `isletter` | `isspace` | `isstrprop` | `iscellstr` | `isnumeric` | `isa` | `is*`

# iscolumn

---

**Purpose** Determine whether input is column vector

**Syntax** `iscolumn(V)`

**Description** `iscolumn(V)` returns logical 1 (true) if `size(V)` returns `[n 1]` with a nonnegative integer value `n`, and logical 0 (false) otherwise.

**Examples** Determine if a vector is a column. This example is a row so `iscolumn` returns 0:

```
V = rand(1,5);  
iscolumn(V)  
ans =  
    0
```

Transpose the vector to make it a column. `iscolumn` returns 1:

```
V1 = V';  
iscolumn(V1)  
ans =  
    1
```

**See Also** `ismatrix` | `isrow` | `isscalar` | `isvector`

<b>Purpose</b>	Determine whether input is COM or ActiveX object
<b>Syntax</b>	<pre>tf = h.iscom tf = iscom(h)</pre>
<b>Description</b>	<p><code>tf = h.iscom</code> returns logical 1 (true) if handle <code>h</code> is a COM or Microsoft ActiveX object. Otherwise, returns logical 0 (false).</p> <p><code>tf = iscom(h)</code> is an alternate syntax.</p> <p>COM functions are available on Microsoft Windows systems only.</p>
<b>Examples</b>	<p>Test an instance of a Microsoft Excel application:</p> <pre>h = actxserver('Excel.Application'); h.iscom</pre> <p>MATLAB displays <code>true</code>, indicating object <code>h</code> is a COM object.</p> <hr/> <p>Test an Excel interface:</p> <pre>h = actxserver('Excel.Application'); %Create a workbooks object w = h.get('workbooks'); w.iscom</pre> <p>MATLAB displays <code>false</code>, indicating object <code>w</code> is not a COM object.</p>
<b>How To</b>	<ul style="list-style-type: none"><li>• “MATLAB COM Integration”</li></ul>

# isdir

---

**Purpose** Determine whether input is folder

**Syntax** `tf = isdir('A')`

**Description** `tf = isdir('A')` returns logical 1 (true) if A is a folder. Otherwise, it returns logical 0 (false).

**Examples** Run:  
`tf=isdir('myfiles/results')`

MATLAB returns

```
tf =  
    1
```

indicating that myfiles/results is a folder.

**See Also** `dir` | `is*`

<b>Purpose</b>	Test if vertices are joined by edge	
<b>Syntax</b>	TF = isEdge(TR, V1, V2) TF = isEdge(TR, EDGE)	
<b>Description</b>	TF = isEdge(TR, V1, V2) returns an array of 1/0 (true/false) flags, where each entry TF(i) is true if V1(i), V2(i) is an edge in the triangulation. V1, V2 are column vectors representing the indices of the vertices in the mesh, that is, indices into the vertex coordinate arrays.  TF = isEdge(TR, EDGE) specifies the edge start and end indices in matrix format.	
<b>Input Arguments</b>	TR	Triangulation representation.
	V1, V2	Column vectors of mesh vertices.
	EDGE	Matrix of size n-by-2 where n is the number of query edges.
<b>Output Arguments</b>	TF	Array of 1/0 (true/false) flags, where each entry TF(i) is true if V1(i), V2(i) is an edge in the triangulation.
<b>Examples</b>	<b>Example 1</b>	
		Load a 2-D triangulation and use TriRep to query the presence of an edge between pairs of points.
		<pre>load trimesh2d trep = TriRep(tri, x,y);</pre>
		Test if vertices 3 and 117 are connected by an edge
		<pre>isEdge(trep, 3, 117)</pre>

Test if vertices 3 and 164 are connected by an edge

```
isEdge(trep, 3, 164)
```

## **Example 2**

Direct query of a 3-D Delaunay triangulation created using DelaunayTri.

```
X = rand(10,3)  
dt = DelaunayTri(X)
```

Test if vertices 2 and 7 are connected by an edge

```
isEdge(dt, 2, 7);
```

## **See Also**

DelaunayTri

<b>Purpose</b>	Determine whether array is empty
<b>Syntax</b>	<code>TF = isempty(A)</code>
<b>Description</b>	<code>TF = isempty(A)</code> returns logical 1 (true) if <code>A</code> is an empty array and logical 0 (false) otherwise. An empty array has at least one dimension of size zero, for example, 0-by-0 or 0-by-5.
<b>Examples</b>	<pre>B = rand(2,2,2); B(:,:,:) = [];  isempty(B)  ans = 1</pre>
<b>See Also</b>	<code>is*</code>

# isempty (tscollection)

---

**Purpose** Determine whether tscollection object is empty

**Syntax** isempty(tsc)

**Description** isempty(tsc) returns a logical value for tscollection object tsc, as follows:

- 1 — When tsc contains neither timeseries members nor a time vector
- 0 — When tsc contains either timeseries members or a time vector

**See Also** timeseries | tscollection | length (tscollection) | size (tscollection)

**Purpose** Test arrays for equality

**Syntax** `tf = isequal(A, B, ...)`

**Description** `tf = isequal(A, B, ...)` returns logical 1 (true) if the input arrays have the same contents, and logical 0 (false) otherwise. Nonempty arrays must be of the same data type and size.

**Tips** When comparing structures, the order in which the fields of the structures were created is not important. As long as the structures contain the same fields, with corresponding fields set to equal values, `isequal` considers the structures to be equal. See Example 2, below.

When comparing numeric values, `isequal` does not consider the data type used to store the values in determining whether they are equal. See Example 3, below. This is also true when comparing numeric values with certain nonnumeric values, such as logical true and 1, or the character A and its numeric equivalent, 65.

When comparing handle objects, use `eq` or the `==` operator to test whether objects are the same handle. Use `isequal` to test if objects have equal property values, even if those objects are different handles.

NaNs (Not a Number), by definition, are not equal. Therefore, arrays that contain NaN elements are not equal, and `isequal` returns zero when comparing such arrays. See Example 4, below. Use the `isequaln` function when you want to test for equality with NaNs treated as equal.

`isequal` recursively compares the contents of cell arrays and structures. If all the elements of a cell array or structure are numerically equal, `isequal` returns logical 1.

## Examples

### Example 1

Given

A =			B =			C =		
	1	0		1	0		1	0
	0	1		0	1		0	0

# isequal

---

`isequal(A,B,C)` returns 0, and `isequal(A,B)` returns 1.

## Example 2

When comparing structures with `isequal`, the order in which the fields of the structures were created is not important:

```
A.f1 = 25;    A.f2 = 50
```

```
A =  
    f1: 25  
    f2: 50
```

```
B.f2 = 50;    B.f1 = 25
```

```
B =  
    f2: 50  
    f1: 25
```

```
isequal(A, B)
```

```
ans =  
     1
```

## Example 3

When comparing numeric values, the data types used to store the values are not important:

```
A = [25 50];    B = [int8(25) int8(50)];
```

```
isequal(A, B)
```

```
ans =  
     1
```

## Example 4

Arrays that contain NaN (Not a Number) elements cannot be equal, since NaNs, by definition, are not equal:

```
A = [32 8 -29 NaN 0 5.7];
```

```
B = A;
```

```
isequal(A, B)
ans =
    0
```

## See Also

[isequaln](#) | [eq](#) | [strcmp](#) | [isa](#) | [is\\*](#) | [relational operators](#)

# isequaln

---

## Purpose

Test arrays for equality, treating NaN values as equal

## Syntax

```
tf = isequaln(A,B)
tf = isequaln(A1,A2,...,An)
```

## Description

`tf = isequaln(A,B)` returns true if A and B are the same size and their contents are of equal value. Otherwise, `isequaln` returns false. All NaN (not a number) values are considered to be equal to each other. `isequaln` recursively compares the contents of cell arrays and structures and the properties of objects. If all contents in the respective locations are numerically equal, `isequaln` returns true.

`tf = isequaln(A1,A2,...,An)` returns logical true if all the inputs are numerically equal.

## Input Arguments

### A,B - Inputs to be compared

arrays | structures | cell arrays | objects

Inputs to be compared, specified as arrays, structures, cell arrays, or objects containing numeric or char values. The numeric types of A and B do not have to match. If A and B are structures, their fields need not be in the same order.

`isequaln` returns false when you pass objects of different classes. This applies even when the objects have the same properties and their values match.

### Data Types

double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | cell | struct

**Complex Number Support:** Yes

### A1,A2,...,An - Series of inputs to be compared

arrays | structures | cell arrays | objects

Series of inputs to be compared, specified as arrays, structures, cell arrays, or objects containing numeric or char values. The numeric types

of  $A_1, A_2, \dots, A_n$  do not have to match. If  $A_1, A_2, \dots, A_n$  are structures, their fields need not be in the same order.

`isequaln` returns `false` when you pass objects of different classes. This applies even when the objects have the same properties and their values match.

### Data Types

`double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `cell` | `struct`

**Complex Number Support:** Yes

## Output Arguments

### tf - Result

`true` | `false`

Result, returned as a logical value. `isequaln` returns `true` if the inputs are numerically equal. Otherwise, it returns `false`.

## Tips

- If you want to test handle objects for equality, use `eq` or the `==` operator to test whether they are the same handle. Use `isequaln` to test handle objects for equal property values, even when the objects are different handles.
- Use `isequal` if you want to test for equality and treat NaN values as unequal.

## Examples

### Compare Two Arrays

```
A = zeros(3,3)+1e-20;  
B = zeros(3,3);  
tf = isequaln(A,B)
```

```
tf =
```

```
0
```

### Compare Two Structures

```
A = struct('field1',0.005,'field2',2500);
```

# isequaln

---

```
B = struct('field2',2500,'field1',0.005);  
tf = isequaln(A,B)
```

```
tf =
```

```
1
```

Even though the ordering of the fields in each structure is different, `isequaln` treats them as the same because the values are equal.

## Comparing Numeric Values with Special Nonnumeric Values

Compare the logical value `true` to the double integer 1.

```
isequaln(true,1)
```

```
ans =
```

```
1
```

Notice that `isequaln` does not consider data type when it tests for equality.

Compare 'A' to the ASCII-equivalent integer, 65.

```
isequaln('A',65)
```

```
ans =
```

```
1
```

## Compare Vectors Containing NaN Values

```
A1 = [1 NaN NaN];  
A2 = [1 NaN NaN];  
A3 = [1 NaN NaN];  
tf = isequaln(A1,A2,A3)
```

```
tf =
```

1

**See Also**    `isequal` | `eq` | `is*` | `isa*` | `strcmp` | relational operators

# isequal (MException)

---

**Purpose** Compare scalar MException objects for equality

**Syntax** TF = isequal(eObj1, eObj2)

**Description** TF = isequal(eObj1, eObj2) tests MException objects eObj1 and eObj2 for equality, returning logical 1 (true) if the two objects are identical, otherwise returning logical 0 (false).

**See Also** try | catch | error | assert | MException | eq(MException) | ne(MException) | getReport(MException) | disp(MException) | throw(MException) | rethrow(MException) | throwAsCaller(MException) | addCause(MException) | last(MException)

**Purpose** Test arrays for equality, treating NaNs as equal

---

**Note** `isequalwithequalnans` is not recommended. Use `isequaln` instead.

---

**Syntax** `tf = isequalwithequalnans(A, B, ...)`

**Description** `tf = isequalwithequalnans(A, B, ...)` returns logical 1 (true) if the input arrays are the same type and size and hold the same contents, and logical 0 (false) otherwise. NaN (Not a Number) values are considered to be equal to each other. Numeric data types and structure field order do not have to match.

**Tips** `isequalwithequalnans` is the same as `isequal`, except `isequalwithequalnans` considers NaN (Not a Number) values to be equal, and `isequal` does not.

`isequalwithequalnans` recursively compares the contents of cell arrays and structures. If all the elements of a cell array or structure are numerically equal, `isequalwithequalnans` returns logical 1.

**Examples** Arrays containing NaNs are handled differently by `isequal` and `isequalwithequalnans`. `isequal` does not consider NaNs to be equal, while `isequalwithequalnans` does.

```
A = [32 8 -29 NaN 0 5.7];
B = A;
isequal(A, B)
ans =
    0
```

```
isequalwithequalnans(A, B)
ans =
    1
```

# isequalwithequalnans

---

The position of NaN elements in the array does matter. If they are not in the same position in the arrays being compared, then `isequalwithequalnans` returns zero.

```
A = [2 4 6 NaN 8];    B = [2 4 NaN 6 8];  
isequalwithequalnans(A, B)  
ans =  
    0
```

## See Also

[isequal](#) | [strcmp](#) | [isa](#) | [is\\*](#) | [relational operators](#) | [isequaln](#)

**Purpose**

Determine whether input is COM object event

**Syntax**

```
tf = h.isevent('eventname')  
tf = isevent(h, 'eventname')
```

**Description**

`tf = h.isevent('eventname')` returns logical 1 (true) if `event_name` is an event recognized by COM object `h`. Otherwise, returns logical 0 (false). The `event_name` argument is not case sensitive.

`tf = isevent(h, 'eventname')` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

**Examples**

Test events in a MATLAB sample control object:

- 1 Create an instance of the `mwsamp` control and test `Db1Click`:

```
f = figure ('position', [100 200 200 200]);  
h = actxcontrol ('mwsamp.mwsampctrl.2', [0 0 200 200], f);  
h.isevent('Db1Click')
```

MATLAB displays `true`, indicating `Db1Click` is an event.

- 2 Try the same test on `Redraw`:

```
h.isevent('Redraw')
```

MATLAB displays `false`, indicating `Redraw` is not an event; it is a method.

---

Test events in a Microsoft Excel workbook object:

- 1 Create a Workbook object `wb`:

```
myApp = actxserver('Excel.Application');  
wbs = myApp.Workbooks;  
wb = wbs.Add;
```

# isevent

---

## 2 Test Activate:

```
wb.isevent('Activate')
```

MATLAB displays `true`, indicating `Activate` is an event.

## 3 Test Save:

```
wb.isevent('Save')
```

MATLAB displays `false`, indicating `Save` is not an event; it is a method.

## See Also

## How To

- “Exploring Events”
- “Functions for Working with Events”

**Purpose**

Determine whether input is structure array field

**Syntax**

```
tf = isfield(S, 'fieldname')  
tf = isfield(S, C)
```

**Description**

`tf = isfield(S, 'fieldname')` examines structure `S` to see if it includes the field specified by the quoted string `'fieldname'`. Output `tf` is set to logical 1 (true) if `S` contains the field, or logical 0 (false) if not. If `S` is not a structure array, `isfield` returns false.

`tf = isfield(S, C)` examines structure `S` for multiple fieldnames as specified in cell array of strings `C`, and returns an array of logical values to indicate which of these fields are part of the structure. Elements of output array `tf` are set to a logical 1 (true) if the corresponding element of `C` holds a fieldname that belongs to structure `S`. Otherwise, logical 0 (false) is returned in that element. In other words, if structure `S` contains the field specified in `C{m,n}`, `isfield` returns a logical 1 (true) in `tf(m,n)`.

---

**Note** `isfield` returns false if the field or fieldnames input is empty.

---

**Examples****Example 1 – Single Fieldname Syntax**

Given the following MATLAB structure,

```
patient.name = 'John Doe';  
patient.billing = 127.00;  
patient.test = [79 75 73; 180 178 177.5; 220 210 205];
```

`isfield` identifies `billing` as a field of that structure.

```
isfield(patient,'billing')  
ans =  
    1
```

# isfield

---

## Example 2 – Multiple Fieldname Syntax

Check structure S for any of four possible fieldnames. Only the first is found, so the first element of the return value is set to true:

```
S = struct('one', 1, 'two', 2);  
  
fields = isfield(S, {'two', 'pi', 'One', 3.14})  
fields =  
     1     0     0     0
```

## How To

- dynamic field names

**Purpose** Array elements that are finite

**Syntax** TF = isfinite(A)

**Description** TF = isfinite(A) returns an array the same size as A containing logical 1 (true) where the elements of the array A are finite and logical 0 (false) where they are infinite or NaN. For a complex number z, isfinite(z) returns 1 if both the real and imaginary parts of z are finite, and 0 if either the real or the imaginary part is infinite or NaN. For any real A, exactly one of the three quantities isfinite(A), isinf(A), and isnan(A) is equal to one.

**Examples**

```
a = [-2 -1 0 1 2];
isfinite(1./a)
ans =
     1     1     0     1     1
isfinite(0./a)
ans =
     1     1     0     1     1
```

**See Also** isinf | isnan | is\*

# isfloat

---

**Purpose** Determine if input is floating-point array

**Syntax** `tf = isfloat(A)`

**Description** `tf = isfloat(A)` returns true if A is a floating-point array and false otherwise. The floating-point types are `single` and `double`, and subclasses of `single` and `double`.

## Examples

These examples show the values `isfloat` returns when passed specific types:

```
% pi returns a floating-point value
isfloat(pi)
ans =
     1

% Complex numbers are floating-point values
isfloat(3+7i)
ans =
     1

% Single-precision numbers are floating-point values
isfloat(realmax('single'))
ans =
     1

% isfloat returns a logical value
isfloat(isfloat(pi))
ans =
     0
```

**See Also** `isa` | `isinteger` | `double` | `single` | `isnumeric`

**Purpose** Determine whether input is global variable

---

**Note** Support for the `isglobal` function will be removed in a future release of the MATLAB software. See “Tips” on page 2-2411 below.

---

**Syntax** `tf = isglobal(A)`

**Description** `tf = isglobal(A)` returns logical 1 (true) if `A` has been declared to be a global variable in the context from which `isglobal` is called, and logical 0 (false) otherwise.

**Tips** `isglobal` is most commonly used in conjunction with conditional global declaration. An alternate approach is to use a pair of variables, one local and one declared global.

Instead of using

```
if condition
    global x
end
```

```
x = some_value
```

```
if isglobal(x)
    do_something
end
```

You can use

```
global gx
if condition
    gx = some_value
else
    x = some_value
end
```

# isglobal

---

```
if condition
    do_something
end
```

If no other workaround is possible, you can replace the command

```
isglobal(variable)
```

with

```
~isempty(whos('global', 'variable'))
```

## See Also

```
global | isvarname | isa | is*
```

**Purpose** Test for valid graphics object handle

**Syntax** `ishandle(H)`

**Description** `ishandle(H)` returns an array whose elements are 1 where the elements of `H` are valid graphics or Java object handles, and 0 where they are not.

#### Non-Graphics Object Handles

Use the `isa` function to determine the class of MATLAB objects and use the `isvalid` handle class method to determine the validity of handle objects. See “Testing Handle Validity” for information on testing for MATLAB handle objects.

**Examples** Ensure that an input argument is the handle to a graphics object.

```
function updateLine(h,x,y)

    if ishandle(h)
        set(h,'XData',x,'YData',y)
        ...
    else
        line('XData',x,'YData',y);
        ...
    end
end
```

**See Also** `findobj` | `gca` | `gcf` | `gco` | `isa` | `set`

**How To** • “Accessing Object Handles”

# ishghandle

---

**Purpose** True for Handle Graphics object handles

**Syntax** `ishghandle(h)`

**Description** `ishghandle(h)` returns an array that contains 1's where the elements of `h` are handles to existing graphic objects and 0's where they are not. Differs from `ishandle` in that Simulink objects handles return false.

**Examples** Create a plot and find the valid handles:

```
x = [1:10];  
y = [1:10];  
p=plot(x,y);  
ishghandle([x y p])  
% This returns a 1-by-21 array of values with ones at the first,  
% eleventh, and last values, if the figure handle is 1.
```

**See Also** `isa` | `ishandle` | `findobj` | `gca` | `gcf` | `set`

**How To** • “Accessing Object Handles”

**Purpose** Current hold state

**Syntax** `ishold`

**Description** `ishold` returns 1 if `hold` is on, and 0 if it is off. When `hold` is on, the current plot and most axis properties are held so that subsequent graphing commands add to the existing graph.

A state of `hold` on implies that both `figure` and axes `NextPlot` properties are set to `add`.

**See Also** `hold` | `newplot`

**How To**

- “Controlling Graphics Output”

# isinf

---

**Purpose** Array elements that are infinite

**Syntax** TF = isinf(A)

**Description** TF = isinf(A) returns an array the same size as A containing logical 1 (true) where the elements of A are +Inf or -Inf and logical 0 (false) where they are not. For a complex number z, isinf(z) returns 1 if either the real or imaginary part of z is infinite, and 0 if both the real and imaginary parts are finite or NaN.

For any real A, exactly one of the three quantities isfinite(A), isinf(A), and isnan(A) is equal to one.

## Examples

```
a = [-2 -1 0 1 2];  
  
isinf(1./a)  
  
ans =  
     0     0     1     0     0  
  
isinf(0./a)  
  
ans =  
     0     0     0     0     0
```

**See Also** isfinite | isnan | is\*

**Purpose** Determine if input is integer array

**Syntax** `tf = isinteger(A)`

**Description** `tf = isinteger(A)` returns true if the array A is an integer type and false otherwise.

An integer array is any of the following integer types and any subclasses of those types:

### **MATLAB Integer Types**

<code>int8</code>	8-bit signed integer array
<code>uint8</code>	8-bit unsigned integer array
<code>int16</code>	16-bit signed integer array
<code>uint16</code>	16-bit unsigned integer array
<code>int32</code>	32-bit signed integer array
<code>uint32</code>	32-bit unsigned integer array
<code>int64</code>	64-bit signed integer array
<code>uint64</code>	64-bit unsigned integer array

**Examples** These examples show the values `isinteger` returns when passed specific types:

```
% uint8 is one of the integer types
isinteger(uint8(1:255))
ans =
     1
% pi returns a double-precision value
isinteger(pi)
ans =
     0
% Constants are double-precision by default
isinteger(3)
```

# isinteger

---

```
ans =  
    0  
% isinteger returns a logical value  
isinteger(isinteger(uint8(3)))  
ans =  
    0
```

# isjava

---

**Purpose** Determine whether input is Java object

**Syntax** `tf = isjava(A)`

**Description** `tf = isjava(A)` returns logical 1 (true) if A is a Java object, and logical 0 (false) otherwise.

**Examples** Create an instance of the Java Date class and `isjava` indicates that it is a Java object.

```
myDate = java.util.Date;  
isjava(myDate)
```

The MATLAB software displays:

```
ans =
```

```
1
```

Note that `isobject`, which tests for MATLAB objects, returns logical 0 (false). Type:

```
isobject(myDate)
```

MATLAB displays:

```
ans =
```

```
0
```

**See Also** `isobject` | `javaArray` | `javaMethod` | `javaObject` | `isa` | `is*`

<b>Purpose</b>	Determine if containers.Map object contains key
<b>Syntax</b>	<code>tf = isKey(mapObj, keySet)</code>
<b>Description</b>	<code>tf = isKey(mapObj, keySet)</code> looks for the specified keys in <code>mapObj</code> , and returns logical <code>true</code> (1) for the keys that it finds, and logical <code>false</code> (0) for those it does not. <code>keySet</code> is a scalar key or a cell array of keys.
<b>Input Arguments</b>	<p><b>mapObj</b> Object of class <code>containers.Map</code>.</p> <p><b>keySet</b> Scalar value, string, or cell array that specifies keys to find in <code>mapObj</code>.</p>
<b>Output Arguments</b>	<p><b>tf</b> Array of logical values. If <code>keySet</code> is a scalar or a string, <code>tf</code> is a scalar. Otherwise, <code>tf</code> has the same size and dimensions as <code>keySet</code>.</p>
<b>Examples</b>	<p><b>Find Keys in a Map</b></p> <p>Construct a map that contains rainfall data for several months:</p> <pre>months = {'Jan', 'Feb', 'Mar', 'Apr'}; rainfall = [327.2, 368.2, 197.6, 178.4]; mapObj = containers.Map(months, rainfall);</pre> <p>Determine if keys Apr, May, and Jun are in the map:</p> <pre>keySet = {'Apr', 'May', 'Jun'}; tf = isKey(mapObj, keySet)</pre> <p>This code returns 1-by-3 vector <code>tf</code>:</p> <pre>tf =     1     0     0</pre>

# containers.Map.isKey

---

## Find a Single Key

Determine if `mapObj` from the previous example contains key `Feb`:

```
keySet = 'Feb';  
tf = isKey(mapObj, keySet)
```

This code returns scalar `tf`:

```
tf =  
    1
```

## See Also

[containers.Map](#) | [keys](#) | [values](#) | [remove](#)

**Purpose** Determine whether input is MATLAB keyword

**Syntax**

```
tf = iskeyword('str')
iskeyword str
iskeyword
```

**Description** `tf = iskeyword('str')` returns logical 1 (true) if the string `str` is a keyword in the MATLAB language and logical 0 (false) otherwise.

`iskeyword str` uses the MATLAB command format.

`iskeyword` returns a list of all MATLAB keywords.

**Examples** To test if the word `while` is a MATLAB keyword,

```
iskeyword while
ans =
     1
```

To obtain a list of all MATLAB keywords,

```
iskeyword
'break'
'case'
'catch'
'classdef'
'continue'
'else'
'elseif'
'end'
'for'
'function'
'global'
'if'
'otherwise'
'parfor'
'persistent'
'return'
```

# iskeyword

---

```
'spmd'  
'switch'  
'try'  
'while'
```

**Purpose** Array elements that are alphabetic letters

**Syntax** `tf = isletter('str')`

**Description** `tf = isletter('str')` returns an array the same size as `str` containing logical 1 (true) where the elements of `str` are letters of the alphabet and logical 0 (false) where they are not.

**Examples** Find the letters in character array `s`.

```
s = 'A1,B2,C3';
```

```
isletter(s)
```

```
ans =
```

```
     1     0     0     1     0     0     1     0
```

# islogical

---

**Purpose** Determine if input is logical array

**Syntax** `tf = islogical(A)`

**Description** `tf = islogical(A)` returns true if A is a logical array and false otherwise. `islogical` also returns true if A is an instance of a class that is derived from the `logical` class.

**Examples** These examples show the values `islogical` returns when passed specific types:

```
% Relational operators return logical values
islogical(5<7)
ans =
     1
```

```
% true and false return logical values
islogical(true) & islogical(false)
ans =
     1
```

```
% Constants are double-precision by default
islogical(1)
ans =
     0
```

```
% logical creates logical values
islogical(logical(1))
ans =
     1
```

**See Also** `logical` | `elementwise` | `short-circuit` | `isa` | `is*`

<b>Purpose</b>	Determine if version is for Mac OS X platform
<b>Syntax</b>	<code>tf = ismac</code>
<b>Description</b>	<code>tf = ismac</code> returns logical 1 (true) if the version of MATLAB software is for the Apple Mac OS X platform, and returns logical 0 (false) otherwise.
<b>See Also</b>	<code>isunix</code>   <code>ispc</code>   <code>computer</code>   <code>isstudent</code>   <code>is*</code>

# ismatrix

---

**Purpose** Determine whether input is matrix

**Syntax** `ismatrix(V)`

**Description** `ismatrix(V)` returns logical 1 (true) if `size(V)` returns `[m n]` with nonnegative integer values `m` and `n`, and logical 0 (false) otherwise.

**Examples** Create three vectors:

```
V1 = rand(5,1);  
V2 = rand(5,1);  
V3 = rand(5,1);
```

Concatenate the vectors and check that the result is a matrix. `ismatrix` returns 1:

```
M = cat(2,V1,V2,V3);  
ismatrix(M)  
ans =  
    1
```

**See Also** `iscolumn` | `isrow` | `isscalar` | `isvector`

<b>Purpose</b>	Array elements that are members of set
<b>Compatibility</b>	In a future release, the behavior of <code>ismember</code> will change. This change is introduced for adoption in R2012a. For a detailed demonstration that shows how you can preview the future behavior and preserve the current behavior of your existing code, see the example, “Assess the Impact of the Forthcoming Changes to <code>ismember</code> ” on page 2-2433. For a detailed explanation of all the forthcoming changes, see “Set Functions Changing Behavior in a Future Release”.
<b>Syntax</b>	<pre>Lia = ismember(A,B) Lia = ismember(A,B,'rows') [Lia,Locb] = ismember(A,B) [Lia,Locb] = ismember(A,B,'rows')  [Lia,Locb] = ismember( __ , 'R2012a' )  [Lia,Locb] = ismember( __ , 'legacy' )</pre>
<b>Description</b>	<p><code>Lia = ismember(A,B)</code> returns an array the same size as A, containing 1 (true) where the elements of A are found in B, and 0 (false) elsewhere.</p> <p><code>Lia = ismember(A,B,'rows')</code> returns a vector containing 1 (true) where the rows of matrix A are also rows of B, and 0 (false) elsewhere.</p> <p><code>[Lia,Locb] = ismember(A,B)</code> also returns an array, <code>Locb</code>, containing the highest index in B for each value in A that is a member of B. The output array, <code>Locb</code>, contains 0 wherever A is not a member of B.</p> <p><code>[Lia,Locb] = ismember(A,B,'rows')</code> also returns a vector, <code>Locb</code>, containing the highest index in B for each row in A that is also a row in B. The output vector, <code>Locb</code>, contains 0 wherever A is not a row of B.</p>

# ismember

---

`[Lia,Locb] = ismember( ___, 'R2012a' )` adopts the future behavior of the `ismember` function. `[Lia,Locb] = ismember( ___, 'legacy' )` preserves the current behavior. You can specify either flag, `'R2012a'` or `'legacy'`, as the final input argument in any previous syntax.

## Input Arguments

### A - Query array

vector | matrix | N-D array

Query array, specified as a vector, matrix, or N-D array, contains the values to search for in B. The query array, A, can be `logical`, `char`, a cell array of strings, or any numeric class. A also can be any object with the class methods: `sort` (or `sortrows` for the `'rows'` option), `eq`, and `ne`. This includes heterogeneous arrays derived from the same root class.

A must belong to the same class as B with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with double arrays.
- Cell arrays of strings can combine with `char` arrays.

If you specify the `'rows'` option, A must have the same number of columns as B.

### Data Types

`double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

**Complex Number Support:** Yes

### B - Set array

vector | matrix | N-D array

Set array, specified as a vector, matrix, or N-D array, contains the values that evaluate to true wherever they are found in A. The set array, B, can be `logical`, `char`, a cell array of strings, or any numeric class. B also can be any object with the class methods: `sort` (or `sortrows` for the `'rows'` option), `eq`, and `ne`. This includes heterogeneous arrays derived from the same root class.

B must belong to the same class as A with the following exceptions:

- logical, char, and all numeric classes can combine with double arrays.
- Cell arrays of strings can combine with char arrays.

If you specify the 'rows' option, B must have the same number of columns as A.

### Data Types

double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

### 'rows' - Rows flag

Rows flag, specified as 'rows', identifies the rows of A and B as individual elements. When you specify this flag, `ismember` returns a vector containing 1 where the rows of A are also rows of B, and 0 elsewhere. A and B must have the same number of columns when you use the rows flag. This option does not support cell arrays.

### 'legacy' - Legacy behavior flag

Legacy behavior flag, when specified, preserves the current behavior. If the new behavior adversely affects your existing code, you can preserve the current behavior by specifying 'legacy' as the final argument.

### 'R2012a' - Future behavior flag

Future behavior flag, when specified, adopts the future behavior change. Specify 'R2012a' as the final argument to see what impact the new behavior has on your existing code.

## Output Arguments

### Lia - Logical results array

vector | matrix | N-D array

Logical results array, returned as a vector, matrix, or N-D array containing 1 (true) wherever the values (or rows) in A are members of B, and 0 (false) elsewhere.

# ismember

---

Lia is an array of the same size as A, unless you specify the 'rows' flag. If 'rows' is specified, Lia is a column vector.

## Locb - Locations in B

vector | matrix

Locations in B, returned as a vector or matrix containing the highest indices to the values (or rows) in B that are found in A.

If you call ismember with the setOrder or 'R2012a' argument, Locb contains the lowest indices to the values (or rows) in B that are found in A.

Locb is an array of the same size as A unless you specify the 'rows' flag. If 'rows' is specified, Locb is a column vector. Furthermore, Locb contains 0 wherever A is not a member of B.

## Examples

### Find Values That Are Members of a Set

```
A = [5 3 4 2]; B = [2 4 4 4 6 8];  
Lia = ismember(A,B)
```

```
Lia =
```

```
    0    0    1    1
```

### Find Members of a Set and Return Indices to Set Values

```
A = [5 3 4 2]; B = [2 4 4 4 6 8];  
[Lia,Locb] = ismember(A,B)
```

```
Lia =
```

```
    0    0    1    1
```

```
Locb =
```

```
    0    0    4    1
```

**Find Rows That Belong to a Set**

```
A = [1 3 5 6; 2 4 6 8];
B = [2 4 6 8; 1 3 5 7; 2 4 6 8];
[Lia, Locb] = ismember(A,B, 'rows')
```

```
Lia =
```

```
0
1
```

```
Locb =
```

```
0
3
```

**Assess the Impact of the Forthcoming Changes to ismember**

Use the 'R2012a' flag to assess the impact of the forthcoming behavior changes. Use the 'legacy' flag to preserve the current behavior of your existing code.

Find the members of B with the current default behavior.

```
A = [5 3 4 2]; B = [2 4 4 4 6 8];
[Lia1,Locb1] = ismember(A,B)
```

```
Lia1 =
```

```
0    0    1    1
```

```
Locb1 =
```

```
0    0    4    1
```

Find the members of B, and adopt the forthcoming behavior. In the future, this behavior will be the default.

# ismember

---

```
[Lia2,Locb2] = ismember(A,B,'R2012a')
```

```
Lia2 =
```

```
    0    0    1    1
```

```
Locb2 =
```

```
    0    0    2    1
```

Locb1 and Locb2 contain different indices.

Find the members of B, and preserve the current behavior.

```
[Lia3,Locb3] = ismember(A,B,'legacy')
```

```
Lia3 =
```

```
    0    0    1    1
```

```
Locb3 =
```

```
    0    0    4    1
```

Locb1 and Locb3 are the same.

## Search Members of Set Containing NaN Values

```
A = [5 NaN NaN]; B = [5 NaN NaN];
```

```
[Lia,Locb] = ismember(A,B)
```

```
Lia =
```

```
    1    0    0
```

```
Locb =
```

```
1 0 0
```

ismember treats NaN values as distinct.

# ismethod

---

**Purpose** Determine if method of object

**Syntax** `tf = ismethod(h, 'methodName')`

**Description** `tf = ismethod(h, 'methodName')` returns logical 1 (true) if the specified `methodName` is a public method of object `obj`. Otherwise, returns logical 0 (false).

**Examples** Determine if objects support equality testing:

```
if ismethod(obj1,'eq') && ismethod(obj2,'eq')
    tf = obj1 == obj2;
end
```

**See Also** `methods` | `isprop` | `isobject` | `class`

**Tutorials** • “Methods”

**Purpose** Determine whether input is COM object method

**Syntax**

```
tf = h.ismethod('methodname')  
tf = ismethod(h,'methodname')
```

**Description** `tf = h.ismethod('methodname')` returns logical 1 (true) if the specified `methodname` is a method you can call on COM object `h`. Otherwise, returns logical 0 (false).

`tf = ismethod(h,'methodname')` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

**Examples** Test members of an instance of a Microsoft Excel application:

```
h = actxserver ('Excel.Application');  
ismethod(h, 'SaveWorkspace')
```

MATLAB returns true, `SaveWorkspace` is a method.

---

Try the same test on `UsableWidth`:

```
ismethod(h, 'UsableWidth')
```

MATLAB returns false, `UsableWidth` is not a method; it is a property.

**See Also** `methods` | `methodsview` | `isprop` | `isevent` | `isobject` | `class`

**How To**

- “Exploring Methods”

# isnan

---

**Purpose** Array elements that are NaN

**Syntax** TF = isnan(A)

**Description** TF = isnan(A) returns an array the same size as A containing logical 1 (true) where the elements of A are NaNs and logical 0 (false) where they are not. For a complex number z, isnan(z) returns 1 if either the real or imaginary part of z is NaN, and 0 if both the real and imaginary parts are finite or Inf.

For any real A, exactly one of the three quantities isfinite(A), isinf(A), and isnan(A) is equal to one.

**Examples**

```
A = [-2 -1 0 1 2];

isnan(1./A)
ans =
     0     0     0     0     0

isnan(0./A)
ans =
     0     0     1     0     0
```

**See Also** isfinite | isinf | is\*

**Purpose** Determine if input is numeric array

**Syntax** `tf = isnumeric(A)`

**Description** `tf = isnumeric(A)` returns true if `A` is a numeric array and false otherwise.

A numeric array is any of the following numeric types and any subclasses of those types:

### **MATLAB Numeric Types**

<code>single</code>	Single-precision floating-point array
<code>double</code>	Double-precision floating-point array
<code>int8</code>	8-bit signed integer array
<code>uint8</code>	8-bit unsigned integer array
<code>int16</code>	16-bit signed integer array
<code>uint16</code>	16-bit unsigned integer array
<code>int32</code>	32-bit signed integer array
<code>uint32</code>	32-bit unsigned integer array
<code>int64</code>	64-bit signed integer array
<code>uint64</code>	64-bit unsigned integer array

**Examples** These examples show the values `isnumeric` returns when passed specific types:

```
% pi returns a numeric value
isnumeric(pi)
ans =
     1
% Complex numbers are numeric
isnumeric(3+7i)
ans =
```

# isnumeric

---

```
    1
% Integers are numeric
isnumeric(uint8(1:255))
ans =
    1
% isnumeric returns a logical value
isnumeric(isnumeric(pi))
ans =
    0
```

<b>Purpose</b>	Determine if input is MATLAB object
<b>Syntax</b>	<code>tf = isobject(A)</code>
<b>Description</b>	<p><code>tf = isobject(A)</code> returns true if A is an object of a MATLAB class. Otherwise, it returns false.</p> <p>Handle Graphics objects return false. Use <code>ishandle</code> to test for Handle Graphics objects.</p> <p>Instances of MATLAB fundamental classes return false. Use <code>isa</code> to test for any of these types. See “Fundamental MATLAB Classes” for more on these classes.</p>
<b>Examples</b>	<p>These examples show the values <code>isobject</code> returns when passed specific types:</p> <p>Define the following MATLAB class:</p> <pre>classdef button &lt; handle     properties         UiHandle     end     methods         function obj = button(pos)             obj.UiHandle = uicontrol('Position',pos,...                 'Style','pushbutton');         end     end end</pre> <p>Determine which objects are MATLAB objects. For example:</p> <pre>h = button([20 20 60 60]); isobject(h) ans =      1 isobject(h.UiHandle)</pre>

# isobject

---

```
ans =  
    0
```

---

Use `isjava` to test for Java objects in MATLAB, where it returns `false` for MATLAB objects:

```
isjava(h)  
ans =  
    0
```

---

Create an object that is a MATLAB numeric type:

```
a = pi;  
isa(a, 'double')  
ans =  
    1  
isobject(a)  
ans =  
    0
```

## Tutorials

- “Class Syntax Fundamentals”

**Purpose** Compute isosurface end-cap geometry

**Syntax**

```
fvc = isocaps(X,Y,Z,V,isovalue)
fvc = isocaps(V,isovalue)
fvc = isocaps(...,'enclose')
fvc = isocaps(...,'whichplane')
[f,v,c] = isocaps(...)
isocaps(...)
```

**Description** `fvc = isocaps(X,Y,Z,V,isovalue)` computes isosurface end-cap geometry for the volume data `V` at isosurface value `isovalue`. The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V`.

The struct `fvc` contains the face, vertex, and color data for the end-caps and can be passed directly to the `patch` command.

`fvc = isocaps(V,isovalue)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)` where `[m,n,p] = size(V)`.

`fvc = isocaps(...,'enclose')` specifies whether the end-caps enclose data values above or below the value specified in `isovalue`. The string `enclose` can be either `above` (default) or `below`.

`fvc = isocaps(...,'whichplane')` specifies on which planes to draw the end-caps. Possible values for `whichplane` are `all` (default), `xmin`, `xmax`, `ymin`, `ymax`, `zmin`, or `zmax`.

`[f,v,c] = isocaps(...)` returns the face, vertex, and color data for the end-caps in three arrays instead of the struct `fvc`.

`isocaps(...)` without output arguments draws a patch with the computed faces, vertices, and colors.

**Examples** This example uses a data set that is a collection of MRI slices of a human skull. It illustrates the use of `isocaps` to draw the end-caps on this cutaway volume.

The red isosurface shows the outline of the volume (skull) and the end-caps show what is inside of the volume.

The patch created from the end-cap data (p2) uses interpolated face coloring, which means the gray colormap and the light sources determine how it is colored. The isosurface patch (p1) used a flat red face color, which is affected by the lights, but does not use the colormap.

```
load mri
D = squeeze(D);
D(:,1:60,:) = [];
p1 = patch(isosurface(D, 5), 'FaceColor', 'red', ...
    'EdgeColor', 'none');
p2 = patch(isocaps(D, 5), 'FaceColor', 'interp', ...
    'EdgeColor', 'none');
view(3); axis tight; daspect([1,1,.4])
colormap(gray(100))
camlight left; camlight; lighting gouraud
isonormals(D,p1)
```

## How To

- “Isocaps Add Context to Visualizations”

# isocolors

---

**Purpose** Calculate isosurface and patch colors

**Syntax**

```
nc = isocolors(X,Y,Z,C,vertices)
nc = isocolors(X,Y,Z,R,G,B,vertices)
nc = isocolors(C,vertices)
nc = isocolors(R,G,B,vertices)
nc = isocolors(...,PatchHandle)
isocolors(...,PatchHandle)
```

**Description** `nc = isocolors(X,Y,Z,C,vertices)` computes the colors of isosurface (patch object) `vertices` using color values `C`. Arrays `X`, `Y`, `Z` define the coordinates for the color data in `C` and must be monotonic vectors that represent a Cartesian, axis-aligned grid (as if produced by `meshgrid`). The colors are returned in `nc`. `C` must be 3-D (index colors).

`nc = isocolors(X,Y,Z,R,G,B,vertices)` uses `R`, `G`, `B` as the red, green, and blue color arrays (true color).

`nc = isocolors(C,vertices)`, and `nc = isocolors(R,G,B,vertices)` assume `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p] = size(C)`.

`nc = isocolors(...,PatchHandle)` uses the vertices from the patch identified by `PatchHandle`.

`isocolors(...,PatchHandle)` sets the `FaceVertexCData` property of the patch specified by `PatchHandle` to the computed colors.

## Examples **Indexed Color Data**

This example displays an isosurface and colors it with random data using indexed color. (See “Interpolating in Indexed Color Versus Truicolor” for information on how patch objects interpret color data.)

```
[x y z] = meshgrid(1:20,1:20,1:20);
```

```

data = sqrt(x.^2 + y.^2 + z.^2);
cdata = smooth3(rand(size(data)), 'box', 7);
p = patch(isosurface(x,y,z,data,10));
isonormals(x,y,z,data,p);
isocolors(x,y,z,cdata,p);
set(p, 'FaceColor', 'interp', 'EdgeColor', 'none')
view(150,30); daspect([1 1 1]); axis tight
camlight; lighting phong;

```

### True Color Data

This example displays an isosurface and colors it with true color (RGB) data.

```

[x y z] = meshgrid(1:20,1:20,1:20);
data = sqrt(x.^2 + y.^2 + z.^2);
p = patch(isosurface(x,y,z,data,20));
isonormals(x,y,z,data,p);
[r g b] = meshgrid(20:-1:1,1:20,1:20);

```

# isocolors

---

```
isocolors(x,y,z,r/20,g/20,b/20,p);  
set(p,'FaceColor','interp','EdgeColor','none')  
view(150,30); daspect([1 1 1]);  
camlight; lighting phong;
```

## Modified True Color Data

This example uses `isocolors` to calculate the true color data using the `isosurface`'s (patch object's) vertices, but then returns the color data in a variable (`c`) in order to modify the values. It then explicitly sets the `isosurface`'s `FaceVertexCData` to the new data (`1-c`).

```
[x y z] = meshgrid(1:20,1:20,1:20);  
data = sqrt(x.^2 + y.^2 + z.^2);  
p = patch(isosurface(data,20));  
isonormals(data,p);  
[r g b] = meshgrid(20:-1:1,1:20,1:20);  
c = isocolors(r/20,g/20,b/20,p);  
set(p,'FaceVertexCData',1-c)
```

```
set(p,'FaceColor','interp','EdgeColor','none')  
view(150,30); daspect([1 1 1]);  
camlight; lighting phong;
```

## See Also

[isosurface](#) | [isocaps](#) | [smooth3](#) | [subvolume](#) | [reducevolume](#) | [reducephatch](#) | [isonormals](#)

# isonormals

---

**Purpose** Compute normals of isosurface vertices

**Syntax**

```
n = isonormals(X,Y,Z,V,vertices)
n = isonormals(V,vertices)
n = isonormals(V,p) and n = isonormals(X,Y,Z,V,p)
n = isonormals(...,'negate')
isonormals(V,p) and isonormals(X,Y,Z,V,p)
```

**Description** `n = isonormals(X,Y,Z,V,vertices)` computes the normals of the isosurface vertices from the vertex list, `vertices`, using the gradient of the data `V`. The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V`. The computed normals are returned in `n`.

`n = isonormals(V,vertices)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)` where `[m,n,p] = size(V)`.

`n = isonormals(V,p)` and `n = isonormals(X,Y,Z,V,p)` compute normals from the vertices of the patch identified by the handle `p`.

`n = isonormals(...,'negate')` negates (reverses the direction of) the normals.

`isonormals(V,p)` and `isonormals(X,Y,Z,V,p)` set the `VertexNormals` property of the patch identified by the handle `p` to the computed normals rather than returning the values.

**Examples** This example compares the effect of different surface normals on the visual appearance of lit isosurfaces. In one case, the triangles used to draw the isosurface define the normals. In the other, the `isonormals` function uses the volume data to calculate the vertex normals based on the gradient of the data points. The latter approach generally produces a smoother-appearing isosurface.

Define a 3-D array of volume data (`cat`, `interp3`):

```
data = cat(3, [0 .2 0; 0 .3 0; 0 0 0], ...
             [.1 .2 0; 0 1 0; .2 .7 0], ...
             [0 .4 .2; .2 .4 0;.1 .1 0]);
```

```
data = interp3(data,3,'cubic');
```

Draw an isosurface from the volume data and add lights. This isosurface uses triangle normals (patch, isosurface, view, daspect, axis, camlight, lighting, title):

```
subplot(1,2,1)
p1 = patch(isosurface(data,.5),...
'FaceColor','red','EdgeColor','none');
view(3); daspect([1,1,1]); axis tight
camlight; camlight(-80,-10); lighting phong;
title('Triangle Normals')
```

Draw the same lit isosurface using normals calculated from the volume data:

```
subplot(1,2,2)
p2 = patch(isosurface(data,.5),...
'FaceColor','red','EdgeColor','none');
isonormals(data,p2)
view(3); daspect([1 1 1]); axis tight
camlight; camlight(-80,-10); lighting phong;
title('Data Normals')
```

These isosurfaces illustrate the difference between triangle and data normals:

# isonormals

---

Triangle Normals

Data Normals

## See Also

`interp3` | `isosurface` | `isocaps` | `smooth3` | `subvolume` | `reducevolume` | `reducepatch`

**Purpose** Extract isosurface data from volume data

**Syntax**

```
fv = isosurface(X,Y,Z,V,isovalue)
fv = isosurface(V,isovalue)
fvc = isosurface(...,colors)
fv = isosurface(...,'noshare')
fv = isosurface(...,'verbose')
[f,v] = isosurface(...)
[f,v,c] = isosurface(...)
isosurface(...)
```

**Description** `fv = isosurface(X,Y,Z,V,isovalue)` computes isosurface data from the volume data `V` at the isosurface value specified in `isovalue`. That is, the isosurface connects points that have the specified value much the way contour lines connect points of equal elevation.

The arrays `X`, `Y`, and `Z` represent a Cartesian, axis-aligned grid. `V` contains the corresponding values at these grid points. The coordinate arrays (`X`, `Y`, and `Z`) must be monotonic and conform to the format produced by `meshgrid`. `V` must be a 3D volume array of the same size as `X`, `Y`, and `Z`.

The struct `fv` contains the faces and vertices of the isosurface, which you can pass directly to the `patch` command.

`fv = isosurface(V,isovalue)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)` where `[m,n,p] = size(V)`.

`fvc = isosurface(...,colors)` interpolates the array `colors` onto the scalar field and returns the interpolated values in the `facevertexcdata` field of the `fvc` structure. The size of the `colors` array must be the same as `V`. The `colors` argument enables you to control the color mapping of the isosurface with data different from that used to calculate the isosurface (e.g., temperature data superimposed on a wind current isosurface).

# isosurface

---

`fv = isosurface(..., 'noshare')` does not create shared vertices. This is faster, but produces a larger set of vertices.

`fv = isosurface(..., 'verbose')` prints progress messages to the command window as the computation progresses.

`[f,v] = isosurface(...)` or `[f,v,c] = isosurface(...)` returns the faces and vertices (and `faceVertexcCData`) in separate arrays instead of a struct.

`isosurface(...)` with no output arguments, creates a patch in the current axes with the computed faces and vertices. If no current axes exists, a new axes is created with a 3-D view and appropriate lighting.

## Special Case Behavior – isosurface Called with No Output Arguments

If there is no current axes and you call `isosurface` with without assigning output arguments, MATLAB creates a new axes, sets it to a 3-D view, and adds lighting to the isosurface graph.

## Tips

You can pass the `fv` structure created by `isosurface` directly to the `patch` command, but you cannot pass the individual faces and vertices arrays (`f`, `v`) to `patch` without specifying property names. For example,

```
patch(isosurface(X,Y,Z,V,isovalue))
```

or

```
[f,v] = isosurface(X,Y,Z,V,isovalue);  
patch('Faces',f,'Vertices',v)
```

## Examples

### Example 1

This example uses the flow data set, which represents the speed profile of a submerged jet within an infinite tank (type `help flow` for more information). The isosurface is drawn at the data value of -3. The statements that follow the `patch` command prepare the isosurface for lighting by

- Recalculating the isosurface normals based on the volume data (`isonormals`)
- Setting the face and edge color (`set`, `FaceColor`, `EdgeColor`)
- Specifying the view (`daspect`, `view`)
- Adding lights (`camlight`, `lighting`)

```
[x,y,z,v] = flow;  
p = patch(isosurface(x,y,z,v,-3));  
isonormals(x,y,z,v,p)  
set(p,'FaceColor','red','EdgeColor','none');  
daspect([1,1,1])  
view(3); axis tight  
camlight  
lighting gouraud
```

# isosurface

---

## Example 2

Visualize the same flow data as above, but color-code the surface to indicate magnitude along the X-axis. Use a sixth argument to `isosurface`, which provides a means to overlay another data set by coloring the resulting isosurface. The `colors` variable is a vector containing a scalar value for each vertex in the isosurface, to be portrayed with the current color map. In this case, it is one of the

variables that define the surface, but it could be entirely independent. You can apply a different color scheme by changing the current figure color map.

```
[x,y,z,v] = flow;  
[faces,verts,colors] = isosurface(x,y,z,v,-3,x);  
patch('Vertices', verts, 'Faces', faces, ...  
      'FaceVertexCData', colors, ...  
      'FaceColor', 'interp', ...  
      'edgecolor', 'interp');  
view(30,-15);  
axis vis3d;  
colormap copper
```

## How To

- “Connecting Equal Values with Isosurfaces”

# ispc

---

**Purpose** Determine if version is for Windows (PC) platform

**Syntax** `tf = ispc`

**Description** `tf = ispc` returns logical 1 (true) if the version of MATLAB software is for the Microsoft Windows platform, and returns logical 0 (false) otherwise.

**See Also** `isunix` | `ismac` | `computer` | `isstudent` | `is*`

---

<b>Purpose</b>	Test for existence of preference
<b>Syntax</b>	<pre>ispref('group','pref') ispref('group') ispref('group',{'pref1','pref2',... 'prefn'})</pre>
<b>Description</b>	<p><code>ispref('group','pref')</code> returns 1 if the preference specified by <code>group</code> and <code>pref</code> exists, and 0 otherwise.</p> <p><code>ispref('group')</code> returns 1 if the <code>GROUP</code> exists, and 0 otherwise.</p> <p><code>ispref('group',{'pref1','pref2',... 'prefn'})</code> returns a logical array the same length as the cell array of preference names, containing 1 where each preference exists, and 0 elsewhere.</p>
<b>Examples</b>	<pre>addpref('mytoolbox','version','1.0') ispref('mytoolbox','version')  ans =      1</pre>
<b>See Also</b>	<code>addpref</code>   <code>getpref</code>   <code>rmpref</code>   <code>setpref</code>   <code>uigetpref</code>   <code>uisetpref</code>

# isprime

---

**Purpose** Array elements that are prime numbers

**Syntax** TF = isprime(A)

**Description** TF = isprime(A) returns an array the same size as A containing logical 1 (true) for the elements of A which are prime, and logical 0 (false) otherwise. A must contain only positive integers.

**Examples**

```
c = [2 3 0 6 10]

c =
     2     3     0     6    10

isprime(c)

ans =
     1     1     0     0     0
```

**See Also** is\*

<b>Purpose</b>	Determine if property of object
<b>Syntax</b>	<code>tf = isprop(obj,'PropertyName')</code>
<b>Description</b>	<p><code>tf = isprop(obj,'PropertyName')</code> returns logical 1 (true) if the specified <code>PropertyName</code> is a property of object <code>obj</code>. Otherwise, returns logical 0 (false).</p> <p>Note that classes can control access to property values by defining property attributes. Property access can be defined as:</p> <ul style="list-style-type: none"><li>• Readable and writable</li><li>• Read only</li><li>• Write only</li><li>• Accessible only to certain class methods</li></ul> <p>See “Property Attributes” for information on restrictions to property access.</p> <p>See “Getting Information About Properties” for information about obtaining specific information about the properties of a class.</p>
<b>Examples</b>	<p>This example uses <code>isprop</code> to determine if <code>XDataSource</code> is a property of object <code>h</code> before attempting to set the property value:</p> <pre>x = 0:pi/10:2*pi; y = sin(x); h = plot(x,y); if isprop(h,'XDataSource')     set(h,'XDataSource','x') else     error(['XDataSource is not a member of class ',class(h)]) end</pre>
<b>See Also</b>	<code>properties</code>   <code>ismethod</code>

## Tutorials

- “Properties”

**Purpose** Determine whether input is COM object property

**Syntax**

```
tf = h.isprop('propertyname')  
tf = isprop(h, 'propertyname')
```

**Description** `tf = h.isprop('propertyname')` returns logical 1 (true) if the specified name is a property of COM object h. Otherwise, returns logical 0 (false).

`tf = isprop(h, 'propertyname')` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

**Examples** Test a property of an instance of a Microsoft Excel application:

```
h = actxserver('Excel.Application');  
isprop(h, 'UsableWidth')
```

MATLAB returns true, UsableWidth is a property.

---

Try the same test on SaveWorkspace:

```
isprop(h, 'SaveWorkspace')
```

MATLAB returns false. SaveWorkspace is not a property; it is a method.

**See Also** `inspect` | `ismethod` | `isevent`

**How To**

- “Exploring Properties”

# isreal

---

**Purpose** Check if input is real array

**Syntax** `TF = isreal(A)`

**Description** `TF = isreal(A)` returns logical 1 (true) if `A` does not have an imaginary part. It returns logical 0 (false) otherwise. If `A` has a stored imaginary part of value 0, `isreal(A)` returns logical 0 (false).

---

**Note** For logical and char data classes, `isreal` always returns true. For numeric data types, if `A` does not have an imaginary part `isreal` returns true; if `A` does have an imaginary part `isreal` returns false. For cell, struct, function\_handle, and object data types, `isreal` always returns false.

---

`~isreal(x)` returns true for arrays that have at least one element with an imaginary component. The value of that component can be 0.

**Tips** If `A` is real, `complex(A)` returns a complex number whose imaginary component is 0, and `isreal(complex(A))` returns false. In contrast, the addition `A + 0i` returns the real value `A`, and `isreal(A + 0i)` returns true.

If `B` is real and `A = complex(B)`, then `A` is a complex matrix and `isreal(A)` returns false, while `A(m:n)` returns a real matrix and `isreal(A(m:n))` returns true.

Because MATLAB software supports complex arithmetic, certain of its functions can introduce significant imaginary components during the course of calculations that appear to be limited to real numbers. Thus, you should use `isreal` with discretion.

**Examples** **Example 1**

If a computation results in a zero-value imaginary component, `isreal` returns true.

```
x=3+4i;  
y=5-4i;  
isreal(x+y)
```

```
ans =
```

```
1
```

### Example 2

These examples use `isreal` to detect the presence or absence of imaginary numbers in an array. Let

```
x = magic(3);  
y = complex(x);
```

`isreal(x)` returns `true` because no element of `x` has an imaginary component.

```
isreal(x)
```

```
ans =
```

```
1
```

`isreal(y)` returns `false`, because every element of `x` has an imaginary component, even though the value of the imaginary components is 0.

```
isreal(y)
```

```
ans =
```

```
0
```

This expression detects strictly real arrays, i.e., elements with 0-valued imaginary components are treated as real.

```
~any(imag(y(:)))
```

```
ans =
```

```
1
```

### Example 3

Given the following cell array,

# isreal

---

```
C{1} = pi; % double
C{2} = 'John Doe'; % char array
C{3} = 2 + 4i; % complex double
C{4} = ispc; % logical
C{5} = magic(3); % double array
C{6} = complex(5,0) % complex double

C =
    [3.1416] 'John Doe' [2.0000+ 4.0000i] [1] [3x3 double] [5]
```

isreal shows that all but C{1,3} and C{1,6} are real arrays.

```
for k = 1:6
x(k) = isreal(C{k});
end

x
x =
     1     1     0     1     1     0
```

---

<b>Purpose</b>	Determine whether input is row vector
<b>Syntax</b>	<code>isrow(V)</code>
<b>Description</b>	<code>isrow(V)</code> returns logical 1 (true) if <code>size(V)</code> returns <code>[1 n]</code> with a nonnegative integer value <code>n</code> , and logical 0 (false) otherwise.
<b>Examples</b>	<p>Determine if a vector is a row. This example is a column so <code>isrow</code> returns 0:</p> <pre>V = rand(5,1); isrow(V) ans =     0</pre> <p>Transpose the vector to make it a row. <code>isrow</code> returns 1:</p> <pre>V1 = V'; isrow(V1) ans =     1</pre>
<b>See Also</b>	<code>iscolumn</code>   <code>ismatrix</code>   <code>isscalar</code>   <code>isvector</code>

# isscalar

---

**Purpose** Determine whether input is scalar

**Syntax** `isscalar(A)`

**Description** `isscalar(A)` returns logical 1 (true) if `size(A)` returns `[1 1]`, and logical 0 (false) otherwise.

**Examples** Test matrix A and one element of the matrix:

```
A = rand(5);
```

```
isscalar(A)
ans =
     0
```

```
isscalar(A(3,2))
ans =
     1
```

**See Also** `isvector` | `ismatrix` | `isrow` | `iscolumn` | `islogical` | `ischar` | `isa` | `is*`

**Purpose** Determine whether set elements are in sorted order

**Syntax**  
 TF = issorted(A)  
 TF = issorted(A, 'rows')

**Description** TF = issorted(A) returns logical 1 (true) if the elements of A are in sorted order, and logical 0 (false) otherwise. Input A can be a vector or an N-by-1 or 1-by-N cell array of strings. A is considered to be sorted if A and the output of sort(A) are equal.

TF = issorted(A, 'rows') returns logical 1 (true) if the rows of two-dimensional matrix A are in sorted order, and logical 0 (false) otherwise. Matrix A is considered to be sorted if A and the output of sortrows(A) are equal.

**Note** Only the issorted(A) syntax supports A as a cell array of strings.

**Tips** For character arrays, issorted uses ASCII, rather than alphabetical, order.

You cannot use issorted on arrays of greater than two dimensions.

**Examples**      **Example 1 – Using issorted on a vector**

```
A = [5 12 33 39 78 90 95 107 128 131];
```

```
issorted(A)
ans =
     1
```

**Example 2 – Using issorted on a matrix**

```
A = magic(5)
A =
    17    24     1     8    15
    23     5     7    14    16
```

# issorted

---

```
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9
```

```
issorted(A, 'rows')
ans =
     0
```

```
B = sortrows(A)
B =
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9
    17    24     1     8    15
    23     5     7    14    16
```

```
issorted(B)
ans =
     1
```

### Example 3 – Using issorted on a cell array

```
x = {'one'; 'two'; 'three'; 'four'; 'five'};
issorted(x)
ans =
     0
```

```
y = sort(x)
y =
    'five'
    'four'
    'one'
    'three'
    'two'
```

```
issorted(y)
```

**See Also**

sort | sortrows | ismember | unique | intersect | union | setdiff  
| setxor | is\*

# isspace

---

**Purpose** Array elements that are space characters

**Syntax** `tf = isspace('str')`

**Description** `tf = isspace('str')` returns an array the same size as 'str' containing logical 1 (true) where the elements of str are Unicode-represented whitespace characters, and logical 0 (false) where they are not.

Whitespace characters for which `isspace` returns true include tab, line feed, vertical tab, form feed, carriage return, and space, in addition to a number of other Unicode characters. To see all characters for which `isspace` returns true, enter the following command, and then look up the returned decimal codes in a Unicode reference:

```
find(isspace(char(1):char(intmax('uint16'))))
```

## Examples

```
isspace(' Find spa ces ')
Columns 1 through 13
    1    1    0    0    0    0    1    0    0    0    1    0    0
Columns 14 through 15
    0    1
```

**See Also** `isletter` | `isstrprop` | `ischar` | `strings` | `isa` | `is*`

**Purpose** Determine whether input is sparse

**Syntax** TF = issparse(S)

**Description** TF = issparse(S) returns logical 1 (true) if the storage class of S is sparse and logical 0 (false) otherwise.

**See Also** is\* | sparse | full

# isstr

---

**Purpose** Determine whether input is character array

---

**Note** `isstr` is not recommended. Use `ischar` instead.

---

**See Also** `ischar` | `isa` | `is*`

**Purpose** Determine whether string is of specified category

**Syntax** `tf = isstrprop('str', 'category')`

**Description** `tf = isstrprop('str', 'category')` returns a logical array the same size as `str` containing logical 1 (true) where the elements of `str` belong to the specified `category`, and logical 0 (false) where they do not.

The `str` input can be a character array, cell array, or any MATLAB numeric type. If `str` is a cell array, then the return value is a cell array of the same shape as `str`.

The `category` input can be any of the strings shown in the left column below:

Category	Description
alpha	True for those elements of <code>str</code> that are alphabetic
alphanum	True for those elements of <code>str</code> that are alphanumeric
cntrl	True for those elements of <code>str</code> that are control characters (for example, <code>char(0:20)</code> )
digit	True for those elements of <code>str</code> that are numeric digits
graphic	True for those elements of <code>str</code> that are graphic characters. These are all values that represent any characters except for the following:  unassigned, space, line separator, paragraph separator, control characters, Unicode format control characters, private user-defined characters, Unicode surrogate characters, Unicode other characters
lower	True for those elements of <code>str</code> that are lowercase letters
print	True for those elements of <code>str</code> that are graphic characters, plus <code>char(32)</code>

Category	Description
punct	True for those elements of <code>str</code> that are punctuation characters
wspace	True for those elements of <code>str</code> that are white-space characters. This range includes the ANSI® C definition of white space, { ' ', '\t', '\n', '\r', '\v', '\f' }, in addition to a number of other Unicode characters.
upper	True for those elements of <code>str</code> that are uppercase letters
xdigit	True for those elements of <code>str</code> that are valid hexadecimal digits

## Tips

Numbers of type `double` are converted to `int32` according to MATLAB rules of double-to-integer conversion. Numbers of type `int64` and `uint64` bigger than `int32(inf)` saturate to `int32(inf)`.

MATLAB classifies the elements of the `str` input according to the Unicode definition of the specified category. If the numeric value of an element in the input array falls within the range that defines a Unicode character category, then this element is classified as being of that category. The set of Unicode character codes includes the set of ASCII character codes, but also covers a large number of languages beyond the scope of the ASCII set. The classification of characters is dependent on the global location of the platform on which MATLAB is installed.

Whitespace characters for which the `wspace` option returns `true` include tab, line feed, vertical tab, form feed, carriage return, and space, in addition to a number of other Unicode characters. To see all characters for which the `wspace` option returns `true`, enter the following command, and then look up the returned decimal codes in a Unicode reference:

```
find(isstrprop(char(1):char(intmax('uint16')), 'wspace'))
```

## Examples

Test for alphabetic characters in a string:

```
A = isstrprop('abc123def', 'alpha')
```

```
A =  
    1 1 1 0 0 0 1 1 1
```

Test for numeric digits in a string:

```
A = isstrprop('abc123def', 'digit')  
A =  
    0 0 0 1 1 1 0 0 0
```

Test for hexadecimal digits in a string:

```
A = isstrprop('abcd1234efgh', 'xdigit')  
A =  
    1 1 1 1 1 1 1 1 1 0 0
```

Test for numeric digits in a character array:

```
A = isstrprop(char([97 98 99 49 50 51 101 102 103]), ...  
              'digit')  
A =  
    0 0 0 1 1 1 0 0 0
```

Test for alphabetic characters in a two-dimensional cell array:

```
A = isstrprop({'abc123def';'456ghi789'}, 'alpha')  
A =  
    [1x9 logical]  
    [1x9 logical]
```

```
A{:, :}  
ans =  
    1 1 1 0 0 0 1 1 1  
    0 0 0 1 1 1 0 0 0
```

Test for white-space characters in a string:

```
A = isstrprop(sprintf('a bc\n'), 'wspace')  
A =  
    0 1 0 0 1
```

# isstrprop

---

## See Also

strings | ischar | isletter | isspace | iscellstr | isnumeric  
| isa | is\*

**Purpose** Determine whether input is structure array

**Syntax** `tf = isstruct(A)`

**Description** `tf = isstruct(A)` returns logical 1 (true) if A is a MATLAB structure and logical 0 (false) otherwise.

**Examples**

```
patient.name = 'John Doe';  
patient.billing = 127.00;  
patient.test = [79 75 73; 180 178 177.5; 220 210 205];  
  
isstruct(patient)  
  
ans =  
  
    1
```

**See Also** `struct` | `isfield` | `iscell` | `ischar` | `isobject` | `isnumeric` | `islogical` | `isa` | `is*`

**How To**

- dynamic field names

# isstudent

---

**Purpose** Determine if version is Student Version

**Syntax** `tf = isstudent`

**Description** `tf = isstudent` returns logical 1 (true) if the version of MATLAB software is the Student Version, and returns logical 0 (false) for commercial versions.

**See Also** `ver` | `version` | `license` | `ispc` | `isunix` | `is*`

**Purpose** Determine if tiled image

**Syntax** `bool = tiffobj.isTiled()`

**Description** `bool = tiffobj.isTiled()` returns true if the image has a tiled organization and false if the image has a stripped organization.

**Examples** Open a Tiff object and check if the image in the TIFF file has a tiled or stripped organization. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path.

```
t = Tiff('myfile.tif', 'r');  
tf = t.isTiled();
```

**References** This method corresponds to the `TIFFIsTiled` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**Tutorials**

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

# isunix

---

**Purpose** Determine if version is for UNIX platform

**Syntax** `tf = isunix`

**Description** `tf = isunix` returns logical 1 (true) if the version of MATLAB software is for the UNIX<sup>7</sup> platform, and returns logical 0 (false) otherwise.

**See Also** `ispc` | `ismac` | `computer` | `isstudent` | `is*`

7. UNIX is a registered trademark of The Open Group in the United States and other countries

**Purpose** Is object valid handle class object

**Syntax** H1 = isvalid(Hobj)

**Description** H1 = isvalid(Hobj) returns a logical array (or scalar if Hobj is scalar) in which each element is true if the corresponding element in Hobj is a valid handle. This method is **Sealed**, so you cannot override it in a handle subclass.

---

**Note** This method does not work with Handle Graphics objects. To determine the validity of a Handle Graphics object handle, use the `ishandle` function.

---

**See Also** delete (handle) | handle

**How To** • “Testing Handle Validity”

# isvalid (serial)

---

**Purpose** Determine whether serial port objects are valid

**Syntax** `out = isvalid(obj)`

**Description** `out = isvalid(obj)` returns the logical array `out`, which contains a 0 where the elements of the serial port object, `obj` are invalid serial port objects and a 1 where the elements of `obj` are valid serial port objects.

**Tips** `obj` becomes invalid after it is removed from memory with the `delete` function. Because you cannot connect an invalid serial port object to the device, you should remove it from the workspace with the `clear` command.

**Examples** Suppose you create the following two serial port objects.

```
s1 = serial('COM1');  
s2 = serial('COM1');
```

`s2` becomes invalid after it is deleted.

```
delete(s2)
```

`isvalid` verifies that `s1` is valid and `s2` is invalid.

```
sarray = [s1 s2];  
isvalid(sarray)  
ans =  
     1     0
```

**See Also** `clear` | `delete`

**Purpose** Determine whether timer object is valid

**Syntax** `out = isvalid(obj)`

**Description** `out = isvalid(obj)` returns a logical array, `out`, that contains a 0 where the elements of `obj` are invalid timer objects and a 1 where the elements of `obj` are valid timer objects.

An invalid timer object is an object that has been deleted and cannot be reused. Use the `clear` command to remove an invalid timer object from the workspace.

**Examples** Create a valid timer object.

```
t = timer;  
out = isvalid(t)  
out =
```

```
1
```

Delete the timer object, making it invalid.

```
delete(t)  
out1 = isvalid(t)  
out1 =
```

```
0
```

**See Also** `timer` | `delete(timer)`

# isvarname

---

**Purpose** Determine whether input is valid variable name

**Syntax** `tf = isvarname('str')`  
`isvarname str`

**Description** `tf = isvarname('str')` returns logical 1 (true) if the string `str` is a valid MATLAB variable name and logical 0 (false) otherwise. A valid variable name is a character string of letters, digits, and underscores, totaling not more than `namelengthmax` characters and beginning with a letter.

MATLAB keywords are not valid variable names. Type the command `iskeyword` with no input arguments to see a list of MATLAB keywords.

`isvarname str` uses the MATLAB command format.

**Examples** This variable name is valid:

```
isvarname foo
ans =
     1
```

This one is not because it starts with a number:

```
isvarname 8th_column
ans =
     0
```

If you are building strings from various pieces, place the construction in parentheses.

```
d = date;

isvarname(['Monday_', d(1:2)])
ans =
     1
```

**See Also** `genvarname` | `isglobal` | `iskeyword` | `namelengthmax` | `is*`

**Purpose** Determine whether input is vector

**Syntax** `isvector(A)`

**Description** `isvector(A)` returns logical 1 (true) if `size(A)` returns `[1 n]` or `[n 1]` with a nonnegative integer value `n`, and logical 0 (false) otherwise.

**Examples** Test matrix A and its row and column vectors:

```
A = rand(5);
```

```
isvector(A)
ans =
     0
```

```
isvector(A(3, :))
ans =
     1
```

```
isvector(A(:, 2))
ans =
     1
```

**See Also** `iscolumn` | `ismatrix` | `isrow` | `isscalar` | `isempty` | `isnumeric` | `islogical` | `ischar` | `isa` | `is*`

**Purpose** Imaginary unit

**Syntax**  
j  
x+yj  
x+j\*y

**Description** As the basic imaginary unit  $\sqrt{-1}$ , `j` is used to enter complex numbers. You can also use the character `i` as the imaginary unit. If you want to create a complex number without using `i` and `j`, you can use the `complex` function.

Since `j` is a function, it can be overridden and used as a variable. However, it is best to avoid using `i` and `j` for variable names if you intend to use them in complex arithmetic.

If desired, you can use the character `j` without a multiplication sign as a suffix in forming a complex numerical constant.

For speed and improved robustness, you can replace complex `i` and `j` by `1i`. For example, instead of using

```
a = j;
```

use

```
a = 1i;
```

**Examples**  
 $Z = 2+3j$   
 $Z = x+j*y$   
 $Z = r*\exp(j*\theta)$

**See Also** `conj` | `i` | `imag` | `real`

**Purpose** Add entries to dynamic Java class path

**Syntax**  
`javaaddpath(dpath1,...,dpathN)`  
`javaaddpath(dpath1,...,dpathN,'-end')`

**Description**  
`javaaddpath(dpath1,...,dpathN)` adds one or more folders or JAR files to the beginning of the current dynamic Java class path.  
`javaaddpath(dpath1,...,dpathN,'-end')` adds files or folders to the end of the path.

**Tips**  
 The Java path consists of two segments: a static path (read only at startup) and a dynamic path. MATLAB always searches the static path before the dynamic path. Java classes on the static path should not have dependencies on classes on the dynamic path. Use `javaclasspath` to see the current static and dynamic Java paths.

MATLAB calls the `clear java` command whenever you change the dynamic path.

Path Type	Description
Static	Loaded at the start of each MATLAB session from the MATLAB built-in Java path and the file <code>javaclasspath.txt</code> . The static Java path offers better Java class loading performance than the dynamic Java path. However, to modify the static Java path you need to edit the file <code>javaclasspath.txt</code> and restart MATLAB.
Dynamic	Loaded at any time during a MATLAB session using the <code>javaclasspath</code> function. You can define the dynamic path (using <code>javaclasspath</code> ), modify the path (using <code>javaaddpath</code> and <code>javarmpath</code> ), and refresh the Java class definitions for all classes on the dynamic path (using <code>clear java</code> ) without restarting MATLAB.

# javaaddpath

---

## Input Arguments

### **dpath1,...,dpathN**

String or cell array of strings specifying the folder or JAR file.

## Examples

This example demonstrates modifying the dynamic Java class path.

- 1 Create a function to set your initial dynamic class path:

```
function setdynpath
javaclasspath({
    'C:\Work\Java\ClassFiles', ...
    'C:\Work\JavaTest\curvefit.jar', ...
    'C:\Work\JavaTest\timer.jar', ...
    'C:\Work\JavaTest\patch.jar'});
% end of file
```

- 2 Call this function to set up your dynamic class path and then display all current static and dynamic paths:

```
setdynpath;
```

```
javaclasspath
```

```
        STATIC JAVA PATH
```

```
D:\Sys0\Java\util.jar
D:\Sys0\Java\widgets.jar
D:\Sys0\Java\beans.jar
```

```
      .
      .
```

```
        DYNAMIC JAVA PATH
```

```
C:\Work\Java\ClassFiles
C:\Work\JavaTest\curvefit.jar
C:\Work\JavaTest\timer.jar
C:\Work\JavaTest\patch.jar
```

- 3 Add the following entries to the dynamic path. One entry specifies a folder and the other a Java Archive (JAR) file. When you add a folder to the path, MATLAB includes all files in that folder as part of the path:

```
javaaddpath({  
    'C:\Work\Java\Curvefit\Test', ...  
    'C:\Work\Java\mywidgets.jar'});
```

- 4 Display the dynamic path:

```
p = javaclasspath  
p =  
    'C:\Work\Java\ClassFiles'  
    'C:\Work\JavaTest\curvefit.jar'  
    'C:\Work\JavaTest\timer.jar'  
    'C:\Work\JavaTest\patch.jar'  
    'C:\Work\Java\Curvefit\Test'  
    'C:\Work\Java\mywidgets.jar'
```

- 5 Create an instance of the `mywidgets` class that is defined on the dynamic path:

```
h = mywidgets.calendar;
```

- 6 If you modify one or more classes defined on the dynamic path, you must clear the former definition for those classes from MATLAB memory. To clear all dynamic class definitions, type:

```
clear java
```

If you then create a new instance of one of these classes, MATLAB uses the latest definition of the class to create the object.

- 7 Remove `mywidgets.jar` from the current dynamic class path:

```
javarmpath('C:\Work\Java\mywidgets.jar');
```

# javaaddpath

---

---

Add a JAR file from an internet URL to the Java path:

```
javaaddpath http://www.example.com/my.jar
```

---

Add the current folder:

```
javaaddpath(pwd)
```

## See Also

```
javaclasspath | javarmpath | clear
```

## How To

- “Bringing Java Classes into MATLAB Workspace”

<b>Purpose</b>	Construct Java array
<b>Syntax</b>	<code>objArray = javaArray(PackageName.ClassName,x1,...,xn)</code>
<b>Description</b>	<code>objArray = javaArray(PackageName.ClassName,x1,...,xn)</code> constructs an empty Java array for objects of the specified Java class.
<b>Tips</b>	<ul style="list-style-type: none"> <li>• The array created by <code>javaArray</code> is equivalent to the array created by the following Java code:  <code>A = new class_name[x1]...[xn];</code></li> <li>• To create an array of primitive Java types, create an array of the equivalent MATLAB type, as shown in the table, “Conversion of MATLAB Types to Java Types”.</li> </ul>
<b>Input Arguments</b>	<p><b>PackageName.ClassName</b> String specifying Java class. You must include the package name when specifying the class.</p> <p><b>x1,...,xn</b> Dimensions of the array.</p>
<b>Output Arguments</b>	<p><b>objArray</b> Java array with dimensions <code>x1, ..., xn</code>.</p>
<b>Examples</b>	<p>This example constructs and populates a 4-by-5 array of <code>java.lang.Double</code> objects.</p> <pre>dblArray = javaArray ('java.lang.Double', 4, 5); for m = 1:4     for n = 1:5         dblArray(m,n) = java.lang.Double((m*10) + n);     end end</pre>

# javaArray

---

```
dblArray
```

```
dblArray =  
java.lang.Double[][]:  
    [11]    [12]    [13]    [14]    [15]  
    [21]    [22]    [23]    [24]    [25]  
    [31]    [32]    [33]    [34]    [35]  
    [41]    [42]    [43]    [44]    [45]
```

## See Also

```
javaObjectEDT | javaMethodEDT | class | methodsvew | isjava
```

**Purpose** Generate error message based on Java feature support

**Syntax**  
javachk(feature)  
javachk(feature, component)

**Description** javachk(feature) returns a generic error message if the specified Java feature is not available in the current MATLAB session. If it is available, javachk returns an error structure with empty message and identifier fields.

The following table shows the valid feature arguments.

Feature	Description
'awt'	Java GUI components in the Abstract Window Toolkit components are available.
'desktop'	The MATLAB interactive desktop is running.
'jvm'	The Java Virtual Machine software (JVM™) is running.
'swing'	Swing components (Java lightweight GUI components in the Java Foundation Classes) are available.

javachk(feature, component) works the same as the above syntax, except that the specified component is also named in the error message.

**See Also** usejava

# javaclasspath

---

**Purpose** Get and set Java class path

**Syntax**

```
javaclasspath
javaclasspath('-dynamic')
javaclasspath('-static')
dpath = javaclasspath
spath = javaclasspath('-static')
jpath = javaclasspath('-all')
javaclasspath(dpath)
javaclasspath(dpath1, dpath2)
javaclasspath(statusmsg)
```

**Description** javaclasspath displays the static and dynamic segments of the Java path.

javaclasspath('-dynamic') displays the dynamic Java path.

javaclasspath('-static') displays the static Java path.

dpath = javaclasspath returns the dynamic segment of the Java path in cell array, dpath. If no dynamic paths are defined, javaclasspath returns an empty cell array.

spath = javaclasspath('-static') returns the static segment of the Java path in cell array, spath. No path information is displayed unless you specify an output variable. If no static paths are defined, javaclasspath returns an empty cell array.

jpath = javaclasspath('-all') returns the entire Java path in cell array, jpath. The returned cell array contains first the static segment of the path, and then the dynamic segment. No path information is displayed unless you specify an output variable. If no dynamic paths are defined, javaclasspath returns an empty cell array.

javaclasspath(dpath) changes the dynamic Java path to dpath, where dpath can be a string or cell array of strings representing path entries. Relative paths are converted to absolute paths. Uses the clear java command to refresh the classes defined on the dynamic Java path.

`javaclasspath(dpath1, dpath2)` changes the dynamic Java path to the concatenation of the two paths `dpath1` and `dpath2`, where `dpath1` and `dpath2` can be a string or cell array of strings representing path entries. Relative paths are converted to absolute paths. Uses the `clear java` command to refresh the classes defined on the dynamic Java path.

`javaclasspath(statusmsg)` enables or disables the display of status messages from the `javaclasspath`, `javaaddpath`, and `javarmppath` functions. Values for the `statusmsg` argument are shown in the following table:

statusmsg	Description
'-v1'	Display status messages while loading the Java path from the file system.
'-v0'	Do not display status messages. This is the default.

## Tips

The Java path consists of two segments: a static path (read only at startup) and a dynamic path. MATLAB always searches the static path before the dynamic path. Java classes on the static path should not have dependencies on classes on the dynamic path. Use `javaclasspath` to see the current static and dynamic Java paths.

MATLAB calls the `clear java` command whenever you change the dynamic path.

Path Type	Description
Static	Loaded at the start of each MATLAB session from the MATLAB built-in Java path and the file <code>javaclasspath.txt</code> . The static Java path offers better Java class loading performance than the dynamic Java path. However, to modify the static Java path you need to edit the file <code>javaclasspath.txt</code> and restart MATLAB.
Dynamic	Loaded at any time during a MATLAB session using the <code>javaclasspath</code> function. You can define the dynamic

# javaclasspath

---

Path Type	Description
	path (using javaclasspath), modify the path (using javaaddpath and javarmpath), and refresh the Java class definitions for all classes on the dynamic path (using clear java) without restarting MATLAB.

## Examples

This examples demonstrates modifying the dynamic Java class path.

- 1 Create a function to set your initial dynamic class path:

```
function setdynpath
javaclasspath({
    'C:\Work\Java\ClassFiles', ...
    'C:\Work\JavaTest\curvefit.jar', ...
    'C:\Work\JavaTest\timer.jar', ...
    'C:\Work\JavaTest\patch.jar'});
% end of file
```

- 2 Call this function to set up your dynamic class path and then display all current static and dynamic paths:

```
setdynpath;

javaclasspath

          STATIC JAVA PATH

D:\Sys0\Java\util.jar
D:\Sys0\Java\widgets.jar
D:\Sys0\Java\beans.jar
      .
      .

          DYNAMIC JAVA PATH

C:\Work\Java\ClassFiles
```

```
C:\Work\JavaTest\curvefit.jar
C:\Work\JavaTest\timer.jar
C:\Work\JavaTest\patch.jar
```

- 3 Add the following entries to the dynamic path. One entry specifies a folder and the other a Java Archive (JAR) file. When you add a folder to the path, MATLAB includes all files in that folder as part of the path:

```
javaaddpath({
    'C:\Work\Java\Curvefit\Test', ...
    'C:\Work\Java\mywidgets.jar'});
```

- 4 Display the dynamic path:

```
p = javaclasspath
p =
    'C:\Work\Java\ClassFiles'
    'C:\Work\JavaTest\curvefit.jar'
    'C:\Work\JavaTest\timer.jar'
    'C:\Work\JavaTest\patch.jar'
    'C:\Work\Java\Curvefit\Test'
    'C:\Work\Java\mywidgets.jar'
```

- 5 Create an instance of the `mywidgets` class that is defined on the dynamic path:

```
h = mywidgets.calendar;
```

- 6 If you modify one or more classes defined on the dynamic path, you must clear the former definition for those classes from MATLAB memory. To clear all dynamic class definitions, type:

```
clear java
```

If you then create a new instance of one of these classes, MATLAB uses the latest definition of the class to create the object.

# javaclasspath

---

**7** Remove mywidgets.jar from the current dynamic class path:

```
javarmpath('C:\Work\Java\mywidgets.jar');
```

## **See Also**

javaaddpath | javarmpath | clear

<b>Purpose</b>	Capture error information for Java exception
<b>Description</b>	Process information from a <code>matlab.exception.JavaException</code> object to handle Java errors thrown from Java methods called from MATLAB. This class is derived from <code>MException</code> .
<b>Construction</b>	<code>e = matlab.exception.JavaException(msgID, errMsg, excObj)</code> constructs instance <code>e</code> of <code>matlab.exception.JavaException</code> class.
	<b>Input Arguments</b>
	<b>msgID</b> message identifier
	<b>errMsg</b> error message string
	<b>excObj</b> <code>java.lang.Throwable</code> object that caused the exception
	<b>Output Arguments</b>
	<b>e</b> Instance of <code>matlab.exception.JavaException</code> class
<b>Properties</b>	<b>ExceptionObject</b> Java exception object that caused the error.
<b>Tips</b>	<ul style="list-style-type: none"><li>You do not typically construct a <code>matlab.exception.JavaException</code> object explicitly. MATLAB automatically constructs a <code>JavaException</code> object whenever Java throws an exception. The <code>JavaException</code> object wraps the original Java exception.</li></ul>
<b>Copy Semantics</b>	Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB Programming Fundamentals documentation.

# matlab.exception.JavaException

---

## Examples

```
try
    java.lang.Class.forName('foo');
catch e
    e.message
    if(isa(e, 'matlab.exception.JavaException'))
        ex = e.ExceptionObject;
        assert(isJava(ex));
        ex.printStackTrace;
    end
end
```

## Concepts

- “Capture Information About Exceptions”
- “Throw an Exception”

**Purpose** Invoke Java method

**Syntax** `javaMethod(MethodName, ClassName, x1, ..., xn)`  
`javaMethod(MethodName, JavaObj, x1, ..., xn)`

**Description** `javaMethod(MethodName, ClassName, x1, ..., xn)` calls the static method `MethodName` in the class `ClassName` with the signature matching the arguments `x1, ..., xn`. `MethodName` and `ClassName` are strings.

`javaMethod(MethodName, JavaObj, x1, ..., xn)` calls the nonstatic method `MethodName` on the Java object array `JavaObj`.

**Tips** Use the `javaMethod` function to:

- Use methods having names longer than 31 characters.
- Specify the method you want to invoke at run-time, for example, as input from an application user.

The `javaMethod` function enables you to use methods having names longer than 31 characters. This is the only way you can invoke such a method in the MATLAB software. For example:

```
javaMethod('DataDefinitionAndDataManipulationTransactions', T);
```

With `javaMethod`, you can also specify the method to be invoked at run-time. In this situation, your code calls `javaMethod` with a string variable in place of the method name argument. When you use `javaMethod` to invoke a static method, you can also use a string variable in place of the class name argument.

---

**Note** Typically, you do not need to use `javaMethod`. Use the default MATLAB syntax for invoking a Java methods instead. Use `javaMethod` for the cases described above.

---

# javaMethod

---

## Examples

To invoke the static Java method `isNaN` on class `java.lang.Double` type:

```
javaMethod('isNaN', 'java.lang.Double', 2.2)
```

The following example invokes the nonstatic method `setMonth`, where `myDate` is a `java.util.Date` object.

```
myDate = java.util.Date;  
javaMethod('setMonth', myDate, 3);
```

## See Also

[javaArray](#) | [javaObject](#) | [import](#) | [methods](#) | [isjava](#) | [javaMethodEDT](#)

**Purpose**

Invoke Java method from Event Dispatch Thread (EDT)

**Syntax**

```
javaMethodEDT(MethodName,ClassName,x1,...,xn)  
javaMethodEDT(MethodName,JavaObj,x1,...,xn)
```

**Description**

javaMethodEDT(MethodName,ClassName,x1,...,xn) invokes the Java class method with the specified input arguments from the Event Dispatch Thread (EDT).

javaMethodEDT(MethodName,JavaObj,x1,...,xn) invokes a nonstatic method on a Java object array.

**Input Arguments****MethodName**

String representing method in Java ClassName class.

**ClassName**

String representing Java class containing MethodName.

**x1,...,xn**

Input arguments matching MethodName signature.

**JavaObj**

Java object array.

**Examples**

Invoke the static method setDefaultLookAndFeelDecorated in class javax.swing.JFrame:

```
javaMethodEDT('setDefaultLookAndFeelDecorated','javax.swing.JFrame',
```

---

Create a vector v on the MATLAB thread and invoke the add method from the EDT.

```
v = java.util.Vector;  
javaMethodEDT('add',v,'string');
```

# javaMethodEDT

---

<b>Purpose</b>	Invoke Java constructor
<b>Syntax</b>	<code>javaObject(ClassName, x1, ..., xn)</code>
<b>Description</b>	<p><code>javaObject(ClassName, x1, ..., xn)</code> calls the Java constructor for class <code>ClassName</code> with the argument list that matches <code>x1, ..., xn</code>, to return a new object. <code>ClassName</code> is a string.</p> <p>If there is no constructor that matches the class name and argument list passed to <code>javaObject</code>, an error occurs.</p>
<b>Tips</b>	For more information, see “Using the <code>javaObjectEDT</code> Function”.
<b>Examples</b>	<p>The following example constructs and returns a Java object of class <code>java.lang.String</code>:</p> <pre>strObj = javaObject('java.lang.String','hello')</pre>
<b>See Also</b>	<code>javaArray</code>   <code>javaMethod</code>   <code>import</code>   <code>methods</code>   <code>fieldnames</code>   <code>isjava</code>   <code>javaObjectEDT</code>

# javaObjectEDT

---

- Purpose** Java object constructor on Event Dispatch Thread (EDT)
- Syntax** `jObj = javaObjectEDT(ClassName,x1,...,xn)`
- Description** `jObj = javaObjectEDT(ClassName,x1,...,xn)` invokes the Java constructor for class `ClassName` with the signature matching the arguments `x1, ..., xn` from the EDT and returns a Java object array.
- Tips**
- Static methods on the specified class or Java object run on the MATLAB thread unless invoked using the `javaMethodEDT` function.

- Input Arguments**
- ClassName**  
Java class name.
- x1,...,xn**  
Optional input arguments for class constructor. If none, MATLAB calls the no-argument constructor.

- Output Arguments**
- jObj**  
Java object array. MATLAB invokes subsequent methods on this object from the EDT.

- Examples** Construct and return a `javax.swing.JFrame` object array from the EDT.

```
f = javaObjectEDT('javax.swing.JFrame', 'New Title')
```

---

Create a `JOptionPane` pane on the EDT and call the `createDialog` method.

```
% Create a JOptionPane pane on the EDT
optPane = javaObjectEDT('javax.swing.JOptionPane');
% Call the createDialog method - automatically done on the EDT
dlg = optPane.createDialog([], 'Sample Dialog');
% Tell MATLAB to dispatch methods on dlg from the EDT
```

```
javaObjectEDT(dlg);
```

**See Also**

```
javaMethodEDT | javaObject | import | methods | isjava
```

# javarmpath

---

**Purpose** Remove entries from dynamic Java class path

**Syntax**  
`javarmpath(dpath)`  
`javarmpath(dpath1,...,dpathN)`  
`javarmpath(v1,...,vN)`

**Description** `javarmpath(dpath)` removes specified file or folder from the current dynamic Java path.  
`javarmpath(dpath1,...,dpathN)` removes multiple files or folders.  
`javarmpath(v1,...,vN)` removes files or folders specified as MATLAB variables.

**Tips** The Java path consists of two segments: a static path (read only at startup) and a dynamic path. MATLAB always searches the static path before the dynamic path. Java classes on the static path should not have dependencies on classes on the dynamic path. Use `javaclasspath` to see the current static and dynamic Java paths.

MATLAB calls the `clear java` command whenever you change the dynamic path.

Path Type	Description
Static	Loaded at the start of each MATLAB session from the MATLAB built-in Java path and the file <code>javaclasspath.txt</code> . The static Java path offers better Java class loading performance than the dynamic Java path. However, to modify the static Java path you need to edit the file <code>javaclasspath.txt</code> and restart MATLAB.
Dynamic	Loaded at any time during a MATLAB session using the <code>javaclasspath</code> function. You can define the dynamic path (using <code>javaclasspath</code> ), modify the path (using <code>javaaddpath</code> and <code>javarmpath</code> ), and refresh the Java class definitions for all classes on the dynamic path (using <code>clear java</code> ) without restarting MATLAB.

**Input Arguments****dpath**

String specifying a file or folder.

**dpath1,...,dpathN**

Strings specifying multiple files or folders.

**v1,...,vN**

One or more MATLAB variables containing file or folder names.

**Examples**

This example demonstrates modifying the dynamic Java class path.

- 1 Create a function to set your initial dynamic class path:

```
function setdynpath
javaclasspath({
    'C:\Work\Java\ClassFiles', ...
    'C:\Work\JavaTest\curvefit.jar', ...
    'C:\Work\JavaTest\timer.jar', ...
    'C:\Work\JavaTest\patch.jar'});
% end of file
```

- 2 Call this function to set up your dynamic class path and then display all current static and dynamic paths:

```
setdynpath;

javaclasspath

        STATIC JAVA PATH

D:\Sys0\Java\util.jar
D:\Sys0\Java\widgets.jar
D:\Sys0\Java\beans.jar
.
.
```

## DYNAMIC JAVA PATH

```
C:\Work\Java\ClassFiles
C:\Work\JavaTest\curvefit.jar
C:\Work\JavaTest\timer.jar
C:\Work\JavaTest\patch.jar
```

- 3 Add the following entries to the dynamic path. One entry specifies a folder and the other a Java Archive (JAR) file. When you add a folder to the path, MATLAB includes all files in that folder as part of the path:

```
javaaddpath({
    'C:\Work\Java\Curvefit\Test', ...
    'C:\Work\Java\mywidgets.jar'});
```

- 4 Display the dynamic path:

```
p = javaclasspath
p =
    'C:\Work\Java\ClassFiles'
    'C:\Work\JavaTest\curvefit.jar'
    'C:\Work\JavaTest\timer.jar'
    'C:\Work\JavaTest\patch.jar'
    'C:\Work\Java\Curvefit\Test'
    'C:\Work\Java\mywidgets.jar'
```

- 5 Create an instance of the mywidgets class that is defined on the dynamic path:

```
h = mywidgets.calendar;
```

- 6 If you modify one or more classes defined on the dynamic path, you must clear the former definition for those classes from MATLAB memory. To clear all dynamic class definitions, type:

```
clear java
```

If you then create a new instance of one of these classes, MATLAB uses the latest definition of the class to create the object.

**7** Remove `mywidgets.jar` from the current dynamic class path:

```
javarmpath('C:\Work\Java\mywidgets.jar');
```

## See Also

`javaclasspath` | `javaaddpath` | `clear`

# keyboard

---

**Purpose** Input from keyboard

**Syntax** keyboard

**Description** keyboard , when placed in a program .m file, stops execution of the file and gives control to the keyboard. The special status is indicated by a K appearing before the prompt. You can examine or change variables; all MATLAB commands are valid. This keyboard mode is useful for debugging your functions.

To terminate the keyboard mode, type return, and then press **Enter**. To terminate keyboard mode and exit the function, type dbquit, and press **Enter**.

**See Also** dbstop | input | quit | pause | return

<b>Purpose</b>	Identify keys of containers.Map object
<b>Syntax</b>	<code>keySet = keys(mapObj)</code>
<b>Description</b>	<code>keySet = keys(mapObj)</code> returns cell array <code>keySet</code> , which contains all of the keys in <code>mapObj</code> .
<b>Input Arguments</b>	<b>mapObj</b> Object of class <code>containers.Map</code> .
<b>Output Arguments</b>	<b>keySet</b> 1-by-n cell array, where n is the number of keys in <code>mapObj</code> .
<b>Examples</b>	<b>Get the Keys in a Map</b> Create a map, and view the keys in the map: <pre>myKeys = {'a','b','c'}; myValues = [1,2,3]; mapObj = containers.Map(myKeys,myValues);  keySet = keys(mapObj)</pre> <p>This code returns 1-by-3 cell array <code>keySet</code>:</p> <pre>keySet =     'a'    'b'    'c'</pre>
<b>See Also</b>	<code>containers.Map</code>   <code>isKey</code>   <code>values</code>   <code>remove</code>

# kron

---

**Purpose** Kronecker tensor product

**Syntax** `K = kron(X,Y)`

**Description** `K = kron(X,Y)` returns the Kronecker tensor product of `X` and `Y`. The result is a large array formed by taking all possible products between the elements of `X` and those of `Y`. If `X` is `m`-by-`n` and `Y` is `p`-by-`q`, then `kron(X,Y)` is `m*p`-by-`n*q`.

**Examples** If `X` is 2-by-3, then `kron(X,Y)` is

```
[ X(1,1)*Y X(1,2)*Y X(1,3)*Y
  X(2,1)*Y X(2,2)*Y X(2,3)*Y ]
```

The matrix representation of the discrete Laplacian operator on a two-dimensional, `n`-by-`n` grid is a `n^2`-by-`n^2` sparse matrix. There are at most five nonzero elements in each row or column. The matrix can be generated as the Kronecker product of one-dimensional difference operators with these statements:

```
I = speye(n,n);
E = sparse(2:n,1:n-1,1,n,n);
D = E+E' -2*I;
A = kron(D,I)+kron(I,D);
```

Plotting this with the `spy` function for `n = 5` yields:

**See Also**

hankel | toeplitz

# last (MException)

---

**Purpose** Last uncaught exception

**Syntax** `exception = MException.last`  
`MException.last('reset')`

**Description** `exception = MException.last` displays the contents of the MException object representing your most recent uncaught error. This is a static method of the MException class; it is not a method of an MException instance.

---

**Note** Use this method from the MATLAB command line only, and not within a function.

---

`MException.last('reset')` sets the `identifier` and `message` properties of the exception retrieved by `MException.last` to the empty string, the `stack` property to a 0-by-1 structure, and `cause` property to an empty cell array.

`MException.last` is not set if an exception is caught by a try-catch statement.

**Examples** This example displays the last error that was caught during this MATLAB session:

```
A = 25;  
A(2)  
??? Index exceeds matrix dimensions.
```

```
MException.last  
ans =
```

MException object with properties:

```
    identifier: 'MATLAB:badsubscript'  
    message: 'Index exceeds matrix dimensions.'
```

```
stack: [0x1 struct]  
cause: {}
```

### See Also

| rethrow(MException) | throwAsCaller(MException) |  
addCause(MException) | getReport(MException)
```

# Tiff.lastDirectory

---

**Purpose** Determine if current IFD is last in file

**Syntax** `bool = tiffobj.lastDirectory()`

**Description** `bool = tiffobj.lastDirectory()` returns true if the current image file directory (IFD) is the last IFD in the TIFF file; otherwise, false.

**Examples** Open a Tiff object and determine if the current directory is the last directory in the file. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path. If the file contains only one image, the current IFD will be the last:

```
t = Tiff('myfile.tif', 'r');
tf = t.lastDirectory();
```

**References** This method corresponds to the `TIFFLastDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**See Also** `Tiff.setDirectory`

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

**Purpose** Last error message

---

**Note** lasterr will be removed in a future version. You can obtain information about any error that has been generated by catching an MException. See “Capture Information About Exceptions” in the Programming Fundamentals documentation.

---

**Syntax**

```
msgstr = lasterr
[msgstr, msgid] = lasterr
lasterr('new_msgstr')
lasterr('new_msgstr', 'new_msgid')
[msgstr, msgid] = lasterr('new_msgstr', 'new_msgid')
```

**Description** msgstr = lasterr returns the last error message generated by the MATLAB software.

[msgstr, msgid] = lasterr returns the last error in msgstr and its message identifier in msgid. If the error was not defined with an identifier, lasterr returns an empty string for msgid. See “Message Identifiers” in the MATLAB Programming Fundamentals documentation for more information on the msgid argument and how to use it.

lasterr('new\_msgstr') sets the last error message to a new string, new\_msgstr, so that subsequent invocations of lasterr return the new error message string. You can also set the last error to an empty string with lasterr('').

lasterr('new\_msgstr', 'new\_msgid') sets the last error message and its identifier to new strings new\_msgstr and new\_msgid, respectively. Subsequent invocations of lasterr return the new error message and message identifier.

[msgstr, msgid] = lasterr('new\_msgstr', 'new\_msgid') returns the last error message and its identifier, also changing these values so that subsequent invocations of lasterr return the message and identifier strings specified by new\_msgstr and new\_msgid respectively.

## Examples

### Example 1

Here is a function that examines the `lasterr` string and displays its own message based on the error that last occurred. This example deals with two cases, each of which is an error that can result from a matrix multiply:

```
function matrix_multiply(A, B)
try
    A * B
catch
    errmsg = lasterr;
    if(strfind(errmsg, 'Inner matrix dimensions'))
        disp('** Wrong dimensions for matrix multiply')
    else
        if(strfind(errmsg, 'not defined for variables of class'))
            disp('** Both arguments must be double matrices')
        end
    end
end
end
```

If you call this function with matrices that are incompatible for matrix multiplication (e.g., the column dimension of A is not equal to the row dimension of B), MATLAB catches the error and uses `lasterr` to determine its source:

```
A = [1  2  3; 6  7  2; 0 -1  5];
B = [9  5  6; 0  4  9];
```

```
matrix_multiply(A, B)
** Wrong dimensions for matrix multiply
```

### Example 2

Specify a message identifier and error message string with `error`:

```
error('MyToolbox:angleTooLarge', ...
    'The angle specified must be less than 90 degrees.');
```

In your error handling code, use `lasterr` to determine the message identifier and error message string for the failing operation:

```
[errmsg, msgid] = lasterr
errmsg =
    The angle specified must be less than 90 degrees.
msgid =
    MyToolbox:angleTooLarge
```

# lasterror

---

## Purpose

Last error message and related information

---

**Note** `lasterror` will be removed in a future version. You can obtain information about any error that has been generated by catching an `MException`. See “Capture Information About Exceptions” in the Programming Fundamentals documentation.

---

## Syntax

```
s = lasterror
s = lasterror(err)
s = lasterror('reset')
```

## Description

`s = lasterror` returns a structure `s` containing information about the most recent error issued by the MATLAB software. The return structure contains the following fields:

Fieldname	Description
message	Character array containing the text of the error message.
identifier	Character array containing the message identifier of the error message. If the last error issued by MATLAB had no message identifier, then the <code>identifier</code> field is an empty character array.
stack	Structure providing information on the location of the error. The structure has fields <code>file</code> , <code>name</code> , and <code>line</code> , and is the same as the structure returned by the <code>dbstack</code> function. If <code>lasterror</code> returns no stack information, <code>stack</code> is a 0-by-1 structure having the same three fields.

---

**Note** The `lasterror` return structure might contain additional fields in future versions of MATLAB.

---

The fields of the structure returned in `stack` are

Fieldname	Description
<code>file</code>	Name of the file in which the function generating the error appears. This field is the empty string if there is no file.
<code>name</code>	Name of the function in which the error occurred. If this is the primary function in the file, and the function name differs from the file name, <code>name</code> is set to the file name.
<code>line</code>	Line number of the file at which the error occurred.

See “Message Identifiers” in the MATLAB Programming Fundamentals documentation for more information on the syntax and usage of message identifiers.

`s = lasterror(err)` sets the last error information to the error message and identifier specified in the structure `err`. Subsequent invocations of `lasterror` return this new error information. The optional return structure `s` contains information on the previous error.

`s = lasterror('reset')` sets the last error information to the default state. In this state, the `message` and `identifier` fields of the return structure are empty strings, and the `stack` field is a 0-by-1 structure.

## Tips

MathWorks is gradually transitioning MATLAB error handling to an object-oriented scheme that is based on the `MException` class. Although support for `lasterror` is expected to continue, using the static `last` method of `MException` is preferable.

## Warning

**`lasterror` and `MException.last` are not guaranteed to always return identical results. For example, `MException.last` updates its error status only on uncaught errors, where `lasterror` can update its error status on any error, whether it is caught or not.**

## Examples

### Example 1

Save the following MATLAB code in a file called `average.m`:

```
function y = average(x)
% AVERAGE Mean of vector elements.
% AVERAGE(X), where X is a vector, is the mean of vector elements.
% Nonvector input results in an error.
check_inputs(x)
y = sum(x)/length(x);    % The actual computation

function check_inputs(x)
[m,n] = size(x);
if (~((m == 1) || (n == 1)) || (m == 1 && n == 1))
    error('AVG:NotAVector', 'Input must be a vector.')
end
```

Now run the function. Because this function requires vector input, passing a scalar value to it forces an error. The error occurs in subroutine `check_inputs`:

```
average(200)
Error using average>check_inputs (line 11)
Input must be a vector.
```

```
Error in average (line 5)
check_inputs(x)
```

Get the three fields from `lasterror`:

```
err = lasterror
err =
    message: [1x61 char]
  identifier: 'AVG:NotAVector'
      stack: [2x1 struct]
```

Display the text of the error message:

```
msg = err.message
```

```
msg =  
    Error using average>check_inputs (line 11)  
    Input must be a vector.
```

Display the fields containing the stack information. `err.stack` is a 2-by-1 structure because it provides information on the failing subroutine `check_inputs` and also the outer, primary function `average`:

```
st1 = err.stack(1,1)  
st1 =  
    file: 'd:\matlab_test\average.m'  
    name: 'check_inputs'  
    line: 11  
  
st2 = err.stack(2,1)  
st2 =  
    file: 'd:\matlab_test\average.m'  
    name: 'average'  
    line: 5
```

---

**Note** As a rule, the name of your primary function should be the same as the name of the file that contains that function. If these names differ, MATLAB uses the file name in the `name` field of the `stack` structure.

---

## Example 2

`lasterror` is often used in conjunction with the `rethrow` function in try-catch statements. For example,

```
try  
    do_something  
catch  
    do_cleanup  
    rethrow(lasterror)  
end
```

# lasterror

---

## See Also

`last(MException)` | `MException` | `try` | `catch` | `error` | `assert` |  
`rethrow` | `lastwarn` | `dbstack`

- Purpose** Last warning message
- Syntax**
- ```
msgstr = lastwarn
[msgstr, msgid] = lastwarn
lastwarn('new_msgstr')
lastwarn('new_msgstr', 'new_msgid')
[msgstr, msgid] = lastwarn('new_msgstr', 'new_msgid')
```
- Description**
- `msgstr = lastwarn` returns the last warning message generated by the MATLAB software.
- `[msgstr, msgid] = lastwarn` returns the last warning in `msgstr` and its message identifier in `msgid`. If the warning was not defined with an identifier, `lastwarn` returns an empty string for `msgid`.
- `lastwarn('new_msgstr')` sets the last warning message to a new string, `new_msgstr`, so that subsequent invocations of `lastwarn` return the new warning message string. You can also set the last warning to an empty string with `lastwarn('')`.
- `lastwarn('new_msgstr', 'new_msgid')` sets the last warning message and its identifier to new strings `new_msgstr` and `new_msgid`, respectively. Subsequent invocations of `lastwarn` return the new warning message and message identifier.
- `[msgstr, msgid] = lastwarn('new_msgstr', 'new_msgid')` returns the last warning message and its identifier, also changing these values so that subsequent invocations of `lastwarn` return the message and identifier strings specified by `new_msgstr` and `new_msgid`, respectively.
- Tips**
- `lastwarn` does not return warnings that are reported during the parsing of MATLAB commands. (Warning messages that include the failing file name and line number are parse-time warnings.)
- Examples**
- Write a short function that generates a warning message. At the start of the function, enable any warnings that have a message identifier called `TestEnv:InvalidInput`:

# lastwarn

---

```
function myfun(p1)
warning on TestEnv:InvalidInput;

exceedMax = find(p1 > 5000);
if any(exceedMax)
    warning('TestEnv:InvalidInput', ...
           '%d values in the "%s" array exceed the maximum.', ...
           length(exceedMax), inputname(1))
end
```

Pass an invalid value to the function:

```
dataIn = magic(10) - 2;

myfun(dataIn)
Warning: 2 values in the "dataIn" array exceed the maximum.
> In myfun at 4
```

Use lastwarn to determine the message identifier and error message string for the operation:

```
[warnmsg, msgid] = lastwarn
warnmsg =
    2 values in the "dataIn" array exceed the maximum.
msgid =
    TestEnv:InvalidInput
```

**Purpose** Least common multiple

**Syntax** `L = lcm(A,B)`

**Description** `L = lcm(A,B)` returns the least common multiple of corresponding elements of arrays `A` and `B`. Inputs `A` and `B` must contain positive integer elements and must be the same size (or either can be scalar).

**Examples**

```
lcm(8,40)

ans =

    40

lcm(pascal(3),magic(3))

ans =

     8     1     6
     3    10    21
     4     9     6
```

**See Also** `gcd`

**Purpose** Block LDL' factorization for Hermitian indefinite matrices

**Syntax**

```
L = ldl(A)
[L,D] = ldl(A)
[L,D,P] = ldl(A)
[L,D,p] = ldl(A, 'vector')
[U,D,P] = ldl(A, 'upper')
[U,D,p] = ldl(A, 'upper', 'vector')
[L,D,P,S] = ldl(A)
[L,D,P,S] = LDL(A, THRESH)
[U,D,p,S] = LDL(A, THRESH, 'upper', 'vector')
```

**Description** `L = ldl(A)` returns only the "psychologically lower triangular matrix" `L` as in the two-output form. The permutation information is lost, as is the block diagonal factor `D`. By default, `ldl` references only the diagonal and lower triangle of `A`, and assumes that the upper triangle is the complex conjugate transpose of the lower triangle. Therefore `[L,D,P] = ldl(TRIL(A))` and `[L,D,P] = ldl(A)` both return the exact same factors. Note, this syntax is not valid for sparse `A`.

`[L,D] = ldl(A)` stores a block diagonal matrix `D` and a "psychologically lower triangular matrix" (i.e a product of unit lower triangular and permutation matrices) in `L` such that  $A = L * D * L'$ . The block diagonal matrix `D` has 1-by-1 and 2-by-2 blocks on its diagonal. Note, this syntax is not valid for sparse `A`.

`[L,D,P] = ldl(A)` returns unit lower triangular matrix `L`, block diagonal `D`, and permutation matrix `P` such that  $P' * A * P = L * D * L'$ . This is equivalent to `[L,D,P] = ldl(A, 'matrix')`.

`[L,D,p] = ldl(A, 'vector')` returns the permutation information as a vector, `p`, instead of a matrix. The `p` output is a row vector such that  $A(p,p) = L * D * L'$ .

`[U,D,P] = ldl(A, 'upper')` references only the diagonal and upper triangle of `A` and assumes that the lower triangle is the complex conjugate transpose of the upper triangle. This syntax returns a unit upper triangular matrix `U` such that  $P' * A * P = U' * D * U$  (assuming that

A is Hermitian, and not just upper triangular). Similarly,  $[L,D,P] = \text{ldl}(A, 'lower')$  gives the default behavior.

$[U,D,p] = \text{ldl}(A, 'upper', 'vector')$  returns the permutation information as a vector,  $p$ , as does  $[L,D,p] = \text{ldl}(A, 'lower', 'vector')$ . A must be a full matrix.

$[L,D,P,S] = \text{ldl}(A)$  returns unit lower triangular matrix  $L$ , block diagonal  $D$ , permutation matrix  $P$ , and scaling matrix  $S$  such that  $P' * S * A * S * P = L * D * L'$ . This syntax is only available for real sparse matrices, and only the lower triangle of  $A$  is referenced. `ldl` uses MA57 for sparse real symmetric  $A$ .

$[L,D,P,S] = \text{LDL}(A, \text{THRESH})$  uses `THRESH` as the pivot tolerance in MA57. `THRESH` must be a double scalar lying in the interval  $[0, 0.5]$ . The default value for `THRESH` is 0.01. Using smaller values of `THRESH` may give faster factorization times and fewer entries, but may also result in a less stable factorization. This syntax is available only for real sparse matrices.

$[U,D,p,S] = \text{LDL}(A, \text{THRESH}, 'upper', 'vector')$  sets the pivot tolerance and returns upper triangular  $U$  and permutation vector  $p$  as described above.

## Examples

These examples illustrate the use of the various forms of the `ldl` function, including the one-, two-, and three-output form, and the use of the `vector` and `upper` options. The topics covered are:

- “Example 1 — Two-Output Form of `ldl`” on page 2-2534
- “Example 2 — Three Output Form of `ldl`” on page 2-2534
- “Example 3 — The Structure of  $D$ ” on page 2-2535
- “Example 4 — Using the `'vector'` Option” on page 2-2535
- “Example 5 — Using the `'upper'` Option” on page 2-2536
- “Example 6 — `linsolve` and the Hermitian indefinite solver” on page 2-2536

Before running any of these examples, you will need to generate the following positive definite and indefinite Hermitian matrices:

```
A = full(delsq(numgrid('L', 10)));
B = gallery('uniformdata',10,0);
M = [eye(10) B; B' zeros(10)];
```

The structure of  $M$  here is very common in optimization and fluid-flow problems, and  $M$  is in fact indefinite. Note that the positive definite matrix  $A$  must be full, as `ldl` does not accept sparse arguments.

## Example 1 – Two-Output Form of `ldl`

The two-output form of `ldl` returns  $L$  and  $D$  such that  $A - (L^*D^*L')$  is small,  $L$  is "psychologically unit lower triangular" (i.e., a permuted unit lower triangular matrix), and  $D$  is a block 2-by-2 diagonal. Note also that, because  $A$  is positive definite, the diagonal of  $D$  is all positive:

```
[LA,DA] = ldl(A);
fprintf(1, ...
'The factorization error ||A - LA*DA*LA' || is %g\n', ...
norm(A - LA*DA*LA'));
neginds = find(diag(DA) < 0)
```

Given a  $b$ , solve  $Ax=b$  using  $LA$ ,  $DA$ :

```
bA = sum(A,2);
x = LA' \ (DA \ (LA \ bA));
fprintf(...
'The absolute error norm ||x - ones(size(bA)) || is %g\n', ...
norm(x - ones(size(bA))));
```

## Example 2 – Three Output Form of `ldl`

The three output form returns the permutation matrix as well, so that  $L$  is in fact unit lower triangular:

```
[Lm, Dm, Pm] = ldl(M);
fprintf(1, ...
'The error norm ||Pm'*M*Pm - Lm*Dm*Lm' || is %g\n', ...
```

```
norm(Pm'*M*Pm - Lm*Dm*Lm');
fprintf(1, ...
'The difference between Lm and tril(Lm) is %g\n', ...
norm(Lm - tril(Lm)));
```

Given  $b$ , solve  $Mx=b$  using  $Lm$ ,  $Dm$ , and  $Pm$ :

```
bM = sum(M,2);
x = Pm*(Lm'\(Dm\(Lm\(Pm'*bM))));
fprintf(...
'The absolute error norm ||x - ones(size(b))|| is %g\n', ...
norm(x - ones(size(bM))));
```

### Example 3 – The Structure of D

$D$  is a block diagonal matrix with 1-by-1 blocks and 2-by-2 blocks. That makes it a special case of a tridiagonal matrix. When the input matrix is positive definite,  $D$  is almost always diagonal (depending on how definite the matrix is). When the matrix is indefinite however,  $D$  may be diagonal or it may express the block structure. For example, with  $A$  as above,  $DA$  is diagonal. But if you shift  $A$  just a bit, you end up with an indefinite matrix, and then you can compute a  $D$  that has the block structure.

```
figure; spy(DA); title('Structure of D from ldl(A)');
[Las, Das] = ldl(A - 4*eye(size(A)));
figure; spy(Das);
title('Structure of D from ldl(A - 4*eye(size(A)))');
```

### Example 4 – Using the 'vector' Option

Like the `lu` function, `ldl` accepts an argument that determines whether the function returns a permutation vector or permutation matrix. `ldl` returns the latter by default. When you select 'vector', the function executes faster and uses less memory. For this reason, specifying the 'vector' option is recommended. Another thing to note is that indexing is typically faster than multiplying for this kind of operation:

```
[Lm, Dm, pm] = ldl(M, 'vector');
```

```

fprintf(1, 'The error norm ||M(pm,pm) - Lm*Dm*Lm'|| is %g\n', ...
        norm(M(pm,pm) - Lm*Dm*Lm'));

% Solve a system with this kind of factorization.
clear x;
x(pm,:) = Lm'\(Dm\(Lm\(bM(pm,:)));
fprintf('The absolute error norm ||x - ones(size(b))|| is %g\n', ...
        norm(x - ones(size(bM))));

```

### Example 5 – Using the 'upper' Option

Like the `chol` function, `ldl` accepts an argument that determines which triangle of the input matrix is referenced, and also whether `ldl` returns a lower (L) or upper (L') triangular factor. For dense matrices, there are no real savings with using the upper triangular version instead of the lower triangular version:

```

M1 = tril(M);
[Lm1, Dm1, Pm1] = ldl(M1, 'lower'); % 'lower' is default behavior.
fprintf(1, ...
        'The difference between Lm1 and Lm is %g\n', norm(Lm1 - Lm));
[Umu, Dmu, pmu] = ldl(triu(M), 'upper', 'vector');
fprintf(1, ...
        'The difference between Umu and Lm'' is %g\n', norm(Umu - Lm'));

% Solve a system using this factorization.
clear x;
x(pm,:) = Umu\(Dmu\(Umu\'(bM(pmu,:)));
fprintf(...
        'The absolute error norm ||x - ones(size(b))|| is %g\n', ...
        norm(x - ones(size(bM))));

```

When specifying both the 'upper' and 'vector' options, 'upper' must precede 'vector' in the argument list.

### Example 6 – linsolve and the Hermitian indefinite solver

When using the `linsolve` function, you may experience better performance by exploiting the knowledge that a system has a symmetric

matrix. The matrices used in the examples above are a bit small to see this so, for this example, generate a larger matrix. The matrix here is symmetric positive definite, and below we will see that with each bit of knowledge about the matrix, there is a corresponding speedup. That is, the symmetric solver is faster than the general solver while the symmetric positive definite solver is faster than the symmetric solver:

```
Abig = full(delsq(numgrid('L', 30)));
bbig = sum(Abig, 2);
LSopts.POSDEF = false;
LSopts.SYM = false;
tic; linsolve(Abig, bbig, LSopts); toc;
LSopts.SYM = true;
tic; linsolve(Abig, bbig, LSopts); toc;
LSopts.POSDEF = true;
tic; linsolve(Abig, bbig, LSopts); toc;
```

## Algorithms

ldl uses the MA57 routines in the Harwell Subroutine Library (HSL) for real sparse matrices.

# ldivide

---

**Purpose** Left array division

**Syntax**  
`x = B.\A`  
`x = ldivide(B,A)`

**Description** `x = B.\A` divides each element of `A` by the corresponding element of `B`.

- If `A` and `B` are arrays, then they must be the same size.
- If either `A` or `B` is a scalar, then MATLAB expands the scalar value into an appropriately sized array.

`x = ldivide(B,A)` is an alternative way to divide `A` by `B`, but is rarely used. It enables operator overloading for classes.

## Input Arguments

### A - Numerator

numeric array | sparse numeric array

Numerator, specified as a full or sparse numeric array. If `B` is an integer data type, then `A` must be the same integer type or a scalar double.

#### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Complex Number Support:** Yes

### B - Denominator

numeric array | sparse numeric array

Denominator, specified as a full or sparse numeric array. If `A` is an integer data type, then `B` must be the same integer type or a scalar double.

#### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Complex Number Support:** Yes

**Output Arguments****x - Solution**

numeric array | sparse numeric array

Solution, specified as a sparse or full numeric array. If either A or B are integer data types, then x is that same integer data type.

**Examples****Divide Two Numeric Arrays**

```
A = ones(2, 3);  
B = [1 2 3;4 5 6];  
x = B.\A
```

```
x =
```

```
    1.0000    0.5000    0.3333  
    0.2500    0.2000    0.1667
```

**Divide a Scalar by a Numeric Array**

```
C = 2;  
D = [1 2 3;4 5 6];  
x = D.\C
```

```
x =
```

```
    2.0000    1.0000    0.6667  
    0.5000    0.4000    0.3333
```

**Tips**

- MATLAB does not support complex integer division.

**See Also**

`rdivide` | `mldivide` | `mrdivide` | Arithmetic Operators \,/

**Purpose** Test for less than or equal to

**Syntax** A <= B  
le(A, B)

**Description** A <= B compares each element of array A with the corresponding element of array B, and returns an array with elements set to logical 1 (true) where A is less than or equal to B, or set to logical 0 (false) where A is greater than B. Each input of the expression can be an array or a scalar value.

If both A and B are scalar (i.e., 1-by-1 matrices), then the MATLAB software returns a scalar value.

If both A and B are nonscalar arrays, then these arrays must have the same dimensions, and MATLAB returns an array of the same dimensions as A and B.

If one input is scalar and the other a nonscalar array, then the scalar input is treated as if it were an array having the same dimensions as the nonscalar input array. In other words, if input A is the number 100, and B is a 3-by-5 matrix, then A is treated as if it were a 3-by-5 matrix of elements, each set to 100. MATLAB returns an array of the same dimensions as the nonscalar input array.

le(A, B) is called for the syntax A <=B when either A or B is an object.

## Examples

Create two 6-by-6 matrices, A and B, and locate those elements of A that are less than or equal to the corresponding elements of B:

```
A = magic(6);  
B = repmat(3*magic(3), 2, 2);  
  
A <= B  
ans =  
    0     1     1     0     0     0  
    1     0     1     0     0     0  
    0     1     1     0     1     0  
    1     0     0     1     0     1
```

---

legend('off'),legend(axes_handle,'off')  
legend('toggle'),legend(axes_handle,'toggle')  
legend('hide'),legend(axes_handle,'hide')  
legend('show'),legend(axes_handle,'show')  
legend('boxoff'),legend(axes_handle,'boxoff')  
legend('boxon'),legend(axes_handle,'boxon')  
legend_handle = legend(...)  
legend(...,'Location','location')  
legend(...,'Orientation','orientation')  
[legend_h,object_h,plot_h,text_strings] = legend(...)
```

## Description

The legend function places a legend on various types of graphs (line plots, bar graphs, pie charts, etc.). For each line plotted, the legend shows a sample of the line type, marker symbol, and color beside the text label you specify. When plotting filled areas (patch or surface objects), the legend contains a sample of the face color next to the text label.

The font size and font name for the legend strings match the axes `FontSize` and `FontName` properties.

`legend('string1','string2',...)` displays a legend in the current axes using the specified strings to label each set of data.

`legend(h,'string1','string2',...)` displays a legend on the plot containing the objects identified by the handles in the vector `h` and uses the specified strings to label the corresponding graphics object (line, barseries, etc.).

`legend(M)` adds a legend containing the rows of the matrix or cell array of strings `M` as labels. For matrices, this is the same as `legend(M(1,:),M(2,:),...)`.

`legend(h,M)` associates each row of the matrix or cell array of strings `M` with the corresponding graphics object (patch or line) in the vector of handles `h`.

`legend(M,'parameter_name','parameter_value',...)` and `legend(h,M,'parameter_name','parameter_value',...)` allow parameter/value pairs to be set when creating a legend (you can also assign them with `set` or with the Property Editor or Property Inspector). `M` must be a cell array of names. Legends inherit the properties of axes, although not all of them are relevant to legend objects.

`legend(axes_handle,...)` displays the legend for the axes specified by `axes_handle`.

`legend('off')`, `legend(axes_handle,'off')` removes the legend in the current axes or the axes specified by `axes_handle`.

`legend('toggle')`, `legend(axes_handle,'toggle')` toggles the legend on or off. If no legend exists for the current axes, one is created using default strings.

The *default string* for an object is the value of the object's `DisplayName` property, if you have defined a value for `DisplayName` (which you can do using the Property Editor or calling `set`). Otherwise, `legend` constructs a string of the form `data1, data2, etc.` Setting display names is useful when you are experimenting with legends and might forget how objects in a lineseries, for example, are ordered.

When you specify legend strings in a `legend` command, their respective `DisplayNames` are set to these strings. If you delete a legend and then create a new legend without specifying labels for it, the values of `DisplayName` are (re)used as label names. Naturally, the associated plot objects must have a `DisplayName` property for this to happen: all `_series` and `_group` plot objects have a `DisplayName` property; Handle Graphics primitives, such as `line` and `patch`, do not.

# legend

---

Legends for graphs that contain groups of objects such as lineseries, barseries, contourgroups, etc. created by high-level plotting commands such as `plot`, `bar`, `contour`, etc., by default display a single legend entry for the entire group, regardless of how many member objects it contains. However, you can customize such legends to show individual entries for all or selected member objects and assign a unique `DisplayName` to any of them. You control how groups appear in the legend by setting values for their `Annotation` and `DisplayName` properties with code. For information and examples about customizing legends in this manner, see “Controlling Legends” in the MATLAB Graphics documentation.

You can specify `EdgeColor` and `TextColor` as RGB triplets or as `ColorSpecs`. You cannot set these colors to `'none'`. To hide the box surrounding a legend, set the `Box` property to `'off'`. To allow the background to show through the legend box, set the legend’s `Color` property to `'none'`, for example,

```
set(legend_handle, 'Box', 'off')
set(legend_handle, 'Color', 'none')
```

This is similar to the effect of the command `legend boxoff`, except that `boxoff` also hides the legend’s border.

You can use a legend’s handle to set text properties for all the strings in a legend at once with a cell array of strings, rather than looping through each of them. See the last line of the example below, which demonstrates setting a legend’s `Interpreter` property. In that example, you could reset the `String` property of the legend as follows:

```
set(h, 'String', {'cos(x)', 'sin(x)'})
```

See the documentation for `Text Properties` for additional details.

`legend('hide')`, `legend(axes_handle, 'hide')` makes the legend in the current axes or the axes specified by `axes_handle` invisible.

`legend('show')`, `legend(axes_handle, 'show')` makes the legend in the current axes or the axes specified by `axes_handle` visible. A legend is created if one did not exist previously. Legends created automatically are limited to depict only the first 20 lines in the plot; if you need more

legend entries, you can manually create a legend for them all with `legend('string1', 'string2', ...)` syntax.

`legend('boxoff')`, `legend(axes_handle, 'boxoff')` removes the box from the legend in the current axes or the axes specified by `axes_handle`, and makes its background transparent.

`legend('boxon')`, `legend(axes_handle, 'boxon')` adds a box with an opaque background to the legend in the current axes or the axes specified by `axes_handle`.

You can also type the above six commands using the syntax

`legend keyword`

If the keyword is not recognized, it is used as legend text, creating a legend or replacing the current legend.

`legend_handle = legend(...)` returns the handle to the legend on the current axes, or `[]` if no legend exists.

`legend(..., 'Location', 'location')` uses *location* to determine where to place the legend. *location* can be either be a 1-by-4 position vector (`[left, bottom, width, height]`) or one of the following strings.

| Specifier    | Location in Axes                         |
|--------------|------------------------------------------|
| North        | Inside plot box near top                 |
| South        | Inside bottom                            |
| East         | Inside right                             |
| West         | Inside left                              |
| NorthEast    | Inside top right (default for 2-D plots) |
| NorthWest    | Inside top left                          |
| SouthEast    | Inside bottom right                      |
| SouthWest    | Inside bottom left                       |
| NorthOutside | Outside plot box near top                |

# legend

---

| Specifier        | Location in Axes                          |
|------------------|-------------------------------------------|
| SouthOutside     | Outside bottom                            |
| EastOutside      | Outside right                             |
| WestOutside      | Outside left                              |
| NorthEastOutside | Outside top right (default for 3-D plots) |
| NorthWestOutside | Outside top left                          |
| SouthEastOutside | Outside bottom right                      |
| SouthWestOutside | Outside bottom left                       |
| Best             | Least conflict with data in plot          |
| BestOutside      | Least unused space outside plot           |

Using one of the ...Outside values for 'Location' ensures that the legend does not overlap the plot, whereas overlaps can occur when you specify any of the other cardinal values. The *location* property applies to colorbars and legends, but not to axes.

---

**Note** You can set the legend location by passing the 4-element position vector to the `legend` function using the 'Location' option. To define the position of an existing legend, use the `set` function to assign the 4-element position vector to the 'Position' property. You cannot use the `Location` option with the `set` function.

---

## Obsolete Location Values

The first column of the following table shows the now-obsolete specifiers for legend locations that were in use prior to Version 7, along with a description of the locations and their current equivalent syntaxes:

| Obsolete Specifier | Location in Axes           | Current Specifier |
|--------------------|----------------------------|-------------------|
| -1                 | Outside axes on right side | NorthEastOutside  |
| 0                  | Inside axes                | Best              |
| 1                  | Upper right corner of axes | NorthEast         |
| 2                  | Upper left corner of axes  | NorthWest         |
| 3                  | Lower left corner of axes  | SouthWest         |
| 4                  | Lower right corner of axes | SouthEast         |

`legend(..., 'Orientation', 'orientation')` creates a legend with the legend items arranged in the specified orientation. *orientation* can be vertical (the default) or horizontal.

`[legend_h, object_h, plot_h, text_strings] = legend(...)` returns

- `legend_h` — Handle of the legend axes
- `object_h` — Handles of the line, patch, and text graphics objects used in the legend
- `plot_h` — Handles of the lines and other objects used in the plot
- `text_strings` — Cell array of the text strings used in the legend

## Relationship to Axes

`legend` associates strings with the objects in the axes in the same order that they are listed in the axes `Children` property. By default, the legend annotates the current axes.

You can only display one legend per axes. `legend` positions the legend based on a variety of factors, such as what objects the legend obscures.

The properties that legends do not share with axes are

- `Location`
- `Orientation`
- `EdgeColor`

# legend

---

- TextColor
- Interpreter
- String

## Tips

### Using Keywords as Legend Labels

To use legend keywords like 'Location', 'Orientation', 'Off', 'Hide', or property names as legend labels, pass the string in a cell array to the legend function as,

```
l = legend({'Location'});
```

## Examples

Add a legend to a graph showing a sine and cosine function. The default location is upper right, within the axes:

```
figure
x = -pi:pi/20:pi;
plot(x,cos(x),'-ro',x,sin(x),'-.b')
hleg1 = legend('cos_x','sin_x');
```

The legend reflects that `plot` specified a solid, red line ('-ro') for the cosine function and a dash-dot, blue line ('-.b') for the sine function.

Update the legend. Use the returned legend handle, `hleg1`, to move the legend to the upper left. Also turn off the TeX interpreter to render underscores in legend text literally rather than as subscripts:

```
set(hleg1,'Location','NorthWest')
set(hleg1,'Interpreter','none')
```

## legend

---

---

Setting the position of the legend at a particular position.

```
set(hleg1, 'Position', [.1,.2,.1,.2]);
```

Use `besselj` to plot Bessel functions for orders 1, 2, and 3. Add a legend for the lines at the upper right, outside the axes.

```
figure
x = 0:.2:12;
plot(x,besselj(1,x),x,besselj(2,x),x,besselj(3,x));
hleg = legend('First','Second','Third',...
             'Location','NorthEastOutside')
% Make the text of the legend italic and color it brown
```

# legend

---

```
set(hleg,'FontAngle','italic','TextColor',[.3,.2,.1])
```

---

Create a bar graph and overlay a line plot on it by setting `hold on`. Create a legend that reflects both graphs and locate it to the lower right, outside the axes:

```
figure  
stream = RandStream('mrg32k3a','Seed',4);  
y1 = rand(stream,10,5);
```

```
hb = bar(y1,'stacked'); colormap(summer); hold on
y2 = rand(stream,10,1);
hp = plot(1:10,y2,'marker','square','markersize',12,...
         'markeredgecolor','y','markerfacecolor',[.6,0,.6],...
         'linestyle','-','color','r','linewidth',2); hold off
legend([hb,hp],'Carrots','Peas','Peppers','Green Beans',...
       'Cucumbers','Eggplant','Location','SouthEastOutside')
```

# legend

---

## Alternatives

Add a legend to a selected axes on a graph with the **Insert Legend** tool

on the figure toolbar, or use **Insert > Legend** from the figure menu. Use the Property Editor to modify the position, font, and other properties of a legend. For details, see Using Plot Edit Mode.

## Moving the Legend

Move the legend by pressing the left mouse button while the cursor is over the legend and dragging the legend to a new location. Double-clicking a label allows you to edit the label.

## How To

- “Adding a Legend to a Graph”

**Purpose** Associated Legendre functions

**Syntax**  
 $P = \text{legendre}(n, X)$   
 $S = \text{legendre}(n, X, 'sch')$   
 $N = \text{legendre}(n, X, 'norm')$

## Definitions **Associated Legendre Functions**

The Legendre functions are defined by

$$P_n^m(x) = (-1)^m (1-x^2)^{m/2} \frac{d^m}{dx^m} P_n(x),$$

where

$$P_n(x)$$

is the Legendre polynomial of degree  $n$ :

$$P_n(x) = \frac{1}{2^n n!} \left[ \frac{d^n}{dx^n} (x^2 - 1)^n \right]$$

## **Schmidt Seminormalized Associated Legendre Functions**

The Schmidt seminormalized associated Legendre functions are related to the nonnormalized associated Legendre functions  $P_n^m(x)$  by

$$P_n(x) \text{ for } m = 0,$$

$$S_n^m(x) = (-1)^m \sqrt{\frac{2(n-m)!}{(n+m)!}} P_n^m(x) \text{ for } m > 0.$$

## **Fully Normalized Associated Legendre Functions**

The fully normalized associated Legendre functions are normalized such that

# legendre

---

$$\int_{-1}^1 (N_n^m(x))^2 dx = 1$$

and are related to the unnormalized associated Legendre functions

$P_n^m(x)$  by

$$N_n^m = (-1)^m \sqrt{\frac{(n + \frac{1}{2})(n - m)!}{(n + m)!}} P_n^m(x)$$

## Description

`P = legendre(n,X)` computes the associated Legendre functions

$P_n^m(x)$  of degree  $n$  and order  $m = 0, 1, \dots, n$ , evaluated for each element of  $X$ . Argument  $n$  must be a scalar integer, and  $X$  must contain real values in the domain  $-1 \leq x \leq 1$ .

If  $X$  is a vector, then  $P$  is an  $(n+1)$ -by- $q$  matrix, where  $q = \text{length}(X)$ . Each element  $P(m+1, i)$  corresponds to the associated Legendre function of degree  $n$  and order  $m$  evaluated at  $X(i)$ .

In general, the returned array  $P$  has one more dimension than  $X$ , and each element  $P(m+1, i, j, k, \dots)$  contains the associated Legendre function of degree  $n$  and order  $m$  evaluated at  $X(i, j, k, \dots)$ . Note that the first row of  $P$  is the Legendre polynomial evaluated at  $X$ , i.e., the case where  $m = 0$ .

`S = legendre(n,X,'sch')` computes the Schmidt seminormalized

associated Legendre functions 
$$P_n^m(x) = (-1)^m (1-x^2)^{m/2} \frac{d^m}{dx^m} P_n(x),$$

`N = legendre(n,X,'norm')` computes the fully normalized associated

Legendre functions 
$$P_n^m(x) = (-1)^m (1-x^2)^{m/2} \frac{d^m}{dx^m} P_n(x),$$

## Examples

### Example 1

The statement `legendre(2,0:0.1:0.2)` returns the matrix

|         | $x = 0$ | $x = 0.1$ | $x = 0.2$ |
|---------|---------|-----------|-----------|
| $m = 0$ | -0.5000 | -0.4850   | -0.4400   |
| $m = 1$ | 0       | -0.2985   | -0.5879   |
| $m = 2$ | 3.0000  | 2.9700    | 2.8800    |

## Example 2

Given,

```
X = rand(2,4,5);
n = 2;
P = legendre(n,X)
```

then

```
size(P)
ans =
     3     2     4     5
```

and

```
P(:,1,2,3)
ans =
    -0.2475
    -1.1225
     2.4950
```

is the same as

```
legendre(n,X(1,2,3))
ans =
    -0.2475
    -1.1225
     2.49501
```

## Algorithms

legendre uses a three-term backward recursion relationship in  $m$ . This recursion is on a version of the Schmidt seminormalized

# Legendre

---

associated Legendre functions  $P_n^m(x) = (-1)^m (1-x^2)^{m/2} \frac{d^m}{dx^m} P_n(x)$ , which are complex spherical harmonics. These functions are related to the standard Abramowitz and Stegun [1] functions

$$P_n^m(x) = (-1)^m (1-x^2)^{m/2} \frac{d^m}{dx^m} P_n(x), \text{ by}$$

$$P_n^m(x) = (-1)^m (1-x^2)^{m/2} \frac{d^m}{dx^m} P_n(x),$$

They are related to the Schmidt form given previously by

$$P_n^m(x) = (-1)^m (1-x^2)^{m/2} \frac{d^m}{dx^m} P_n(x),$$

## References

- [1] Abramowitz, M. and I. A. Stegun, *Handbook of Mathematical Functions*, Dover Publications, 1965, Ch.8.
- [2] Jacobs, J. A., *Geomagnetism*, Academic Press, 1987, Ch.4.

**Purpose** Length of vector or largest array dimension

**Syntax** `numberOfElements = length(array)`

**Description** `numberOfElements = length(array)` finds the number of elements along the largest dimension of an array. `array` is an array of any MATLAB data type and any valid dimensions. `numberOfElements` is a whole number of the MATLAB double class.

For nonempty arrays, `numberOfElements` is equivalent to `max(size(array))`. For empty arrays, `numberOfElements` is zero.

**Examples** Create a 1-by-8 array `X` and use `length` to find the number of elements in the second (largest) dimension:

```
X = [5, 3.4, 72, 28/4, 3.61, 17 94 89];
```

```
length(X)
ans =
     8
```

---

Create a 4-dimensional array `Y` in which the third dimension is the largest. Use `length` to find the number of elements in that dimension:

```
Y = rand(2, 5, 17, 13);
```

```
length(Y)
ans =
    17
```

---

Create a struct array `S` with character and numeric fields of different lengths. Use the `structfun` function to apply `length` to each field of `S`:

```
S = struct('f1', 'Name:', 'f2', 'Charlie', ...
          'f3', 'DOB:', 'f4', 1917)
```

# length

---

```
S =  
    f1: 'Name:'  
    f2: 'Charlie'  
    f3: 'DOB:'  
    f4: 1917  
  
structfun(@(field)length(field), S)  
ans =  
     5  
     7  
     4  
     1
```

# length (serial)

---

**Purpose** Length of serial port object array

**Syntax** length(obj)

**Description** length(obj) returns the length of the serial port object, obj. It is equivalent to the command max(size(obj)).

**See Also** size

|                    |                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Length of time vector                                                                                                                                 |
| <b>Syntax</b>      | <code>length(tsc)</code>                                                                                                                              |
| <b>Description</b> | <code>length(tsc)</code> returns an integer that represents the length of the time vector for the <code>tscollection</code> object <code>tsc</code> . |
| <b>See Also</b>    | <code>tscollection</code>   <code>isempty (tscollection)</code>   <code>size (tscollection)</code>                                                    |

# libfunctions

---

**Purpose** Return information on functions in shared library

**Syntax** `libfunctions libname`

```
m = libfunctions(libname)
___ = libfunctions( ___, '-full')
```

**Description** `libfunctions libname` displays names of functions defined in library, `libname`. If you called `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

`m = libfunctions(libname)` returns names of functions in cell array `m`.

`___ = libfunctions( ___, '-full')` returns function signatures.

## Examples

### Display Function Signatures

Load the example library, `shrlibsample`, and list the functions.

```
if not(libisloaded('shrlibsample'))
    addpath(fullfile(matlabroot,'extern','examples','shrlib'))
    loadlibrary('shrlibsample')
end
m = libfunctions('shrlibsample','-full')

m =

    '[double, doublePtr] addDoubleRef(double, doublePtr, double)'
    'double addMixedTypes(int16, int32, double)'
    '[double, c_structPtr] addStructByRef(c_structPtr)'
    'double addStructFields(c_struct)'
    'c_structPtrPtr allocateStruct(c_structPtrPtr)'
    'voidPtr deallocateStruct(voidPtr)'
    'lib.pointer exportedDoubleValue'
    'lib.pointer getListOfStrings'
    'doublePtr multDoubleArray(doublePtr, int32)'
```

```
'[lib.pointer, doublePtr] multDoubleRef(doublePtr)'  
'int16Ptr multiplyShort(int16Ptr, int32)'  
'doublePtr print2darray(doublePtr, int32)'  
'printExportedDoubleValue'  
'cstring readEnum(Enum1)'  
'[cstring, cstring] stringToUpper(cstring)'
```

## Limitations

- Use with libraries that are loaded using the `loadlibrary` function.

## See Also

`loadlibrary` | `libfunctionsview` | `calllib`

# libfunctionsview

---

**Purpose** Display shared library function signatures in window

**Syntax** `libfunctionsview libname`

**Description** `libfunctionsview libname` displays information about functions in library, `libname`, in a new window.

**Input Arguments** **libname - Name of shared library**  
`string`

Name of shared library, specified as a string. If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

**Limitations**

- Use with libraries that are loaded using the `loadlibrary` function.

**Examples** **Display Function Signatures for Library libmx**

```
if not(libisloaded('libmx'))
    hfile = fullfile(matlabroot,'extern','include','matrix.h');
    loadlibrary('libmx',hfile)
end
libfunctionsview libmx
```

MATLAB creates a new window displaying function signatures.

**See Also** `libfunctions` | `calllib`

**Purpose** Determine if shared library is loaded

**Syntax** `tf = libisloaded(libname)`

**Description** `tf = libisloaded(libname)` returns logical 1 (true) if the shared library, `libname`, is loaded. Otherwise, it returns logical 0 (false).

**Input Arguments** **libname - Name of shared library**  
*string*

Name of shared library, specified as a string. If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

**Examples** **Load Functions in Library**

Load example library, `shrlibsample`, if it is not already loaded.

```
if ~libisloaded('shrlibsample')
    loadlibrary('shrlibsample')
end
```

**See Also** `loadlibrary` | `unloadlibrary`

# libpointer

---

**Purpose** Pointer object for use with shared library

**Syntax**

```
p = libpointer
p = libpointer(DataType)
p = libpointer(DataType,Value)
```

**Description**

`p = libpointer` creates NULL pointer `p`.

`p = libpointer(DataType)` creates an empty pointer of specified `DataType`.

`p = libpointer(DataType,Value)` creates a pointer initialized to `Value`.

**Limitations**

- Use with libraries that are loaded using the `loadlibrary` function.

## Input Arguments

### **DataType - Type of pointer**

string

Type of pointer, specified as a string, of any MATLAB numeric type, structure defined in the library, or enumeration defined in the library. For a list of valid MATLAB numeric types, see “Equivalent MATLAB Type” in the tables “MATLAB Primitive Types” and “MATLAB Extended Types”.

**Example:** `p = libpointer('int16Ptr')`

### **Value - Value for pointer object**

Any valid value

Value, specified as any valid value for given type.

**Example:** `v = [4 6 8; 7 5 3];`  
`p = libpointer('int16Ptr',v);`

## Tips

- This is an advanced feature for experienced C programmers. MATLAB automatically converts data passed to and from external

library functions to the data type expected by the external function. Use the `libpointer` function when you want to manually convert argument data, using the `setdatatype` method.

# libstruct

---

**Purpose** Convert MATLAB structure to C-style structure for use with shared library

**Syntax**  
S = libstruct(structtype)  
S = libstruct(structtype,mlstruct)

**Description**  
S = libstruct(structtype) creates NULL pointer to MATLAB libstruct object S.  
  
S = libstruct(structtype,mlstruct) creates pointer initialized to mlstruct.

**Limitations**

- Use with libraries that are loaded using the loadlibrary function.
- You can only use the libstruct function on scalar structures.
- When converting a MATLAB structure to a libstruct object, the structure must adhere to the requirements listed in “Structure Argument Requirements”.

**Input Arguments**

**structtype - C structure**  
structure  
C structure defined in shared library.

**mlstruct - MATLAB structure**  
structure  
MATLAB structure used to initialize the fields in S.

**Output Arguments**

**S - Pointer**  
MATLAB libstruct object  
Pointer, returned as MATLAB libstruct object.

## Examples

### Call Function with `c_struct` Input Argument

Call the `addStructFields` function by creating a variable of type `c_struct`.

Load the `shrlibsample` library, which contains the `c_struct` type.

```
if ~libisloaded('shrlibsample')
    addpath(fullfile(matlabroot,'extern','examples','shrlib'))
    loadlibrary('shrlibsample')
end
```

Display function signatures for `shrlibsample` and search the list for the `addStructFields` entry.

```
libfunctionsview shrlibsample

double addStructFields(c_struct)
```

The input argument is a pointer to a `c_struct` data type.

Create a MATLAB structure, `sm`.

```
sm.p1 = 476;    sm.p2 = -299;    sm.p3 = 1000;
```

Construct a `libstruct` object `sc` from the `c_struct` type.

```
sc = libstruct('c_struct',sm)
```

The fields of `sc` contain the values of the MATLAB structure, `sm`.

Call the `addStructFields` function.

```
calllib('shrlibsample','addStructFields',sc)
```

# libstruct

---

```
ans =  
    1177
```

To clean up, first clear the `libstruct` object, and then unload the library.

```
clear sc  
unloadlibrary shrlibsampl
```

## Tips

- If a function in the shared library has a structure argument, use `libstruct` to create the argument. The `libstruct` function creates a C-style structure that you pass to functions in the library. You handle this structure in MATLAB as you would a true MATLAB structure.

## Concepts

- “Working with Structure Arguments”

**Purpose** Return license number or perform licensing task

**Syntax**

```
license
license('inuse')
S = license('inuse')
S = license('inuse', feature)
license('test', feature)
license('test', feature, toggle)
[TF errmsg] = license('checkout', feature)
```

**Description** `license` returns the license number for this MATLAB product. The return value is always a string but is not guaranteed to be a number. The following table lists text strings that `license` can return.

| String    | Description                         |
|-----------|-------------------------------------|
| 'demo'    | MATLAB is a demonstration version   |
| 'student' | MATLAB is the student version       |
| 'unknown' | License number cannot be determined |

`license('inuse')` returns a list of licenses checked out in the current MATLAB session. In the list, products are listed alphabetically by their license feature names, i.e., the text string used to identify products in the INCREMENT lines in a License File (`license.dat`). Note that the feature names returned in the list contain only lower-case characters.

`S = license('inuse')` returns an array of structures, where each structure represents a checked-out license. The structures contains two fields: `feature` and `user`. The `feature` field contains the license feature name. The `user` field contains the username of the person who has the license checked out.

`S = license('inuse', feature)` checks if the product specified by the text string `feature` is checked out in the current MATLAB session. If the product is checked out, the `license` function returns the product name and the username of the person who has it checked out in the

# license

---

structure `S`. If the product is not currently checked out, the fields in the structure are empty.

The `feature` string must be a license feature name, spelled exactly as it appears in the `INCREMENT` lines in a License File. For example, the string `'Identification_Toolbox'` is the feature name for the System Identification Toolbox™. The `feature` string is not case-sensitive and must not exceed 27 characters.

`license('test', feature)` tests if a license exists for the product specified by the text string `feature`. The `license` command returns 1 if the license exists and 0 if the license does not exist. The `feature` string identifies a product, as described in the previous syntax.

---

**Note** Testing for a license only confirms that the license exists. It does not confirm that the license can be checked out. For example, `license` will return 1 if a license exists, even if the license has expired or if a system administrator has excluded you from using the product in an options file. The existence of a license does not indicate that the product is installed.

---

`license('test', feature, toggle)` enables or disables testing of the product specified by the text string `feature`, depending on the value of `toggle`. The parameter `toggle` can have either of two values:

'enable' The syntax `license('test', feature)` returns 1 if the product license exists and 0 if the product license does not exist.

'disable' The syntax `license('test', feature)` always returns 0 (product license does not exist) for the specified product.

---

**Note** Disabling a test for a particular product can impact other tests for the existence of the license, not just tests performed using the `license` command.

---

`[TF errmsg] = license('checkout',feature)` checks out a license for the product specified by the text string `feature`, returning 1 if it could check out a license or 0 if it could not check out a license. If you specify the optional second output argument, `errmsg`, the `license` function returns the text of any error message encountered, or an empty string if the checkout succeeded.

## Examples

Get the license number for this MATLAB.

```
license
```

Get a list of licenses currently being used. Note that the products appear in alphabetical order by their license feature name in the list returned.

```
license('inuse')
```

```
image_toolbox  
map_toolbox  
matlab
```

Get a list of licenses in use with information about who is using the license.

```
S = license('inuse');  
  
S(1)  
  
ans =  
  
    feature: 'image_toolbox'  
      user: 'juser'
```

# license

---

Determine if the license for MATLAB is currently in use.

```
S = license('inuse','MATLAB')
```

```
S =
```

```
    feature: 'matlab'  
    user: 'jsmith'
```

Determine if a license exists for the Mapping Toolbox™.

```
license('test','map_toolbox')
```

```
ans =
```

```
    1
```

Check out a license for the Control System Toolbox™.

```
license('checkout','control_toolbox')
```

```
ans =
```

```
    1
```

Determine if the license for the Control System Toolbox is checked out.

```
license('inuse')
```

```
control_toolbox  
image_toolbox  
map_toolbox  
matlab
```

|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Create light object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Syntax</b>      | <pre>light('PropertyName',propertyvalue,...) handle = light(...)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Properties</b>  | For a list of properties, see Light Properties.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | <p><code>light</code> creates a light object in the current axes. Lights affect only patch and surface objects.</p> <p><code>light('PropertyName',propertyvalue,...)</code> creates a light object using the specified values for the named properties. For a description of the properties, see Light Properties. The MATLAB software parents the light to the current axes unless you specify another axes with the Parent property.</p> <p><code>handle = light(...)</code> returns the handle of the light object created.</p>                                                                                                                                                                                                                                                                                                       |
| <b>Tips</b>        | <p>You cannot see a light object <i>per se</i>, but you can see the effects of the light source on patch and surface objects. You can also specify an axes-wide ambient light color that illuminates these objects. However, ambient light is visible only when at least one light object is present and visible in the axes.</p> <p>You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see <code>set</code> and <code>get</code> for examples of how to specify these data types).</p> <p>See also the patch and surface <code>AmbientStrength</code>, <code>DiffuseStrength</code>, <code>SpecularStrength</code>, <code>SpecularExponent</code>, <code>SpecularColorReflectance</code>, and <code>VertexNormals</code> properties. Also see the lighting and material commands.</p> |
| <b>Examples</b>    | <p>Light the peaks surface plot with a light source located at infinity and oriented along the direction defined by the vector <code>[1 0 0]</code>, that is, along the <i>x</i>-axis.</p> <pre>h = surf(peaks);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

# light

---

```
set(h, 'FaceLighting', 'phong', 'FaceColor', 'interp', ...  
    'AmbientStrength', 0.5)  
light('Position', [1 0 0], 'Style', 'infinite');
```

## Setting Default Properties

You can set default light properties on the axes, figure, and root object levels:

```
set(0, 'DefaultLightProperty', PropertyValue...)  
set(gcf, 'DefaultLightProperty', PropertyValue...)  
set(gca, 'DefaultLightProperty', PropertyValue...)
```

where *Property* is the name of the light property and *PropertyValue* is the value you are specifying. Use `set` and `get` to access light properties.

## Tutorials

For more information about lighting, see “Lighting Overview”.

## Purpose

Light properties

## Creating Light Objects

Use `light` to create light objects.

## Modifying Properties

You can set and query graphics object properties in two ways:

- “The Property Editor” is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see “Setting Default Property Values”.

See “Core Graphics Objects” for general information about this type of object.

## Light Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

`BeingDeleted`  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s `delete` function callback is called (see the `DeleteFcn` property). It remains set to `on` while the `delete` function executes, after which the object no longer exists.

For example, an object’s `delete` function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

`BusyAction`  
cancel | {queue}

# Light Properties

---

## *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`  
function handle

This property is not used on lights.

`Children`  
handles

The empty matrix; light objects have no children.

`Clipping`  
on | off

*Clipping mode.* This property has no effect on light objects.

`Color`  
`ColorSpec`

*Light color.* Defines the color of the light emanating from the light object. Use a three-element RGB vector or one of the MATLAB predefined names. Default value is [1 1 1] (white). See the `ColorSpec` reference page for more information on specifying color.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Executes when MATLAB creates a light object. You must define this property as a default value for lights or in a call to the `light` function to create a new light object. For example, the following statement:

```
set(0,'DefaultLightCreateFcn',@light_create)
```

defines a default value for the line `CreateFcn` property on the root level that sets the current figure colormap to `gray` and uses a reddish light color whenever you create a light object.

```
function light_create(src,evnt)
% src - the object that is the source of the event
% evnt - empty for this property
    set(src,'Color',[.9 .2 .2])
    set(gcf,'Colormap',gray)
end
```

MATLAB executes this function after setting all light properties. Setting this property on an existing light object has no effect. The function must define at least two input arguments (handle of light object created and an event structure, which is empty for this property).

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

# Light Properties

---

See Function Handle Callbacks for information on how to use function handles to define the callback function.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Delete light callback function.* Executes when you delete the light object (for example, when you issue a `delete` command or clear the axes `cla` or figure `clf`).

For example, the following function displays object property data before the object is deleted.

```
function delete_fcn(src, evnt)
% src - the object that is the source of the event
% evnt - empty for this property
    obj_tp = get(src, 'Type');
    disp([obj_tp, ' object deleted'])
    disp('Its user data is:')
    disp(get(src, 'UserData'))
end
```

MATLAB executes the function before deleting the object's properties so these values are available to the callback function. The function must define at least two input arguments (handle of object being deleted and an event structure, which is empty for this property).

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

# Light Properties

---

Handles that are hidden are still valid. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HitTest  
{on} | off

This property is not used by light objects.

Interruptible  
off | {on}

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

**BusyAction** property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting **Interruptible** property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

## Parent

handle of parent axes

*Parent of light object.* This property contains the handle of the light object’s parent. The parent of a light object is the axes object that contains it.

Note that light objects cannot be parented to `hggroup` or `hgtransform` objects.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## Position

[*x,y,z*] in axes data units

*Location of light object.* Vector defining the location of the light object. The vector is defined from the origin to the specified *x*-,

# Light Properties

---

*y*-, and *z*-coordinates. The placement of the light depends on the setting of the `Style` property:

- If the `Style` property is `local`, `Position` specifies the actual location of the light (which is then a point source that radiates from the location in all directions).
- If the `Style` property is `infinite`, `Position` specifies the direction from which the light shines in parallel rays.

`Selected`

`on` | `off`

This property is not used by light objects.

`SelectionHighlight`

`{on}` | `off`

This property is not used by light objects.

`Style`

`{infinite}` | `local`

*Parallel or divergent light source.*

- `infinite` — MATLAB places the light object at infinity (light rays are parallel).
- `local` — MATLAB places the light object at the location specified by the `Position` property (light rays diverge in all directions).

`Tag`

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

## Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For light objects, Type is always 'light'.

## UIContextMenu

handle of uicontextmenu object

This property is not used by light objects.

## UserData

matrix

*User-specified data.* Data you want to associate with the light object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## Visible

{on} | off

*Light visibility.* While light objects themselves are not visible, you can see the light on patch and surface objects. When you set Visible to off, the light emanating from the source is not visible. There must be at least one light object in the axes whose Visible property is on for any lighting features to be enabled (including the axes AmbientLightColor and patch and surface AmbientStrength).

light

# lightangle

---

**Purpose** Create or position light object in spherical coordinates

**Syntax**

```
lightangle(az,e1)
light_handle = lightangle(az,e1)
lightangle(light_handle,az,e1)
[az,e1] = lightangle(light_handle)
```

**Description** `lightangle(az,e1)` creates a light at the position specified by azimuth and elevation. `az` is the azimuthal (horizontal) rotation and `e1` is the vertical elevation (both in degrees). The interpretation of azimuth and elevation is the same as that of the `view` command.

`light_handle = lightangle(az,e1)` creates a light and returns the handle of the light in `light_handle`.

`lightangle(light_handle,az,e1)` sets the position of the light specified by `light_handle`.

`[az,e1] = lightangle(light_handle)` returns the azimuth and elevation of the light specified by `light_handle`.

**Tips** By default, when a light is created, its style is `infinite`. If the light handle passed in to `lightangle` refers to a local light, the distance between the light and the camera target is preserved as the position is changed.

**Examples**

```
surf(peaks)
axis vis3d
h = light;
for az = -50:10:50
    lightangle(h,az,30)
end
drawnow
end
```

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Specify lighting algorithm                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Syntax</b>      | <code>lighting flat</code><br><code>lighting gouraud</code><br><code>lighting phong</code><br><code>lighting none</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p><code>lighting</code> selects the algorithm used to calculate the effects of light objects on all surface and patch objects in the current axes. In order for the <code>lighting</code> command to have any effects, however, you must create a lighting object by using the <code>light</code> function.</p> <p><code>lighting flat</code> produces uniform lighting across each of the faces of the object. Select this method to view faceted objects.</p> <p><code>lighting gouraud</code> calculates the vertex normals and interpolates linearly across the faces. Select this method to view curved surfaces.</p> <p><code>lighting phong</code> interpolates the vertex normals across each face and calculates the reflectance at each pixel. Select this choice to view curved surfaces. Phong lighting generally produces better results than Gouraud lighting, but it takes longer to render.</p> <p><code>lighting none</code> turns off lighting.</p> |
| <b>Tips</b>        | The <code>surf</code> , <code>mesh</code> , <code>pcolor</code> , <code>fill</code> , <code>fill3</code> , <code>surface</code> , and <code>patch</code> functions create graphics objects that are affected by light sources. The <code>lighting</code> command sets the <code>FaceLighting</code> and <code>EdgeLighting</code> properties of surfaces and patches appropriately for the graphics object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>See Also</b>    | <code>fill</code>   <code>fill3</code>   <code>light</code>   <code>material</code>   <code>mesh</code>   <code>patch</code>   <code>pcolor</code>   <code>shading</code>   <code>surface</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>How To</b>      | <ul style="list-style-type: none"><li>• “Lighting Overview”</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

# lin2mu

---

**Purpose** Convert linear audio signal to mu-law

**Syntax** `mu = lin2mu(y)`

**Description** `mu = lin2mu(y)` converts linear audio signal amplitudes in the range  $-1 \leq Y \leq 1$  to mu-law encoded “flints” in the range  $0 \leq u \leq 255$ .

**See Also** `auwrite` | `mu2lin`

**Purpose**

Create line object

**Syntax**

```
line
line(X,Y)
line(X,Y,Z)
line(X,Y,Z,'PropertyName',propertyvalue,...)
line('XData',x,'YData',y,'ZData',z,...)
h = line(...)
```

**Properties**

For a list of properties, see Line Properties.

**Description**

`line` creates a line object in the current axes with default values `x = [0 1]` and `y = [0 1]`. You can specify the color, width, line style, and marker type, as well as other characteristics.

The `line` function has two forms:

- Automatic color and line style cycling. When you specify multiple line coordinate data as a column array using the informal syntax (i.e., the first three arguments are interpreted as the coordinates),

```
line(X,Y,Z)
```

MATLAB cycles through the axes `ColorOrder` and `LineStyleOrder` property values the way the `plot` function does. However, unlike `plot`, `line` does not call the `newplot` function.

- Purely low-level behavior. When you call `line` with only property name/property value pairs,

```
line('XData',x,'YData',y,'ZData',z)
```

MATLAB draws a line object in the current axes using the default line color (see the `colordef` function for information on color defaults). Note that you cannot specify matrix coordinate data with the low-level form of the `line` function.

`line(X,Y)` adds the line defined in vectors `X` and `Y` to the current axes. If `X` and `Y` are matrices of the same size, `line` draws one line per column.

# line

---

`line(X,Y,Z)` creates lines in three-dimensional coordinates.

`line(X,Y,Z, 'PropertyName', propertyvalue, ...)` creates a line using the values for the property name/property value pairs specified and default values for all other properties. For a description of the properties, see [Line Properties](#).

See the `LineStyle` and `Marker` properties for a list of supported values.

`line('XData',x, 'YData',y, 'ZData',z, ...)` creates a line in the current axes using the property values defined as arguments. This is the low-level form of the `line` function, which does not accept matrix coordinate data as the other informal forms described above.

`h = line(...)` returns a column vector of handles corresponding to each line object the function creates.

## Tips

In its informal form, the `line` function interprets the first three arguments (two for 2-D) as the X, Y, and Z coordinate data, allowing you to omit the property names. You must specify all other properties as name/value pairs. For example,

```
line(X,Y,Z, 'Color', 'r', 'LineWidth', 4)
```

The low-level form of the `line` function can have arguments that are only property name/property value pairs. For example,

```
line('XData',x, 'YData',y, 'ZData',z, 'Color', 'r', 'LineWidth', 4)
```

Line properties control various aspects of the line object and are described in [Line Properties](#). You can also set and query property values after creating the line using `set` and `get`.

You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see the `set` and `get` reference pages for examples of how to specify these data types).

Unlike high-level functions such as `plot`, `line` does not respect the settings of the figure and axes `NextPlot` properties. It simply adds line objects to the current axes. However, axes properties that are under

automatic control, such as the axis limits, can change to accommodate the line within the current axes.

### Connecting the dots

The coordinate data is interpreted as vectors of corresponding x, y, and z values:

```
X = [x(1) x(2) x(3)...x(n)]
Y = [y(1) y(2) y(3)...y(n)]
Z = [z(1) z(2) z(3)...z(n)]
```

where a point is determined by the corresponding vector elements:

```
p1(x(i),y(i),z(i))
```

For example, to draw a line from the point located at  $x = .3$  and  $y = .4$  and  $z = 1$  to the point located at  $x = .7$  and  $y = .9$  and  $z = 1$ , use the following data:

```
axis([0 1 0 1])
line([.3 .7],[.4 .9],[1 1],'Marker','.', 'LineStyle','-')
```

## Examples

This example uses the `line` function to add a shadow to plotted data. First, plot some data and save the line's handle:

```
t = 0:pi/20:2*pi;
hline1 = plot(t,sin(t),'k');
```

Next, add a shadow by offsetting the  $x$ -coordinates. Make the shadow line light gray and wider than the default `LineWidth`:

```
hline2 = line(t+.06,sin(t),'LineWidth',4,'Color',[.8 .8 .8]);
```

Finally, pull the first line to the front:

```
set(gca,'Children',[hline1 hline2])
```

# line

---

## Drawing Lines Interactively

You can use the `ginput` function to select points from a figure. For example:

```
[x,y] = ginput(5);  
line(x,y)
```

## Drawing with mouse motion

You can use the axes `CurrentPoint` property and the figure `WindowButtonDownFcn` and `WindowButtonMotionFcn` properties to select a point with a mouse click and draw a line to another point by dragging the mouse, like a simple drawing program. The following

example illustrates a few useful techniques for doing this type of interactive drawing.

Click to view in editor — This example enables you to click and drag the cursor to draw lines.

Click to run example — Click the left mouse button in the axes and move the cursor, left-click to define the line end point, right-click to end drawing mode.

### Input Argument Dimensions – Informal Form

This statement reuses the one-column matrix specified for ZData to produce two lines, each having four points.

```
line(rand(4,2),rand(4,2),rand(4,1))
```

If all the data has the same number of columns and one row each, MATLAB transposes the matrices to produce data for plotting. For example,

```
line(rand(1,4),rand(1,4),rand(1,4))
```

is changed to

```
line(rand(4,1),rand(4,1),rand(4,1))
```

This also applies to the case when just one or two matrices have one row. For example, the statement

```
line(rand(2,4),rand(2,4),rand(1,4))
```

is equivalent to

```
line(rand(4,2),rand(4,2),rand(4,1))
```

## Setting Default Properties

You can set default line properties on the axes, figure, and root object levels:

```
set(0,'DefaultLinePropertyName',PropertyValue,...)  
set(gcf,'DefaultLinePropertyName',PropertyValue,...)
```

# line

---

```
set(gca, 'DefaultLinePropertyName', PropertyValue, ...)
```

Where *PropertyName* is the name of the line property and *PropertyValue* is the value you are specifying. Use `set` and `get` to access line properties.

## See Also

## Purpose

Line properties

## Creating Line Objects

Use `line` to create line objects.

## Modifying Properties

You can set and query graphics object properties in two ways:

- “The Property Editor” is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see “Setting Default Property Values”.

See *Core Graphics Objects* for general information about this type of object.

## Line Property Descriptions

Annotation

`hg.Annotation` object (read-only)

*Handle of Annotation object.* The `Annotation` property enables you to specify whether this line object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the line object is displayed in a figure legend:

# Line Properties

---

| IconDisplayStyle Value | Purpose                                              |
|------------------------|------------------------------------------------------|
| on                     | Represent this line object in a legend (default)     |
| off                    | Do not include this line object in a legend          |
| children               | Same as on because line objects do not have children |

## Setting the IconDisplayStyle property

Set the IconDisplayStyle of a graphics object with handle `hobj` to off:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'off')
```

## Using the IconDisplayStyle property

See “Controlling Legends” for more information and examples.

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to on when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to on while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

## BusyAction

cancel | {queue}

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## ButtonDownFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over the line object. The default is an empty array.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

Set this property to a function handle that references the callback. The function must define at least two input arguments (handle

# Line Properties

---

of line associated with the button down event and an event structure, which is empty for this property).

The following example shows how to access the callback object's handle as well as the handle of the figure that contains the object from the callback function.

```
function button_down(src, evnt)
% src - the object that is the source of the event
% evnt - empty for this property
    sel_typ = get(gcf, 'SelectionType')
    switch sel_typ
        case 'normal'
            disp('User clicked left-mouse button')
            set(src, 'Selected', 'on')
        case 'extend'
            disp('User did a shift-click')
            set(src, 'Selected', 'on')
        case 'alt'
            disp('User did a control-click')
            set(src, 'Selected', 'on')
            set(src, 'SelectionHighlight', 'off')
    end
end
```

Suppose `h` is the handle of a line object and the `button_down` function is on your MATLAB path. The following statement assigns the `button_down` function to the `ButtonDownFcn` property:

```
set(h, 'ButtonDownFcn', @button_down)
```

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

**Children**  
vector of handles

The empty matrix; line objects have no children.

## Clipping

{on} | off

*Clipping mode.* MATLAB clips lines to the axes plot box by default. If you set `Clipping` to `off`, lines are displayed outside the axes plot box. This occurs if you create a line, set `hold` to `on`, freeze axis scaling (set `axis` to `manual`), and then create a longer line.

## Color

ColorSpec

*Line color.* A three-element RGB vector, or one of the MATLAB predefined names, specifying the line color. See the `ColorSpec` reference page for more information on specifying color.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Executes when MATLAB creates a line object. The default is an empty array.

You must specify the callback during the creation of the line or in a call to the `line` function to create a new line object.

For example, the statement:

```
set(0,'DefaultLineCreateFcn',@line_create)
```

defines a default value for the line `CreateFcn` property on the root level that sets the axes `LineStyleOrder` whenever you create a line object. The following callback function must be on your MATLAB path when you execute the above statement.

```
function line_create(src,evnt)
% src - the object that is the source of the event
% evnt - empty for this property
axh = get(src,'Parent');
set(axh,'LineStyleOrder','-.-')
```

# Line Properties

---

end

MATLAB executes this function after setting all line properties. Setting this property on an existing line object has no effect.

The function must define at least two input arguments (handle of line object created and an event structure, which is empty for this property).

The handle of the object whose `CreateFcn` is being executed is MATLAB as the first argument to the callback function and is also accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Delete line callback function.* Executes when you delete the line object. This happens when you call the `delete` command on the object, its parent axes, or the figure containing it. The default is an empty array.

For example, the following function displays object property data before the object is deleted.

```
function delete_fcn(src, evnt)
% src - the object that is the source of the event
% evnt - empty for this property
    obj_tp = get(src, 'Type');
    disp([obj_tp, ' object deleted'])
    disp('Its user data is:')
    disp(get(src, 'UserData'))
end
```

MATLAB executes the function before deleting the object's properties so these values are available to the callback function. The function must define at least two input arguments (handle of line object being deleted and an event structure, which is empty for this property).

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

`DisplayName`  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the line object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

# Line Properties

---

See “Controlling Legends” for more information and examples.

The following code shows how to use the `DisplayName` property from the command line or in a file.

```
t = 0:.1:2*pi;
a(:,1)=sin(t); a(:,2)=cos(t);
h = plot(a);
set(h,{'DisplayName'},{'Sine','Cosine'})
legend show
```

## EraseMode

{normal} | none | xor | background

*Erase mode.* Controls the technique MATLAB uses to draw and erase line objects. Alternative erase modes are useful for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- **normal** — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- **none** — Do not erase the line when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it, because MATLAB stores no information about its former location.
- **xor** — Draw and erase the line by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath the line. However, the line’s color depends on the color of whatever is beneath it on the display.
- **background** — Erase the line by drawing it in the axes `background Color`, or the figure `background Color` if the axes

Color is none. This damages objects that are behind the erased line, but lines are always properly colored.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

### `HandleVisibility`

`{on} | callback | off`

*Control access to object handle.* Determine when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

# Line Properties

---

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

For more information, see “`HandleVisibility` Property”, “`Functions Affected by Handle Visibility`”, and “`Properties Affected by Handle Visibility`”.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* Determines if the line can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the line. If `HitTest` is `off`, clicking the line selects the object below it (which might be the axes containing it).

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

# Line Properties

---

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

`LineStyle`

{-} | -- | : | -. | none

*Line style.*

## Line Style Specifiers Table

| Specifier | Line Style           |
|-----------|----------------------|
| '-'       | Solid line (default) |
| '--'      | Dashed line          |
| ':'       | Dotted line          |
| '-.'      | Dash-dot line        |
| 'none'    | No line              |

Use `LineStyle` `none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`

scalar

*Width of the line* . Specify this value in points. The default value is 0.5 points.

## Marker

character (see table)

*Marker symbol.* Specifies marks displayed at data points. You can set values for the Marker property independently from the LineStyle property. For a list of supported marker symbols, see the following table.

**Marker Specifiers Table**

| Specifier               | Marker Type                   |
|-------------------------|-------------------------------|
| '+'                     | Plus sign                     |
| 'o'                     | Circle                        |
| '*'                     | Asterisk                      |
| '.'                     | Point                         |
| 'x'                     | Cross                         |
| 'square' or 's'         | Square                        |
| 'diamond' or 'd'        | Diamond                       |
| '^'                     | Upward-pointing triangle      |
| 'v'                     | Downward-pointing triangle    |
| '>'                     | Right-pointing triangle       |
| '<'                     | Left-pointing triangle        |
| 'pentagram' or 'p'      | Five-pointed star (pentagram) |
| 'hexagram' or 'h' ' ' ' | Six-pointed star (hexagram)   |
| 'none'                  | No marker (default)           |

## MarkerEdgeColor

ColorSpec | none | {auto}

# Line Properties

---

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Specifies no color, which makes nonfilled markers invisible.
- `auto` — Use same color as the line `Color` property.

`MarkerFaceColor`

`ColorSpec` | `{none}` | `auto`

*Fill color for closed-shape markers.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Sets the fill color to the axes `Color` property. If the axes `Color` property is `none` (the factory default for axes objects), sets the fill color to the figure `Color`.

`MarkerSize`

scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

`Parent`

handle of axes, `hgggroup`, or `hgtransform`

*Parent of line object.* Handle of the line object's parent. The parent of a line object is the axes that contains it. You can reparent line objects to other axes, hggroup, or hgtransform objects.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## Selected

on | off

*Selection status* When this property is on, MATLAB displays selection handles if the SelectionHighlight property is also on. You can, for example, define the ButtonDownFcn to set this property, allowing users to select the object with the mouse.

## SelectionHighlight

{on} | off

*Object highlighted when selected.* When the Selected property is on, MATLAB indicates the selected state by drawing handles at each vertex. When SelectionHighlight is off, MATLAB does not draw the handles.

## Tag

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use this property when constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callbacks. You can define Tag as any string.

Use the Tag property and the findobj function to manipulate specific objects within a plotting hierarchy.

## Type

string (read-only)

# Line Properties

---

*Class of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For line objects, Type is always 'line'.

## UIContextMenu

handle of uicontextmenu object

*Associate context menu with line.* Assign this property the handle of a uicontextmenu object created in the same figure as the line. Use the uicontextmenu function to create the context menu. MATLAB displays the context menu whenever you right-click over the line.

## UserData

matrix

*User-specified data.* Data you want to associate with the line object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

---

**Note** Setting the UserData property more than once erases previous entries.

---

## Visible

{on} | off

*Line visibility.*

- on — All lines are visible.
- off — Line is not visible, but still exists, and you can `get` and `set` its properties.

## XData

vector

*x-coordinates of line.* Vector of *x*-coordinates defining the line. The default is [0 1].

YData and ZData, if set, must be the same length and have the same number of rows.

Create a line using the line function, then change its XData property:

```
mylin = line(rand(1,10),rand(1,10));
set(mylin,'XData',rand(1,15));
% A warning appears, since you did not set the YData property.
set(mylin,'XData',rand(1,15),'YData',rand(1,15));
% No warning appears and the plot draws as expected.
```

## YData

vector

*y-coordinates of line.* Vector of *y*-coordinates defining the line. The default is [0 1]. XData and ZData, if set, must be the same length and have the same number of rows.

Create a line using the line function, then change its YData property:

```
mylin = line(rand(1,10),rand(1,10));
set(mylin,'YData',rand(1,15));
% A warning appears, since you did not set the YData property.
set(mylin,'YData',rand(1,15),'XData',rand(1,15));
% No warning appears and the plot draws as expected.
```

## ZData

vector

*z-coordinates of line.* Vector of *z*-coordinates defining the line. The default is [] (empty). XData and YData must have the same number of rows.

Create a line using the line function, then change its ZData property:

# Line Properties

---

```
mylin = line(rand(1,10),rand(1,10),rand(1,10));  
view(3)  
set(mylin,'ZData',rand(1,15));  
% A warning appears, since you did not set the YData property.  
set(mylin,'XData',rand(1,15),'YData',rand(1,15),'ZData',rand(1,15));  
% No warning appears and the plot draws as expected.
```

**See Also**      `line`

## Purpose

Description of lineseries properties

## Modifying Properties

You can set and query graphics object properties using the set and get commands or with the property editor (propertyeditor).

See “Plot Objects” for more information on lineseries objects.

Note that you cannot define default properties for lineseries objects.

## Lineseries Property Descriptions

This section lists property names along with the type of values each accepts. Curly braces {} enclose default values.

### Annotation

hg.Annotation object (read-only)

*Control the display of lineseries objects in legends.* Specifies whether this lineseries object is represented in a figure legend.

Querying the Annotation property returns the handle of an hg.Annotation object. The hg.Annotation object has a property called LegendInformation, which contains an hg.LegendEntry object.

Once you have obtained the hg.LegendEntry object, you can set its IconDisplayStyle property to control whether the lineseries object is displayed in a figure legend.

| IconDisplayStyle Value | Purpose                                                                              |
|------------------------|--------------------------------------------------------------------------------------|
| on                     | Include the lineseries object in a legend as one entry, but not its children objects |
| off                    | Do not include the lineseries or its children in a legend (default)                  |
| children               | Include only the children of the lineseries as separate entries in the legend        |

# Lineseries Properties

---

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Controlling Legends” for more information and examples.

### BeingDeleted

`on` | `{off}` (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-to-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

### BusyAction

`cancel` | `{queue}`

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the

*running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## `Children`

vector of handles

# Lineseries Properties

---

The empty matrix; line objects have no children.

## Clipping

{on} | off

*Clipping mode.* MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

## Color

ColorSpec

*Color of the object.* A three-element RGB vector or one of the MATLAB predefined names, specifying the object's color. The default value is `[0 0 0]` (black).

See the `ColorSpec` reference page for more information on specifying color. See “Adding Arrows and Lines to Graphs”.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function and `graphicfcn` is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## `DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

## `DisplayName`

string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the lineseries object in the legend. The default is an empty string.

# Lineseries Properties

---

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

## EraseMode

`{normal} | none | xor | background`

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.

- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

### `HandleVisibility`

`{on} | callback | off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.

# Lineseries Properties

---

- **callback** — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- **off** — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

`HitTest`  
`{on} | off`

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the line. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

# Lineseries Properties

---

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a *drawnow*, *figure*, *getframe*, *waitfor*, or *pause* command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

BusyAction property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting Interruptible property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the *gca* or *gcf* command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

LineStyle  
{-} | -- | : | -. | none

*Line style of lineseries object.*

## Line Style Specifiers Table

| Specifier | Line Style           |
|-----------|----------------------|
| '-'       | Solid line (default) |
| '--'      | Dashed line          |
| ':'       | Dotted line          |
| '-.'      | Dash-dot line        |
| 'none'    | No line              |

Use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

### LineWidth

size in points

*Width of linear objects and edges of filled areas. Specify in points. 1 point =  $\frac{1}{72}$  inch. The default is 0.5 points.*

### Marker

character (see table)

*Marker symbol.* Specifies marks that display at data points. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

## Marker Specifiers Table

| Specifier | Marker Type |
|-----------|-------------|
| '+'       | Plus sign   |
| 'o'       | Circle      |
| '*'       | Asterisk    |

# Lineseries Properties

---

| Specifier             | Marker Type                   |
|-----------------------|-------------------------------|
| '.'                   | Point                         |
| 'x'                   | Cross                         |
| 'square' or 's'       | Square                        |
| 'diamond' or 'd'      | Diamond                       |
| '^'                   | Upward-pointing triangle      |
| 'v'                   | Downward-pointing triangle    |
| '>'                   | Right-pointing triangle       |
| '<'                   | Left-pointing triangle        |
| 'pentagram' or 'p'    | Five-pointed star (pentagram) |
| 'hexagram' or 'h' ' ' | Six-pointed star (hexagram)   |
| 'none'                | No marker (default)           |

## MarkerEdgeColor

ColorSpec | none | {auto}

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — User-defined color.
- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Uses same color as the Color property.

## MarkerFaceColor

ColorSpec | {none} | auto

*Fill color for closed-shape markers.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Sets the fill color to the axes `Color` property. If the axes `Color` property is `none` (the factory default for axes objects), sets the fill color to the figure `Color`.

`MarkerSize`  
scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

`Parent`

handle of parent axes, `hgggroup`, or `hgtransform`

*Parent of object.* Handle of the object's parent. The parent is normally the axes, `hgggroup`, or `hgtransform` object that contains the object.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

`Selected`

`on` | `{off}`

*Object selection state.* When you set this property to `on`, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

# Lineseries Properties

---

SelectionHighlight  
{on} | off

*Object highlighted when selected.*

- on — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- off — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

Tag  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the Tag property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an `areaseries` object and set the Tag property.

```
t = area(Y, 'Tag', 'area1')
```

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose Tag is `area1`.

```
set(findobj('Tag', 'area1'), 'FaceColor', 'red')
```

Type  
string (read-only)

*Class of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For lineseries objects, Type is always the string `line`.

UIContextMenu  
handle of `uicontextmenu` object

*Associate context menu with object.* Handle of a `uicontextmenu` object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

**UserData**  
array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

**Visible**  
{on} | off

*Visibility of object and its children.*

- **on** — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- **off** — Object not displayed. However, the object still exists and you can set and query its properties.

**XData**  
vector | matrix

*x-axis values for graph.* The *x*-axis values for graphs are specified by the `X` input argument. If `XData` is a vector, `length(XData)` must equal `length(YData)` and must be monotonic. If `XData` is a matrix, `size(XData)` must equal `size(YData)` and each column must be monotonic.

You can use `XData` to define meaningful coordinates for an underlying surface whose topography is being mapped. See “Changing the Offset of a Contour” for more information.

**XDataMode**  
{auto} | manual

# Lineseries Properties

---

*Use automatic or user-specified x-axis values.* If you specify XData (by setting the XData property or specifying the X input argument), MATLAB sets this property to manual and uses the specified values to label the x-axis.

If you set XDataMode to auto after specifying XData, MATLAB resets the x-axis ticks to 1:size(YData,1) or to the column indices of the ZData, overwriting any previous values for XData.

## XDataSource

MATLAB variable, as a string

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the XData. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatavariablename')
```

MATLAB requires a call to refreshdata when you set this property. Changing workspace variables used as an object's XDataSource does not change the object's XData values, but you can use refreshdata to force an update of the object's data. refreshdata also lets you specify that the data source variable be evaluated in the workspace of a function from which you call refreshdata.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## YData

vector | matrix

*Y-coordinates.* A vector of *y*-coordinates defining the values along the *y*-axis for the graph. *XData* and *ZData* must be the same length and have the same number of rows.

## **YDataSource**

MATLAB variable, as a string

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the *YData*. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's *YDataSource* does not change the object's *YData* values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## **ZData**

vector

*Z-coordinates.* A vector defining the *z*-coordinates for the graph. *XData* and *YData* must be the same length and have the same number of rows.

## **ZDataSource**

MATLAB variable, as a string

# Lineseries Properties

---

*Link ZData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the ZData. The default value is an empty array.

```
set(h, 'ZDataSource', 'zdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `ZDataSource` does not change the object's `ZData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

**Purpose** Line specification string syntax

**Description** Plotting functions accept *string specifiers* as arguments and modify the graph generated accordingly. Three components can be specified in the *string specifiers* along with the plotting command. They are:

- Line style
- Marker symbol
- Color

For example:

```
plot(x,y, '-.or')
```

plots *y* versus *x* using a dash-dot line (-.), places circular markers (o) at the data points, and colors both line and marker red (r). Specify the components (in any order) as a quoted string after the data arguments. Note that linespecs are single strings, not property-value pairs.

### Plotting Data Points with No Line

If you specify a marker, but not a line style, only the markers are plotted. For example:

```
plot(x,y, 'd')
```

### Line Style Specifiers

You indicate the line styles, marker types, and colors you want to display using *string specifiers*, detailed in the following tables:

| Specifier | LineStyle            |
|-----------|----------------------|
| '-'       | Solid line (default) |
| '--'      | Dashed line          |

# LineStyle (Line Specification)

---

| Specifier | LineStyle     |
|-----------|---------------|
| '.'       | Dotted line   |
| '-.'      | Dash-dot line |

## Marker Specifiers

| Specifier            | Marker Type                   |
|----------------------|-------------------------------|
| '+'                  | Plus sign                     |
| 'o'                  | Circle                        |
| '*'                  | Asterisk                      |
| '.'                  | Point                         |
| 'x'                  | Cross                         |
| 'square' or 's'      | Square                        |
| 'diamond' or 'd'     | Diamond                       |
| '^'                  | Upward-pointing triangle      |
| 'v'                  | Downward-pointing triangle    |
| '>'                  | Right-pointing triangle       |
| '<'                  | Left-pointing triangle        |
| 'pentagram' or 'p'   | Five-pointed star (pentagram) |
| 'hexagram' or 'h ' ' | Six-pointed star (hexagram)   |

---

**Note** The point (.) marker type does not change size when the specified value is less than 5.

---

## Color Specifiers

| Specifier | Color   |
|-----------|---------|
| r         | Red     |
| g         | Green   |
| b         | Blue    |
| c         | Cyan    |
| m         | Magenta |
| y         | Yellow  |
| k         | Black   |
| w         | White   |

## Related Properties

This page also describes how to specify the properties of lines used for plotting. MATLAB graphics give you control over these visual characteristics:

- **LineWidth** — Specifies the width (in points) of the line.
- **MarkerEdgeColor** — Specifies the color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).
- **MarkerFaceColor** — Specifies the color of the face of filled markers.
- **MarkerSize** — Specifies the size of the marker in points (must be greater than 0).

In addition, you can specify the **LineStyle**, **Color**, and **Marker** properties instead of using the symbol string. This is useful if you want to specify a color that is not in the list by using RGB values. See **Lineseries Properties** for details on these properties and **ColorSpec** for more information on color.

## Examples

Plot the sine function over three different ranges using different line styles, colors, and markers.

# LineSpec (Line Specification)

---

```
figure
t = 0:pi/20:2*pi;
plot(t,sin(t),'-.r*')
hold on
plot(t,sin(t-pi/2),'--mo')
plot(t,sin(t-pi),':bs')
hold off
```

---

Create a plot illustrating how to set line properties:

# LineStyle (Line Specification)

```
figure
plot(t,sin(2*t),'-mo',...
     'LineWidth',2,...
     'MarkerEdgeColor','k',...
     'MarkerFaceColor',[.49 1 .63],...
     'MarkerSize',10)
```

# linkaxes

---

**Purpose** Synchronize limits of specified 2-D axes

**Syntax** `linkaxes(axes_handles)`  
`linkaxes(axes_handles, 'option')`

**Description** Use `linkaxes` to synchronize the individual axis limits across several figures or subplots within a figure. Calling `linkaxes` makes all input axes have identical limits. Linking axes is best when you want to zoom or pan in one subplot and display the same range of data in another subplot.

`linkaxes(axes_handles)` links the  $x$ - and  $y$ -axis limits of the axes specified in the vector `axes_handles`. You can link any number of existing plots or subplots. The `axes_handles` input should be a vector of the handles for each plot or subplot. Entering an array of values results in an error message.

`linkaxes(axes_handles, 'option')` links the axes' `axes_handles` according to the specified option. The `option` argument can be one of the following strings:

|                  |                               |
|------------------|-------------------------------|
| <code>x</code>   | Link $x$ -axis only.          |
| <code>y</code>   | Link $y$ -axis only.          |
| <code>xy</code>  | Link $x$ -axis and $y$ -axis. |
| <code>off</code> | Remove linking.               |

See the `linkprop` function for more advanced capabilities that allow you to link object properties on any graphics object.

**Tips** The first axes you supply to `linkaxes` determines the  $x$ - and  $y$ -limits for all linked axes. This can cause plots to partly or entirely disappear if their limits or scaling are very different. To override this behavior, after calling `linkaxes`, specify the limits of the axes that you want to control with the `set` command, as the third example illustrates.

---

**Note** `linkaxes` is not designed to be transitive across multiple invocations. If you have three axes, `ax1`, `ax2`, and `ax3` and want to link them together, call `linkaxes` with `[ax1, ax2, ax3]` as the first argument. Linking `ax1` to `ax2`, then `ax2` to `ax3`, "unbinds" the `ax1-ax2` linkage.

---

## Examples

You can use interactive zooming or panning (selected from the figure toolbar) to see the effect of axes linking. For example, pan in one graph and notice how the  $x$ -axis also changes in the other. The axes responds in the same way to zoom and pan directives you type in the Command Window.

This example loads three vectors of data and creates a subplot for each vector. After a three-second pause, it then calls `linkaxes` with the argument `'xy'` to synchronize both the  $x$  and  $y$  axes limits. By specifying the third subplot first to `linkaxes`, you establish its  $y$ -limit for all the subplots:

```
load count.dat % Contains a 3-column vector named count
figure
ax(1) = subplot(3,1,1);
bar(ax(1),count(:,1),'g');
ax(2) = subplot(3,1,2);
bar(ax(2),count(:,2),'b');
ax(3) = subplot(3,1,3);
bar(ax(3),count(:,3),'m');
```

# linkaxes

```
% Wait three seconds and then link the axes  
pause(3)  
linkaxes([ax(3) ax(2) ax(1)], 'xy'); % Base Y-limits on bottom subplot
```

Click the **Zoom in** icon  to enter Zoom mode, and click the mouse near the middle of the top axes. You observe all three axes respond the same. If you pan in any of the axes, all of them also respond the same.

# linkaxes

---

---

Create two subplots containing related bar graphs. Call `linkaxes` to link only the *x*-axis limits of the two axes. Unlike in the previous example, the *y*-limits of the graphs remain unchanged. The example shows the effect of restricting the *x*-values to a range of 5 units and then manually panning either subplot:

```
load count.dat
figure
ax(1) = subplot(2,1,1);
```

```
bar(ax(1),count(:,1),'g');  
ax(2) = subplot(2,1,2);  
bar(ax(2),count(:,2),'b');  
linkaxes(ax,'x');  
set(ax(1),'XLim',[4.5 9.5])    % Restrict either axis to show 5 values
```

Choose the Pan tool (**Tools > Pan**) (or type `pan` on). Drag the top axes. Both axes pan uniformly in  $x$ , but only the one you pan moves in the  $y$  direction.

# linkaxes

---

Create two subplots containing data having different ranges. The first axes handle passed to `linkaxes` determines the data range for all other linked axes. In this example, calling `set` for the lower axes overrides the *x*-limits established by the call to `linkaxes`:

```
a1 = subplot(2,1,1);  
plot(randn(10,1));      % Plot 10 numbers on top  
a2 = subplot(2,1,2);  
plot(a2,randn(100,1))  % Plot 100 numbers below  
linkaxes([a1 a2], 'x'); % Link the axes; subplot 2 now out of range
```

In order to display the full range of  $x$ -values, override the axes limits that `linkaxes` established.

```
set(a2,'xlimmode','auto'); % Now both axes run from 1-100 in x
                           % You could also use set(a2,'xlim',[1 100])
```

# linkaxes

---

|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Automatically update graphs when variables change                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Syntax</b>      | <pre>linkdata on linkdata off linkdata linkdata(<i>figure_handle</i>,...) linkobj = linkdata(<i>figure_handle</i>)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b> | <p><code>linkdata on</code> turns on data linking for the current figure.</p> <p><code>linkdata off</code> turns data linking off.</p> <p><code>linkdata</code> by itself toggles the state of data linking.</p> <p><code>linkdata(<i>figure_handle</i>,...)</code> applies the function to the specified figure handle.</p> <p><code>linkobj = linkdata(<i>figure_handle</i>)</code> returns a <i>linkdata object</i> for the specified figure. The object has one read-only property, <code>Enable</code>, the string 'on' or 'off', depending on the linked state of the figure.</p> <p>Data linking connects graphs in figure windows to variables in the base or a function's workspace via their <code>XDataSource</code>, <code>YDataSource</code>, and <code>ZDataSource</code> properties. When you turn on data linking for a figure, MATLAB compares variables in the current (base or function caller) workspace with the <code>XData</code>, <code>YData</code>, and <code>ZData</code> properties of graphs in the affected figure to try to match them. When a match is found, the appropriate <code>XDataSource</code>, <code>YDataSource</code> and/or <code>ZDataSource</code> for the graph are set to strings that name the matching variables.</p> <p>Any subsequent changes to linked variables are reflected in graphs that use them as data sources and in the Variables editor, if the linked variables are displayed there. Conversely, any changes to plotted data values made at the command line, in the Variables editor, or with the Brush tool (such as deleting or replacing data points), are immediately reflected in the workspace variables linked to the data points.</p> <p>When a figure containing graphs is linked and any variable identified as <code>XDataSource</code>, <code>YDataSource</code>, and/or <code>ZDataSource</code> changes its values in the workspace, all graphs displaying it in that and other linked figures</p> |

automatically update. This operation is equivalent to automatically calling the `refreshdata` function on the corresponding figure when a variable changes.

Linked figure windows identify themselves by the appearance of the Linked Plot information bar at the top of the window. When `linkdata` is off for a figure, the Linked Plot information bar is removed. If `linkdata` cannot unambiguously identify data sources for a graph in a linked figure, it reports this via the Linked Plot information bar, which gives the user an opportunity to identify data sources. The information bar displays a warning icon and a message, **No graphics have data sources** and also prompts **fix it**. Clicking **fix it** opens the Specify Data Source Properties dialog box for identifying variable names and ranges of data sources used in the graph.

## Tips

- “Types of Variables You Can Link” on page 2-2648
- “Restoring Links that Break” on page 2-2648
- “Linking Rapidly Changing Data” on page 2-2649
- “Linking Brushed Graphs” on page 2-2649

## Types of Variables You Can Link

You can use `linkdata` to connect a graph with scalar, vector and matrix numeric variables of any class (including `complex`, if the graphing function can plot it) — essentially any data for which `isnumeric` equals `true`. See “Example 3” on page 2-2651 for instructions on linking complex variables. You can also link plots to numeric fields within structures. You can specify MATLAB expressions as data sources, for example, `sqrt(y)+1`.

## Restoring Links that Break

Refreshing data on a linked plot fails if the strings in the `XDataSource`, `YDataSource`, or `ZDataSource` properties, when evaluated, are incompatible with what is in the current workspace, such that the corresponding `XData`, `YData`, or `ZData` are unable to respond. The visual appearance of the object in the graph is not affected by such failures, so graphic objects show no indication of broken links. Instead,

a warning icon and the message **Failing links** appear on the Linked Plot information bar along with an **Edit** button that opens the Specify Data Sources dialog box.

### Linking Rapidly Changing Data

linkdata buffers updates to data and dispatches them to plots at roughly half-second intervals. This makes data linking not suitable for smoothly animating changes in data values unless they are updated in loops that are forced to execute two times per second or less.

One consequence of buffering link updates is that linkdata might not detect changes in data streams it monitors. If you are running a function that uses `assignin` or `evalin` to update workspace variables, linkdata can sometimes fail to process updates that change values but not the size and class of workspace variables. Such failures only happen when the function itself updates the plot.

### Linking Brushed Graphs

If you link data sources to graphs that have been brushed, their brushing marks can change or vanish. This is because the workspace variables in those graphs now dictate which, if any, observations are brushed, superseding any brushing annotations that were applied to their graphical data (YData, etc.). For more details, see “How Data Linking Affects Data Brushing” on page 2-534 in the brush reference page.

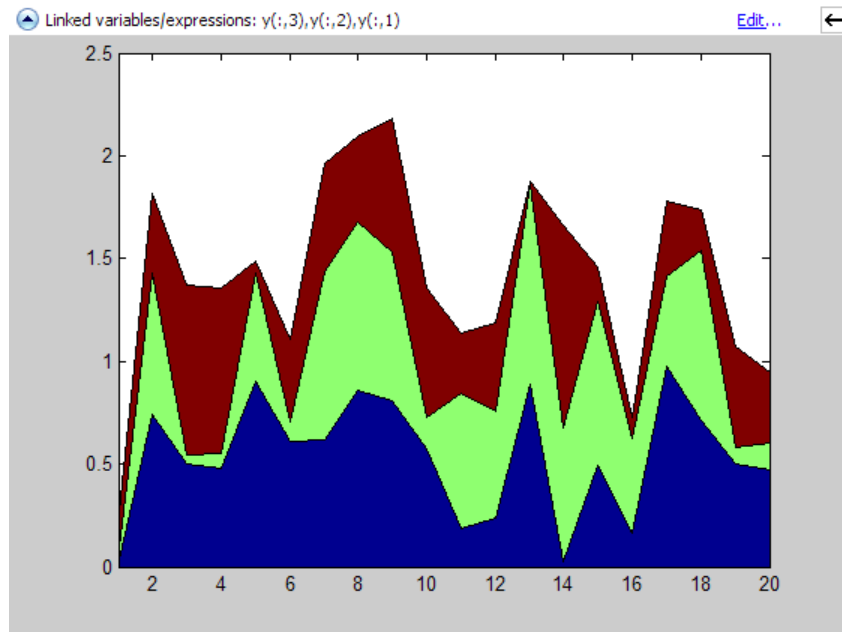

## Examples

### Example 1

Create two variables, graph them as areseries, and link the plot to them:

```
x = [1:20];  
y = rand(20,3);  
area(x,y)  
linkdata on
```

# linkdata

Change values for linked variable  $y$  in the workspace:

```
y(10,:) = 0;
```

The area graph immediately updates.

### Example 2

Delete a figure if it is not linked, based on a returned linkdata object:

```
ld = linkdata(fig)

ld =
    graphics.linkdata

if strcmp(ld.Enable,'off')
    delete(fig)
end
```

### Example 3

If a graphing function can display a complex variable, you can link such plots. To do so, you need to describe the data sources as expressions to separate the real and imaginary parts of the variable. For example,

# linkdata

---

```
x = eig(randn(20,20))
```

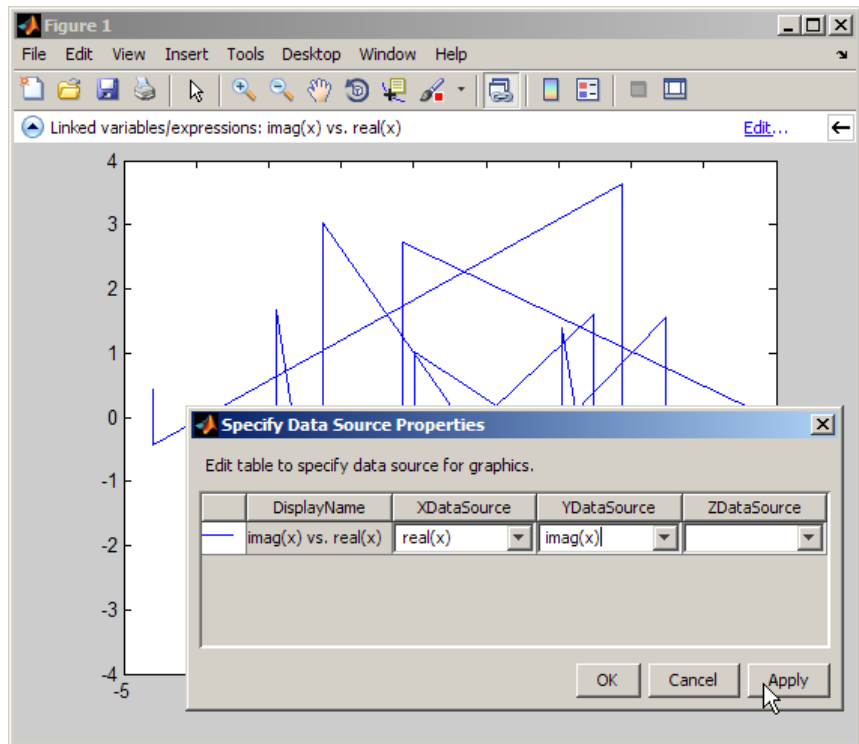

```
whos
```

| Name | Size | Bytes | Class  | Attributes |
|------|------|-------|--------|------------|
| x    | 20x1 | 320   | double | complex    |

yields a complex vector. You can use `plot` to display the real portion as  $x$  and the imaginary portion as  $y$ , then link the graph to the variable:

```
plot(x)  
linkdata
```

However, `linkdata` cannot unambiguously identify the graph's data sources, and you must tell it by typing `real(x)` and `imag(x)` into the Specify Data Source Properties dialog box that displays when you click **fix it** in the Linked Plot information bar.

To avoid having to type the data source names in the dialog box, you can specify them when you plot:

```
plot(x, 'XDataSource', 'real(x)', 'YDataSource', 'imag(x)')
```

If you subsequently change values of  $x$  programmatically or manually, the plot updates accordingly.

# linkdata

---

---

**Note** Although you can use data brushing on linked plots of complex data, your brush marks only appear in the plot you are brushing, not in other plots or in the Variables editor. This is because function calls, such as `real(x)` and `imag(x)`, that you specify as data sources are not interpreted when brushing graphed data.

## How To

- “Making Graphs Responsive with Data Linking”

## Purpose

Keep same value for corresponding properties of graphics objects

## Syntax

```
hlink = linkprop(obj_handles, 'PropertyName')  
hlink = linkprop(obj_handles, {'PropertyName1', 'PropertyName2', ...})
```

## Description

Use `linkprop` to maintain the same values for the corresponding properties of different graphics objects.

---

**Note** Use `linkprop` only with Handle Graphics objects.

---

`hlink = linkprop(obj_handles, 'PropertyName')` maintains the same value for the property *PropertyName* on all objects whose handles appear in `obj_handles`. `linkprop` returns the link object in `hlink`. See “About Link Objects” on page 2-2656 for more information.

`hlink = linkprop(obj_handles, {'PropertyName1', 'PropertyName2', ...})` maintains the same respective values for all properties passed as a cell array on all objects whose handles appear in `obj_handles`.

MATLAB updates the linked properties of all linked objects immediately when `linkprop` is called. The first object in the list `obj_handles` determines the property values for the other objects.

A set of graphics objects can have only one link object connecting their properties at any given time. Calling `linkprop` creates a new link object. This new link object replaces any existing link object that is associated with the objects specified in `obj_handles`. However, you can manage which properties and which objects are linked by calling methods on that object:

- To add an object to the list of linked objects, use the `addtarget` method.
- To link new properties of currently-linked objects, use the `addprop` method.
- To stop linking an object, use the `removetarget` method.

## About Link Objects

- To stop properties from linking, use the `removeprop` method.

The link object that `linkprop` returns stores the mechanism that links the properties of different graphics objects. Therefore, the link object must exist within the context where you want property linking to occur (such as in the base workspace if users are to interact with the objects from the command line or figure tools).

The following list describes ways to maintain a reference to the link object.

- Return the link object as an output argument from a function and keep it in the base workspace while interacting with the linked objects.
- Make the `hlink` variable global.
- Store the `hlink` variable in an object's `UserData` property or in application data. See the “Examples” on page 2-2657 section for an example that uses application data.

## Updating a Link Object

If you want to change either the graphics objects or the properties that are linked, you need to use the link object methods designed for that purpose. These methods are functions that operate only on link objects. To use them, you must first create a link object using `linkprop`.

| Method                    | Purpose                                                          |
|---------------------------|------------------------------------------------------------------|
| <code>addtarget</code>    | Add specified graphics object to the link object's targets.      |
| <code>removetarget</code> | Remove specified graphics object from the link object's targets. |
| <code>addprop</code>      | Add specified property to the linked properties.                 |
| <code>removeprop</code>   | Remove specified property from the linked properties.            |

### Method Syntax

`addtarget(hlink,obj_handles)`

```
removetarget(hlink,obj_handles)
addprop(hlink,'PropertyName')
removeprop(hlink,'PropertyName')
```

### Method Arguments

- `hlink` — Link object returned by `linkprop`
- `obj_handles` — One or more graphic object handles
- `PropertyName` — Name of a property common to all target objects

## Examples

This example creates four isosurface graphs of fluid flow data, each displaying a different isovalue. The `CameraPosition` and `CameraUpVector` properties of each subplot axes are linked so that the user can rotate all subplots in unison.

After running the example, select **Rotate 3D** from the figure **Tools** menu and observe how all subplots rotate together.

---

**Note** You can run this example or open it in the MATLAB editor.

---

The property linking code is in step 3.

- 1 Define the data using `flow` and specify property values for the isosurface (which is a patch object).

```
[x,y,z,v] = flow;
isoval = [-3,-1,0,1];
props.FaceColor = [0,0,0.5];
props.EdgeColor = 'none';
props.AmbientStrength = 1;
props.FaceLighting = ' gouraud';
```

- 2 Create four subplot axes and add an isosurface graph to each one. Add a title and set viewing and lighting parameters. MATLAB functions used are `subplot`, `patch`, `isosurface`, `title`, and `num2str`.

Also set the viewing and lighting parameters for each axes to be the same by calling `view`, `axis`, and `camlight`.

```
figure
% Preallocate h
h = zeros(1,4);
for k = 1:4
    h(k) = subplot(2,2,k);
    patch(isosurface(x,y,z,v,isoval(k)),props)
    title(h(k),['Isovalue = ',num2str(k)])
    % Set the view and add lighting
    view(h(k),3); axis(h(k),'tight','equal')
    camlight left; camlight right
    % Make axes invisible and title visible
    axis(h(k),'off')
    set(get(h(k),'title'),'Visible','on')
end
```

- 3 Link the `CameraPosition` and `CameraTarget` properties of all subplot axes. Since this code already is completed executing when you rotate the subplots, the link object is stored in the first subplot axes application data. See `setappdata` for more information on using application data.

```
if ishghandle(h)
    hlink = linkprop(h,{'CameraPosition','CameraUpVector'});
    key = 'graphics_linkprop';
    % Store link object on first subplot axes
    setappdata(h(1),key,hlink);
end
```

- 4** Turn on the **Rotate 3D** tool. Click any object in the figure and rotate it. As you turn it, all three other subplots turn in the same manner.

`rotate3d on`

### Linking an Additional Property

Suppose you want to add the axes `PlotBoxAspectRatio` to the linked properties in the previous example. You can do this by modifying the link object that is stored in the first subplot axes' application data.

# linkprop

---

- 1 First click the first subplot axes to make it the current axes (since its handle was saved only within the creating function). Then get the link object's handle from application data (`getappdata`).

```
hlink = getappdata(gca, 'graphics_linkprop');
```

- 2 Use the `addprop` method to add a new property to the link object.

```
addprop(hlink, 'PlotBoxAspectRatio')
```

Since `hlink` is a reference to the link object (i.e., not a copy), `addprop` can change the object that is stored in application data.

**Purpose** Solve linear system of equations

**Syntax**  
`X = linsolve(A,B)`  
`X = linsolve(A,B,opts)`

**Description** `X = linsolve(A,B)` solves the linear system  $A*X = B$  using LU factorization with partial pivoting when  $A$  is square and QR factorization with column pivoting otherwise. The number of rows of  $A$  must equal the number of rows of  $B$ . If  $A$  is  $m$ -by- $n$  and  $B$  is  $m$ -by- $k$ , then  $X$  is  $n$ -by- $k$ . `linsolve` returns a warning if  $A$  is square and ill conditioned or if it is not square and rank deficient.

`[X, R] = linsolve(A,B)` suppresses these warnings and returns  $R$ , which is the reciprocal of the condition number of  $A$  if  $A$  is square, or the rank of  $A$  if  $A$  is not square.

`X = linsolve(A,B,opts)` solves the linear system  $A*X = B$  or  $A'*X = B$ , using the solver that is most appropriate given the properties of the matrix  $A$ , which you specify in `opts`. For example, if  $A$  is upper triangular, you can set `opts.UT = true` to make `linsolve` use a solver designed for upper triangular matrices. If  $A$  has the properties in `opts`, `linsolve` is faster than `mldivide`, because `linsolve` does not perform any tests to verify that  $A$  has the specified properties.

---

**Notes** If  $A$  does not have the properties that you specify in `opts`, `linsolve` returns incorrect results and does not return an error message. If you are not sure whether  $A$  has the specified properties, use `mldivide` instead.

For small problems, there is no speed benefit in using `linsolve` on triangular matrices as opposed to using the `mldivide` function.

---

The `TRANSA` field of the `opts` structure specifies the form of the linear system you want to solve:

# linsolve

- If you set `opts.TRANSA = false`, `linsolve(A,B,opts)` solves  $A * X = B$ .
- If you set `opts.TRANSA = true`, `linsolve(A,B,opts)` solves  $A' * X = B$ .

The following table lists all the field of `opts` and their corresponding matrix properties. The values of the fields of `opts` must be logical and the default value for all fields is `false`.

| Field Name | Matrix Property                                                                         |
|------------|-----------------------------------------------------------------------------------------|
| LT         | Lower triangular                                                                        |
| UT         | Upper triangular                                                                        |
| UHESS      | Upper Hessenberg                                                                        |
| SYM        | Real symmetric or complex Hermitian                                                     |
| POSDEF     | Positive definite                                                                       |
| RECT       | General rectangular                                                                     |
| TRANSA     | Conjugate transpose — specifies whether the function solves $A * X = B$ or $A' * X = B$ |

The following table lists all combinations of field values in `opts` that are valid for `linsolve`. A true/false entry indicates that `linsolve` accepts either true or false.

| LT    | UT    | UHESS | SYM   | POSDEF     | RECT       | TRANSA     |
|-------|-------|-------|-------|------------|------------|------------|
| true  | false | false | false | false      | true/false | true/false |
| false | true  | false | false | false      | true/false | true/false |
| false | false | true  | false | false      | false      | true/false |
| false | false | false | true  | true/false | false      | true/false |
| false | false | false | false | false      | true/false | true/false |

**Examples**

The following code solves the system  $A'x = b$  for an upper triangular matrix  $A$  using both `mldivide` and `linsolve`.

```
A = triu(rand(5,3)); x = [1 1 1 0 0]'; b = A'*x;  
y1 = (A')\b  
opts.UT = true; opts.TRANSA = true;  
y2 = linsolve(A,b,opts)
```

y1 =

```
1.0000  
1.0000  
1.0000  
0  
0
```

y2 =

```
1.0000  
1.0000  
1.0000  
0  
0
```

---

**Note** If you are working with matrices having different properties, it is useful to create an options structure for each type of matrix, such as `opts_sym`. This way you do not need to change the fields whenever you solve a system with a different type of matrix  $A$ .

---

**See Also**

`mldivide`

# linspace

---

**Purpose** Generate linearly spaced vectors

**Syntax** `y = linspace(a,b)`  
`y = linspace(a,b,n)`

**Description** The `linspace` function generates linearly spaced vectors. It is similar to the colon operator `:`, but gives direct control over the number of points.

`y = linspace(a,b)` generates a row vector `y` of 100 points linearly spaced between and including `a` and `b`.

`y = linspace(a,b,n)` generates a row vector `y` of `n` points linearly spaced between and including `a` and `b`. For `n < 2`, `linspace` returns `b`.

**Examples** Create a vector of 100 linearly spaced numbers from 1 to 500:

```
A = linspace(1,500);
```

Create a vector of 12 linearly spaced numbers from 1 to 36:

```
A = linspace(1,36,12);
```

**See Also** `logspace` | colon operator

**Purpose** Random number generator algorithms

**Class** RandStream

**Syntax** RandStream.list

**Description** RandStream.list lists all the generator algorithms that may be used when creating a random number stream with RandStream or RandStream.create. The available generator algorithms and their properties are given in the following table.

| <b>Keyword</b> | <b>Generator</b>                                            | <b>Multiple Stream and Substream Support</b> | <b>Approximate Period In Full Precision</b> |
|----------------|-------------------------------------------------------------|----------------------------------------------|---------------------------------------------|
| mt19937ar      | Mersenne twister (used by default stream at MATLAB startup) | No                                           | $2^{19937} - 1$                             |
| mcg16807       | Multiplicative congruential generator                       | No                                           | $2^{31} - 2$                                |
| mlfg6331_64    | Multiplicative lagged Fibonacci generator                   | Yes                                          | $2^{124}$                                   |
| mrg32k3a       | Combined multiple recursive generator                       | Yes                                          | $2^{127}$                                   |

# RandStream.list

---

| <b>Keyword</b> | <b>Generator</b>                                                   | <b>Multiple Stream and Substream Support</b> | <b>Approximate Period In Full Precision</b> |
|----------------|--------------------------------------------------------------------|----------------------------------------------|---------------------------------------------|
| shr3cong       | Shift-register generator summed with linear congruential generator | No                                           | $2^{64}$                                    |
| swb2712        | Modified subtract with borrow generator                            | No                                           | $2^{1492}$                                  |

See “Choosing a Random Number Generator” for details about these generator algorithms. See <http://www.math.sci.hiroshima-u.ac.jp/~m-mat/MT/emt.html> for a full description of the Mersenne twister algorithm.

**Purpose** Create and open list-selection dialog box

**Syntax** [Selection,ok] = listdlg('ListString',S)

**Description** [Selection,ok] = listdlg('ListString',S) creates a modal dialog box that enables you to select one or more items from a list. **Selection** is a vector of indices of the selected strings (in single selection mode, its length is 1). **Selection** is [] when **ok** is 0. **ok** is 1 if you click the **OK** button, or 0 if you click the **Cancel** button or close the dialog box. Double-clicking on an item or pressing **Return** when multiple items are selected has the same effect as clicking the **OK** button. The dialog box has a **Select all** button (when in multiple selection mode) that enables you to select all list items.

Inputs are in parameter/value pairs:

| Parameter       | Description                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------|
| 'ListString'    | Cell array of strings that specify the list box items.                                             |
| 'SelectionMode' | String indicating whether one or many items can be selected: 'single' or 'multiple' (the default). |
| 'ListSize'      | List box size in pixels, specified as a two-element vector [width height]. Default is [160 300].   |
| 'InitialValue'  | Vector of indices of the list box items that are initially selected. Default is 1, the first item. |
| 'Name'          | String for the dialog box's title. Default is ''.                                                  |
| 'PromptString'  | String matrix or cell array of strings that appears as text above the list box. Default is {}.     |
| 'OKString'      | String for the OK button. Default is 'OK'.                                                         |
| 'CancelString'  | String for the Cancel button. Default is 'Cancel'.                                                 |
| 'uh'            | Uicontrol button height, in pixels. Default is 18.                                                 |

# listdlg

---

| Parameter | Description                                       |
|-----------|---------------------------------------------------|
| 'fus'     | Frame/uicontrol spacing, in pixels. Default is 8. |
| 'ffs'     | Frame/figure spacing, in pixels. Default is 8.    |

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowStyle` in the MATLAB Figure Properties.

---

## Examples

This example displays a dialog box that enables the user to select a file from the current directory. The function returns a vector. Its first element is the index to the selected file; its second element is 0 if no selection is made, or 1 if a selection is made.

```
d = dir;  
str = {d.name};  
[s,v] = listdlg('PromptString','Select a file:',...  
               'SelectionMode','single',...  
               'ListString',str)
```

**See Also**

# listfonts

---

**Purpose** List available system fonts

**Syntax**  
`c = listfonts`  
`c = listfonts(h)`

**Description** `c = listfonts` returns sorted list of available system fonts.  
`c = listfonts(h)` returns sorted list of available system fonts and includes the `FontName` property of the object with handle `h`.

**Tips** Calling `listfonts` returns a list of all fonts residing on your system, possibly including fonts that cannot be used because they are bitmapped. You can instead use the `uisetfont` utility (a GUI) to preview fonts you might want to use; it only displays fonts that can be rendered in MATLAB figures and GUIs. Like `uisetfont`, the **Custom Fonts** pane of MATLAB Preferences also previews available fonts and only shows those that can be rendered.

## Examples **Example 1**

This example returns a list of available system fonts similar in format to the one shown.

```
list = listfonts

list =
    'Agency FB'
    'Algerian'
    'Arial'
    ...
    'ZapfChancery'
    'ZapfDingbats'
    'ZWAdobeF'
```

## **Example 2**

This example returns a list of available system fonts with the value of the `FontName` property, for the object with handle `h`, sorted into the list.

```
h = uicontrol('Style','text','String',...
    'My Font','FontName','MyFont');
list = listfonts(h)

list =
    'Agency FB'
    'Algerian'
    'Arial'
    ...
    'MyFont'
    ...
    'ZapfChancery'
    'ZapfDingbats'
    'ZWAdobeF'
```

## See Also

`uisetfont`

# load

---

## Purpose

Load data from MAT-file into workspace

## Syntax

```
S = load(filename)
S = load(filename, variables)
S = load(filename, '-mat', variables)
S = load(filename, '-ascii')
load(filename, ___)
load filename ___
```

## Description

`S = load(filename)` loads the variables from a MAT-file into a structure array, or data from an ASCII file into a double-precision array.

`S = load(filename, variables)` loads the specified variables from a MAT-file.

`S = load(filename, '-mat', variables)` forces `load` to treat the file as a MAT-file, regardless of the extension. Specifying *variables* is optional.

`S = load(filename, '-ascii')` forces `load` to treat the file as an ASCII file, regardless of the extension.

`load(filename, ___)` loads without combining MAT-file variables into a structure array.

`load filename ___` is the command form of the syntax, for convenient loading from the command line. With command syntax, you do not need to enclose input strings in single quotation marks. Separate inputs with spaces instead of commas. Do not use command syntax if inputs such as *filename* are variables. For more information, see “Command vs. Function Syntax” in the MATLAB Programming Fundamentals documentation.

## Input Arguments

### **filename**

Name of a file. If you do not specify *filename*, the `load` function searches for a file named `matlab.mat`.

*filename* can include a file extension and a full or partial path. If *filename* has no extension (that is, no text after a period), `load` looks

for a file named *filename.mat*. If *filename* has an extension other than *.mat*, the `load` function treats the file as ASCII data.

**Default:** `'matlab.mat'`

### **variables**

List of variables to load from the file. Valid for MAT-files only. Use one of the following forms:

|                                    |                                                                                                                                                |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>var1, var2, ...</code>       | Load the listed variables. Use the '*' wildcard to match patterns. For example, <code>load('A*')</code> loads all variables that start with A. |
| <code>'-regex', expressions</code> | Load only the variables or fields that match the specified regular expressions.                                                                |

**Default:** all variables in file

### **'-mat'**

Keyword that indicates that the specified file is a MAT-file, regardless of the extension.

### **'-ascii'**

Keyword that indicates that the specified file is an ASCII file, regardless of the extension.

The following remarks apply to loading all ASCII files, even when you do not include the `-ascii` keyword, but load a file with an extension other than *.mat*:

- The file must contain a rectangular table of numbers, with an equal number of elements in each row. The file delimiter (the character between elements in each row) can be a blank, comma, semicolon, or

# load

---

tab character. The file can contain MATLAB comments (lines that begin with a percent sign, %).

- MATLAB returns the data as a single two-dimensional array of type `double`. The number of rows in the array is equal to the number of lines in the file. The number of columns is equal to the number of values on a line.
- If you do not specify an output for the `load` function, MATLAB creates a variable named after the loaded file (minus any file extension). For example, the command

```
load mydata.dat
```

reads data into a variable called `mydata`.

To create the variable name, `load` precedes any leading underscores or digits in *filename* with an `X` and replaces any other nonalphabetic characters with underscores. For example, the command

```
load 10-May-data.dat
```

creates a variable called `X10_May_data`.

## Examples

Load all variables from the example MAT-file `gong.mat`. Check the contents of the workspace before and after the load operation.

```
disp('Contents of workspace before loading file:')  
whos
```

```
disp('Contents of gong.mat:')  
whos -file gong.mat
```

```
load gong.mat  
disp('Contents of workspace after loading file:')  
whos
```

---

---

Load only the variable `y` from the example file `handel.mat`. If the workspace already contains a variable `y`, the `load` operation overwrites it with data from the file.

```
load('handel.mat', 'y')
```

---

Create a list of variables to load using a cell array. Call `load` using function syntax.

```
%This example file contains variables X, caption, and map.  
exampleFile = 'durer.mat';
```

```
% Load selected variables.  
vars = {'X', 'caption'};  
load(exampleFile, vars{:});
```

---

Use regular expressions to load four variables from the example file `accidents.mat` that do not begin with `'hwy'`:

```
load('accidents.mat', '-regexp', '^(!hwy)...');
```

---

Load the first three variables from `accidents.mat`, determined alphabetically by variable name:

```
vars = whos('-file', 'accidents.mat');  
load('accidents.mat', vars(1:3).name);
```

---

Create an ASCII file from several 4-column matrices, and load the data back into a double array named `mydata`:

```
a = magic(4);  
b = ones(2, 4) * -5.7;
```

# load

---

```
c = [8 6 4 2];  
save -ascii mydata.dat a b c  
clear a b c  
  
load mydata.dat
```

## See Also

## How To

- [“Supported File Formats”](#)
- [“Ways to Load MAT-Files”](#)
- [“Ways to Import Text Files”](#)
- [“Troubleshooting: Loading Variables within a Function”](#)
- [“Process a Sequence of Files”](#)

**Purpose** Initialize control object from file

**Syntax**

```
h.load('filename')
load(h, 'filename')
```

**Description** `h.load('filename')` initializes the COM object associated with the interface represented by the MATLAB COM object `h` from file specified in the string `filename`. The file must have been created previously by serializing an instance of the same control.

`load(h, 'filename')` is an alternate syntax for the same operation.

---

**Note** The COM load function is only supported for controls at this time.

---

**Tips** COM functions are available on Microsoft Windows systems only.

**Examples** Create an `mwsamp` control and save its original state to the file `mwsample`:

```
f = figure('position', [100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], f);
h.save('mwsample')
```

Now, alter the figure by changing its label and the radius of the circle:

```
h.Label = 'Circle';
h.Radius = 50;
h.Redraw;
```

Using the `load` function, you can restore the control to its original state:

```
h.load('mwsample');
h.get
```

MATLAB displays the original values:

```
ans =
```

# load (COM)

---

Label: 'Label'  
Radius: 20

## **See Also**

save (COM) | actxcontrol | actxserver | release | delete (COM)

**Purpose** Load serial port objects and variables into MATLAB workspace

**Syntax** `load filename`  
`load filename obj1 obj2...`

**Description** `load filename` returns all variables from the file specified by `filename` into the MATLAB workspace.

`load filename obj1 obj2...` returns the serial port objects specified by `obj1 obj2 ...` from the file `filename` into the MATLAB workspace.

`out = load('filename','obj1','obj2',...)` returns the specified serial port objects from the file `filename` as a structure to `out` instead of directly loading them into the workspace. The field names in `out` match the names of the loaded serial port objects.

**Tips** Values for read-only properties are restored to their default values upon loading. For example, the `Status` property is restored to `closed`. To determine if a property is read-only, examine its reference pages.

## Examples

---

**Note** This example is based on a Windows platform.

---

Suppose you create the serial port objects `s1` and `s2`, configure a few properties for `s1`, and connect both objects to their instruments:

```
s1 = serial('COM1');
s2 = serial('COM2');
set(s1,'Parity','mark','DataBits',7);
fopen(s1);
fopen(s2);
```

Save `s1` and `s2` to the file `MyObject.mat`, and then load the objects back into the workspace:

```
save MyObject s1 s2;
load MyObject s1;
```

## load (serial)

---

```
load MyObject s2;

get(s1, {'Parity', 'DataBits'})
ans =
    'mark'    [7]
get(s2, {'Parity', 'DataBits'})
ans =
    'none'    [8]
```

**Purpose** Load shared library into MATLAB

**Syntax** `loadlibrary(libname,hfile)`  
`loadlibrary(libname,hfile,Name,Value)`

`loadlibrary(libname,@protofile)`

`[notfound,warnings] = loadlibrary( __ )`

**Description** `loadlibrary(libname,hfile)` loads functions from shared library, `libname`, defined in header file, `hfile`, into MATLAB.

`loadlibrary(libname,hfile,Name,Value)` loads the library with one or more `Name,Value` arguments.

`loadlibrary(libname,@protofile)` uses a prototype file, `protofile`, in place of a header file.

`[notfound,warnings] = loadlibrary( __ )` returns warning information, and can include any of the input arguments in previous syntaxes.

## Limitations

- You must select a supported C compiler and Perl must be available. To select a compiler, use the `mex -setup` command, described in “Selecting a Compiler on Windows Platforms” or “Selecting a Compiler on UNIX Platforms”. For an up-to-date list of supported compilers, see the Supported and Compatible Compilers Web page.
- Do not call `loadlibrary` if the library is already in memory. To test this condition, call `libisloaded`.
- `loadlibrary` does not support libraries generated by the MATLAB Compiler™ product.
- The MATLAB Shared Library interface does not support library functions with function pointer inputs.

# loadlibrary

---

## Input Arguments

### **libname - Name of shared library**

string

Name of shared library, specified as a string. The name is case sensitive and must match the file on your system.

On Microsoft Windows systems, `libname` refers to the name of a shared library (.dll) file. On Linux systems, it refers to the name of a shared object (.so) file. On Apple Macintosh systems, it refers to a dynamic shared library (.dylib).

If you do not include a file extension with the `libname` argument, `loadlibrary` attempts to find the library with either the appropriate platform MEX-file extension or the appropriate platform library extension (usually .dll, .so, or .dylib). For a list of MEX-file extensions, see “Binary MEX-File Extensions”.

### **hfile - Name of C header file**

string

Name of C header file, specified as a string. The name is case sensitive and must match the file on your system. If you do not include a file extension in the file name, `loadlibrary` uses .h for the extension.

### **protofile - Name of prototype file**

string

Name of prototype file, specified as a string. The name is case sensitive and must match the file on your system. The string `@protofile` specifies a function handle to the prototype file. When using a prototype file, the only valid Name, Value pair argument is **alias**.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments, where Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

## **addheader - Additional header file**

string

Additional header file, specified as the comma-separated pair consisting of 'addheader' and a string. Specify the file name without a file extension. Loads the functions defined in the additional header file. Each file specified by addheader must have a corresponding #include statement in the base header file.

MATLAB does not verify the existence of header files and ignores any that are not needed.

## **alias - Alternative name for library**

string

Alternative name for library, specified as the comma-separated pair consisting of 'alias' and a string. Associates the specified name with the library. All subsequent calls to MATLAB functions that reference this library must use this alias until the library is unloaded.

## **includepath - Additional search path for header files**

string

Additional search path for header files, specified as the comma-separated pair consisting of 'includepath' and a string.

## **mfilename - Prototype file**

string

Prototype file, specified as the comma-separated pair consisting of 'mfilename' and a string. Generates a prototype file in the current folder. The prototype file name must be different from the library name. Use this file in place of a header file when loading the library.

## **thunkfilename - Thunk file**

string

Thunk file, specified as the comma-separated pair consisting of 'thunkfilename' and a string. Overrides the default thunk file name.

# loadlibrary

---

## Output Arguments

### **notfound** - Names of functions

cell array

Names of functions found in header files but missing from the library, returned as cell array.

### **warnings** - Warnings

character array

Warnings produced while processing the header file, returned as character array.

## Examples

### **Load Functions in shrlibsample Library**

Add path to examples folder.

```
addpath(fullfile(matlabroot,'extern','examples','shrlib'))
```

Load shrlibsample.

```
loadlibrary('shrlibsample')
```

Clean up.

```
unloadlibrary shrlibsample
```

### **Load Library Using Header File**

The header file for the libmx library is matrix.h.

```
hfile = fullfile(matlabroot,'extern','include','matrix.h');  
loadlibrary('libmx',hfile)
```

Clean up.

```
unloadlibrary libmx
```

### **Load Library Using Multiple Header Files**

Suppose you have a library, mylib, with the header file, mylib.h. The header file contains the statement, #include header2.h. To use

functions defined in `header2.h`, call `loadlibrary` with the `addheader` option.

```
loadlibrary('mylib','mylib.h','addheader','header2')
```

## Load Library Using an Alias Name

Create an alias, `lib`, for library, `shrlibsample`.

```
loadlibrary('shrlibsample','alias','lib')
```

Use the alias name, `lib`, to call a function in the library.

```
str = 'This was a Mixed Case string';  
calllib('lib','stringToUpper',str)
```

```
ans =  
    THIS WAS A MIXED CASE STRING
```

Clean up.

```
unloadlibrary lib
```

## Search Alternative Paths for Header Files

Create an alternative path, `apath`, containing header files.

```
apath = fullfile(matlabroot,'extern','include');
```

Load `shrlibsample`.

```
loadlibrary('shrlibsample','includepath',apath);
```

Clean up.

```
unloadlibrary shrlibsample
```

## Tips

- If you have more than one library file of the same name, load the first using the library file name, and load the additional libraries using the **alias** option.

# loadlibrary

---

## Definitions

### Prototype File

A file of MATLAB commands which you can modify and use in place of a header file.

### Thunk File

A compatibility layer to a 64-bit library generated by MATLAB. The name of the thunk file is:

```
BASENAME_thunk_COMPUTER.c
```

where *BASENAME* is either the name of the shared library or the *mfilename* prototype name, if specified. *COMPUTER* is the string returned by the `computer` function. MATLAB compiles this file and creates the file:

```
BASENAME_thunk_COMPUTER.LIBEXT
```

where *LIBEXT* is the platform-dependent default shared library extension, for example, `dll` on Windows.

| <b>Purpose</b>         | Modify load process for object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Syntax</b>          | <code>b = loadobj (a)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b>     | <p><code>b = loadobj (a)</code> is called by the <code>load</code> function if the class of <code>a</code> defines a <code>loadobj</code> method. <code>load</code> returns <code>b</code> as the value loaded from a MAT-file.</p> <p>Define a <code>loadobj</code> method when objects of the class require special processing when loaded from MAT-files. If you define a <code>saveobj</code> method, then define a <code>loadobj</code> method to restore the object to the desired state. Define <code>loadobj</code> as a static method so it can accept as an argument whatever object or structure that you saved in the MAT-file. See “Implement <code>loadobj</code> as a Static Method”.</p> <p>When loading a subclass object, <code>load</code> calls only the subclass <code>loadobj</code> method. If a superclass defines a <code>loadobj</code> method, the subclass inherits this method. However, it is possible that the inherited method does not perform the necessary operations to load the subclass object. Consider overriding superclass <code>loadobj</code> methods.</p> <p>If any superclass in a class hierarchy defines a <code>loadobj</code> method, then the subclass <code>loadobj</code> method must ensure that the subclass and superclass objects load properly. Ensure proper loading by calling the superclass <code>loadobj</code> (or other methods) from the subclass <code>loadobj</code> method. See “Saving and Loading Objects from Class Hierarchies”.</p> |
| <b>Input Arguments</b> | <p><b>a</b></p> <p>The input argument, <code>a</code>, can be:</p> <ul style="list-style-type: none"><li>• The object as loaded from the MAT-file.</li><li>• A structure created by <code>load</code> (if <code>load</code> cannot resolve the object).</li><li>• A struct returned by the <code>saveobj</code> method.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>See Also</b>        | <code>load</code>   <code>save</code>   <code>saveobj</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

# log

---

**Purpose** Natural logarithm

**Syntax**  $Y = \log(X)$

**Description** The log function operates element-wise on arrays. Its domain includes complex and negative numbers, which may lead to unexpected results if used unintentionally.

$Y = \log(X)$  returns the natural logarithm of the elements of  $X$ . For complex or negative  $z$  where  $z = x + y*i$ , the complex logarithm is returned.

$$\log(z) = \log(\text{abs}(z)) + i*\text{atan2}(y,x)$$

**Examples** The statement `abs(log(-1))` is a clever way to generate  $\pi$ .

```
ans =
```

```
3.1416
```

**See Also** `exp` | `log10` | `log2` | `logm` | `reallog`

**Purpose** Common (base 10) logarithm

**Syntax**  $Y = \log_{10}(X)$

**Description** The `log10` function operates element-by-element on arrays. Its domain includes complex numbers, which may lead to unexpected results if used unintentionally.

$Y = \log_{10}(X)$  returns the base 10 logarithm of the elements of  $X$ .

**Examples** `log10(realmax)` is 308.2547

and

`log10(eps)` is -15.6536

**See Also** `exp` | `log` | `log2` | `logm`

# log1p

---

**Purpose** Compute  $\log(1+x)$  accurately for small values of  $x$

**Syntax**  $y = \log1p(x)$

**Description**  $y = \log1p(x)$  computes  $\log(1+x)$ , compensating for the roundoff in  $1+x$ .  $\log1p(x)$  is more accurate than  $\log(1+x)$  for small values of  $x$ . For small  $x$ ,  $\log1p(x)$  is approximately  $x$ , whereas  $\log(1+x)$  can be zero.

**See Also** `log` | `expm1`

**Purpose** Base 2 logarithm and dissect floating-point numbers into exponent and mantissa

**Syntax**  $Y = \log_2(X)$   
 $[F, E] = \log_2(X)$

**Description**  $Y = \log_2(X)$  computes the base 2 logarithm of the elements of  $X$ .  
 $[F, E] = \log_2(X)$  returns arrays  $F$  and  $E$ . Argument  $F$  is an array of real values, usually in the range  $0.5 \leq \text{abs}(F) < 1$ . For real  $X$ ,  $F$  satisfies the equation:  $X = F \cdot 2.^E$ . Argument  $E$  is an array of integers that, for real  $X$ , satisfy the equation:  $X = F \cdot 2.^E$ .

**Tips** This function corresponds to the ANSI C function `frexp()` and the IEEE floating-point standard function `logb()`. Any zeros in  $X$  produce  $F = 0$  and  $E = 0$ .

**Examples** For IEEE arithmetic, the statement  $[F, E] = \log_2(X)$  yields the values:

| <b>X</b> | <b>F</b>  | <b>E</b> |
|----------|-----------|----------|
| 1        | 1/2       | 1        |
| pi       | pi/4      | 2        |
| -3       | -3/4      | 2        |
| eps      | 1/2       | -51      |
| realmax  | 1 - eps/2 | 1024     |
| realmin  | 1/2       | -1021    |

**See Also** `log` | `pow2`

# logical

---

**Purpose** Convert numeric values to logical

**Syntax** `K = logical(A)`

**Description** `K = logical(A)` returns an array that can be used for logical indexing or logical tests.

`A(B)`, where `B` is a logical array that is the same size as `A`, returns the values of `A` at the indices where the real part of `B` is nonzero.

`A(B)`, where `B` is a logical array that is smaller than `A`, returns the values of column vector `A(:)` at the indices where the real part of column vector `B(:)` is nonzero.

**Tips** Most arithmetic operations remove the logicalness from an array. For example, adding zero to a logical array removes its logical characteristic. `A = +A` is the easiest way to convert a logical array, `A`, to a numeric double array.

Logical arrays are also created by the relational operators (`==`, `<`, `>`, `~`, etc.) and functions like `any`, `all`, `isnan`, `isinf`, and `isfinite`.

**Examples** Given `A = [1 2 3; 4 5 6; 7 8 9]`, the statement `B = logical(eye(3))` returns a logical array

```
B =  
  1   0   0  
  0   1   0  
  0   0   1
```

which can be used in logical indexing that returns `A`'s diagonal elements:

```
A(B)
```

```
ans =  
  1  
  5  
  9
```

However, attempting to index into A using the *numeric* array `eye(3)` results in:

```
A(eye(3))
```

```
??? Subscript indices must either be real positive integers or  
logicals.
```

# loglog

---

## Purpose

Log-log scale plot

## Syntax

```
loglog(Y)
loglog(X1,Y1,...)
loglog(X1,Y1,LineStyle,...)
loglog(...,'PropertyName',PropertyValue,...)
h = loglog(...)
```

## Description

`loglog(Y)` plots the columns of `Y` versus their index if `Y` contains real numbers. If `Y` contains complex numbers, `loglog(Y)` and `loglog(real(Y),imag(Y))` are equivalent. `loglog` ignores the imaginary component in all other uses of this function.

`loglog(X1,Y1,...)` plots all  $X_n$  versus  $Y_n$  pairs. If only  $X_n$  or  $Y_n$  is a matrix, `loglog` plots the vector argument versus the rows or columns of the matrix, along the dimension of the matrix whose length matches the length of the vector. If the matrix is square, its columns plot against the vector if their lengths match.

`loglog(X1,Y1,LineStyle,...)` plots all lines defined by the  $X_n, Y_n, LineSpec$  triples, where `LineStyle` determines line type, marker symbol, and color of the plotted lines. You can mix  $X_n, Y_n, LineSpec$  triples with  $X_n, Y_n$  pairs, for example,

```
loglog(X1,Y1,X2,Y2,LineStyle,X3,Y3)
```

`loglog(...,'PropertyName',PropertyValue,...)` sets property values for all lineseries properties graphics objects created by `loglog`.

`h = loglog(...)` returns a column vector of handles to lineseries graphics objects, one handle per line.

If you do not specify a color when plotting more than one line, `loglog` automatically cycles through the colors and line styles in the order specified by the current axes.

If you attempt to add a `loglog`, `semilogx`, or `semilogy` plot to a linear axis mode graph with `hold on`, the axis mode remains as it is and the new data plots as linear.

## Renderer Support

The OpenGL renderer does not support logarithmic-scale axes. MATLAB automatically selects a different renderer when using logarithmic scaling. If you set the figure `Renderer` property to `opengl`, axis scales become linear. See the figure `Renderer` property for more information on renderers.

## Examples

Create a simple `loglog` plot with square markers.

```
x = logspace(-1,2);  
loglog(x,exp(x),'-s')  
grid on
```

# loglog

**See Also**

LineSpec | plot | semilogx | semilogy

**Purpose** Matrix logarithm

**Syntax**  $L = \text{logm}(A)$   
 $[L, \text{exitflag}] = \text{logm}(A)$

**Description**  $L = \text{logm}(A)$  is the principal matrix logarithm of  $A$ , the inverse of  $\text{expm}(A)$ .  $L$  is the unique logarithm for which every eigenvalue has imaginary part lying strictly between  $-\pi$  and  $\pi$ . If  $A$  is singular or has any eigenvalues on the negative real axis, the principal logarithm is undefined. In this case, `logm` computes a nonprincipal logarithm and returns a warning message.

$[L, \text{exitflag}] = \text{logm}(A)$  returns a scalar `exitflag` that describes the exit condition of `logm`:

- If `exitflag` = 0, the algorithm was successfully completed.
- If `exitflag` = 1, too many matrix square roots had to be computed. However, the computed value of  $L$  might still be accurate.

The input  $A$  can have class `double` or `single`.

**Tips** If  $A$  is real symmetric or complex Hermitian, then so is  $\text{logm}(A)$ .

Some matrices, like  $A = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$ , do not have any logarithms, real or complex, so `logm` cannot be expected to produce one.

**Limitations** For most matrices:

$$\text{logm}(\text{expm}(A)) = A = \text{expm}(\text{logm}(A))$$

These identities may fail for some  $A$ . For example, if the computed eigenvalues of  $A$  include an exact zero, then  $\text{logm}(A)$  generates infinity. Or, if the elements of  $A$  are too large,  $\text{expm}(A)$  may overflow.

**Examples** Suppose  $A$  is the 3-by-3 matrix

$$\begin{bmatrix} 1 & 1 & 0 \\ 0 & 0 & 2 \end{bmatrix}$$

```
      0      0      -1
```

and  $Y = \text{expm}(A)$  is

```
Y =
  2.7183    1.7183    1.0862
      0    1.0000    1.2642
      0      0    0.3679
```

Then  $A = \text{logm}(Y)$  produces the original matrix  $A$ .

```
Y =
  1.0000    1.0000    0.0000
      0      0    2.0000
      0      0   -1.0000
```

But  $\text{log}(A)$  involves taking the logarithm of zero, and so produces

```
ans =
  0.0000      0   -35.5119
  -Inf      -Inf    0.6931
  -Inf      -Inf    0.0000 + 3.1416i
```

## Algorithms

The algorithm `logm` uses is described in [1].

# logspace

---

**Purpose** Generate logarithmically spaced vectors

**Syntax**  
`y = logspace(a,b)`  
`y = logspace(a,b,n)`  
`y = logspace(a,pi)`

**Description** The `logspace` function generates logarithmically spaced vectors. Especially useful for creating frequency vectors, it is a logarithmic equivalent of `linspace` and the “:” or colon operator.

`y = logspace(a,b)` generates a row vector `y` of 50 logarithmically spaced points between decades  $10^a$  and  $10^b$ .

`y = logspace(a,b,n)` generates `n` points between decades  $10^a$  and  $10^b$ .

`y = logspace(a,pi)` generates the points between  $10^a$  and  $\pi$ , which is useful for digital signal processing where frequencies over this interval go around the unit circle.

**Tips** All the arguments to `logspace` must be scalars.

## How To

- “Find Functions Using the Function Browser”
- “Search Syntax and Tips”

**Purpose** Convert string to lowercase

**Syntax**  
`t = lower('str')`  
`B = lower(A)`

**Description** `t = lower('str')` returns the string formed by converting any uppercase characters in `str` to the corresponding lowercase characters and leaving all other characters unchanged.

`B = lower(A)` when `A` is a cell array of strings, returns a cell array the same size as `A` containing the result of applying `lower` to each string within `A`.

**Examples** `lower('MathWorks')` is `mathworks`.

**Tips** Character sets supported:

- PC: Latin-1 for the Microsoft Windows operating system
- Other: ISO Latin-1 (ISO 8859-1)

**See Also** `upper`

# ls

---

**Purpose** List folder contents

**Syntax** `ls`  
`ls name`  
`list = ls(name)`

**Description** `ls` lists the contents of the current folder.

`ls name` lists the files and folders in the current folder that match the specified name. You can use wildcards.

`list = ls(name)` returns the files and folders in the current folder that match the specified `name` to `list`.

**Tips**

- On UNIX platforms, you can add any flags to `ls` that the operating system supports.

**Input Arguments**

**name**  
A string value specifying a file or folder name.

**Output Arguments**

**list**

- On UNIX platforms, `list` is a character row vector of names separated by tab and space characters.
- On Microsoft Windows platforms, `list` is an `m`-by-`n` character array of names—`m` is the number of names and `n` is the number of characters in the longest name. MATLAB pads names shorter than `n` characters with space characters.

**Examples** List all the files and folders in the current folder:

```
ls
```

---

List all the files and folders in the current folder that begin with the letter `h`:

```
ls h*
```

---

Return the list of all the files and folders in the current folder to `mylist`:

```
mylist = ls;
```

**Alternatives**

- View files and folders in the Current Folder browser.  
Open the Current Folder browser by issuing the `filebrowser` command.

**See Also**

```
dir | pwd
```

**How To**

- “Working with Files and Folders”

**Purpose** Least-squares solution in presence of known covariance

**Syntax**

```
x = lscov(A,b)
x = lscov(A,b,w)
x = lscov(A,b,V)
x = lscov(A,b,V,alg)
[x,stdx] = lscov(...)
[x,stdx,mse] = lscov(...)
[x,stdx,mse,S] = lscov(...)
```

**Description** `x = lscov(A,b)` returns the ordinary least squares solution to the linear system of equations  $A*x = b$ , i.e.,  $x$  is the  $n$ -by-1 vector that minimizes the sum of squared errors  $(b - A*x)'*(b - A*x)$ , where  $A$  is  $m$ -by- $n$ , and  $b$  is  $m$ -by-1.  $b$  can also be an  $m$ -by- $k$  matrix, and `lscov` returns one solution for each column of  $b$ . When  $\text{rank}(A) < n$ , `lscov` sets the maximum possible number of elements of  $x$  to zero to obtain a "basic solution".

`x = lscov(A,b,w)`, where  $w$  is a vector length  $m$  of real positive weights, returns the weighted least squares solution to the linear system  $A*x = b$ , that is,  $x$  minimizes  $(b - A*x)'*diag(w)*(b - A*x)$ .  $w$  typically contains either counts or inverse variances.

`x = lscov(A,b,V)`, where  $V$  is an  $m$ -by- $m$  real symmetric positive definite matrix, returns the generalized least squares solution to the linear system  $A*x = b$  with covariance matrix proportional to  $V$ , that is,  $x$  minimizes  $(b - A*x)'*inv(V)*(b - A*x)$ .

More generally,  $V$  can be positive semidefinite, and `lscov` returns  $x$  that minimizes  $e'*e$ , subject to  $A*x + T*e = b$ , where the minimization is over  $x$  and  $e$ , and  $T*T' = V$ . When  $V$  is semidefinite, this problem has a solution only if  $b$  is consistent with  $A$  and  $V$  (that is,  $b$  is in the column space of  $[A \ T]$ ), otherwise `lscov` returns an error.

By default, `lscov` computes the Cholesky decomposition of  $V$  and, in effect, inverts that factor to transform the problem into ordinary least squares. However, if `lscov` determines that  $V$  is semidefinite, it uses an orthogonal decomposition algorithm that avoids inverting  $V$ .

$x = \text{lscov}(A, b, V, \text{alg})$  specifies the algorithm used to compute  $x$  when  $V$  is a matrix.  $\text{alg}$  can have the following values:

- 'chol' uses the Cholesky decomposition of  $V$ .
- 'orth' uses orthogonal decompositions, and is more appropriate when  $V$  is ill-conditioned or singular, but is computationally more expensive.

$[x, \text{stdx}] = \text{lscov}(\dots)$  returns the estimated standard errors of  $x$ . When  $A$  is rank deficient,  $\text{stdx}$  contains zeros in the elements corresponding to the necessarily zero elements of  $x$ .

$[x, \text{stdx}, \text{mse}] = \text{lscov}(\dots)$  returns the mean squared error. If  $b$  is assumed to have covariance matrix  $\sigma^2 V$  (or  $(\sigma^2) \times \text{diag}(1./W)$ ), then  $\text{mse}$  is an estimate of  $\sigma^2$ .

$[x, \text{stdx}, \text{mse}, S] = \text{lscov}(\dots)$  returns the estimated covariance matrix of  $x$ . When  $A$  is rank deficient,  $S$  contains zeros in the rows and columns corresponding to the necessarily zero elements of  $x$ .  $\text{lscov}$  cannot return  $S$  if it is called with multiple right-hand sides, that is, if  $\text{size}(B, 2) > 1$ .

The standard formulas for these quantities, when  $A$  and  $V$  are full rank, are

- $x = \text{inv}(A' * \text{inv}(V) * A) * A' * \text{inv}(V) * B$
- $\text{mse} = B' * (\text{inv}(V) - \text{inv}(V) * A * \text{inv}(A' * \text{inv}(V) * A) * A' * \text{inv}(V)) * B ./ (m - n)$
- $S = \text{inv}(A' * \text{inv}(V) * A) * \text{mse}$
- $\text{stdx} = \text{sqrt}(\text{diag}(S))$

However,  $\text{lscov}$  uses methods that are faster and more stable, and are applicable to rank deficient cases.

$\text{lscov}$  assumes that the covariance matrix of  $B$  is known only up to a scale factor.  $\text{mse}$  is an estimate of that unknown scale factor, and  $\text{lscov}$  scales the outputs  $S$  and  $\text{stdx}$  appropriately. However, if  $V$  is known to be exactly the covariance matrix of  $B$ , then that scaling is unnecessary.

To get the appropriate estimates in this case, you should rescale  $S$  and  $stdx$  by  $1/mse$  and  $\sqrt{1/mse}$ , respectively.

## Algorithms

The vector  $x$  minimizes the quantity  $(A*x-b)'*inv(V)*(A*x-b)$ . The classical linear algebra solution to this problem is

$$x = inv(A'*inv(V)*A)*A'*inv(V)*b$$

but the `lscov` function instead computes the QR decomposition of  $A$  and then modifies  $Q$  by  $V$ .

## Examples

### Example 1 – Computing Ordinary Least Squares

The MATLAB backslash operator (`\`) enables you to perform linear regression by computing ordinary least-squares (OLS) estimates of the regression coefficients. You can also use `lscov` to compute the same OLS estimates. By using `lscov`, you can also compute estimates of the standard errors for those coefficients, and an estimate of the standard deviation of the regression error term:

```
x1 = [.2 .5 .6 .8 1.0 1.1]';  
x2 = [.1 .3 .4 .9 1.1 1.4]';  
X = [ones(size(x1)) x1 x2];  
y = [.17 .26 .28 .23 .27 .34]';
```

```
a = X\y  
a =  
    0.1203  
    0.3284  
   -0.1312
```

```
[b,se_b,mse] = lscov(X,y)  
b =  
    0.1203  
    0.3284  
   -0.1312  
se_b =  
    0.0643
```

```
    0.2267
    0.1488
mse =
    0.0015
```

### Example 2 – Computing Weighted Least Squares

Use `lscov` to compute a weighted least-squares (WLS) fit by providing a vector of relative observation weights. For example, you might want to downweight the influence of an unreliable observation on the fit:

```
w = [1 1 1 1 1 .1]';

[bw,sew_b,msew] = lscov(X,y,w)
bw =
    0.1046
    0.4614
   -0.2621
sew_b =
    0.0309
    0.1152
    0.0814
msew =
    3.4741e-004
```

### Example 3 – Computing General Least Squares

Use `lscov` to compute a general least-squares (GLS) fit by providing an observation covariance matrix. For example, your data may not be independent:

```
V = .2*ones(length(x1)) + .8*diag(ones(size(x1)));

[bg,sew_b,mseg] = lscov(X,y,V)
bg =
    0.1203
    0.3284
   -0.1312
sew_b =
```

```
    0.0672
    0.2267
    0.1488
mse =
    0.0019
```

## Example 4 – Estimating the Coefficient Covariance Matrix

Compute an estimate of the coefficient covariance matrix for either OLS, WLS, or GLS fits. The coefficient standard errors are equal to the square roots of the values on the diagonal of this covariance matrix:

```
[b,se_b,mse,S] = lscov(X,y);
```

```
S
S =
    0.0041   -0.0130    0.0075
   -0.0130    0.0514   -0.0328
    0.0075   -0.0328    0.0221
```

```
[se_b sqrt(diag(S))]
ans =
    0.0643    0.0643
    0.2267    0.2267
    0.1488    0.1488
```

lsqnonneg | qr | Arithmetic Operator \

**Purpose** Solve nonnegative least-squares constraints problem

**Equation** Solves nonnegative least-squares curve fitting problems of the form

$$\min_x \|C \cdot x - d\|_2^2, \text{ where } x \geq 0.$$

**Syntax**

```
x = lsqnonneg(C,d)
x = lsqnonneg(C,d,options)
[x,resnorm] = lsqnonneg(...)
[x,resnorm,residual] = lsqnonneg(...)
[x,resnorm,residual,exitflag] = lsqnonneg(...)
[x,resnorm,residual,exitflag,output] = lsqnonneg(...)
[x,resnorm,residual,exitflag,output,lambda] = lsqnonneg(...)
```

**Description**

`x = lsqnonneg(C,d)` returns the vector `x` that minimizes `norm(C*x-d)` subject to `x >= 0`. `C` and `d` must be real.

`x = lsqnonneg(C,d,options)` minimizes with the optimization parameters specified in the structure `options`. You can define these parameters using the `optimset` function. `lsqnonneg` uses these `options` structure fields:

**Display** Level of display. 'off' displays no output; 'final' displays just the final output; 'notify' (default) displays output only if the function does not converge.

**TolX** Termination tolerance on `x`.

`[x,resnorm] = lsqnonneg(...)` returns the value of the squared 2-norm of the residual: `norm(C*x-d)^2`.

`[x,resnorm,residual] = lsqnonneg(...)` returns the residual, `d-C*x`.

`[x,resnorm,residual,exitflag] = lsqnonneg(...)` returns a value `exitflag` that describes the exit condition of `lsqnonneg`:

# lsqnonneg

---

>0            Indicates that the function converged to a solution  $x$ .  
0             Indicates that the iteration count was exceeded.  
              Increasing the tolerance (TolX parameter in options)  
              may lead to a solution.

`[x,resnorm,residual,exitflag,output] = lsqnonneg(...)` returns a structure output that contains information about the operation in the following fields:

algorithm        'active-set'  
iterations       The number of iterations taken  
message          Exit message

`[x,resnorm,residual,exitflag,output,lambda] = lsqnonneg(...)` returns the dual vector (Lagrange multipliers) `lambda`, where `lambda(i) <= 0` when `x(i)` is (approximately) 0, and `lambda(i)` is (approximately) 0 when `x(i) > 0`.

## Examples

Compare the unconstrained least squares solution to the `lsqnonneg` solution for a 4-by-2 problem:

```
C = [  
    0.0372    0.2869  
    0.6861    0.7071  
    0.6233    0.6245  
    0.6344    0.6170];  
d = [  
    0.8587  
    0.1781  
    0.0747  
    0.8405];  
[C\d lsqnonneg(C,d)] =  
   -2.5627         0  
    3.1108    0.6929  
[norm(C*(C\d) - d) norm(C*lsqnonneg(C,d) - d)] =  
    0.6674    0.9118
```

The solution from `lsqnonneg` does not fit as well (has a larger residual), as the least squares solution. However, the nonnegative least squares solution has no negative components.

## Algorithms

`lsqnonneg` uses the algorithm described in [1]. The algorithm starts with a set of possible basis vectors and computes the associated dual vector `lambda`. It then selects the basis vector corresponding to the maximum value in `lambda` in order to swap out of the basis in exchange for another possible candidate. This continues until `lambda <= 0`.

## Purpose

LSQR method

## Syntax

```
x = lsqr(A,b)
lsqr(A,b,tol)
lsqr(A,b,tol,maxit)
lsqr(A,b,tol,maxit,M)
lsqr(A,b,tol,maxit,M1,M2)
lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres,iter] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres,iter,resvec] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres,iter,resvec,lsvec] = lsqr(A,b,tol,maxit,M1,M2,x0)
```

## Description

`x = lsqr(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$  if  $A$  is consistent, otherwise it attempts to solve the least squares solution  $x$  that minimizes  $\text{norm}(b-A*x)$ . The  $m$ -by- $n$  coefficient matrix  $A$  need not be square but it should be large and sparse. The column vector  $b$  must have length  $m$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x, 'notransp')` returns  $A*x$  and `afun(x, 'transp')` returns  $A'*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `lsqr` converges, a message to that effect is displayed. If `lsqr` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`lsqr(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `lsqr` uses the default,  $1e-6$ .

`lsqr(A,b,tol,maxit)` specifies the maximum number of iterations.

`lsqr(A,b,tol,maxit,M)` and `lsqr(A,b,tol,maxit,M1,M2)` use  $n$ -by- $n$  preconditioner  $M$  or  $M = M1*M2$  and effectively solve the system  $A*inv(M)*y = b$  for  $y$ , where  $y = M*x$ . If  $M$  is `[]` then `lsqr` applies no preconditioner.  $M$  can be a function `mfun` such that `mfun(x, 'notransp')` returns  $M \setminus x$  and `mfun(x, 'transp')` returns  $M' \setminus x$ .

`lsqr(A,b,tol,maxit,M1,M2,x0)` specifies the  $n$ -by-1 initial guess. If `x0` is `[]`, then `lsqr` uses the default, an all zero vector.

`[x,flag] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns a convergence flag.

| Flag | Convergence                                                                                                           |
|------|-----------------------------------------------------------------------------------------------------------------------|
| 0    | <code>lsqr</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.           |
| 1    | <code>lsqr</code> iterated <code>maxit</code> times but did not converge.                                             |
| 2    | Preconditioner $M$ was ill-conditioned.                                                                               |
| 3    | <code>lsqr</code> stagnated. (Two consecutive iterates were the same.)                                                |
| 4    | One of the scalar quantities calculated during <code>lsqr</code> became too small or too large to continue computing. |

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if you specify the `flag` output.

`[x,flag,relres] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns an estimate of the relative residual norm  $(b-A*x)/norm(b)$ . If `flag` is 0, `relres <= tol`.

`[x,flag,relres,iter] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns the iteration number at which `x` was computed, where  $0 \leq iter \leq maxit$ .

`[x,flag,relres,iter,resvec] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns a vector of the residual norm estimates at each iteration, including  $norm(b-A*x0)$ .

```
[x,flag,relres,iter,resvec,lsvec] =  
lsqr(A,b,tol,maxit,M1,M2,x0) also returns a vector of estimates  
of the scaled normal equations residual at each iteration:  
norm((A*inv(M))'*(B-A*X))/norm(A*inv(M), 'fro'). Note that the  
estimate of norm(A*inv(M), 'fro') changes, and hopefully improves,  
at each iteration.
```

## Examples

### Example 1

```
n = 100;  
on = ones(n,1);  
A = spdiags([-2*on 4*on -on],-1:1,n,n);  
b = sum(A,2);  
tol = 1e-8;  
maxit = 15;  
M1 = spdiags([on/(-2) on],-1:0,n,n);  
M2 = spdiags([4*on -on],0:1,n,n);
```

```
x = lsqr(A,b,tol,maxit,M1,M2);
```

displays the following message:

```
lsqr converged at iteration 11 to a solution with relative  
residual 3.5e-009
```

### Example 2

This example replaces the matrix  $A$  in Example 1 with a handle to a matrix-vector product function `afun`. The example is contained in a function `run_lsqr` that

- Calls `lsqr` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_lsqr` are available to `afun`.

The following shows the code for `run_lsqr`:

```
function x1 = run_lsqr  
n = 100;
```

```

on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = lsqr(@afun,b,tol,maxit,M1,M2);

function y = afun(x,transp_flag)
    if strcmp(transp_flag,'transp') % y = A'*x
        y = 4 * x;
        y(1:n-1) = y(1:n-1) - 2 * x(2:n);
        y(2:n) = y(2:n) - x(1:n-1);
    elseif strcmp(transp_flag,'notransp') % y = A*x
        y = 4 * x;
        y(2:n) = y(2:n) - 2 * x(1:n-1);
        y(1:n-1) = y(1:n-1) - x(2:n);
    end
end
end

```

When you enter

```
x1=run_lsqr;
```

MATLAB software displays the message

```
lsqr converged at iteration 11 to a solution with relative
residual 3.5e-009
```

**Purpose** Test for less than

**Syntax** `A < B`  
`lt(A, B)`

**Description** `A < B` compares each element of array `A` with the corresponding element of array `B`, and returns an array with elements set to logical 1 (true) where `A` is less than `B`, or set to logical 0 (false) where `A` is greater than or equal to `B`. Each input of the expression can be an array or a scalar value.

If both `A` and `B` are scalar (i.e., 1-by-1 matrices), then the MATLAB software returns a scalar value.

If both `A` and `B` are nonscalar arrays, then these arrays must have the same dimensions, and MATLAB returns an array of the same dimensions as `A` and `B`.

If one input is scalar and the other a nonscalar array, then the scalar input is treated as if it were an array having the same dimensions as the nonscalar input array. In other words, if input `A` is the number 100, and `B` is a 3-by-5 matrix, then `A` is treated as if it were a 3-by-5 matrix of elements, each set to 100. MATLAB returns an array of the same dimensions as the nonscalar input array.

`lt(A, B)` is called for the syntax `A < B` when either `A` or `B` is an object.

## Examples

Create two 6-by-6 matrices, `A` and `B`, and locate those elements of `A` that are less than the corresponding elements of `B`:

```
A = magic(6);  
B = repmat(3*magic(3), 2, 2);
```

```
A < B  
ans =  
     0     1     1     0     0     0  
     1     0     1     0     0     0  
     0     1     1     0     0     0  
     1     0     0     1     0     1
```

**How To**

- “Relational Operators”

**Purpose**

LU matrix factorization

**Syntax**

```

Y = lu(A)
[L,U] = lu(A)
[L,U,P] = lu(A)
[L,U,P,Q] = lu(A)
[L,U,P,Q,R] = lu(A)
[...] = lu(A,'vector')
[...] = lu(A,thresh)
[...] = lu(A,thresh,'vector')

```

**Description**

The `lu` function expresses a matrix  $A$  as the product of two essentially triangular matrices, one of them a permutation of a lower triangular matrix and the other an upper triangular matrix. The factorization is often called the  $LU$ , or sometimes the  $LR$ , factorization.  $A$  can be rectangular.

`Y = lu(A)` returns matrix  $Y$  that, for sparse  $A$ , contains the strictly lower triangular  $L$ , i.e., without its unit diagonal, and the upper triangular  $U$  as submatrices. That is, if `[L,U,P] = lu(A)`, then  $Y = U+L - \text{eye}(\text{size}(A))$ . For nonsparse  $A$ ,  $Y$  is the output from the LAPACK `dgetrf` or `zgetrf` routine. The permutation matrix  $P$  is not returned.

`[L,U] = lu(A)` returns an upper triangular matrix in  $U$  and a permuted lower triangular matrix in  $L$  such that  $A = L*U$ . Return value  $L$  is a product of lower triangular and permutation matrices.

`[L,U,P] = lu(A)` returns an upper triangular matrix in  $U$ , a lower triangular matrix  $L$  with a unit diagonal, and a permutation matrix  $P$ , such that  $L*U = P*A$ . The statement `lu(A,'matrix')` returns identical output values.

`[L,U,P,Q] = lu(A)` for sparse nonempty  $A$ , returns a unit lower triangular matrix  $L$ , an upper triangular matrix  $U$ , a row permutation matrix  $P$ , and a column reordering matrix  $Q$ , so that  $P*A*Q = L*U$ . If  $A$  is empty or not sparse, `lu` displays an error message. The statement `lu(A,'matrix')` returns identical output values.

`[L,U,P,Q,R] = lu(A)` returns unit lower triangular matrix `L`, upper triangular matrix `U`, permutation matrices `P` and `Q`, and a diagonal scaling matrix `R` so that  $P*(R\backslash A)*Q = L*U$  for sparse non-empty `A`. Typically, but not always, the row-scaling leads to a sparser and more stable factorization. The statement `lu(A, 'matrix')` returns identical output values.

`[...]` = `lu(A, 'vector')` returns the permutation information in two row vectors `p` and `q`. You can specify from 1 to 5 outputs. Output `p` is defined as  $A(p,:) = L*U$ , output `q` is defined as  $A(p,q) = L*U$ , and output `R` is defined as  $R(:,p)\backslash A(:,q) = L*U$ .

`[...]` = `lu(A,thresh)` controls pivoting. This syntax applies to sparse matrices only. The `thresh` input is a one- or two-element vector of type `single` or `double` that defaults to `[0.1, 0.001]`. If `A` is a square matrix with a mostly symmetric structure and mostly nonzero diagonal, MATLAB uses a symmetric pivoting strategy. For this strategy, the diagonal where

$$A(i,j) \geq \text{thresh}(2) * \max(\text{abs}(A(j:m,j)))$$

is selected. If the diagonal entry fails this test, a pivot entry below the diagonal is selected, using `thresh(1)`. In this case, `L` has entries with absolute value  $1/\min(\text{thresh})$  or less.

If `A` is not as described above, MATLAB uses an asymmetric strategy. In this case, the sparsest row `i` where

$$A(i,j) \geq \text{thresh}(1) * \max(\text{abs}(A(j:m,j)))$$

is selected. A value of 1.0 results in conventional partial pivoting. Entries in `L` have an absolute value of  $1/\text{thresh}(1)$  or less. The second element of the `thresh` input vector is not used when MATLAB uses an asymmetric strategy.

Smaller values of `thresh(1)` and `thresh(2)` tend to lead to sparser LU factors, but the solution can become inaccurate. Larger values can lead to a more accurate solution (but not always), and usually an increase in the total work and memory usage. The statement `lu(A,thresh, 'matrix')` returns identical output values.

[...] = lu(A,thresh,'vector') controls the pivoting strategy and also returns the permutation information in row vectors, as described above. The thresh input must precede 'vector' in the input argument list.

---

**Note** In rare instances, incorrect factorization results in  $P*A*Q \neq L*U$ . Increase thresh, to a maximum of 1.0 (regular partial pivoting), and try again.

---

## Tips

Most of the algorithms for computing LU factorization are variants of Gaussian elimination. The factorization is a key step in obtaining the inverse with inv and the determinant with det. It is also the basis for the linear equation solution or matrix division obtained with \ and /.

## Arguments

|        |                                                                                                                                                                      |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A      | Rectangular matrix to be factored.                                                                                                                                   |
| thresh | Pivot threshold for sparse matrices. Valid values are in the interval [0, 1]. If you specify the fourth output Q, the default is 0.1. Otherwise, the default is 1.0. |
| L      | Factor of A. Depending on the form of the function, L is either a unit lower triangular matrix, or else the product of a unit lower triangular matrix with P'.       |
| U      | Upper triangular matrix that is a factor of A.                                                                                                                       |
| P      | Row permutation matrix satisfying the equation $L*U = P*A$ , or $L*U = P*A*Q$ . Used for numerical stability.                                                        |
| Q      | Column permutation matrix satisfying the equation $P*A*Q = L*U$ . Used to reduce fill-in in the sparse case.                                                         |
| R      | Row-scaling matrix                                                                                                                                                   |

**Examples****Example 1**

Start with

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 0 \end{bmatrix};$$

To see the LU factorization, call `lu` with two output arguments.

$$[L1,U] = \text{lu}(A)$$

L1 =

$$\begin{bmatrix} 0.1429 & 1.0000 & 0 \\ 0.5714 & 0.5000 & 1.0000 \\ 1.0000 & 0 & 0 \end{bmatrix}$$

U =

$$\begin{bmatrix} 7.0000 & 8.0000 & 0 \\ 0 & 0.8571 & 3.0000 \\ 0 & 0 & 4.5000 \end{bmatrix}$$

Notice that L1 is a permutation of a lower triangular matrix: if you switch rows 2 and 3, and then switch rows 1 and 2, the resulting matrix is lower triangular and has 1s on the diagonal. Notice also that U is upper triangular. To check that the factorization does its job, compute the product

$L1*U$

which returns the original A. The inverse of the example matrix,  $X = \text{inv}(A)$ , is actually computed from the inverses of the triangular factors

$$X = \text{inv}(U)*\text{inv}(L1)$$

Using three arguments on the left side to get the permutation matrix as well,

$$[L2,U,P] = \text{lu}(A)$$

returns a truly lower triangular L2, the same value of U, and the permutation matrix P.

L2 =

|        |        |        |
|--------|--------|--------|
| 1.0000 | 0      | 0      |
| 0.1429 | 1.0000 | 0      |
| 0.5714 | 0.5000 | 1.0000 |

U =

|        |        |        |
|--------|--------|--------|
| 7.0000 | 8.0000 | 0      |
| 0      | 0.8571 | 3.0000 |
| 0      | 0      | 4.5000 |

P =

|   |   |   |
|---|---|---|
| 0 | 0 | 1 |
| 1 | 0 | 0 |
| 0 | 1 | 0 |

Note that  $L2 = P*L1$ .

P\*L1

ans =

|        |        |        |
|--------|--------|--------|
| 1.0000 | 0      | 0      |
| 0.1429 | 1.0000 | 0      |
| 0.5714 | 0.5000 | 1.0000 |

To verify that  $L2*U$  is a permuted version of A, compute  $L2*U$  and subtract it from  $P*A$ :

$P*A - L2*U$

ans =

|   |   |   |
|---|---|---|
| 0 | 0 | 0 |
| 0 | 0 | 0 |
| 0 | 0 | 0 |

In this case,  $\text{inv}(U) * \text{inv}(L)$  results in the permutation of  $\text{inv}(A)$  given by  $\text{inv}(P) * \text{inv}(A)$ .

The determinant of the example matrix is

$$d = \det(A)$$

$$d = 27$$

It is computed from the determinants of the triangular factors

$$d = \det(L) * \det(U)$$

The solution to  $Ax = b$  is obtained with matrix division

$$x = A \backslash b$$

The solution is actually computed by solving two triangular systems

$$y = L \backslash b$$

$$x = U \backslash y$$

### **Example 2**

The 1-norm of their difference is within roundoff error, indicating that  $L*U = P*B*Q$ .

Generate a 60-by-60 sparse adjacency matrix of the connectivity graph of the Buckminster-Fuller geodesic dome.

$$B = \text{bucky};$$

Use the sparse matrix syntax with four outputs to get the row and column permutation matrices.

$$[L,U,P,Q] = \text{lu}(B);$$

Apply the permutation matrices to B, and subtract the product of the lower and upper triangular matrices.

$$Z = P*B*Q - L*U;$$

```
norm(Z,1)

ans =
    7.9936e-015
```

### Example 3

This example illustrates the benefits of using the 'vector' option. Note how much memory is saved by using the `lu(F, 'vector')` syntax.

```
F = gallery('uniformdata',[1000 1000],0);
g = sum(F,2);
[L,U,P] = lu(F);
[L,U,p] = lu(F,'vector');
whos P p
```

| Name | Size      | Bytes   | Class  | Attributes |
|------|-----------|---------|--------|------------|
| P    | 1000x1000 | 8000000 | double |            |
| p    | 1x1000    | 8000    | double |            |

The following two statements are equivalent. The first typically requires less time:

```
x = U\(L\(g(p,:)));
y = U\(L\(P*g));
```

# luinc

---

**Purpose** Sparse incomplete LU factorization

---

**Note** `luinc` will be removed in a future version. Use `ilu` instead.

---

**Syntax**

```
luinc(A, '0')  
luinc(A, droptol)  
luinc(A, options)  
[L,U] = luinc(A,0)  
[L,U] = luinc(A,options)  
[L,U,P] = luinc(...)
```

**Description** `luinc` produces a unit lower triangular matrix, an upper triangular matrix, and a permutation matrix.

`luinc(A, '0')` computes the incomplete LU factorization of level 0 of a square sparse matrix. The triangular factors have the same sparsity pattern as the permutation of the original sparse matrix `A`, and their product agrees with the permuted `A` over its sparsity pattern. `luinc(A, '0')` returns the strict lower triangular part of the factor and the upper triangular factor embedded within the same matrix. The permutation information is lost, but `nnz(luinc(A, '0')) = nnz(A)`, with the possible exception of some zeros due to cancellation.

`luinc(A, droptol)` computes the incomplete LU factorization of any sparse matrix using the drop tolerance specified by the non-negative scalar `droptol`. The result is an approximation of the complete LU factors returned by `lu(A)`. For increasingly smaller values of the drop tolerance, this approximation improves until the drop tolerance is 0, at which time the complete LU factorization is produced, as in `lu(A)`.

As each column `j` of the triangular incomplete factors is being computed, the entries smaller in magnitude than the local drop tolerance (the product of the drop tolerance and the norm of the corresponding column of `A`)

```
droptol*norm(A(:,j))
```

are dropped from the appropriate factor.

The only exceptions to this dropping rule are the diagonal entries of the upper triangular factor, which are preserved to avoid a singular factor.

`luinc(A,options)` computes the factorization with up to four options. These options are specified by fields of the input structure `options`. The fields must be named exactly as shown in the table below. You can include any number of these fields in the structure and define them in any order. Any additional fields are ignored.

| Field Name           | Description                                                                                                                                                                                                                                        |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>droptol</code> | Drop tolerance of the incomplete factorization.                                                                                                                                                                                                    |
| <code>milu</code>    | If <code>milu</code> is 1, <code>luinc</code> produces the modified incomplete LU factorization that subtracts the dropped elements in any column from the diagonal element of the upper triangular factor. The default value is 0.                |
| <code>udiag</code>   | If <code>udiag</code> is 1, any zeros on the diagonal of the upper triangular factor are replaced by the local drop tolerance. The default is 0.                                                                                                   |
| <code>thresh</code>  | Pivot threshold between 0 (forces diagonal pivoting) and 1, the default, which always chooses the maximum magnitude entry in the column to be the pivot. <code>thresh</code> is described in greater detail in the <code>lu</code> reference page. |

`luinc(A,options)` is the same as `luinc(A,droptol)` if `options` has `droptol` as its only field.

`[L,U] = luinc(A,0)` returns the product of permutation matrices and a unit lower triangular matrix in `L` and an upper triangular matrix in `U`. The exact sparsity patterns of `L`, `U`, and `A` are not comparable but the number of nonzeros is maintained with the possible exception of some zeros in `L` and `U` due to cancellation:

$$\text{nnz}(L) + \text{nnz}(U) = \text{nnz}(A) + n, \text{ where } A \text{ is } n\text{-by-}n.$$

The product  $L*U$  agrees with  $A$  over its sparsity pattern.  
 $(L*U) .* \text{spones}(A) - A$  has entries of the order of  $\text{eps}$ .

$[L,U] = \text{luinc}(A,\text{options})$  returns a permutation of a unit lower triangular matrix in  $L$  and an upper triangular matrix in  $U$ . The product  $L*U$  is an approximation to  $A$ .  $\text{luinc}(A,\text{options})$  returns the strict lower triangular part of the factor and the upper triangular factor embedded within the same matrix. The permutation information is lost.

$[L,U,P] = \text{luinc}(\dots)$  returns a unit lower triangular matrix in  $L$ , an upper triangular matrix in  $U$ , and a permutation matrix in  $P$ .

$[L,U,P] = \text{luinc}(A, '0')$  returns a unit lower triangular matrix in  $L$ , an upper triangular matrix in  $U$  and a permutation matrix in  $P$ .  $L$  has the same sparsity pattern as the lower triangle of permuted  $A$

```
spones(L) = spones(tril(P*A))
```

with the possible exceptions of 1s on the diagonal of  $L$  where  $P*A$  may be zero, and zeros in  $L$  due to cancellation where  $P*A$  may be nonzero.  $U$  has the same sparsity pattern as the upper triangle of  $P*A$

```
spones(U) = spones(triu(P*A))
```

with the possible exceptions of zeros in  $U$  due to cancellation where  $P*A$  may be nonzero. The product  $L*U$  agrees within rounding error with the permuted matrix  $P*A$  over its sparsity pattern.  
 $(L*U) .* \text{spones}(P*A) - P*A$  has entries of the order of  $\text{eps}$ .

$[L,U,P] = \text{luinc}(A,\text{options})$  returns a unit lower triangular matrix in  $L$ , an upper triangular matrix in  $U$ , and a permutation matrix in  $P$ . The nonzero entries of  $U$  satisfy

```
abs(U(i,j)) >= droptol*norm((A:,j)),
```

with the possible exception of the diagonal entries, which were retained despite not satisfying the criterion. The entries of  $L$  were tested against the local drop tolerance before being scaled by the pivot, so for nonzeros in  $L$

```
abs(L(i,j)) >= droptol*norm(A(:,j))/U(j,j).
```

The product  $L*U$  is an approximation to the permuted  $P*A$ .

## Tips

These incomplete factorizations may be useful as preconditioners for solving large sparse systems of linear equations. The lower triangular factors all have 1s along the main diagonal but a single 0 on the diagonal of the upper triangular factor makes it singular. The incomplete factorization with a drop tolerance prints a warning message if the upper triangular factor has zeros on the diagonal. Similarly, using the `udiag` option to replace a zero diagonal only gets rid of the symptoms of the problem but does not solve it. The preconditioner may not be singular, but it probably is not useful and a warning message is printed.

## Limitations

`luinc(X, '0')` works on square matrices only.

## Examples

Start with a sparse matrix and compute its LU factorization.

```
load west0479;
S = west0479;
[L,U] = lu(S);
```

Compute the incomplete LU factorization of level 0.

```
[L,U,P] = luinc(S, '0');
```

```
D = (L*U).*spones(P*S) - P*S;
```

`spones(U)` and `spones(triu(P*S))` are identical.

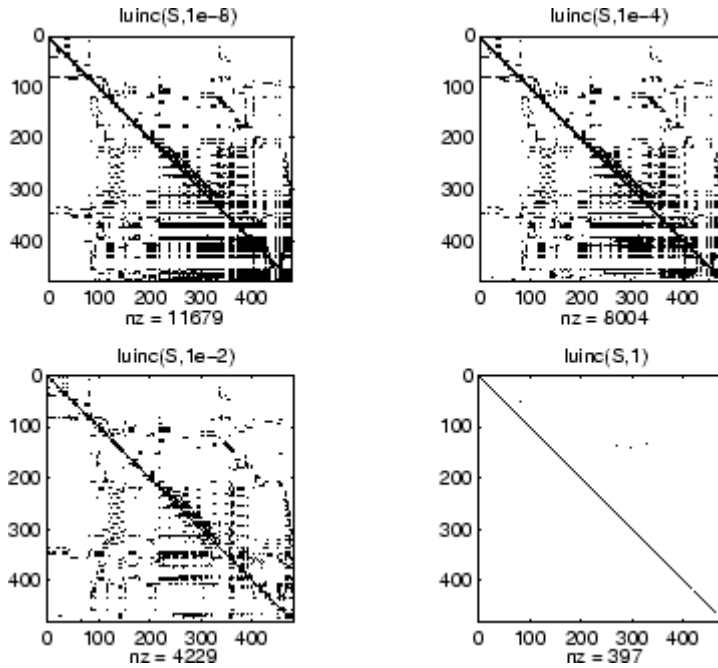

`spones(L)` and `spones(tril(P*S))` disagree at 73 places on the diagonal, where L is 1 and P\*S is 0, and also at position (206,113), where L is 0 due to cancellation, and P\*S is -1. D has entries of the order of eps.

```
[ILO,IU0,IP0] = luinc(S,0);  
[IL1,IU1,IP1] = luinc(S,1e-10);
```

```
·  
·  
·
```

A drop tolerance of 0 produces the complete LU factorization. Increasing the drop tolerance increases the sparsity of the factors (decreases the number of nonzeros) but also increases the error in the factors, as seen in the plot of drop tolerance versus  $\text{norm}(L*U-P*S, 1) / \text{norm}(S, 1)$  in the second figure below.

## Algorithms

`luinc(A, '0')` is based on the “KJJ” variant of the LU factorization with partial pivoting. Updates are made only to positions which are nonzero in A.

`luinc(A,droptol)` and `luinc(A,options)` are based on the column-oriented lu for sparse matrices.

## See Also

`bicg` | `cholinc` | `ilu` | `lu`

**Purpose** Magic square

**Syntax** `M = magic(n)`

**Description** `M = magic(n)` returns an  $n$ -by- $n$  matrix constructed from the integers 1 through  $n^2$  with equal row and column sums. The order  $n$  must be a scalar greater than or equal to 3.

**Tips** A magic square, scaled by its magic sum, is doubly stochastic.

**Examples** The magic square of order 3 is

```
M = magic(3)
```

```
M =
```

```
     8     1     6
     3     5     7
     4     9     2
```

This is called a magic square because the sum of the elements in each column is the same.

```
sum(M) =
```

```
    15    15    15
```

And the sum of the elements in each row, obtained by transposing twice, is the same.

```
sum(M')' =
```

```
    15
    15
    15
```

This is also a special magic square because the diagonal elements have the same sum.

```
sum(diag(M)) =
```

```
15
```

The value of the characteristic sum for a magic square of order  $n$  is

```
sum(1:n^2)/n
```

which, when  $n = 3$ , is 15.

## Algorithms

There are three different algorithms:

- $n$  odd
- $n$  even but not divisible by four
- $n$  divisible by four

To make this apparent, type

```
for n = 3:20
    A = magic(n);
    r(n) = rank(A);
end
```

For  $n$  odd, the rank of the magic square is  $n$ . For  $n$  divisible by 4, the rank is 3. For  $n$  even but not divisible by 4, the rank is  $n/2 + 2$ .

```
[(3:20)', r(3:20)']
```

```
ans =
     3     3
     4     3
     5     5
     6     5
     7     7
     8     3
     9     9
    10     7
    11    11
    12     3
```

|    |    |
|----|----|
| 13 | 13 |
| 14 | 9  |
| 15 | 15 |
| 16 | 3  |
| 17 | 17 |
| 18 | 11 |
| 19 | 19 |
| 20 | 3  |

Plotting A for  $n = 18, 19, 20$  shows the characteristic plot for each category.

**Limitations**

If you supply  $n$  less than 3, `magic` returns either a nonmagic square, or else the degenerate magic squares 1 and [].

`ones` | `rand`

# makehgtform

---

**Purpose** Create 4-by-4 transform matrix

**Syntax**

```
M = makehgtform
M = makehgtform('translate',[tx ty tz])
M = makehgtform('scale',s)
M = makehgtform('scale',[sx,sy,sz])
M = makehgtform('xrotate',t)
M = makehgtform('yrotate',t)
M = makehgtform('zrotate',t)
M = makehgtform('axisrotate',[ax,ay,az],t)
```

**Description** Use `makehgtform` to create transform matrices for translation, scaling, and rotation of graphics objects. Apply the transform to graphics objects by assigning the transform to the `Matrix` property of a parent `hgtransform` object. See [Examples](#) for more information.

`M = makehgtform` returns an identity transform.

`M = makehgtform('translate',[tx ty tz])` or `M = makehgtform('translate',tx,ty,tz)` returns a transform that translates along the *x*-axis by `tx`, along the *y*-axis by `ty`, and along the *z*-axis by `tz`.

`M = makehgtform('scale',s)` returns a transform that scales uniformly along the *x*-, *y*-, and *z*-axes.

`M = makehgtform('scale',[sx,sy,sz])` returns a transform that scales along the *x*-axis by `sx`, along the *y*-axis by `sy`, and along the *z*-axis by `sz`.

`M = makehgtform('xrotate',t)` returns a transform that rotates around the *x*-axis by `t` radians.

`M = makehgtform('yrotate',t)` returns a transform that rotates around the *y*-axis by `t` radians.

`M = makehgtform('zrotate',t)` returns a transform that rotates around the *z*-axis by `t` radians.

`M = makehgtform('axisrotate',[ax,ay,az],t)` Rotate around axis [`ax ay az`] by `t` radians.

Note that you can specify multiple operations in one call to `makehgtform` and the MATLAB software returns a transform matrix that is the result of concatenating all specified operations. For example,

```
m = makehgtform('xrotate',pi/2,'yrotate',pi/2);
```

is the same as

```
m = makehgtform('xrotate',pi/2)*makehgtform('yrotate',pi/2);
```

## How To

- “Group Objects”

# containers.Map

---

**Purpose** Map values to unique keys

**Description** A Map object is a data structure that allows you to retrieve values using a corresponding key. Keys can be real numbers or text strings and provide more flexibility for data access than array indices, which must be positive integers. Values can be scalar or nonscalar arrays.

**Construction** `mapObj = containers.Map` constructs an empty Map container `mapObj`.

`mapObj = containers.Map(keySet,valueSet)` constructs a Map that contains one or more values and a unique key for each value.

`mapObj = containers.Map(keySet,valueSet,'UniformValues',isUniform)` specifies whether all values must be uniform (either all scalars of the same data type, or all strings). Possible values for `isUniform` are logical true (1) or false (0).

`mapObj = containers.Map('KeyType',kType,'ValueType',vType)` constructs an empty Map object and sets the `KeyType` and `ValueType` properties. The order of the key type and value type argument pairs is not important, but both pairs are required.

## Input Arguments

### **keySet**

1-by-n array that specifies n unique keys for the map.

All keys in a Map object are real numeric values or all keys are strings. If  $n > 1$  and the keys are strings, `keySet` must be a cell array. The number of keys in `keySet` must equal the number of values in `valueSet`.

### **valueSet**

1-by-n array of any class that specifies n values for the map. The number of values in `valueSet` must equal the number of keys in `keySet`.

### **'UniformValues'**

Parameter string to use with the `isUniform` argument.

## **isUniform**

Logical value that specifies whether all values are uniform. If `isUniform` is `true` (1), all values must be scalars of the same data type, or all values must be strings. If `isUniform` is `false` (0), then `containers.Map` sets the `ValueType` to `'any'`.

**Default:** `true` for empty `Map` objects, otherwise determined by the data types of values in `valueSet`.

## **'KeyType'**

Parameter string to use with the `kType` argument.

## **kType**

String that specifies the data type for the keys. Possible values are `'char'`, `'double'`, `'single'`, `'int32'`, `'uint32'`, `'int64'`, or `'uint64'`.

**Default:** `'char'` for empty `Map` objects, otherwise determined by the data types of keys in `keySet`. If you specify keys of different numeric types, `kType` is `'double'`.

## **'ValueType'**

Literal string parameter to use with the `vType` argument.

## **vType**

String that specifies the data type for the keys. Possible values are `'any'`, `'char'`, `'logical'`, `'double'`, `'single'`, `'int8'`, `'uint8'`, `'int16'`, `'uint16'`, `'int32'`, `'uint32'`, `'int64'`, or `'uint64'`.

**Default:** `'any'` when you create an empty `Map` object or when you specify values of different sizes or types, otherwise determined by the data type of `valueSet`.

# containers.Map

---

## Properties

### Count

Unsigned 64-bit integer that represents the total number of key-value pairs contained in the `Map` object. Read only.

### KeyType

Character array that indicates the data type of all keys in the `Map` object. The default `KeyType` for empty `Map` objects is `'char'`. Otherwise, `KeyType` is determined from the data type of the `keySet` inputs. Read only.

### ValueType

Character array that indicates the data type of all values in the `Map` object. If you construct an empty `Map` object or specify values with different data types, then the value of `ValueType` is `'any'`. Otherwise, `ValueType` is determined from the data type of the `valueSet` inputs. Read only.

## Methods

|                     |                                                                |
|---------------------|----------------------------------------------------------------|
| <code>isKey</code>  | Determine if <code>containers.Map</code> object contains key   |
| <code>keys</code>   | Identify keys of <code>containers.Map</code> object            |

| <code>remove</code> | Remove key-value pairs from <code>containers.Map</code> object |
| <code>size</code>   | Size of <code>containers.Map</code> object                     |
| <code>values</code> | Identify values in <code>containers.Map</code> object          |

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB Programming Fundamentals documentation](#).

## Examples

### Construct a Map and View Properties

Construct a Map object that contains rainfall data for several months:

```
keySet =    {'Jan', 'Feb', 'Mar', 'Apr'};  
valueSet = [327.2, 368.2, 197.6, 178.4];  
mapObj = containers.Map(keySet,valueSet)
```

This code returns a description of the map, including the property values:

```
mapObj =  
  
    containers.Map handle  
    Package: containers  
  
    Properties:  
        Count: 4  
        KeyType: 'char'  
        ValueType: 'double'  
  
    Methods, Events, Superclasses
```

Get a specific property using dot notation, such as

```
mapObj.Count
```

which returns

```
ans =  
  
         4
```

### Look Up Values in a Map

Use the map created in the previous example to find the rainfall data for February:

```
rainFeb = mapObj('Feb')
```

This code returns

# containers.Map

---

```
rainFeb =  
    368.2000
```

## Add a Single Value and Key to a Map

Add data for the month of May to the map created in the first example:

```
mapObj('May') = 100.0;
```

## Add Multiple Values and Keys by Concatenating Maps

Create a map that contains rainfall data for June, July, and August, and add the data to `mapObj` (from previous examples):

```
keySet    = {'Jun', 'Jul', 'Aug'};  
valueSet  = [ 69.9, 32.3, 37.3];  
newMap    = containers.Map(keySet, valueSet);  
  
mapObj    = [mapObj; newMap];
```

Map objects only support vertical concatenation (that is, adding columns with a semicolon, `;`). When concatenating maps, the data type of all values must be consistent with the `ValueType` of the leftmost map. In this example, both maps have the a `ValueType` of `double`.

## Get the Keys or Values in a Map

Determine all the keys of `mapObj` (from previous examples) by calling the `keys` method:

```
allKeys = keys(mapObj)
```

This method returns the keys in alphabetical order:

```
allKeys =  
    'Apr'    'Aug'    'Feb'    'Jan'    'Jul'    'Jun'    'Mar'    'May'
```

Get multiple values from the map by calling the `values` method. Like the `keys` method, you can request all values with the syntax `values(mapObj)`. Alternatively, request values for specific keys. For example, view the values for March, April, and May in `mapObj`:

```
springValues = values(mapObj,{'Mar','Apr','May'})
```

This method returns the values in a cell array, in the order corresponding to the specified keys:

```
springValues =  
    [197.6000]    [178.4000]    [100]
```

## Remove Keys and Values

Remove the data for March and April from mapObj (from previous examples) by calling the remove method, and view the remaining keys:

```
remove(mapObj,{'Mar','Apr'});  
keys(mapObj)
```

This code returns

```
ans =  
    'Aug'    'Feb'    'Jan'    'Jul'    'Jun'    'May'
```

## Create a Map with Nonscalar Values

Map integer keys to nonscalar arrays, and view the value for one of the keys:

```
keySet = [5,10,15];  
valueSet = {magic(5),magic(10),magic(15)};  
mapObj = containers.Map(keySet,valueSet);  
mapObj(5)
```

This code returns

```
ans =  
    17    24     1     8    15  
    23     5     7    14    16  
     4     6    13    20    22  
    10    12    19    21     3  
    11    18    25     2     9
```

# containers.Map

---

## Construct an Empty Map

Construct a map with no values, but set the KeyType and ValueType properties:

```
mapObj = containers.Map('KeyType', 'char', 'ValueType', 'int32')
```

This code returns

```
mapObj =  
  
containers.Map handle  
Package: containers  
  
Properties:  
    Count: 0  
    KeyType: 'char'  
    ValueType: 'int32'
```

Methods, Events, Superclasses

## Specify Whether Values Are Uniform

Construct a map with numeric values, and specify that the values do not have to be uniform:

```
keySet = {'a', 'b', 'c'};  
valueSet = {1,2,3};  
mapObj = containers.Map(keySet,valueSet,'UniformValues',false);
```

This map allows nonnumeric values, so

```
mapObj('d') = 'OK';  
values(mapObj)
```

returns

```
ans =  
    [1]    [2]    [3]    'OK'
```

**See Also**    keys | isKey | values

# mat2cell

---

**Purpose** Convert array to cell array with potentially different sized cells

**Syntax**  
`C = mat2cell(A,dim1Dist,...,dimNDist)`  
`C = mat2cell(A,rowDist)`

**Description** `C = mat2cell(A,dim1Dist,...,dimNDist)` divides array `A` into smaller arrays within cell array `C`. Vectors `dim1Dist,...,dimNDist` specify how to divide the rows, columns, and (when applicable) higher dimensions of `A`.

`C = mat2cell(A,rowDist)` divides array `A` into an `n`-by-1 cell array `C`, where `n == numel(rowDist)`.

## Input Arguments

**A**  
Any type of array.

### **dim1Dist,...,dimNDist**

Numeric vectors that describe how to divide each dimension of `A`. For example, this command

```
c = mat2cell(x, [10, 20, 30], [25, 25])
```

divides a 60-by-50 array into six arrays contained in a cell array.

For the  $k$ th dimension, `sum(dimkDist) == size(A, k)`.

If the  $k$ th dimension of `A` is zero, set the corresponding `dimkDist` to the empty array, `[]`. For example,

```
a = rand(3, 0, 4);
c = mat2cell(a, [1, 2], [], [2, 1, 1]);
```

### rowDist

Numeric vector that describes how to divide the rows of `A`. When you do not specify distributions for any other dimension, the `mat2cell` function creates an  $n$ -by-1 cell array `C`, where  $n == \text{numel}(\text{rowDist})$ .

## Output Arguments

### C

Cell array. The  $k$ th dimension of array `C` is given by `size(C, k) == numel(dimkDist)`. The  $k$ th dimension of the  $i$ th cell of `C` is given by `size(C{i}, k) == dimkDist(i)`.

## Examples

Divide the 5-by-4 matrix `X` into 2-by-3 and 2-by-2 matrices contained in a cell array.

```
X = reshape(1:20,5,4)';
C = mat2cell(X, [2 2], [3 2])
celldisp(C)
```

This code returns

```
X =
     1     2     3     4     5
     6     7     8     9    10
    11    12    13    14    15
    16    17    18    19    20
```

```
C =
 [2x3 double]    [2x2 double]
 [2x3 double]    [2x2 double]
```

# mat2cell

---

```
C{1,1} =  
    1     2     3  
    6     7     8  
  
C{2,1} =  
   11    12    13  
   16    17    18  
  
C{1,2} =  
    4     5  
    9    10  
  
C{2,2} =  
   14    15  
   19    20
```

---

Divide X (created in the previous example) into a 2-by-1 cell array.

```
C = mat2cell(X, [1 3])  
celldisp(C)
```

This code returns

```
C =  
    [1x5 double]  
    [3x5 double]  
  
C{1} =  
    1     2     3     4     5  
  
C{2} =  
    6     7     8     9    10  
   11    12    13    14    15  
   16    17    18    19    20
```

[cell2mat](#) | [num2cell](#)

**Purpose** Convert matrix to string

**Syntax**

```
str = mat2str(A)
str = mat2str(A,n)
str = mat2str(A, 'class')
str = mat2str(A, n, 'class')
```

**Description**

`str = mat2str(A)` converts matrix `A` into a string. This string is suitable for input to the `eval` function such that `eval(str)` produces the original matrix to within 15 digits of precision.

`str = mat2str(A,n)` converts matrix `A` using `n` digits of precision.

`str = mat2str(A, 'class')` creates a string with the name of the class of `A` included. This option ensures that the result of evaluating `str` will also contain the class information.

`str = mat2str(A, n, 'class')` uses `n` digits of precision and includes the class information.

**Limitations** The `mat2str` function is intended to operate on scalar, vector, or rectangular array inputs only. An error will result if `A` is a multidimensional array.

## Examples

### Example 1

Consider the matrix

```
x = [3.85 2.91; 7.74 8.99]
x =
    3.8500    2.9100
    7.7400    8.9900
```

The statement

```
A = mat2str(x)
```

produces

```
A =  
    [3.85 2.91;7.74 8.99]
```

where A is a string of 21 characters, including the square brackets, spaces, and a semicolon.

`eval(mat2str(x))` reproduces x.

## Example 2

Create a 1-by-6 matrix of signed 16-bit integers, and then use `mat2str` to convert the matrix to a 1-by-33 character array, A. Note that output string A includes the class name, `int16`:

```
x1 = int16([-300 407 213 418 32 -125]);
```

```
A = mat2str(x1, 'class')  
A =  
    int16([-300 407 213 418 32 -125])
```

```
class(A)  
ans =  
    char
```

Evaluating the string A gives you an output x2 that is the same as the original `int16` matrix:

```
x2 = eval(A);  
  
if isnumeric(x2) && isa(x2, 'int16') && all(x2 == x1)  
    disp 'Conversion back to int16 worked'  
end
```

Conversion back to int16 worked

**Purpose** Control reflectance properties of surfaces and patches

**Syntax**

```
material shiny
material dull
material metal
material([ka kd ks])
material([ka kd ks n])
material([ka kd ks n sc])
material default
```

**Description** `material` sets the lighting characteristics of surface and patch objects.

`material shiny` sets the reflectance properties so that the object has a high specular reflectance relative to the diffuse and ambient light, and the color of the specular light depends only on the color of the light source.

`material dull` sets the reflectance properties so that the object reflects more diffuse light and has no specular highlights, but the color of the reflected light depends only on the light source.

`material metal` sets the reflectance properties so that the object has a very high specular reflectance, very low ambient and diffuse reflectance, and the color of the reflected light depends on both the color of the light source and the color of the object.

`material([ka kd ks])` sets the ambient/diffuse/specular strength of the objects.

`material([ka kd ks n])` sets the ambient/diffuse/specular strength and specular exponent of the objects.

`material([ka kd ks n sc])` sets the ambient/diffuse/specular strength, specular exponent, and specular color reflectance of the objects.

`material default` sets the ambient/diffuse/specular strength, specular exponent, and specular color reflectance of the objects to their defaults.

# material

---

## Tips

The `material` command sets the `AmbientStrength`, `DiffuseStrength`, `SpecularStrength`, `SpecularExponent`, and `SpecularColorReflectance` properties of all surface and patch objects in the axes. There must be visible light objects in the axes for lighting to be enabled. Look at the `material.m` file to see the actual values set (enter the command type `material`).

- `true` (1) Enable saving. If the file is read only, change the system permissions with `fileattrib`.
- `false` (0) Disable saving with `matfile`. MATLAB does not change the system permissions.

**Default:** `true` for new files, `false` for existing files

## Output Arguments

### `matObj`

Object of class `matlab.io.MatFile` that corresponds to a MAT-file.

Access variables in the MAT-file as properties of `matObj`, with dot notation similar to accessing fields of structs. The syntax for loading and saving part of variable `varName` in the MAT-file corresponding to `matObj` is:

```
loadedData = matObj.varName(indices);    % Load into workspace
matObj.varName(indices) = dataToSave;    % Save to file
```

When indexing, specify indices for all dimensions. Indices can be a single value, an equally spaced range of increasing values, or a colon (:), such as

```
matObj.varName(100:500, 200:600)
matObj.varName(:, 501:1000)
matObj.varName(1:2:1000, 80)
```

### Limitations

- Using the end keyword as part of an index causes MATLAB to load the entire variable into memory. For very large variables, this load operation results in Out of Memory errors. Rather than using end, determine the extent of a variable with the `size` method, such as:

```
sizeMyVar = size(matObj, 'myVar')
```

- `matfile` does not support linear indexing. You must specify indices for all dimensions.

- `matfile` does not support indexing into:
  - Cells of cell arrays
  - Fields of structs
  - User-defined classes
  - Sparse arrays
- You cannot assign complex values to an indexed portion of a real array.
- You cannot evaluate function handles using a `MatFile` object. For example, if your MAT-file contains function handle `myfunc`, the syntax `matObj.myfunc()` attempts to index into the function handle, and does not invoke the function.

## Examples

Create `myFile.mat` in a temporary folder and save data to part of variable `savedVar`:

```
filename = fullfile(tempdir,'myFile.mat');  
matObj = matfile(filename);  
matObj.savedVar(81:100,81:100) = magic(20);
```

Load part of the data into variable `loadVar`:

```
loadVar = matObj.savedVar(85:94,85:94);
```

---

Load or save an entire variable by omitting the indices. For example, load variable `topo` from `topography.mat`:

```
filename = 'topography.mat';  
matObj = matfile(filename);  
topo = matObj.topo;
```

---

# matfile

---

Determine the dimensions of a variable, and process one part of the variable at a time. In this case, calculate and store the average of each column of variable `stocks` in the example file `stocks.mat`:

```
filename = 'stocks.mat';
matObj = matfile(filename);
[nrows, ncols] = size(matObj,'stocks');

avgs = zeros(1,ncols);
for idx = 1:ncols
    avgs(idx) = mean(matObj.stocks(:,idx));
end
```

---

By default, `matfile` only supports loading data from existing files. To enable saving, set `Writable` to `true` either during construction of the object,

```
filename = 'myFile.mat';
matObj = matfile(filename,'Writable',true);
```

or in a separate step, by setting `Properties.Writable`:

```
filename = 'myFile.mat';
matObj = matfile(filename);
matObj.Properties.Writable = true;
```

**Purpose**

Load and save parts of variables in MAT-files

**Description**

The `matfile` function constructs a `matlab.io.MatFile` object that corresponds to a MAT-File, such as

```
matObj = matfile('myFile.mat')
```

Access variables in the MAT-file as properties of `matObj`, with dot notation similar to accessing fields of structs. The syntax for loading and saving part of variable `varName` in the MAT-file corresponding to `matObj` is:

```
loadedData = matObj.varName(indices);    % Load into workspace  
matObj.varName(indices) = dataToSave;    % Save to file
```

When indexing, specify indices for all dimensions. Indices can be a single value, an equally spaced range of increasing values, or a colon (:), such as

```
matObj.varName(100:500, 200:600)  
matObj.varName(:, 501:1000)  
matObj.varName(1:2:1000, 80)
```

**Limitations**

- Using the `end` keyword as part of an index causes MATLAB to load the entire variable into memory. For very large variables, this load operation results in Out of Memory errors. Rather than using `end`, determine the extent of a variable with the `size` method, such as:

```
sizeMyVar = size(matObj, 'myVar')
```

- `matfile` does not support linear indexing. You must specify indices for all dimensions.
- `matfile` does not support indexing into:
  - Cells of cell arrays
  - Fields of structs

- User-defined classes
- Sparse arrays
- You cannot assign complex values to an indexed portion of a real array.
- You cannot evaluate function handles using a `MatFile` object. For example, if your MAT-file contains function handle `myfunc`, the syntax `matObj.myfunc()` attempts to index into the function handle, and does not invoke the function.

## Construction

`matObj = matfile(filename)` constructs a `matlab.io.MatFile` object that can load or save parts of variables in MAT-file `filename`. MATLAB does not load any data from the file into memory when creating the object.

`matObj = matfile(filename, 'Writable', isWritable)` enables or disables write access to the file for object `matObj`. Possible values for `isWritable` are logical `true` (1) or `false` (0).

## Input Arguments

### **filename**

String enclosed in single quotation marks that specifies the name of a MAT-file.

`filename` can include a full or partial path, otherwise `matfile` searches for the file along the MATLAB search path. If `filename` does not include an extension, `matfile` appends `.mat`.

If the file does not exist, `matfile` creates a Version 7.3 MAT-file on the first assignment to a variable.

`matfile` only supports partial loading and saving for MAT-files in Version 7.3 format (described in *MAT-File Versions*). If you index into a variable in a Version 7 (the current default) or earlier MAT-file, MATLAB warns and temporarily loads the entire contents of the variable.

### **'Writable'**

Parameter to use with the `isWritable` argument.

### **isWritable**

Logical value that specifies whether to allow saving to the file.

Possible values:

|                           |                                                                                                       |
|---------------------------|-------------------------------------------------------------------------------------------------------|
| <code>true</code><br>(1)  | Enable saving. If the file is read only, change the system permissions with <code>fileattrib</code> . |
| <code>false</code><br>(0) | Disable saving with <code>matfile</code> . MATLAB does not change the system permissions.             |

**Default:** `true` for new files, `false` for existing files

## **Properties**

### **Properties.Source**

String that contains the fully qualified path to the file. Read only.

### **Properties.Writable**

Logical value that specifies whether to allow saving to the file.

Possible values:

|                           |                                                                                                       |
|---------------------------|-------------------------------------------------------------------------------------------------------|
| <code>true</code><br>(1)  | Enable saving. If the file is read only, change the system permissions with <code>fileattrib</code> . |
| <code>false</code><br>(0) | Disable saving with <code>matfile</code> . MATLAB does not change the system permissions.             |

**Default:** `true` for new files, `false` for existing files

## **Methods**

|                   |                                                  |
|-------------------|--------------------------------------------------|
| <code>size</code> | Array dimensions                                 |
| <code>who</code>  | Names of variables in MAT-file                   |
| <code>whos</code> | Names, sizes, and types of variables in MAT-file |

You cannot access help for these methods using the `help` command. Find help on the methods from the command line using the `doc` command, such as `doc matlab.io.MatFile/size`.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB Programming Fundamentals documentation.

## Examples

Create `myFile.mat` in a temporary folder and save data to part of variable `savedVar`:

```
filename = fullfile(tempdir,'myFile.mat');
matObj = matfile(filename);
matObj.savedVar(81:100,81:100) = magic(20);
```

Load part of the data into variable `loadVar`:

```
loadVar = matObj.savedVar(85:94,85:94);
```

---

Load or save an entire variable by omitting the indices. For example, load variable `topo` from `topography.mat`:

```
filename = 'topography.mat';
matObj = matfile(filename);
topo = matObj.topo;
```

---

Determine the dimensions of a variable, and process one part of the variable at a time. In this case, calculate and store the average of each column of variable `stocks` in the example file `stocks.mat`:

```
filename = 'stocks.mat';
matObj = matfile(filename);
[nrows, ncols] = size(matObj,'stocks');

avgs = zeros(1,ncols);
for idx = 1:ncols
```

```
        avgs(idx) = mean(matObj.stocks(:,idx));  
end
```

---

By default, `matfile` only supports loading data from existing files. To enable saving, set `Writable` to `true` either during construction of the object,

```
filename = 'myFile.mat';  
matObj = matfile(filename, 'Writable', true);
```

or in a separate step, by setting `Properties.Writable`:

```
filename = 'myFile.mat';  
matObj = matfile(filename);  
matObj.Properties.Writable = true;
```

## Purpose

Startup file for MATLAB program

## Description

At startup time, MATLAB automatically executes the file `matlabrc.m`. This function establishes the MATLAB path, sets the default figure size, and sets some uicontrol defaults.

On multiuser or networked systems, system administrators can put any messages, definitions, or other code that applies to all users in their `matlabrc.m` file.

The file `matlabrc.m` invokes the `startup.m` file, if it exists on the search path MATLAB uses.

Individual users should use the `startup.m` file to customize MATLAB startup. The `matlabrc.m` file is reserved for system administrators.

## Algorithms

MATLAB invokes `matlabrc` at startup. `matlabrc.m` contains the statements

```
if exist('startup') == 2
    startup
end
```

that invokes `startup.m`, if it exists. Extend this process to create additional startup files, if required.

## Tips

You can also start MATLAB using options you define at the Command Window prompt or in your Microsoft Windows shortcut for MATLAB.

## Examples

### Turning Off the Figure Window Toolbar

If you do not want the toolbar to appear in the figure window, remove the comment marks from the following line in the `matlabrc.m` file, or create a similar line in your own `startup.m` file.

```
% set(0,'defaultfiguretoolbar','none')
```

## How To

- Startup Options

# matlabroot

---

**Purpose** Root folder

**Syntax** matlabroot  
mr = matlabroot

**Description** matlabroot returns the name of the folder where the MATLAB software is installed. Use matlabroot to create a path to MATLAB and toolbox folders that does not depend on a specific platform, MATLAB version, or installation location.

mr = matlabroot returns the name of the folder in which the MATLAB software is installed and assigns it to mr.

**Tips** **matlabroot as Folder Name**

The term *matlabroot* also refers to the folder where MATLAB files are installed. For example, “save to *matlabroot/toolbox/local*” means save to the *toolbox/local* folder in the MATLAB root folder.

**Using \$matlabroot as a Literal**

In some files, \$matlabroot is literal. In those files, MATLAB interprets \$matlabroot as the full path to the MATLAB root folder. For example, including the line:

```
$matlabroot/toolbox/local/myfile.jar
```

in *javaclasspath.txt*, adds *myfile.jar*, which is located in the *toolbox/local* folder, to the static Java class path.

Sometimes, particularly in older code examples, the term \$matlabroot or \$MATLABROOT is not meant to be interpreted literally but is used to represent the value returned by the *matlabroot* function.

**matlabroot on Macintosh Platforms**

In R2008b (V7,7) and more recent versions, running *matlabroot* on Apple Macintosh platforms returns

```
/Applications/MATLAB_R2008b.app
```

In versions prior to R2008b (V7.7), such as R2008a (V7.6), running `matlabroot` on Macintosh platforms returns, for example

```
/Applications/MATLAB_R2008a
```

When you use GUIs on Macintosh platforms, you cannot directly view the contents of the MATLAB root folder. For more information, see “Navigating Within the MATLAB Root Folder on Macintosh Platforms”.

## Examples

Get the location where MATLAB is installed:

```
matlabroot
```

MATLAB returns:

```
C:\Program Files\MATLAB\R2009a
```

Produce a full path to the `toolbox/matlab/general` folder that is correct for the platform on which it is executed:

```
fullfile(matlabroot,'toolbox','matlab','general')
```

Change the current folder to the MATLAB root folder:

```
cd(matlabroot)
```

To add the folder `myfiles` to the MATLAB search path, run

```
addpath([matlabroot '/toolbox/local/myfiles'])
```

## How To

- “Understanding File Locations in MATLAB”

# matlab (UNIX)

---

**Purpose** Start MATLAB program (UNIX platforms)

**Syntax**

```
matlab helpOption
matlab envDispOption
matlab archOption
matlab dispOption
matlab modeOption
matlab -c licensefile
matlab -debug
matlab -Ddebugger options
matlab -jdb portnumber
matlab -logfile filename
matlab -mwvisual visualid
matlab -nosplash
matlab -nouserjavapath
matlab -r matlab_command
matlab -singleCompThread
```

---

**Note** You can enter more than one of these options in the same `matlab` command. If you use `-Ddebugger` to start MATLAB in debug mode, the first option in the command must be `-Ddebugger`.

---

**Description** `matlab` is a Bourne shell script that starts the MATLAB executable on UNIX platforms. (In this document, `matlab` refers to this script; MATLAB refers to the application program). Before actually initiating the execution of MATLAB, this script configures the run-time environment by

- Determining the MATLAB root folder
- Determining the host machine architecture
- Processing any command line options
- Reading the MATLAB startup file, `.matlab7rc.sh`
- Setting MATLAB environment variables

There are two ways in which you can control the way the matlab script works:

- By specifying command line options
- By assigning values in the MATLAB startup file, `.matlab7rc.sh`

### Specifying Options at the Command Line

Options that you can enter at the command line are as follows:

`matlab helpOption` displays information that matches the specified `helpOption` argument without starting MATLAB. `helpOption` can be any one of the keywords shown in the table below. Enter only one `helpOption` keyword in a `matlab` command.

#### Values for helpOption

| Option             | Description                                |
|--------------------|--------------------------------------------|
| <code>-help</code> | Display <code>matlab</code> command usage. |
| <code>-h</code>    | The same as <code>-help</code> .           |

`matlab envDispOption` displays the values of environment variables passed to MATLAB or their values just prior to exiting MATLAB. `envDispOption` can be either one of the options shown in the table below.

#### Values for envDispOption

| Option          | Description                                                                                                                                                             |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-n</code> | Display all the final values of the environment variables and arguments passed to the MATLAB executable as well as other diagnostic information. Does not start MATLAB. |
| <code>-e</code> | Display <i>all</i> environment variables and their values just prior to exiting. This argument must have been parsed before exiting for anything to be displayed. The   |

## Values for envDispOption (Continued)

| Option | Description                                                                                                                                                                                                                         |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|        | last possible exiting point is just before the MATLAB image would have been executed and a status of 0 is returned. If the exit status is not 0 on return, then the variables and values may not be correct. Does not start MATLAB. |

`matlab archOption` starts MATLAB and assumes that you are running on the system architecture specified by `arch`, or using the MATLAB version specified by `variant`, or both. The values for the `archOption` argument are shown in the table below. Enter only one of these options in a `matlab` command.

## Values for archOption

| Option                      | Description                                                                                                                                                                                                                                             |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-arch</code>          | Run MATLAB assuming this architecture rather than the actual architecture of the machine you are using. Replace the term <code>arch</code> with a string representing a recognized system architecture.                                                 |
| <code>v=variant</code>      | Execute the version of MATLAB found in the folder <code>bin/\$ARCH/variant</code> instead of <code>bin/\$ARCH</code> . Replace the term <code>variant</code> with a string representing a MATLAB version.                                               |
| <code>v=arch/variant</code> | Execute the version of MATLAB found in the folder <code>bin/arch/variant</code> instead of <code>bin/\$ARCH</code> . Replace the terms <code>arch</code> and <code>variant</code> with strings representing a specific architecture and MATLAB version. |

`matlab dispOption` starts MATLAB using one of the display options shown in the table below. Enter only one of these options in a `matlab` command.

## Values for dispOption

| Option                | Description                                                                                                                                     |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-display</b> xDisp | Send X commands to X Window Server display xDisp. This supersedes the value of the DISPLAY environment variable.                                |
| <b>-nodisplay</b>     | Start the Oracle JVM software, but do not start the MATLAB desktop. Do not display any X commands, and ignore the DISPLAY environment variable, |

matlab modeOption starts MATLAB without its usual desktop component. Enter only one of the options shown below.

## Values for modeOption

| Option            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-desktop</b>   | Allow the MATLAB desktop to be started by a process without a controlling terminal. This is usually a required command line argument when attempting to start MATLAB from a window manager menu or desktop icon.                                                                                                                                                                                                                                                                                                                                                    |
| <b>-nodesktop</b> | Start MATLAB without bringing up the MATLAB desktop. The JVM software <i>is</i> started. Use the current window in the operating system to enter commands. Use this option to run without an X-window, for example, in VT100 mode, or in batch processing mode. Note that if you pipe to MATLAB using the > constructor, the nodesktop option is used automatically. With nodesktop, MATLAB does not save statements to the Command History. With nodesktop, you can still use most development environment tools by starting them via a function. For example, use |

## Values for modeOption (Continued)

| Option        | Description                                                                                                                                                                                                                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | preferences to open the Preferences dialog box and doc to open the Help browser. Do not use nodedesktop to provide a Command Window-only interface; instead, select <b>Desktop &gt; Desktop Layout &gt; Command Window Only</b> .                                                                             |
| <b>-nojvm</b> | Start MATLAB without the JVM software. Use the current window to enter commands. The MATLAB desktop does not open. Any tools that require Java software, such as the desktop tools, cannot be used. Handle Graphics and related functionality are not supported; MATLAB produces a warning when you use them. |

`matlab -c licensefile` starts MATLAB using the specified license file. The `licensefile` argument can have the form `port@host` or it can be a colon-separated list of license filenames. This option causes the `LM_LICENSE_FILE` and `MLM_LICENSE_FILE` environment variables to be ignored.

`matlab -debug` starts MATLAB and displays debugging information that can be useful, especially for X based problems. This option should be used only when working with a Technical Support Representative from The MathWorks, Inc.

`matlab -Ddebugger options` starts MATLAB in debug mode, using the named debugger (e.g., `dbx`, `gdb`, `xdb`, `cvd`). A full path can be specified for debugger.

The `options` argument can include *only* those options that follow the debugger name in the syntax of the actual debug command. For most debuggers, there is a very limited number of such options. Options that would normally be passed to the MATLAB executable should be used as

parameters of a command inside the debugger (like `run`). They should not be used when running the `matlab` script.

If any other `matlab` command options are placed before the `-Ddebugger` argument, they will be handled as if they were part of the options after the `-Ddebugger` argument and will be treated as illegal options by most debuggers. The `MATLAB_DEBUG` environment variable is set to the filename part of the debugger argument.

To customize your debugging session, use a startup file. See your debugger documentation for details.

---

**Note** For certain debuggers like `gdb`, the `SHELL` environment variable is *always* set to `/bin/sh`.

---

`matlab -jdb portnumber` starts MATLAB, enabling use of the Java debugger. If you specify a port number, the Java debugger uses that port to communicate with MATLAB. You can specify any port number in the range 0-65535 that is not reserved or currently in use by another application on your system. By default, MATLAB uses port 4444. If you are running multiple MATLAB sessions and want to use the Java debugger, be sure to specify a port number.

`matlab -logfile filename` starts MATLAB and makes a copy of any output to the command window in file `log`. This includes all crash reports.

`matlab -mwvisual visualid` starts MATLAB and uses `visualid` as the default X visual for figure windows. `visualid` is a hexadecimal number that can be found using `xdpyinfo`.

`matlab -nosplash` starts MATLAB but does not display the splash screen during startup.

`matlab -nouserjavapath` disables `javaclasspath.txt` and `javalibrarypath.txt` files.

# matlab (UNIX)

---

`matlab -r matlab_command` starts MATLAB and executes the specified MATLAB command.

`matlab -singleCompThread` limits MATLAB to a single computational thread. By default, MATLAB makes use of the multithreading capabilities of the computer on which it is running.

## Specifying Options in the MATLAB Startup File

The `.matlab7rc.sh` shell script contains definitions for a number of variables that the `matlab` script uses. These variables are defined within the `matlab` script, but can be redefined in `.matlab7rc.sh`. When invoked, `matlab` looks for the first occurrence of `.matlab7rc.sh` in the current folder, in the home folder (`$HOME`), and in the `matlabroot/bin` folder, where the template version of `.matlab7rc.sh` is located.

You can edit the template file to redefine information used by the `matlab` script. If you do not want your changes applied systemwide, copy the edited version of the script to your current or home folder. Ensure that you edit the section that applies to your machine architecture.

The following table lists the variables defined in the `.matlab7rc.sh` file. See the comments in the `.matlab7rc.sh` file for more information about these variables.

| Variable | Definition and Standard Assignment Behavior                                                                                                                                                                                                                                                                               |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ARCH     | The machine architecture.<br><br>The value ARCH passed with the <code>-arch</code> or <code>-arch/ext</code> argument to the script is tried first, then the value of the environment variable <code>MATLAB_ARCH</code> is tried next, and finally it is computed. The first one that gives a valid architecture is used. |
| DISPLAY  | The hostname of the X Window display MATLAB uses for output.                                                                                                                                                                                                                                                              |

| Variable        | Definition and Standard Assignment Behavior                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | <p>The value of <code>Xdisplay</code> passed with the <code>-display</code> argument to the script is used; otherwise, the value in the environment is used. <code>DISPLAY</code> is ignored by MATLAB if the <code>-nodisplay</code> argument is passed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| LD_LIBRARY_PATH | <p>Final Load library path. The name <code>LD_LIBRARY_PATH</code> is platform dependent.</p> <p>The final value is normally a colon-separated list of four sublists, each of which could be empty. The first sublist is defined in <code>.matlab7rc.sh</code> as <code>LDPATH_PREFIX</code>. The second sublist is computed in the script and includes folders inside the MATLAB root folder and relevant Java folders. The third sublist contains any nonempty value of <code>LD_LIBRARY_PATH</code> from the environment possibly augmented in <code>.matlab7rc.sh</code>. The final sublist is defined in <code>.matlab7rc.sh</code> as <code>LDPATH_SUFFIX</code>.</p>                                                               |
| LM_LICENSE_FILE | <p>The FLEX lm license variable.</p> <p>The license file value passed with the <code>-c</code> argument to the script is used; otherwise it is the value set in <code>.matlab7rc.sh</code>. In general, the final value is a colon-separated list of license files and/or <code>port@host</code> entries. The shipping <code>.matlab7rc.sh</code> file starts out the value by prepending <code>LM_LICENSE_FILE</code> in the environment to a default <code>license.file</code>.</p> <p>Later in the <code>matlab</code> script, if the <code>-c</code> option is not used, the <code>matlabroot/etc</code> folder is searched for the files that start with <code>license.dat.DEMO</code>. These files are assumed to contain demo</p> |

| XKEYSYMDB   | The X keysym database file (Linux systems only).<br><br>A nonempty value in the environment is used first unless XKEYSYMDB is reset in <code>.matlab7rc.sh</code> .          |

The `matlab` script determines the path of the MATLAB root folder by looking up the folder tree from the `matlabroot/bin` folder (where the `matlab` script is located). The MATLAB variable is then used to locate all files within the MATLAB folder tree.

You can change the definition of MATLAB if, for example, you want to run a different version of MATLAB or if, for some reason, the path determined by the `matlab` script is not correct. (This can happen when certain types of automounting schemes are used by your system.)

## How To

- “Starting the MATLAB Program on Linux Platforms”
- “Starting the MATLAB Program on Macintosh Platforms”
- “Startup Options”

**Purpose** Start MATLAB program (Windows platforms)

**Syntax**

```
matlab helpOption
matlab -automation
matlab -c licensefile
matlab -jdb portnumber
matlab -logfile filename
matlab -noFigureWindows
matlab -nosplash
matlab -nouserjavapath
matlab -r "statement"
matlab -regserver
matlab -sd "startdir"
matlab shieldOption
matlab -singleCompThread
matlab -unregserver
matlab -wait
```

---

**Note** You can enter more than one of these options in the same `matlab` command.

---

**Description** `matlab` is a script that runs the main MATLAB executable on Microsoft Windows platforms. (In this document, the term `matlab` refers to the script, and MATLAB refers to the main executable). Before actually initiating the execution of MATLAB, it configures the run-time environment by

- Determining the MATLAB root directory
- Determining the host machine architecture
- Selectively processing command line options with the rest passed to MATLAB.
- Setting certain MATLAB environment variables

There are two ways in which you can control the way `matlab` works:

# matlab (Windows)

---

- By specifying command line options
- By setting environment variables before calling the program

## Specifying Options at the Command Line

Options that you can enter at the command line are as follows:

`matlab helpOption` displays information that matches the specified *helpOption* argument without starting MATLAB. *helpOption* can be any one of the keywords shown in the table below. Enter only one *helpOption* keyword in a `matlab` statement.

### Values for helpOption

| Option       | Description                   |
|--------------|-------------------------------|
| <b>-help</b> | Display matlab command usage. |
| <b>-h</b>    | The same as <b>-help</b> .    |
| <b>-?</b>    | The same as <b>-help</b> .    |

`matlab -automation` starts MATLAB as an automation server. The server window is minimized, and the MATLAB splash screen does not display on startup.

`matlab -c licensefile` starts MATLAB using the specified license file. The `licensefile` argument can have the form `port@host`. This option causes MATLAB to ignore the `LM_LICENSE_FILE` and `MLM_LICENSE_FILE` environment variables.

`matlab -jdb portnumber` starts MATLAB, enabling use of the Java debugger. If you specify a port number, the Java debugger uses that port to communicate with MATLAB. You can specify any port number in the range 0-65535 that is not reserved or currently in use by another application on your system. By default, MATLAB uses port 4444. If you are running multiple MATLAB sessions and want to use the Java debugger, be sure to specify a port number.

`matlab -logfile filename` starts MATLAB and makes a copy of any output to the Command Window in `filename`. This includes all crash reports.

`matlab -noFigureWindows` starts MATLAB, but disables the display of any figure windows in MATLAB.

`matlab -nosplash` starts MATLAB, but does not display the splash screen during startup.

`matlab -nouserjavapath` disables `javaclasspath.txt` and `javalibrarypath.txt` files.

`matlab -r "statement"` starts MATLAB and executes the specified MATLAB statement. Any required file must be on the MATLAB search path or in the startup directory.

`matlab -regserver` registers MATLAB as a Component Object Model (COM) server.

`matlab -sd "startdir"` specifies the startup directory for MATLAB (the current directory in MATLAB after startup). The `-sd` option has been deprecated. For information about alternatives, see “Startup Folder on Windows Platforms”.

`matlab shieldOption` provides the specified level of protection of the address space used by MATLAB during startup on Windows 32-bit platforms. It attempts to help ensure the largest contiguous block of memory available after startup, which is useful for processing large data sets. The `shieldOption` does this by ensuring resources such as DLLs, are loaded into locations that will not fragment the address space. With `shieldOption` set to a value other than none, address space is protected up to or after the processing of `matlabrc`. Use higher levels of protection to secure larger initial blocks of contiguous memory, however a higher level might not always provide a larger size block and might cause startup problems. Therefore, start with a lower level of protection, and if successful, try the next higher level. You can use the `memory` function after startup to see the size of the largest contiguous block of memory; this helps you determine the actual effect of the `shieldOption` setting you used. If your `matlabrc` (or `startup.m`) requires significant memory,

# matlab (Windows)

---

a higher level of protection for *shieldOption* might cause startup to fail; in that event try a lower level. Values for *shieldOption* can be any one of the keywords shown in the table below.

| Option                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-shield minimum</b> | <p>This is the default setting. It protects the range 0x50000000 to 0x70000000 during MATLAB startup until just before startup processes <code>matlabrc</code>. It ensures there is at least approximately 500 MB of contiguous memory up to this point.</p> <p>Start with this, the default value. To use the default, do not specify a shield option upon startup.</p> <p>If MATLAB fails to start successfully using the default option, <b>-shield minimum</b>, instead use <b>-shield none</b>.</p> <p>If MATLAB starts successfully with the default value for <i>shieldOption</i> and you want to try to ensure an even larger contiguous block after startup, try using the <b>-shield medium</b> option.</p> |
| <b>-shield medium</b>  | <p>This protects the same range as for minimum, 0x50000000 to 0x70000000, but protects the range until just after startup processes <code>matlabrc</code>. It ensures there is at least approximately 500 MB of contiguous memory up to this point.</p> <p>If MATLAB fails to start successfully with the <b>-shield medium</b> option, instead use the default option (<b>-shield minimum</b>).</p> <p>If MATLAB starts successfully with the <b>-shield medium</b> option and you want to try</p>                                                                                                                                                                                                                   |

| Option                 | Description                                                                                                                                                                                                                                                                      |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | to ensure an even larger contiguous block after startup, try using the <b>-shield maximum</b> option.                                                                                                                                                                            |
| <b>-shield maximum</b> | This protects the maximum possible range, which can be up to approximately 1.5 GB, until just after startup processes <code>matlabrc</code> .<br><br>If MATLAB fails to start successfully with the <b>-shield maximum</b> option, instead use the <b>-shield medium</b> option. |
| <b>-shield none</b>    | This completely disables address shielding. Use this if MATLAB fails to start successfully with the default ( <b>-shield minimum</b> ) option.                                                                                                                                   |

`matlab -singleCompThread` limits MATLAB to a single computational thread. By default, MATLAB makes use of the multithreading capabilities of the computer on which it is running.

`matlab -unregserver` removes all MATLAB COM server entries from the registry.

`matlab -wait` MATLAB is started by a separate starter program which normally launches MATLAB and then immediately quits. Using this option tells the starter program not to quit until MATLAB has terminated. This option is useful when you need to process the results from MATLAB in a script. Calling MATLAB with this option blocks the script from continuing until the results are generated.

## Setting Environment Variables

You can set the following environment variables before starting MATLAB.

# matlab (Windows)

---

| Variable Name   | Description                                                                                                                                                                                                                                           |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LM_LICENSE_FILE | This variable specifies the License File to use. If you use the <b>-c</b> argument to specify the License File it overrides this variable. The value of this variable can be a list of License Files, separated by semi-colons, or port@host entries. |

## How To

- “Starting the MATLAB Program on Windows Platforms”
- “Startup Options”

**Purpose** Largest elements in array

**Syntax**

```
C = max(A)
C = max(A,B)
C = max(A,[],dim)
[C,I] = max(...)
```

**Description**

`C = max(A)` returns the largest elements along different dimensions of an array.

If `A` is a vector, `max(A)` returns the largest element in `A`.

If `A` is a matrix, `max(A)` treats the columns of `A` as vectors, returning a row vector containing the maximum element from each column.

If `A` is a multidimensional array, `max(A)` treats the values along the first non-singleton dimension as vectors, returning the maximum value of each vector.

`C = max(A,B)` returns an array the same size as `A` and `B` with the largest elements taken from `A` or `B`. The dimensions of `A` and `B` must match, or they may be scalar.

`C = max(A,[],dim)` returns the largest elements along the dimension of `A` specified by scalar `dim`. For example, `max(A,[],1)` produces the maximum values along the first dimension of `A`.

`[C,I] = max(...)` finds the indices of the maximum values of `A`, and returns them in output vector `I`. If there are several identical maximum values, the index of the first one found is returned.

**Examples** Return the maximum of a 2-by-3 matrix from each column:

```
X = [2 8 4; 7 3 9];
max(X,[],1)
ans =
```

```
7     8     9
```

Return the maximum from each row:

# max

---

```
max(X, [], 2)
ans =
```

```
8
9
```

Compare each element of X to a scalar:

```
max(X, 5)
ans =
```

```
5    8    5
7    5    9
```

## Tips

For complex input A, `max` returns the complex number with the largest complex modulus (magnitude), computed with `max(abs(A))`. Then computes the largest phase angle with `max(angle(x))`, if necessary.

The `max` function ignores NaNs.

`isnan` | `mean` | `median` | `min` | `sort`

**Purpose** Open Automation server window

**Syntax** **MATLAB Client**  
h.MaximizeCommandWindow  
MaximizeCommandWindow(h)

**IDL Method Signature**

HRESULT MaximizeCommandWindow(void)

**Microsoft Visual Basic Client**

MaximizeCommandWindow

**Description** h.MaximizeCommandWindow displays the window for the server attached to handle h, and makes it the currently active window on the desktop.

MaximizeCommandWindow(h) is an alternate syntax.

MaximizeCommandWindow restores the window to the size it had at the time it was minimized, not to the maximum size on the desktop. If the server window was not previously in a minimized state, MaximizeCommandWindow does nothing.

**Examples** From a MATLAB client, modify the size of the command window in a MATLAB Automation server:

```
h = actxserver('matlab.application');  
h.MinimizeCommandWindow;  
% Now return the server window to its former state on  
% the desktop and make it the currently active window.  
h.MaximizeCommandWindow;
```

---

From a Visual Basic .NET client, modify the size of the command window in a MATLAB Automation server:

```
Dim Matlab As Object
```

# MaximizeCommandWindow

---

```
Matlab = CreateObject("matlab.application")  
Matlab.MinimizeCommandWindow
```

```
'Now return the server window to its former state on  
'the desktop and make it the currently active window.
```

```
Matlab.MaximizeCommandWindow
```

## See Also

MinimizeCommandWindow

## How To

- “MATLAB COM Automation Server Interface”
- “Controlling the Server Window”

## Purpose

Control maximum number of computational threads

---

**Note** `maxNumCompThreads` will be removed in a future version. You can set the `-singleCompThread` option when starting MATLAB to limit MATLAB to a single computational thread. By default, MATLAB makes use of the multithreading capabilities of the computer on which it is running.

---

## Syntax

```
N = maxNumCompThreads
LASTN = maxNumCompThreads(N)
LASTN = maxNumCompThreads('automatic')
```

## Description

`N = maxNumCompThreads` returns the current maximum number of computational threads `N`.

`LASTN = maxNumCompThreads(N)` sets the maximum number of computational threads to `N`, and returns the previous maximum number of computational threads, `LASTN`.

`LASTN = maxNumCompThreads('automatic')` sets the maximum number of computational threads using what the MATLAB software determines to be the most desirable. It additionally returns the previous maximum number of computational threads, `LASTN`.

Currently, the maximum number of computational threads is equal to the number of computational cores on your machine.

---

**Note** Setting the maximum number of computational threads using `maxNumCompThreads` does not propagate to your next MATLAB session.

---

# mean

---

**Purpose** Average or mean value of array

**Syntax**  
M = mean(A)  
M = mean(A,dim)

**Description** M = mean(A) returns the mean values of the elements along different dimensions of an array.

If A is a vector, mean(A) returns the mean value of A.

If A is a matrix, mean(A) treats the columns of A as vectors, returning a row vector of mean values.

If A is a multidimensional array, mean(A) treats the values along the first non-singleton dimension as vectors, returning an array of mean values.

M = mean(A,dim) returns the mean values for elements along the dimension of A specified by scalar dim. For matrices, mean(A,2) is a column vector containing the mean value of each row.

**Examples**

```
A = [1 2 3; 3 3 6; 4 6 8; 4 7 7];
mean(A)
ans =
    3.0000    4.5000    6.0000

mean(A,2)
ans =
    2.0000
    4.0000
    6.0000
    6.0000
```

**See Also** [corrcoef](#) | [cov](#) | [max](#) | [median](#) | [min](#) | [mode](#) | [std](#) | [var](#)

**Purpose** Median value of array

**Syntax** `M = median(A)`  
`M = median(A,dim)`

**Description** `M = median(A)` returns the median values of the elements along different dimensions of an array. `A` should be of type `single` or `double`.  
If `A` is a vector, `median(A)` returns the median value of `A`.  
If `A` is a matrix, `median(A)` treats the columns of `A` as vectors, returning a row vector of median values.  
If `A` is a multidimensional array, `median(A)` treats the values along the first nonsingleton dimension as vectors, returning an array of median values.  
`M = median(A,dim)` returns the median values for elements along the dimension of `A` specified by scalar `dim`.

**Examples**

```
A = [1 2 4 4; 3 4 6 6; 5 6 8 8; 5 6 8 8];
median(A)

ans =

     4     5     7     7

median(A,2)

ans =

     3
     5
     7
     7
```

**See Also** `corrcoef` | `cov` | `max` | `mean` | `min` | `mode` | `std` | `var`

# memmapfile

---

**Purpose** Construct memmapfile object

**Syntax**  
`m = memmapfile(filename)`  
`m = memmapfile(filename, prop1, value1, prop2, value2, ...)`

**Description** `m = memmapfile(filename)` constructs an object of the `memmapfile` class that maps file `filename` to memory using the default property values. The `filename` input is a quoted string that specifies the path and name of the file to be mapped into memory. `filename` must include a filename extension if the name of the file being mapped has an extension. The `filename` argument cannot include any wildcard characters (e.g., `*` or `?`), is case sensitive on The Open Group UNIX platforms, but is not case sensitive on Microsoft Windows platforms.

`m = memmapfile(filename, prop1, value1, prop2, value2, ...)` constructs an object of the `memmapfile` class that maps file `filename` into memory and sets the properties of that object that are named in the argument list (`prop1`, `prop2`, etc.) to the given values (`value1`, `value2`, etc.). All property name arguments must be quoted strings (e.g., `'Writable'`). Any properties that are not specified are given their default values.

Optional properties are shown in the table below and are described in the sections that follow.

| Property | Description                                                                                                        | Data Type                       | Default |
|----------|--------------------------------------------------------------------------------------------------------------------|---------------------------------|---------|
| Format   | Format of the contents of the mapped region, including data type, array shape, and variable or field name by which | char array or N-by-3 cell array | uint8   |

| Property | Description                                                                                                                                                  | Data Type | Default |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|---------|
|          | to access the data                                                                                                                                           |           |         |
| Offset   | Number of bytes from the start of the file to the start of the mapped region. This number is zero-based. That is, offset 0 represents the start of the file. | double    | 0       |
| Repeat   | Number of times to apply the specified format to the mapped region of the file                                                                               | double    | Inf     |
| Writable | Type of access allowed to the mapped region                                                                                                                  | logical   | false   |

There are three different ways you can specify a value for the Format property. See the following sections in the MATLAB Data Import and Export documentation for more information:

- “Mapping a Single Data Type”
- “Formatting the Mapped Data to an Array”
- “Mapping Multiple Data Types and Arrays”

Any of the following data types can be used when you specify a Format value. The default type is uint8.

# memmapfile

---

| Format String | Data Type Description    |
|---------------|--------------------------|
| 'int8'        | Signed 8-bit integers    |
| 'int16'       | Signed 16-bit integers   |
| 'int32'       | Signed 32-bit integers   |
| 'int64'       | Signed 64-bit integers   |
| 'uint8'       | Unsigned 8-bit integers  |
| 'uint16'      | Unsigned 16-bit integers |
| 'uint32'      | Unsigned 32-bit integers |
| 'uint64'      | Unsigned 64-bit integers |
| 'single'      | 32-bit floating-point    |
| 'double'      | 64-bit floating-point    |

## Tips

You can only map an existing file. You cannot create a new file and map that file to memory in one operation. Use the MATLAB file I/O functions to create the file before attempting to map it to memory.

Once `memmapfile` locates the file, MATLAB stores the absolute pathname for the file internally, and then uses this stored path to locate the file from that point on. This enables you to work in other directories outside your current work directory and retain access to the mapped file.

Once a `memmapfile` object has been constructed, you can change the value of any of its properties. Use the `objname.property` syntax in assigning the new value. To set a new offset value for memory map object `m`, type

```
m.Offset = 2048;
```

Property names are not case sensitive. For example, MATLAB considers `m.Offset` to be the same as `m.offset`.

## Examples

To run the following examples, create a file in your current folder called `records.dat`. Example 2 expects that `records.dat` contains

5000 double-precision values. The following code shows one method to create this file:

```
randData = gallery('uniformdata', [5000, 1], 0, 'double');

fid = fopen('records.dat','w');
fwrite(fid, randData, 'double');
fclose(fid);
```

## Example 1

To construct a map for `records.dat`, type the following:

```
m = memmapfile('records.dat');
```

MATLAB constructs an instance of the `memmapfile` class, assigns it to the variable `m`, and maps the entire `records.dat` file to memory, setting all properties of the object to their default values. In this example, the command maps the entire file as a sequence of unsigned 8-bit integers and gives the caller read-only access to its contents.

## Example 2

To construct a map using nondefault values for the `Offset`, `Format`, and `Writable` properties, type the following, enclosing all property names in single quotation marks:

```
m = memmapfile('records.dat',           ...
               'Offset', 1024,          ...
               'Format', 'uint32',      ...
               'Writable', true);
```

Type the object name to see the current settings for all properties:

```
m
```

```
m =
  Filename: 'd:\matlab\records.dat'
  Writable: true
  Offset: 1024
```

# memmapfile

---

```
Format: 'uint32'  
Repeat: Inf  
Data: 9744x1 uint32 array
```

## Example 3

Construct a `memmapfile` object for the entire file `records.dat` and set the `Format` property for that object to `uint64`. Any read or write operations made via the memory map will read and write the file contents as a sequence of unsigned 64-bit integers:

```
m = memmapfile('records.dat', 'Format', 'uint64');
```

## Example 4

Construct a `memmapfile` object for a region of `records.dat` such that the contents of the region are handled by MATLAB as a 4-by-10-by-18 array of unsigned 32-bit integers, and can be referenced in the structure of the returned object using the field name `x`:

```
m = memmapfile('records.dat', ...  
              'Offset', 1024, ...  
              'Format', {'uint32' [4 10 18] 'x'});
```

```
A = m.Data(1).x;
```

```
whos A
```

| Name | Size    | Bytes | Class        |
|------|---------|-------|--------------|
| A    | 4x10x18 | 2880  | uint32 array |

## Example 5

Map a file to three different data types: `int16`, `uint32`, and `single`. The `int16` data is mapped as a 2-by-2 matrix that can be accessed using the field name `model`. The `uint32` data is a scalar value accessed as field `serialno`. The `single` data is a 1-by-3 matrix named `expenses`. Repeat the pattern 1000 times.

Each of the fields belongs to the 1000-by-1 structure array `m.Data`:

```
m = memmapfile('records.dat', ...
               'Format', { ...
                   'int16' [2 2] 'model'; ...
                   'uint32' [1 1] 'serialno'; ...
                   'single' [1 3] 'expenses'}, ...
               'Repeat', 1000);
```

# memory

---

**Purpose** Display memory information

**Syntax**  
`memory`  
`userview = memory`  
`[userview systemview] = memory`

**Description** `memory` displays information showing how much memory is available and how much the MATLAB software is currently using. The information displayed at your computer screen includes the following items, each of which is described in a section below:

- “Maximum Possible Array” on page 2-2799
- “Memory Available for All Arrays” on page 2-2800
- “Memory Used By MATLAB” on page 2-2801
- “Total Physical Memory (RAM)” on page 2-2801

`userview = memory` returns user-focused information on memory use in structure `userview`. The information returned in `userview` includes the following items, each of which is described in a section below:

- “Maximum Possible Array” on page 2-2799
- “Memory Available for All Arrays” on page 2-2800
- “Memory Used By MATLAB” on page 2-2801

`[userview systemview] = memory` returns both user- and system-focused information on memory use in structures `userview` and `systemview`, respectively. The `userview` structure is described in the command syntax above. The information returned in `systemview` includes the following items, each of which is described in a section below:

- “Virtual Address Space” on page 2-2802
- “System Memory” on page 2-2802
- “Physical Memory” on page 2-2803

## Output Arguments

Each of the sections below describes a value that is displayed or returned by the `memory` function.

### Maximum Possible Array

Maximum Possible Array is the size of the largest contiguous free memory block. As such, it is an upper bound on the largest single array MATLAB can create at this time.

MATLAB derives this number from the smaller of the following two values:

- The largest contiguous memory block found in the MATLAB virtual address space
- The total available system memory

To see how many array elements this number represents, divide by the number of bytes in the array class. For example, for a `double` array, divide by 8. The actual number of elements MATLAB can create is always fewer than this number.

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. When you do assign the output, MATLAB returns the information in a structure field. See the table below.

| Command                    | Returned in                                             |
|----------------------------|---------------------------------------------------------|
| <code>memory</code>        | String labelled Maximum possible array:                 |
| <code>user = memory</code> | Structure field <code>user.MaxPossibleArrayBytes</code> |

All values are double-precision and in units of bytes.

### Footnotes

When you enter the `memory` command without specifying any outputs, MATLAB may also display one of the following footnotes. 32-bit systems show either the first or second footnote; 64-bit systems show only the second footnote:

Limited by contiguous virtual address space available.

There is sufficient system memory to allow mapping of all virtual addresses in the largest available block of the MATLAB process.

The maximum amount of total MATLAB virtual address space is either 2 GB or 3 GB, depending on whether the /3GB switch is in effect or not.

Limited by System Memory (physical + swap file) available.

There is insufficient system memory to allow mapping of all virtual addresses in the largest available block of the MATLAB process.

## Memory Available for All Arrays

Memory Available for All Arrays is the total amount of memory available to hold data. The amount of memory available is guaranteed to be at least as large as this field.

MATLAB derives this number from the smaller of the following two values:

- The total available MATLAB virtual address space
- The total available system memory

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. When you do assign the output, MATLAB returns the information in a structure field. See the table below.

| Command                    | Returned in                                             |
|----------------------------|---------------------------------------------------------|
| <code>memory</code>        | String labelled Memory available for all arrays:        |
| <code>user = memory</code> | Structure field <code>user.MemAvailableAllArrays</code> |

## Footnotes

When you enter the `memory` command without specifying any outputs, MATLAB may also display one of the following footnotes. 32-bit systems show either the first or second footnote; 64-bit systems show only the latter footnote:

Limited by virtual address space available.

There is sufficient system memory to allow mapping of all available virtual addresses in the MATLAB process virtual address space to system memory. The maximum amount of total MATLAB virtual address space is either 2 GB or 3 GB, depending on whether the /3GB switch is in effect or not.

Limited by System Memory (physical + swap file) available.

There is insufficient system memory to allow mapping of all available virtual addresses in the MATLAB process.

### Memory Used By MATLAB

Memory Used By MATLAB is the total amount of system memory reserved for the MATLAB process. It is the sum of the physical memory and potential swap file usage.

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. When you do assign the output, MATLAB returns the information in a structure field. See the table below.

| Command                    | Returned in                                     |
|----------------------------|-------------------------------------------------|
| <code>memory</code>        | String labelled Memory used by MATLAB:          |
| <code>user = memory</code> | Structure field <code>user.MemUsedMATLAB</code> |

### Total Physical Memory (RAM)

Physical Memory (RAM) is the total physical memory (or RAM) in the computer.

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. See the table below.

| Command             | Returned in                            |
|---------------------|----------------------------------------|
| <code>memory</code> | String labelled Physical Memory (RAM): |

## Virtual Address Space

Virtual Address Space is the amount of available and total virtual memory for the MATLAB process. MATLAB returns the information in two fields of the return structure: Available and Total.

| Command                | Return Value        | Returned in Structure Field       |
|------------------------|---------------------|-----------------------------------|
| [user,sys] =<br>memory | Available<br>memory | sys.VirtualAddressSpace.Available |
|                        | Total memory        | sys.VirtualAddressSpace.Total     |

You can monitor the difference:

```
VirtualAddressSpace.Total - VirtualAddressSpace.Available
```

as the Virtual Bytes counter in the WindowsPerformance program. (e.g., Windows XP Control Panel/Administrative Tool/Performance program).

## System Memory

System Memory is the amount of available system memory on your computer system. This number includes the amount of available physical memory and the amount of available swap file space on the computer running MATLAB. MATLAB returns the information in the SystemMemory field of the return structure.

| Command                | Return Value        | Returned in Structure Field |
|------------------------|---------------------|-----------------------------|
| [user,sys] =<br>memory | Available<br>memory | sys.SystemMemory            |

This is the same as the difference:

```
limit - total (in bytes)
```

found in the Windows Task Manager: Performance/Commit Charge.

## Physical Memory

Physical Memory is the available and total amounts of physical memory (RAM) on the computer running MATLAB. MATLAB returns the information in two fields of the return structure: Available and Total.

| Command                | Value               | Returned in Structure Field  |
|------------------------|---------------------|------------------------------|
| [user,sys] =<br>memory | Available<br>memory | sys.PhysicalMemory.Available |
|                        | Total memory        | sys.PhysicalMemory.Total     |

Available physical memory is the same as:

Available (in bytes)

found in the Windows Task Manager: Performance/Physical Memory

The total physical memory is the same as

Total (in bytes)

found in the Windows Task Manager: Performance/Physical Memory

You can use the amount of available physical memory as a measure of how much data you can access quickly.

## Tips

The `memory` function is currently available on Microsoft Windows systems only. Results vary, depending on the computer running MATLAB, the load on that computer, and what MATLAB is doing at the time.

## Details on Memory Used By MATLAB

MATLAB computes the value for Memory Used By MATLAB by walking the MATLAB process memory structures and summing all the sections that have physical storage allocated in memory or in the paging file on disk.

Using the Windows Task Manager, you have for the MATLAB.exe image:

$$\text{Mem Usage} < \text{MemUsedMATLAB} < \text{Mem Usage} + \text{VM Size (in bytes)}$$

where both of the following are true:

- Mem Usage is the working set size in kilobytes.
- VM Size is the page file usage, or private bytes, in kilobytes.

The working set size is the portion of the MATLAB virtual address space that is *currently* resident in RAM and can be referenced without a memory page fault. The page file usage gives the portion of the MATLAB virtual address space that requires a backup that doesn't already exist. Another name for page file usage is *private bytes*. It includes all MATLAB variables and workspaces. Since some of the pages in the page file may also be part of the working set, this sum is an overestimate of MemUsedMATLAB. Note that there are virtual pages in the MATLAB process space that already have a backup. For example, code loaded from EXEs and DLLs and memory-mapped files. If any part of those files is in memory when the memory builtin is called, that memory will be counted as part of MemUsedMATLAB.

## Reserved Addresses

Reserved addresses are addresses sets aside in the process virtual address space for some specific future use. These reserved addresses reduce the size of MemAvailableAllArrays and can reduce the size of the current or future value of MaxPossibleArrayBytes.

### Example 1 – Java Virtual Machine (JVM)

At MATLAB startup, part of the MATLAB virtual address space is reserved by the Java Virtual Machine (JVM) and cannot be used for storing MATLAB arrays.

### Example 2 – Standard Windows Heap Manager

MATLAB, by default, uses the standard Windows heap manager except for a set of small preselected allocation sizes. One characteristic of this heap manager is that its behavior depends upon whether the requested allocation is less than or greater than the fixed number of 524,280 bytes.

For, example, if you create a sequence of MATLAB arrays, each less than 524,280 bytes, and then clear them all, the MemUsedMATLAB value before and after shows little change, and the MemAvailableAllArrays value is now smaller by the total space allocated.

The result is that, instead of globally freeing the extra memory, the memory becomes reserved. It can *only* be reused for arrays less than 524,280 bytes. You cannot reclaim this memory for a larger array except by restarting MATLAB.

## Examples

Display memory statistics on a 32-bit Windows system:

```
memory
```

```
Maximum possible array:          677 MB (7.101e+008 bytes) *
Memory available for all arrays: 1601 MB (1.679e+009 bytes) **
Memory used by MATLAB:           446 MB (4.681e+008 bytes)
Physical Memory (RAM):           3327 MB (3.489e+009 bytes)
```

\* Limited by contiguous virtual address space available.

\*\* Limited by virtual address space available.

Return in the structure `userview`, information on the largest array MATLAB can create at this time, how much memory is available to hold data, and the amount of memory currently being used by your MATLAB process:

```
userview = memory
```

```
userview =
    MaxPossibleArrayBytes: 710127616
    MemAvailableAllArrays: 1.6792e+009
    MemUsedMATLAB: 468127744
```

Assign the output to two structures, `user` and `sys`, to obtain the information shown here:

```
[user sys] = memory;
```

# memory

---

```
% --- Largest array MATLAB can create ---
user.MaxPossibleArrayBytes
ans =
    710127616

% --- Memory available for data ---
user.MemAvailableAllArrays
ans =
    1.6797e+009

% --- Memory used by MATLAB process ---
user.MemUsedMATLAB
ans =
    467603456

% --- Virtual memory for MATLAB process ---
sys.VirtualAddressSpace
ans =
    Available: 1.6797e+009
    Total: 2.1474e+009

% --- Physical memory and paging file ---
sys.SystemMemory
ans =
    Available: 4.4775e+009

% --- Computer's physical memory ---
sys.PhysicalMemory
ans =
    Available: 2.3941e+009
    Total: 3.4889e+009
```

# menu

---

**Purpose** Generate menu of choices for user input

**Syntax**  
`choice = menu('mtitle','opt1','opt2',..., 'optn')`  
`choice = menu('mtitle',options)`

**Description** `choice = menu('mtitle','opt1','opt2',..., 'optn')` displays the menu whose title is in the string variable 'mtitle' and whose choices are string variables 'opt1', 'opt2', and so on. The menu opens in a modal dialog box. `menu` returns the number of the selected menu item, or 0 if the user clicks the close button on the window.

`choice = menu('mtitle',options)` , where `options` is a 1-by-N cell array of strings containing the menu choices.

If the user's terminal provides a graphics capability, `menu` displays the menu items as push buttons in a figure window (Example 1). Otherwise, they will be given as a numbered list in the Command Window (Example 2).

**Tips** To call `menu` from a `uicontrol` or other `ui` object, set that object's `Interruptible` property to 'on'. For more information, see `Uicontrol Properties`.

## **Examples** **Example 1**

On a system with a display, `menu` displays choices as buttons in a dialog box:

```
choice = menu('Choose a color','Red','Blue','Green')
```

displays the following dialog box.

The number entered by the user in response to the prompt is returned as `choice` (i.e., `choice = 2` implies that the user selected Blue).

After input is accepted, the dialog box closes, returning the output in `choice`. You can use `choice` to control the color of a graph:

```
t = 0:.1:60;  
s = sin(t);  
color = ['r','g','b']  
plot(t,s,color(choice))
```

## Example 2

On a system without a display, `menu` displays choices in the Command Window:

```
choice = menu('Choose a color','Red','Blue','Green')
```

displays the following text.

```
----- Choose a color -----  
1) Red  
2) Blue  
3) Green  
Select a menu number:
```

# mesh

---

## Purpose

Mesh plot

## Syntax

```
mesh(X,Y,Z)
mesh(Z)
mesh(...,C)
mesh(...,'PropertyName',PropertyValue,...)
mesh(axes_handles,...)
h = mesh(...)
```

## Description

`mesh(X,Y,Z)` draws a wireframe mesh with color determined by `Z`, so color is proportional to surface height. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case,  $(X(j), Y(i), Z(i,j))$  are the intersections of the wireframe grid lines; `X` and `Y` correspond to the columns and rows of `Z`, respectively. If `X` and `Y` are matrices,  $(X(i,j), Y(i,j), Z(i,j))$  are the intersections of the wireframe grid lines.

`mesh(Z)` draws a wireframe mesh using `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a rectangular grid. Color is proportional to surface height.

`mesh(...,C)` draws a wireframe mesh with color determined by matrix `C`. MATLAB performs a linear transformation on the data in `C` to obtain colors from the current colormap. If `X`, `Y`, and `Z` are matrices, they must be the same size as `C`.

`mesh(...,'PropertyName',PropertyValue,...)` sets the value of the specified surface property. Multiple property values can be set with a single statement.

`mesh(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = mesh(...)` returns a handle to a Surfaceplot graphics object.

**Tips**

mesh does not accept complex inputs.

A mesh is drawn as a `Surfaceplot` graphics object with the viewpoint specified by `view(3)`. The face color is the same as the background color (to simulate a wireframe with hidden-surface elimination), or none when drawing a standard see-through wireframe. The current colormap determines the edge color. The `hidden` command controls the simulation of hidden-surface elimination in the mesh, and the `shading` command controls the shading model.

**Examples**

Evaluate  $\sin(r)/r$ , or the *sinc* function

```
figure;  
[X,Y] = meshgrid(-8:.5:8);  
R = sqrt(X.^2 + Y.^2) + eps;  
Z = sin(R)./R;  
mesh(Z);
```

# mesh

---

---

Displaying the *sinc* function between -8 and 8 on a 2-D grid

```
figure;  
mesh(X,Y,Z);  
axis([-8 8 -8 8 -0.5 1]);
```

Specifying color matrix for the data in the mesh function

```
C = gradient(Z);  
figure;  
mesh(X,Y,Z,C);
```

# mesh

---

---

Specifying the property name-value pairs in the argument list.

```
C = del2(Z);  
h = axes;  
mesh(h,Z,C,'FaceLighting','gouraud','LineWidth',0.3);
```

`meshc` | `meshz` | `hidden` | `griddata` | `TriScatteredInterp` | `meshgrid` | `surface` | `surf` | `waterfall` | `axis` | `colormap` | `hold` | `shading` | `view`

**How To**

- “Representing Data as a Surface”

# meshc

---

## Purpose

Plot a contour graph under mesh graph

## Syntax

```
meshc(X,Y,Z)
meshc(Z)
meshc(...,C)
meshc(axes_handles,...)
h = meshc(...)
```

## Description

`meshc(X,Y,Z)` draws a wireframe mesh and a contour plot under it with color determined by `Z`, so color is proportional to surface height. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case, `(X(j), Y(i), Z(i,j))` are the intersections of the wireframe grid lines; `X` and `Y` correspond to the columns and rows of `Z`, respectively. If `X` and `Y` are matrices, `(X(i,j), Y(i,j), Z(i,j))` are the intersections of the wireframe grid lines.

`meshc(Z)` draws a contour plot under wireframe mesh using `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a rectangular grid. Color is proportional to surface height.

`meshc(...,C)` draws a `meshc` graph with color determined by matrix `C`. MATLAB performs a linear transformation on the data in `C` to obtain colors from the current colormap. If `X`, `Y`, and `Z` are matrices, they must be the same size as `C`.

`meshc(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = meshc(...)` returns a handle to a `Surfaceplot` graphics object.

## Tips

`meshc` does not accept complex inputs.

A mesh is drawn as a `Surfaceplot` graphics object with the viewpoint specified by `view(3)`. The face color is the same as the background

color (to simulate a wireframe with hidden-surface elimination), or none when drawing a standard see-through wireframe. The current colormap determines the edge color. The hidden command controls the simulation of hidden-surface elimination in the mesh, and the shading command controls the shading model.

## Examples

Produce a combination mesh and contour plot of the peaks surface with meshc:

```
figure
[X,Y] = meshgrid(-3:.125:3);
Z = peaks(X,Y);
meshc(Z);
```

---

Specifying axes limits for the meshc function.

```
figure;  
meshc(X,Y,Z);  
axis([-3 3 -3 3 -10 5]);
```

## Algorithms

The range of  $X$ ,  $Y$ , and  $Z$ , or the current settings of the axes `XLimMode`, `YLimMode`, and `ZLimMode` properties, determine the axis limits. `axis` sets these properties.

The range of  $C$ , or the current settings of the axes `CLim` and `CLimMode` properties (also set by the `caxis` function), determine the color scaling. The scaled color values are used as indices into the current colormap.

The mesh rendering functions produce color values by mapping the  $z$  data values (or an explicit color array) onto the current colormap. The

# meshc

---

MATLAB default behavior is to compute the color limits automatically using the minimum and maximum data values (also set using `caxis auto`). The minimum data value maps to the first color value in the colormap and the maximum data value maps to the last color value in the colormap. MATLAB performs a linear transformation on the intermediate values to map them to the current colormap.

`meshc` calls `mesh`, turns `hold` on, and then calls `contour` and positions the contour on the  $x$ - $y$  plane. For additional control over the appearance of the contours, issue these commands directly. You can combine other types of graphs in this manner, for example `surf` and `pcolor` plots.

`meshc` assumes that  $X$  and  $Y$  are monotonically increasing. If  $X$  or  $Y$  is irregularly spaced, `contour3` calculates contours using a regularly spaced contour grid, and then it transforms the data to  $X$  or  $Y$ .

**Purpose** Plot a curtain around mesh plot

**Syntax**

```
meshz(X,Y,Z)
meshz(Z)
meshz(...,C)
meshz(axes_handles,...)
h = meshz(...)
```

**Description** `meshz(X,Y,Z)` draws a curtain around the wireframe mesh with color determined by `Z`, so color is proportional to surface height. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case, `(X(j), Y(i), Z(i,j))` are the intersections of the wireframe grid lines; `X` and `Y` correspond to the columns and rows of `Z`, respectively. If `X` and `Y` are matrices, `(X(i,j), Y(i,j), Z(i,j))` are the intersections of the wireframe grid lines.

`meshz(Z)` draws a curtain around the wireframe mesh using `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a rectangular grid. Color is proportional to surface height.

`meshz(...,C)` draws a `meshz` graph with color determined by matrix `C`. MATLAB performs a linear transformation on the data in `C` to obtain colors from the current colormap. If `X`, `Y`, and `Z` are matrices, they must be the same size as `C`.

`meshz(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = meshz(...)` returns a handle to a `Surfaceplot` graphics object.

**Tips** `meshz` does not accept complex inputs.

A mesh is drawn as a `Surfaceplot` graphics object with the viewpoint specified by `view(3)`. The face color is the same as the background

color (to simulate a wireframe with hidden-surface elimination), or none when drawing a standard see-through wireframe. The current colormap determines the edge color. The hidden command controls the simulation of hidden-surface elimination in the mesh, and the shading command controls the shading model.

## Examples

Generate a curtain plot for the peaks function using meshz

```
figure
[X,Y] = meshgrid(-3:.125:3);
Z = peaks(X,Y);
meshz(Z);
```

Specifying axes limits for the graph

```
figure;  
meshz(X,Y,Z);  
axis([-3 3 -3 3 -7 9]);
```

---

Specifying a color matrix

```
C = gradient(Z);  
figure;  
meshz(X,Y,Z,C);
```

**See Also**

`mesh` | `meshc` | `contour` | `hidden` | `meshgrid` | `surface` | `surf` |

`shading` | `view`

# meshgrid

---

**Purpose** Rectangular grid in 2-D and 3-D space

**Syntax**  
`[X,Y] = meshgrid(xgv,ygv)`  
`[X,Y,Z] = meshgrid(xgv,ygv,zgv)`  
`[X,Y] = meshgrid(gv)`  
`[X,Y,Z] = meshgrid(gv)`

**Description** `[X,Y] = meshgrid(xgv,ygv)` replicates the grid vectors `xgv` and `ygv` to produce a full grid. This grid is represented by the output coordinate arrays `X` and `Y`. The output coordinate arrays `X` and `Y` contain copies of the grid vectors `xgv` and `ygv` respectively. The sizes of the output arrays are determined by the length of the grid vectors. For grid vectors `xgv` and `ygv` of length `M` and `N` respectively, `X` and `Y` will have `N` rows and `M` columns.

`[X,Y,Z] = meshgrid(xgv,ygv,zgv)` produces three-dimensional coordinate arrays. The output coordinate arrays `X`, `Y`, and `Z` contain copies of the grid vectors `xgv`, `ygv`, and `zgv` respectively. The sizes of the output arrays are determined by the length of the grid vectors. For grid vectors `xgv`, `ygv`, and `zgv` of length `M`, `N`, and `P` respectively, `X`, `Y`, and `Z` will have `N` rows, `M` columns, and `P` pages.

`[X,Y] = meshgrid(gv)` is the same as `[X,Y] = meshgrid(gv,gv)`. In other words, you can reuse the same grid vector in each respective dimension. The dimensionality of the output arrays is determined by the number of output arguments.

`[X,Y,Z] = meshgrid(gv)` is the same as `[X,Y,Z] = meshgrid(gv,gv,gv)`. Again, the dimensionality of the output arrays is determined by the number of output arguments.

The output coordinate arrays are typically used to evaluate functions of two or three variables. They are also frequently used to create surface and volumetric plots.

**Input Arguments**

**`xgv,ygv,zgv`**

Grid vectors specifying a series of grid point coordinates in the `x`, `y` and `z` directions, respectively.

## gv

Generic grid vector specifying a series of point coordinates.

## Output Arguments

### X,Y,Z

Output arrays that specify the full grid.

## Tips

The `meshgrid` function is similar to `ndgrid`, however `meshgrid` is restricted to 2-D and 3-D while `ndgrid` supports 1-D to N-D. The coordinates output by each function are the same, but the shape of the output arrays in the first two dimensions are different. For grid vectors `x1gv`, `x2gv` and `x3gv` of length `M`, `N` and `P` respectively, `meshgrid(x1gv, x2gv)` will output arrays of size `N-by-M` while `ndgrid(x1gv, x2gv)` outputs arrays of size `M-by-N`. Similarly, `meshgrid(x1gv, x2gv, x3gv)` will output arrays of size `N-by-M-by-P` while `ndgrid(x1gv, x2gv, x3gv)` outputs arrays of size `M-by-N-by-P`. See “Grid Representation” in the MATLAB Mathematics documentation for more information.

## Examples

Create a full grid from two monotonically increasing grid vectors:

```
[X,Y] = meshgrid(1:3,10:14)
```

```
X =
```

```

     1     2     3
     1     2     3
     1     2     3
     1     2     3
     1     2     3
```

```
Y =
```

```

    10    10    10
    11    11    11
    12    12    12
    13    13    13
    14    14    14
```

Use `meshgrid` to create a 3-D surface plot of a function:

# meshgrid

---

```
[X,Y] = meshgrid(-2:.2:2, -2:.2:2);  
Z = X .* exp(-X.^2 - Y.^2);  
surf(X,Y,Z)
```

## See Also

## How To

- “Interpolating Gridded Data”

## Purpose

`meta.class` class describes MATLAB classes

## Description

Instances of the `meta.class` class contains information about MATLAB classes. The read/write properties of the `meta.class` class correspond to class attributes and are set only from within class definitions on the `classdef` line. You can query the read-only properties of the `meta.class` object to obtain information that is specified syntactically by the class (for example, to obtain the name of the class).

You cannot instantiate a `meta.class` object directly. You can construct a `meta.class` object from an instance of a class or using the class name:

- `metaclass` — returns a `meta.class` object representing the object passed as an argument.
- `?ClassName` — returns a `meta.class` object representing the named class.
- `fromName` — static method returns a `meta.class` object representing the named class.

For example, the `metaclass` function returns the `meta.class` object representing `MyClass`.

```
ob = MyClass;  
obmeta = metaclass(ob);  
obmeta.Name  
ans =  
MyClass
```

You can use the class name to obtain the `meta.class` object:

```
obmeta = ?MyClass;
```

You can also use the `fromName` static method:

```
obmeta = meta.class.fromName('MyClass');
```

# meta.class

---

## Properties

| Property                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**How To**

- “Getting Information About Classes and Objects”

# meta.class.fromName

---

**Purpose** Return `meta.class` object associated with named class

**Syntax** `mcls = meta.class.fromName('ClassName')`

**Description** `mcls = meta.class.fromName('ClassName')` is a static method that returns the `meta.class` object associated with the class `ClassName`. Note that you can also use the `?` operator to obtain the `meta.class` object for a class name:

```
mcls = ?ClassName;
```

The equivalent call to `meta.class.fromName` is:

```
mcls = meta.class.fromName('ClassName');
```

Use `meta.class.fromName` when using a char variable for the class name:

```
function mcls = getMetaClass(cname)
    % Do error checking
    mcls = meta.class.fromName(cname);
    ...
end
```

**See Also** `meta.class`

## Purpose

`meta.DynamicProperty` class describes dynamic property of MATLAB object

## Description

The `meta.DynamicProperty` class contains descriptive information about dynamic properties that you have added to an instance of a MATLAB classes. The MATLAB class must be a subclass of `dynamicprops`. The properties of the `meta.DynamicProperty` class correspond to property attributes that you specify from within class definitions. Dynamic properties are not defined in `classdef` blocks, but you can set their attributes by setting the `meta.DynamicProperty` object properties.

You add a dynamic property to an object using the `addprop` method of the `dynamicprops` class. The `addprop` method returns a `meta.DynamicProperty` instance representing the new dynamic property. You can modify the properties of the `meta.DynamicProperty` object to set the attributes of the dynamic property or to add set and get access methods, which would be defined in the `classdef` for regular properties.

You cannot instantiate the `meta.DynamicProperty` class. You must use `addprop` to obtain a `meta.DynamicProperty` object.

To remove the dynamic property, call the `delete` handle class method on the `meta.DynamicProperty` object.

Obtain a `meta.DynamicProperty` object from the `addprops` method, which returns an array of `meta.DynamicProperty` objects, one for each dynamic property.

See “Dynamic Properties — Adding Properties to an Instance” for more information.

## Properties

# meta.DynamicProperty

---

| Property                                 | Purpose                                                                                                                                                                                                                                   |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DefiningClass                            | The meta.class object representing the class that defines this property.                                                                                                                                                                  |
| GetAccess attribute, default = public    | public – unrestricted access<br>protected – access from class or subclasses<br>private – access by class members only                                                                                                                     |
| SetAccess attribute, default = public    | public – unrestricted access<br>protected – access from class or subclasses<br>private – access by class members only                                                                                                                     |
| Dependent attribute, default = false     | If false, property value is stored in object. If true, property value is not stored in object and the set and get functions cannot access the property by indexing into the object using the property name.<br>See “Property Get Methods” |
| Transient attribute, default = false     | If true, property value is not saved when object is saved to a file. See “Understanding the Save and Load Process” for more about saving objects.                                                                                         |
| Hidden attribute, default = false        | Determines whether the property should be shown in a property list (e.g., Property Inspector, call to properties, etc.).                                                                                                                  |
| GetObservable attribute, default = false | If true, and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are queried. See “Property-Set and Query Events”                                 |

| Property                                       | Purpose                                                                                                                                                                                                    |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SetObservable<br>attribute, default<br>= false | If true, and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are modified. See “Property-Set and Query Events” |
| GetMethod                                      | Function handle of the get method associated with this property. Empty if there is no get method specified. See “Get Method Syntax”                                                                        |
| SetMethod                                      | Function handle of the set method associated with this property. Empty if there is no set method specified. See “Property Set Methods”                                                                     |
| HasDefault                                     | Always false. Dynamic properties cannot define default values.                                                                                                                                             |

## Events

See “Listen for Changes to Property Values” for information on using property events.

| Event Name           | Purpose                                                 |
|----------------------|---------------------------------------------------------|
| PreGet               | Event occurs just before property is queried.           |
| PostGet              | Event occurs just after property has been queried       |
| PreSet               | Event occurs just before this property is modified      |
| PostSet              | Event occurs just after this property has been modified |
| ObjectBeingDestroyed | Inherited from handle                                   |

# meta.EnumeratedValue

---

## Purpose

Describes enumeration members of MATLAB class

## Description

The `meta.EnumeratedValue` class contains information about enumeration members defined by MATLAB classes. The properties of a `meta.EnumeratedValue` object correspond to the attributes of the enumeration member being described.

All `meta.EnumeratedValue` properties are read-only. Query the `meta.EnumeratedValue` object to obtain information about the enumeration member it describes.

Obtain a `meta.EnumeratedValue` object from the `EnumerationMemberList` property of the `meta.class` object. `EnumerationMemberList` is an array of `Meta.EnumeratedValue` instances, one per enumeration member.

The `meta.EnumeratedValue` class is a subclass of the `handle` class.

## Example

To access the `meta.EnumeratedValue` objects for a class, first create a `meta.class` object for that class. For example, give the following `OnOff` class definition:

```
classdef OnOff < logical
    enumeration
        On (true)
        Off (false)
    end
end
```

Obtain a `meta.EnumeratedValue` object from the `EnumerationMemberList` property of the `meta.class` object:

```
% Obtain the meta.class instance for the OnOff class
mc = ?OnOff;
% Get the array of EnumerateValue objects
enumList = mc.EnumerationMemberList;
% Access the Name property of the first object in the array
enumList(1).Name =
```

```
ans =  
On
```

## Properties

| Property                      | Purpose                                                                         |
|-------------------------------|---------------------------------------------------------------------------------|
| Name read only                | Name of the enumeration member associated with this meta.EnumeratedValue object |
| Description read only         | This property is not used                                                       |
| DetailedDescription read only | This property is not used                                                       |

## How To

- “Working with Enumerations”
- “Getting Information About Classes and Objects”

# meta.event

---

## Purpose

meta.event class describes MATLAB class events

## Description

The meta.event class provides information about MATLAB class events. The read/write properties of the meta.event class correspond to event attributes and are specified only from within class definitions.

You can query the read-only properties of the meta.event object to obtain information that is specified syntactically by the class (for example, to obtain the name of the class defining the event).

You cannot instantiate a meta.event object directly. Obtain a meta.event object from the meta.class EventList property, which contains an array of meta.event objects, one for each event defined by the class. For example, replace *ClassName* with the name of the class whose events you want to query:

```
mco = ?ClassName;  
elist = mco.EventList;  
elist(1).Name; % name of first event in list
```

Use the metaclass function to obtain a meta.class object from a class instance:

```
mco = metaclass(obj);
```

## Properties

| Property                      | Purpose            |
|-------------------------------|--------------------|
| Name read only                | Name of the event. |
| Description read only         | Currently not used |
| DetailedDescription read only | Currently not used |

| Property     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hidden       | If true, the event does not appear in the list of events returned by the events function (or other event listing functions or viewers)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| ListenAccess | <p>Determines where you can create listeners for the event.</p> <ul style="list-style-type: none"><li>• <code>public</code> — unrestricted access</li><li>• <code>protected</code> — access from methods in class or subclasses</li><li>• <code>private</code> — access by class methods only (not from subclasses)</li><li>• List classes that have listen access to this event. | <b>Superclasses</b>   | Heterogeneous                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Purpose</b>        | Superclass for MATLAB object metadata                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b>    | <p>The <code>meta.MetaData</code> class of objects represent MATLAB class definitions and the constituent parts of those definitions, such as properties and methods. Metadata enable a program to get information about a class definition.</p> <p>The <code>meta.MetaData</code> class forms the root of the metadata class hierarchy, which enables the formation of arrays of metadata objects belonging to different specific classes.</p> <p>MATLAB uses instances of the <code>meta.MetaData</code> class as the default object to fill in missing array elements.</p> <p><code>findobj</code> and <code>findprop</code>, can search the metadata hierarchy and return an array of different metadata objects. These function require the ability to form heterogeneous arrays containing various metaclass objects.</p> <p>See the <code>matlab.mixin.Heterogeneous</code> class for more information on heterogeneous hierarchies.</p> |
| <b>Construction</b>   | You cannot create an instance of the <code>meta.MetaData</code> class directly. MATLAB constructs instances of this class as required.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Copy Semantics</b> | Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB Programming Fundamentals documentation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Examples</b>       | <p>This example shows how the <code>meta.MetaData</code> class facilitates working with metaclasses.</p> <p>Create a <code>meta.class</code> instance representing the MATLAB <code>timeseries</code> class:</p> <pre>&gt;&gt; mc = ?timeseries;</pre> <p>MATLAB uses <code>meta.MetaData</code> objects to fill empty array elements:</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

# meta.MetaData

---

```
>> m(2) = mc
>> class(m(1))
```

```
ans =
```

```
meta.MetaData
>> class(m(2))
```

```
ans =
```

```
meta.class
```

Use `findobj` to find all properties and methods that have protected access:

```
>> protectedMembers = findobj(mc,{'Access','protected'},...
'-or',{'SetAccess','protected'},...
'-or',{'GetAccess','protected'}});
```

The `timeseries` class defines both properties and methods that have protected access. Therefore, `findobj` returns a heterogeneous array of class `meta.MetaData`. This array contains both `meta.property` and `meta.method` objects.

```
>> protectedMembers
```

```
protectedMembers =
```

```
11x1 heterogeneous meta.MetaData (meta.property, meta.method)
```

```
handle with no properties.
```

```
Package: meta
```

```
>> class(protectedMembers(1))
```

```
ans =
```

```
meta.property
```

```
>> protectedMembers(1).Name
```

```
ans =  
  
Length  
>> protectedMembers(1).SetAccess  
  
ans =  
  
protected  
>> protectedMembers(1).GetAccess  
  
ans =  
  
public
```

# meta.method

---

## Purpose

`meta.method` class describes MATLAB class methods

## Description

The `meta.method` class provides information about the methods of MATLAB classes. The read/write properties of the `meta.method` class correspond to method attributes and are specified only from within class definitions.

You can query the read-only properties of the `meta.method` object to obtain information that is specified syntactically by the class (for example, to obtain the name of the class defining a method).

You cannot instantiate a `meta.method` object directly. Obtain a `meta.method` object from the `meta.class` `MethodList` property, which contains an array of `meta.method` objects, one for each class method. For example, replace `ClassName` with the name of the class whose methods you want to query:

```
mco = ?ClassName;  
mlist = mco.MethodList;  
mlist(1).Name; % name of first method in the list
```

Use the `metaclass` function to obtain a `meta.class` object from a class instance:

```
mco = metaclass(obj);
```

## Properties

| Property | Purpose                                                                                                                                                                                                                                                                                            |

| Hidden attribute, default = <code>false</code>  | When <code>false</code> , the method name shows in the list of methods displayed using the <code>methods</code> or <code>methodsview</code> commands. If set to <code>true</code> , the method name is not included in these listings.                       |
| Name read only                                  | Name of the method.                                                                                                                                                                                                                                          |

# meta.method

---

| Property                          | Purpose                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sealed attribute, default = false | If true, the method cannot be redefined in a subclass. Attempting to define a method with the same name in a subclass causes an error.                                                                                                                                                                                                                      |
| Static attribute, default = false | Set to true to define a method that does not depend on an object of the class and does not require an object argument. Call static methods using the class name in place of the object:<br><br><code>classname.methodname()</code><br><br>Or with an instance of the class, like any method:<br><br><code>o.methodname()</code><br><br>See “Static Methods” |

## How To

- “Methods”
- “Getting Information About Classes and Objects”

**Purpose** meta.package class describes MATLAB packages

**Description** The meta.package class contains information about MATLAB packages. You cannot instantiate a meta.package object directly. Obtain a meta.package object from the meta.class ContainingPackage property, which contains a meta.package object, or an empty object, if the class is not in a package.

## Properties

| Property                                     | Purpose                                                                                                                                |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| Name read only                               | Name of the package associated with this meta.package object                                                                           |
| ClassList read only                          | List of classes that are scoped to this package. An object array of meta.class objects.                                                |
| Classes read only Use ClassList instead      | List of classes that are scoped to this package. A cell array of meta.class objects.                                                   |
| FunctionList read only                       | List of functions that are scoped to this package. An object array of function handles.                                                |
| Functions read only Use FunctionList instead | List of functions that are scoped to this package. A cell array of function handles.                                                   |
| PackageList read only                        | List of packages that are scoped to this package. An object array of meta.package objects.                                             |
| Packages read only Use PackageList instead   | List of packages that are scoped to this package. A cell array of meta.package objects.                                                |
| ContainingPackage read only                  | A meta.package object describing the package within which this package is contained, or an empty object if this package is not nested. |

# meta.package

---

## Methods

| Method         | Purpose                                                                                                      |
|----------------|--------------------------------------------------------------------------------------------------------------|
| fromName       | Static method returns a <code>meta.package</code> object for a specified package name.                       |
| getAllPackages | Static method returns a cell array of <code>meta.package</code> objects representing all top-level packages. |

## How To

- “Getting Information About Classes and Objects”

## Purpose

Find abstract methods and properties

## Syntax

```
meta.abstractDetails(ClassName)
meta.abstractDetails(mc)
absMembers = meta.abstractDetails( ___ )
```

## Description

`meta.abstractDetails(ClassName)` displays a list of abstract methods and properties for the class with name `ClassName`. Use the fully specified name for classes in packages. MATLAB displays all public and protected abstract methods and properties, including those declared `Hidden`.

`meta.abstractDetails(mc)` displays a list of abstract methods and properties for the class represented by the `meta.class` object `mc`.

`absMembers = meta.abstractDetails( ___ )` returns an array of the metaclass objects corresponding to the abstract members of the class, and can include any of the input arguments in previous syntaxes. If the class has both abstract methods and abstract properties, `absMembers` is a heterogeneous array of class `meta.Metadata` containing `meta.method` and `meta.property` objects.

A class can be abstract without defining any abstract methods or properties if it declares the `Abstract` class attribute. In this case, `meta.abstractDetails` returns no abstract members for that class, but the class is abstract. See “Determine If a Class Is Abstract” for more information.

## Input Arguments

### ClassName

Name of the class specified as a character string (for example, 'MyClass')

### mc

`meta.class` object representing the class (for example, ?MyClass)

# meta.abstractDetails

---

## Output Arguments

### **absMembers**

Array of metaclass objects representing abstract class members

## Examples

### **Display Abstract Member Names**

Define the class, AbsBase, with an abstract property:

```
classdef AbsBase
    properties (Abstract)
        Prop1
    end
    methods(Abstract)
        result = methodOne(obj)
        output = methodTwo(obj)
    end
end
```

Pass the class name (AbsBase) as a string:

```
meta.abstractDetails('AbsBase')
```

meta.abstractDetails displays the names of the abstract properties and methods defined in the class AbsBase.

```
Abstract methods for class AbsBase:
    methodTwo    % defined in AbsBase
    methodOne    % defined in AbsBase
```

```
Abstract properties for class AbsBase:
    Prop1    % defined in AbsBase
```

### **Return Abstract Member Metaclass Objects**

Pass a meta.class object representing the AbsBase class and return the metaclass objects for the abstract members. Use the definition of the AbsBase class from the previous example.

```
mc = ?AbsBase;
```

```
absMembers = meta.abstractDetails(mc);
```

`absMembers` is a heterogeneous array containing a `meta.property` object for the `Prop1` abstract property and `meta.method` objects for the `methodOne` and `methodTwo` abstract methods.

List the names of the metaclass objects.

```
for k=1:length(absMembers)
    disp(absMembers(k).Name)
end
```

```
methodTwo
methodOne
Prop1
```

## Find Inherited Abstract Members

Derive the `SubAbsBase` class from `AbsBase`, which is defined in a previous example.

```
classdef SubAbsBase < AbsBase
    properties
        SubProp = 1;
    end
    methods
        function result = methodOne(obj)
            result = obj.SubProp + 1;
        end
    end
end
```

Display the names of the abstract members inherited by `SubAbsBase`.

```
meta.abstractDetails('SubAbsBase')
```

```
Abstract methods for class SubAbsBase:
    methodTwo    % defined in AbsBase
```

# meta.abstractDetails

---

```
Abstract properties for class SubAbsBase:  
  Prop1  % defined in AbsBase
```

To make SubAbsBase a concrete class, you need to implement concrete versions of methodTwo and Prop1 in the subclass.

## Concepts

- “Defining Abstract Classes”
- “Getting Information About Classes and Objects”

**Purpose** Return meta.package object for specified package

**Syntax** `mpkg = meta.package.fromName('pkgname')`

**Description** `mpkg = meta.package.fromName('pkgname')` is a static method that returns the meta.package object associated with the named package. If `pkgname` is a nested package, then you must provide the fully qualified name (e.g., `'pkgname1.pkgname2'`).

**Examples** List the classes in the event package:

```
mev = meta.package.fromName('event');
for k=1:length(mev.Classes)
    disp(mev.Classes{k}.Name)
end
event.EventData
event.PropertyEvent
event.listener
event.propListener
```

**See Also** `meta.package` | `meta.package.getAllPackages`

# meta.package.getAllPackages

---

**Purpose** Get all top-level packages

**Syntax** `P = meta.package.getAllPackages`

**Description** `P = meta.package.getAllPackages` is a static method that returns a cell array of `meta.package` objects representing all the top-level packages that are visible on the MATLAB path or defined as top-level built-in packages. You can access subpackages using the `Packages` property of each `meta.package` object.

Note that the time required to find all the packages on the path might be excessively long in some cases. You should therefore avoid using this method in any code where execution time is a consideration. `getAllPackages` is generally intended for interactive use only.

**See Also** `meta.package` | `meta.package.fromName`

## Purpose

meta.property class describes MATLAB class properties

## Description

The meta.property class provides information about the properties of MATLAB classes. The read/write properties of the meta.property class correspond to property attributes and are specified only from within your class definitions.

You can query the read-only properties of the meta.property object to obtain information that is specified syntactically by the class (for example, to obtain the function handle of a property's set access method).

You cannot instantiate a meta.property object directly. Obtain a meta.property object from the meta.class PropertyList property, which contains an array of meta.property objects, one for each class property. For example, replace *ClassName* with the name of the class whose properties you want to query:

```
mco = ?ClassName;
plist = mco.PropertyList;
plist(1).Name; % name of first property
```

Use the metaclass function to obtain a meta.class object from a class instance:

```
mco = metaclass(obj);
```

## Properties

| Property                      | Purpose               |

| GetAccess attribute, default = public | <p>public – unrestricted access</p> <p>protected – access from class or subclasses</p> <p>private – access by class members only</p> <p>List classes that have get access to this property. Specify classes as <code>meta.class</code> objects in the form:</p> <ul style="list-style-type: none"><li>• A single <code>meta.class</code> object</li><li>• A cell array of <code>meta.class</code> objects. An empty cell array, {}, is the same as private access.</li></ul> <p>See “Controlling Access to Class Members”</p> |
| Dependent attribute, default = false  | <p>If false, property value is stored in object. If true, property value is not stored in object and the set and get functions cannot access the property by indexing into the object using the property name.</p> <p>See “Property Get Methods”</p>                                                                                                                                                                                                                                                                          |
| Transient attribute, default = false  | <p>If true, property value is not saved when object is saved to a file. See “Understanding the Save and Load Process” for more about saving objects.</p>                                                                                                                                                                                                                                                                                                                                                                      |
| GetMethod read only                   | <p>Function handle of the get method associated with this property. Empty if there is no get method specified. See “Get Method Syntax”</p>                                                                                                                                                                                                                                                                                                                                                                                    |

| Property                                 | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GetObservable attribute, default = false | If true, and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are queried. See “Property-Set and Query Events”                                                                                                                                                                                                                                                                                                                                                                                               |
| HasDefault                               | Property contains a boolean value indicating if the property defines a default value. Test HasDefault before querying the DefaultValue property to avoid a MATLAB:class:NoDefaultDefined error.                                                                                                                                                                                                                                                                                                                                                                                                         |
| Hidden attribute, default = false        | Determines whether the property should be shown in a property list (e.g., Property Inspector, call to properties, etc.).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| SetAccess attribute, default = public    | <p>public – unrestricted access</p> <p>protected – access from class or subclasses</p> <p>private – access by class members only</p> <p>immutable — property can be set only in the constructor.</p> <p>See “Mutable and Immutable Properties”</p> <p>List classes that have set access to this property. Specify classes as meta.class objects in the form:</p> <ul style="list-style-type: none"> <li>• A single meta.class object</li> <li>• A cell array of meta.class objects. An empty cell array, {}, is the same as private access.</li> </ul> <p>See “Controlling Access to Class Members”</p> |

# meta.property

---

| Property                                 | Purpose                                                                                                                                                                                                    |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SetMethod read only                      | Function handle of the set method associated with this property. Empty if there is no set method specified. See “Property Set Methods”                                                                     |
| SetObservable attribute, default = false | If true, and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are modified. See “Property-Set and Query Events” |

## Events

See for information on using property events.

| Event Name | Purpose                                                 |
|------------|---------------------------------------------------------|
| PreGet     | Event occurs just before property is queried.           |
| PostGet    | Event occurs just after property has been queried       |
| PreSet     | Event occurs just before this property is modified      |
| PostSet    | Event occurs just after this property has been modified |

## How To

- “Properties”
- “Getting Information About Classes and Objects”

**Purpose** Obtain `meta.class` object

**Syntax** `mc = metaclass(object)`  
`mc = ?ClassName`

**Description** `mc = metaclass(object)` returns the `meta.class` object for the class of `object`. The `object` input argument can be a scalar or an array of objects. However, `metaclass` always returns a scalar `meta.class` object.

`mc = ?ClassName` returns the `meta.class` object for the class with name, `ClassName`. The `?` operator works only with a class name, not an object.

If you pass a class name as a string to the `metaclass` function, it returns the `meta.class` object for the `char` class. Use the `?` operator or the `meta.class.fromName` method to obtain the `meta.class` object from a class name. Use this method if you want to pass the class name in a string variable.

**Examples** Return the `meta.class` object for an instance of the `MException` class:

```
obj = MException('Msg:ID', 'MsgTxt');  
mc = metaclass(obj);
```

Use the `?` operator to get the `meta.class` object for the `hgsetget` class:

```
mc = ?hgsetget;
```

**See Also** `meta.class` | `meta.class.fromName`

- “Class Metadata”

# methods

---

## Purpose

Class method names

## Syntax

```
methods('classname')  
methods(..., '-full')  
m = methods(...)
```

## Description

`methods('classname')` displays the names of the methods for the class `classname`. If `classname` is a MATLAB or Java class, then `methods` displays only public methods, including those methods inherited from superclasses.

`methods(..., '-full')` displays a full description of the methods, including inheritance information and, for MATLAB and Java methods, method attributes and signatures. `methods` does not remove duplicate method names with different signatures. Do not use this option with classes defined before MATLAB 7.6.

`m = methods(...)` returns the method names in a cell array of strings.

`methods` is also a MATLAB class-definition keyword. See `classdef` for more information on class-definition keywords.

This function does not show generic methods from classes based on the Microsoft .NET Framework. Use your product documentation to get information on generic methods.

## Examples

Retrieve the names of the static methods in class `MException`:

```
methods('MException')
```

Methods for class `MException`:

```
addCause      getReport     ne            throw  
eq            isequal      rethrow      throwAsCaller
```

Static methods:

```
last
```

**Tutorials**

- “Methods”

# methodsview

---

**Purpose** View class methods

**Syntax** `methodsview packagename.classname`  
`methodsview classname`  
`methodsview(object)`

**Description** `methodsview packagename.classname` displays information about the methods in the class, `classname`. If the class is in a package, include `packagename`. If `classname` is a MATLAB or Java class, `methodsview` lists only public methods, including those methods inherited from superclasses.

`methodsview classname` displays information describing the class `classname`.

`methodsview(object)` displays information about the methods of the class of `object`.

`methodsview` creates a window that displays the methods defined in the specified class. `methodsview` provides additional information like arguments, returned values, and superclasses. It also includes method qualifiers (for example, `abstract` or `synchronized`) and possible exceptions thrown.

**Examples** List information on all methods in the `java.awt.MenuItem` class:

```
methodsview java.awt.MenuItem
```

MATLAB displays this information in a new window.

**See Also** `methods` | `import` | `class` | `javaArray`

**Purpose**

Compile MEX-function from C/C++ or Fortran source code

**Syntax**

```
mex -help
mex -setup
mex filenames
mex options filenames
```

**Description**

`mex -help` displays the help file for `mex`.

`mex -setup` lets you select or change the compiler configuration. MATLAB software searches for installed compilers and allows you to choose an options file as the default for future invocations of `mex`. For more information, see “Build MEX-Files” and `mex.getCompilerConfigurations`.

`mex filenames` compiles and links one or more C/C++ or Fortran source files specified in `filenames` into a shared library called a binary MEX-file from MATLAB.

`mex options filenames` compiles and links one or more source files specified in `filenames` using one or more of the specified command-line options.

The MEX-file has a platform-dependent extension. Use the `mexext` function to return the extension for the current machine or for all supported platforms.

`filenames` can be any combination of source files, Simulink S-function files, object files, and library files. Include both the file name and the file extension in `filenames`. A non-source-code `filenames` parameter is passed to the linker without being compiled.

All valid command-line options are shown in the on page 2-2870 table. These options are available on all platforms except where noted.

`mex` also can build executable files for stand alone MATLAB engine and MAT-file applications. For more information, see “Engine/MAT Stand Alone Application Details” on page 2-2875.

You can run `mex` from the MATLAB Command Prompt, the Microsoft Windows Command Prompt, or the UNIX shell. `mex` is a script named

`mex.bat` on Windows systems and `mex` on UNIX systems. It is located in the `matlabroot/bin` folder.

The first file listed in `filenames` becomes the name of the binary MEX-file. You can list other source, object, or library files as additional `filenames` parameters to satisfy external references.

`mex` uses an options file to specify variables and values that are passed as arguments to the compiler, linker, and other tools (for example, the resource linker on Windows systems). For more information, see “Options File Details” on page 2-2874. The default name for the options file is `mexopts.bat` (Windows systems) or `mexopts.sh` (UNIX systems).

Command-line options to `mex` may supplement or override contents of the options file. For more information, see “Override Option Details” on page 2-2874.

For an up-to-date list of supported compilers, see the Supported and Compatible Compilers Web page.

## MEX Script Switches

| Switch                 | Function                                                                                                                                                                                                                                                                             |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>@rsp_file</code> | (Windows systems only) Include the contents of the text file <code>rsp_file</code> as command-line arguments to <code>mex</code> .                                                                                                                                                   |
| <code>-arch</code>     | Build an output file for architecture <code>arch</code> . To determine the value for <code>arch</code> , type <code>computer('arch')</code> at the MATLAB Command Prompt on the target machine. Valid values for <code>arch</code> depend on the architecture of the build platform. |
| <code>-c</code>        | Compile only. Creates an object file, but not a binary MEX-file.                                                                                                                                                                                                                     |

(Continued)

| Switch                            | Function                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-compatibleArrayDims</code> | <p>Build a binary MEX-file using the MATLAB Version 7.2 array-handling API, which limits arrays to <math>2^{31}-1</math> elements. Default option. (See the <code>-largeArrayDims</code> option.)</p> <p>In verbose mode, if you do not specify either the <code>-largeArrayDims</code> or the <code>-compatibleArrayDims</code> switches, MATLAB displays a message showing the default switch.</p> |
| <code>-cxx</code>                 | <p>(UNIX systems only) Use the C++ linker to link the MEX-file if the first source file is in C and there are one or more C++ source or object files. This option overrides the assumption that the first source file in the list determines which linker to use.</p>                                                                                                                                |
| <code>-Dname</code>               | <p>Define a symbol name to the C preprocessor. Equivalent to a <code>#define name</code> directive in the source.</p> <p>Do not add a space after this switch.</p>                                                                                                                                                                                                                                   |
| <code>-Dname=value</code>         | <p>Define a symbol name and value to the C preprocessor. Equivalent to a <code>#define name value</code> directive in the source.</p> <p>Do not add a space after this switch.</p>                                                                                                                                                                                                                   |
| <code>-f optionsfile</code>       | <p>Specify location and name of options file to use. Overrides the mex default-options-file search mechanism.</p>                                                                                                                                                                                                                                                                                    |

**(Continued)**

| <b>Switch</b>      | <b>Function</b>                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -fortran           | (UNIX systems only) Specify that the gateway routine is in Fortran. This option overrides the assumption that the first source file in the list determines which linker to use.                                                                            |
| -g                 | Create a binary MEX-file containing additional symbolic information for use in debugging. This option disables the mex default behavior of optimizing built object code (see the -O option).                                                               |
| -h[elp]            | Print help for mex.                                                                                                                                                                                                                                        |
| -I <i>pathname</i> | Add <i>pathname</i> to the list of folders to search for #include files.<br><br>Do not add a space after this switch.                                                                                                                                      |
| -inline            | This option has been removed.                                                                                                                                                                                                                              |
| -lname             | Link with object library. On Windows systems, <i>name</i> expands to <i>name.lib</i> or <i>libname.lib</i> and on UNIX systems, to <i>libname.so</i> or <i>libname.dylib</i> .<br><br>Do not add a space after this switch.                                |
| -L <i>folder</i>   | Add <i>folder</i> to the list of folders to search for libraries specified with the -l option. On UNIX systems, you must also set the run-time library path, as explained in “Setting Run-Time Library Path”.<br><br>Do not add a space after this switch. |

(Continued)

| Switch                    | Function                                                                                                                                                                                                                                                                                                                                      |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -largeArrayDims           | Build a binary MEX-file using the MATLAB large-array-handling API. This API can handle arrays with more than $2^{31}-1$ elements. (See the -compatibleArrayDims option.)<br><br>In verbose mode, if you do not specify either the -largeArrayDims or the -compatibleArrayDims switches, MATLAB displays a message showing the default switch. |
| -n                        | No execute mode. Print any commands that mex would otherwise have executed, but do not actually execute any of them.                                                                                                                                                                                                                          |
| -O                        | Optimize the object code. Optimization is enabled by default and by including this option on the command line. If the -g option appears without the -O option, optimization is disabled.                                                                                                                                                      |
| -outdir <i>dirname</i>    | Place all output files in folder <i>dirname</i> .                                                                                                                                                                                                                                                                                             |
| -output <i>resultname</i> | Create binary MEX-file named <i>resultname</i> . Automatically appends the appropriate MEX-file extension. Overrides the default MEX-file naming mechanism.                                                                                                                                                                                   |
| -setup                    | Specify the compiler options file to use when calling the mex function. When you use this option, all other command-line options are ignored.                                                                                                                                                                                                 |

**(Continued)**

| <b>Switch</b>     | <b>Function</b>                                                                                                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>-Uname</i>     | Remove any initial definition of the C preprocessor symbol <i>name</i> . (Inverse of the <i>-D</i> option.)<br><br>Do not add a space after this switch.                                                         |
| <i>-v</i>         | Verbose mode. Print the values for important internal variables after the options file is processed and all command-line arguments are considered. Prints each compile step and final link step fully evaluated. |
| <i>name=value</i> | Override an options file variable for variable <i>name</i> . For examples, see <a href="#">Override Option Details</a> on <a href="#">mex</a> reference page.                                                    |

## Tips

### Options File Details

MATLAB provides template options files for the compilers that are supported by `mex`. These templates are located in the `matlabroot\bin\win32\mexopts` or the `matlabroot\bin\win64\mexopts` folders on Windows systems, or the `matlabroot/bin` folder on UNIX systems. These template options files are used by the `-setup` option to define the selected default options file.

### Override Option Details

Use the `name=value` command-line argument to override a variable specified in the options file at the command line. When using this option, you may need to use the shell's quoting syntax to protect characters such as spaces, which have a meaning in the shell syntax.

This option is processed after the options file is processed and all command line arguments are considered.

On Windows platforms, at either the MATLAB prompt or the DOS prompt, use double quotes ("). For example:

```
mex -v COMPFLAGS="$COMPFLAGS -Wall" LINKFLAGS="$LINKFLAGS /VERBOSE" yprime.c
```

At the MATLAB command line on UNIX platforms, use double quotes ("). Use the backslash (\) escape character before the dollar sign (\$). For example:

```
mex -v CFLAGS="\$CFLAGS -Wall" LDFLAGS="\$LDFLAGS -w" yprime.c
```

At the shell command line on UNIX platforms, use single quotes ('). For example:

```
mex -v CFLAGS='$CFLAGS -Wall' LDFLAGS='$LDFLAGS -w' yprime.c
```

### **Engine/MAT Stand Alone Application Details**

mex can build executable files for stand alone MATLAB engine and MAT-file applications. For these applications, mex does not use the default options file; you must use the -f option to specify an options file.

The options files used to generate stand alone MATLAB engine and MAT-file executables are named \*engmatopts.bat on Windows systems, or engopts.sh and matopts.sh on UNIX systems, and are located in the same folder as the template options files referred to above in Options File Details.

## **Examples**

### **Compiling a C File**

The following command compiles yprime.c:

```
mex yprime.c
```

### **Using Verbose Mode**

When debugging, it is often useful to use verbose mode, as well as include symbolic debugging information:

```
mex -v -g yprime.c
```

## **Overriding Command Line Options**

For examples, see “Override Option Details” on page 2-2874.

## **List of Examples**

For a list of MEX example files available with MATLAB, see “Table of MEX-File Source Code Files”.

## **See Also**

`computer` | `dbmex` | `inmem` | `loadlibrary` | `mexext` | `pcode` | `prefdir`  
| `system` | `mex.getCompilerConfigurations` | `clear`

**Purpose** Get compiler configuration information for building MEX-files

**Syntax**

```
cc = mex.getCompilerConfigurations()  
cc = mex.getCompilerConfigurations('lang')  
cc = mex.getCompilerConfigurations('lang','list')
```

**Description** `cc = mex.getCompilerConfigurations()` returns a `mex.CompilerConfiguration` object `cc` containing information about the selected compiler configuration used by `mex`. The selected compiler is the one you choose when you run the `mex -setup` command. For details about the `mex.CompilerConfiguration` class, see “`mex.CompilerConfiguration`” on page 2-2878.

`cc = mex.getCompilerConfigurations('lang')` returns an array of `mex.CompilerConfiguration` objects `cc` containing information about the selected configuration for the given `lang`. If the language of the selected compiler is different from `lang`, then `cc` is empty.

Language `lang` is a string with one of the following values:

- **'Any'** — All supported languages. This is the default value.
- **'C'** — All C compiler configurations, including C++ configurations.
- **'C++'** or **'CPP'** — All C++ compiler configurations.
- **'Fortran'** — All Fortran compiler configurations.

`cc = mex.getCompilerConfigurations('lang','list')` returns an array of `mex.CompilerConfiguration` objects `cc` containing information about configurations for the given language and the given `list`. Values for `list` are:

- **'Selected'** — The compiler you chose when you ran `mex-setup`. This is the default value.
- **'Installed'** — All supported compilers `mex` finds installed on your system.
- **'Supported'** — All compilers supported in the current release. For an up-to-date list of supported compilers, see the Supported and Compatible Compilers Web page.

# mex.getCompilerConfigurations

---

## Classes

### mex.CompilerConfiguration

The `mex.CompilerConfiguration` class contains the following read-only properties about compiler configurations.

| Property     | Purpose                                                                                                                                            |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| Name         | Name of the compiler                                                                                                                               |
| Manufacturer | Name of the manufacturer of the compiler                                                                                                           |
| Language     | Compiler language                                                                                                                                  |
| Version      | (Windows platforms only) Version of the compiler                                                                                                   |
| Location     | (Windows platforms only) Folder where compiler is installed                                                                                        |
| Details      | Additional read-only properties about the compiler configuration. These properties can differ across compilers, platforms, and releases of MATLAB. |

## Examples

### Selected Compiler Example

```
myCompiler = mex.getCompilerConfigurations()
```

MATLAB software displays information similar to the following (depending on your architecture, your version of MATLAB, and what you selected when you ran `mex -setup`):

```
myCompiler =  
  
mex.CompilerConfiguration  
Package: mex  
  
Properties:  
    Name: 'Microsoft Visual C++ 2005'  
    Manufacturer: 'Microsoft'  
    Language: 'C++'  
    Version: '8.0'
```

```
Location: '%VS80COMNTOOLS%\\.\\.\\.\\'
Details: [1x1 mex.CompilerConfigurationDetails]
```

Methods

## Supported Compiler Configurations Example

```
allCC = mex.getCompilerConfigurations('Any','Supported')
```

MATLAB displays information similar to the following:

```
allCC =
```

```
1x11 mex.CompilerConfiguration
Package: mex
```

Properties:

```
Name
Manufacturer
Language
Version
Location
Details
```

Methods

This version of MATLAB supports eleven configurations, hence, `allCC` is a 1-by-11 matrix.

## Supported C Compilers Example

To see what C compilers MATLAB supports, type:

```
cLanguageCC = mex.getCompilerConfigurations('C','Supported')
```

MATLAB displays the following information (the number of compilers for your version of MATLAB may be different):

# mex.getCompilerConfigurations

---

```
cLanguageCC =  
  
    1x9 mex.CompilerConfiguration  
    Package: mex  
  
    Properties:  
        Name  
        Manufacturer  
        Language  
        Version  
        Location  
        Details  
  
    Methods
```

To display the compiler names, type:

```
format compact  
cLanguageCC.Name
```

MATLAB displays information similar to the following:

```
ans =  
Intel C++  
ans =  
Lcc-win32  
ans =  
Microsoft Visual C++  
ans =  
Microsoft Visual C++ 2003  
ans =  
Microsoft Visual C++ 2005 Express Edition  
ans =  
Microsoft Visual C++ 2005  
ans =  
Microsoft Visual C++ 2008  
ans =
```

Open WATCOM C/C++

## Example – Viewing Build Options for a C Compiler

To see what build options MATLAB uses with a particular C compiler, create an array `CC` of all supported C compiler configurations:

```
CC = mex.getCompilerConfigurations('C','Supported');
disp('Compiler Name')
for i = 1:3; disp(CC(i).Name); end;
```

MATLAB displays a list similar to:

```
Intel C++
Lcc-win32
Microsoft Visual C++
```

To see the build options for the Microsoft Visual C++ compiler, type:

```
CC(3).Details
```

MATLAB displays information similar to the following (output is formatted):

```
ans =
    mex.CompilerConfigurationDetails
    Package: mex

    Properties:
        CompilerExecutable: 'cl'
        CompilerFlags: '-c -Zp8 -G5 -W3 -Ehs
-DMATLAB_MEX_FILE -nologo /MD'
        OptimizationFlags: '-O2 -Oy- -DNDEBUG'
        DebugFlags: '-Zi
-Fd"%OUTDIR%%MEX_NAME%.pdb"'
        LinkerExecutable: 'link'
        LinkerFlags: [1x258 char]
        LinkerOptimizationFlags: ''
```

# mex.getCompilerConfigurations

---

LinkerDebugFlags: '/debug'  
Methods

**See Also**      mex

## Purpose

Capture error information

## Syntax

```
exception = MException(msgIdent, msgString, v1, v2, ..., vN)
```

## Description

`exception = MException(msgIdent, msgString, v1, v2, ..., vN)` captures information about a specific error and stores it in MException object, *exception*. Information stored in the object includes a message identifier *msgIdent* and an error message string *msgString*. Optional arguments *v<sub>1</sub>*, *v<sub>2</sub>*, ... represent text or numeric values that replace conversion specifiers in *msgString* at run time.

Message identifier *msgIdent* is a character string composed of at least two substrings, the *component* and the *mnemonic*, separated by a colon (e.g., *component:mnemonic*). The purpose of the identifier is to better identify the source of the error. See the documentation on “Message Identifiers” for more information.

Message string *msgString* is a character string that informs the user about the cause of the error and can also suggest how to correct the faulty condition. The *msgString* string can include escape sequences such as `\t` or `\n`, as well as any of the format specifiers supported by the `sprintf` function (such as `%s` or `%d`). Additional arguments *v<sub>1</sub>*, *v<sub>2</sub>*, ..., *v<sub>N</sub>* provide values that correspond to and replace the conversion specifiers.

For example, if *msgString* is “Error on line %d, command %s”, then *v<sub>1</sub>* is the line number at which the error was detected, and *v<sub>2</sub>* is the command that failed. See “Formatting Strings” in the MATLAB Programming Fundamentals documentation for more detailed information on using string formatting commands.

The *exception* output is an object of the MException class. MException is the constructor for this class. In addition to calling the constructor directly, you can also create an object of MException with any of the following functions: `error` and `assert`. See the documentation and figure in the section “The MException Class” for more information on this class.

# MException

---

## Properties

The MException object has four properties: `identifier`, `message`, `stack`, and `cause`. Click any of the links below to find out more about MException properties:

| Property                | Description                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <code>identifier</code> | Identifies the error.                                                                                                           |
| <code>message</code>    | Formatted error message that is displayed.                                                                                      |
| <code>stack</code>      | Structure containing stack trace information such as file name, function name, and line number where the MException was thrown. |
| <code>cause</code>      | Cell array of MException that caused this exception to be created.                                                              |

## Methods

The MException class has the following methods. Click any of the links below to find out more about MException methods:

| Method                 | Description                                                                                            |
|------------------------|--------------------------------------------------------------------------------------------------------|
| <code>addCause</code>  | Appends an MException to the <code>cause</code> field of another MException.                           |
| <code>eq</code>        | Tests scalar MException objects for equality.                                                          |
| <code>getReport</code> | Returns a formatted message string that uses the same format as errors thrown by internal MATLAB code. |
| <code>isequal</code>   | Tests scalar MException objects for equality.                                                          |
| <code>last</code>      | Returns an MException object for the most recently thrown exception.                                   |
| <code>ne</code>        | Tests scalar MException objects for inequality.                                                        |

| Method        | Description                                                                                                                                                       |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rethrow       | Reissues an exception that has been caught, causing the program to stop.                                                                                          |
| throw         | Issues an exception from the currently running function.                                                                                                          |
| throwAsCaller | Issues an exception from the currently running function, also omitting the current stack frame from the <code>stack</code> field of the <code>MException</code> . |

## Tips

Valid escape sequences for the `msgString` argument are `\b`, `\f`, `\n`, `\r`, `\t`, and `\x` or `\o` when followed by a valid hexadecimal or octal number, respectively. Following a backslash in the `msgString` with any other character causes MATLAB to issue a warning. Conversion specifiers are similar to those used in the C programming language and in the `sprintf` function.

All string input arguments must be enclosed in single quotation marks.

## Examples

### Example 1 – Formatted Messages

If your message string requires formatting specifications like those used with the `sprintf` function, you can use this syntax to compose the error message string:

```
exception = MException(msgIdent, msgString, v1, v2, ...)
```

For example,

```
exception = MException('AcctError:Incomplete', ...  
    'Field ''%.%.s'' is not defined.', ...  
    'Accounts', 'ClientName');
```

```
exception.message  
ans =  
    Field 'Accounts.ClientName' is not defined.
```

## Example 2

The catch block in this example checks to see if the specified file could not be found. If this is the case, the program allows for the possibility that a common variation of the filename extension (e.g., jpeg instead of jpg) was used by retrying the operation with a modified extension. This is done using a try/catch statement that is nested within the original try/catch.

```
function d_in = read_image(filename)
[path name ext] = fileparts(filename);
try
    fid = fopen(filename, 'r');
    d_in = fread(fid);
catch exception

    % Did the read fail because the file could not be found?
    if ~exist(filename, 'file')

        % Yes. Try modifying the filename extension.
        switch ext
        case '.jpg'      % Change jpg to jpeg
            altFilename = strrep(filename, '.jpg', '.jpeg')
        case '.jpeg'   % Change jpeg to jpg
            altFilename = strrep(filename, '.jpeg', '.jpg')
        case '.tif'    % Change tif to tiff
            altFilename = strrep(filename, '.tif', '.tiff')
        case '.tiff'   % Change tiff to tif
            altFilename = strrep(filename, '.tiff', '.tif')
        otherwise
            rethrow(exception);
        end

        % Try again, with modified filename.
        try
            fid = fopen(altFilename, 'r');
            d_in = fread(fid);
        catch
```

```
        rethrow(exception)
    end
end
end
```

### Example 3 – Nested try/catch

This example attempts to open a file in a folder that is not on the MATLAB path. It uses a nested try-catch block to give the user the opportunity to extend the path. If the file still cannot be found, the program issues an exception with the first error appended to the second:

```
function data = read_it(filename);
try
    % Attempt to open and read from a file.
    fid = fopen(filename, 'r');
    data = fread(fid);
catch exception1
    % If the error was caused by an invalid file ID, try
    % reading from another location.
    if strcmp(exception1.identifier, 'MATLAB:FileIO:InvalidFid')
        msg = sprintf( ...
            '\nCannot open file %s. Try another location? ', ...
            filename);
        reply = input(msg, 's')
        if reply(1) == 'y'
            newFolder = input('Enter folder name: ', 's');
        else
            throw(exception1);
        end
        oldpath = addpath(newFolder);
    try
        fid = fopen(filename, 'r');
        data = fread(fid);
    catch exception2
        exception3 = addCause(exception2, exception1)
        path(oldpath);
        throw(exception3);
    end
end
```

# MException

---

```
        end
        path(oldpath);
    end
end
fclose(fid);
```

If you run this function in a try-catch block at the command line, you can look at the MException object by assigning it to a variable (e) with the catch command.

| <b>See Also</b>    | <code>mex</code>                                                                                                                                                                                                                                                                                                                                                                                                                                         |

# mfilename

---

**Purpose** File name of currently running function

**Syntax**

```
mfilename  
p = mfilename('fullpath')  
c = mfilename('class')
```

**Description** mfilename returns a string containing the file name of the most recently invoked function. When called from within the file, it returns the name of that file. This allows a function to determine its name, even if the file name has been changed.

p = mfilename('fullpath') returns the full path and name of the file in which the call occurs, not including the filename extension.

c = mfilename('class') in a method, returns the class of the method, not including the leading @ sign. If called from a nonmethod, it yields the empty string.

**Tips** If mfilename is called with any argument other than the above two, it behaves as if it were called with no argument.

When called from the command line, mfilename returns an empty string.

To get the names of the callers of a MATLAB function file, use dbstack with an output argument.

| <b>See Also</b>        | <code>cd</code>   <code>ftp</code>   <code>mput</code>                                                                                                                                                                                                                                                                                                                                                  |

# min

---

**Purpose** Smallest elements in array

**Syntax**

```
C = min(A)
C = min(A,B)
C = min(A,[],dim)
[C,I] = min(...)
```

**Description** `C = min(A)` returns the smallest elements along different dimensions of an array.

If `A` is a vector, `min(A)` returns the smallest element in `A`.

If `A` is a matrix, `min(A)` treats the columns of `A` as vectors, returning a row vector containing the minimum element from each column.

If `A` is a multidimensional array, `min` operates along the first nonsingleton dimension.

`C = min(A,B)` returns an array the same size as `A` and `B` with the smallest elements taken from `A` or `B`. The dimensions of `A` and `B` must match, or they may be scalar.

`C = min(A,[],dim)` returns the smallest elements along the dimension of `A` specified by scalar `dim`. For example, `min(A,[],1)` produces the minimum values along the first dimension of `A`.

`[C,I] = min(...)` finds the indices of the minimum values of `A`, and returns them in output vector `I`. If there are several identical minimum values, the index of the first one found is returned.

## Examples

Return the minimum of a 2-by-3 matrix from each column:

```
X = [2 8 4; 7 3 9];
min(X,[],1)
ans =
```

```
2     3     4
```

Return the minimum from each row:

```
min(X,[],2)
ans =
```

```
    2
    3
```

Compare each element of X to a scalar:

```
min(X,5)
ans =
```

```
    2    5    4
    5    3    5
```

### Tips

For complex input A, `min` returns the complex number with the smallest complex modulus (magnitude), computed with `min(abs(A))`. Then computes the smallest phase angle with `min(angle(x))`, if necessary.

The `min` function ignores NaNs.

# MinimizeCommandWindow

---

**Purpose** Minimize size of Automation server window

**Syntax** **MATLAB Client**  
h.MinimizeCommandWindow  
MinimizeCommandWindow(h)

**IDL Method Signature**

HRESULT MinimizeCommandWindow(void)

**Microsoft Visual Basic Client**

MinimizeCommandWindow

**Description** h.MinimizeCommandWindow minimizes the window for the server attached to handle h, and makes it inactive.

MinimizeCommandWindow(h) is an alternate syntax.

If the server window was already in a minimized state, MinimizeCommandWindow does nothing.

**Examples** From a MATLAB client, modify the size of the command window in a MATLAB Automation server:

```
h = actxserver('matlab.application');  
h.MinimizeCommandWindow;  
% Now return the server window to its former state on  
% the desktop and make it the currently active window.  
h.MaximizeCommandWindow;
```

---

From a Visual Basic .NET client, modify the size of the command window in a MATLAB Automation server:

```
Dim Matlab As Object  
  
Matlab = CreateObject("matlab.application")  
Matlab.MinimizeCommandWindow
```

'Now return the server window to its former state on  
'the desktop and make it the currently active window.

Matlab.MaximizeCommandWindow

## How To

- “MATLAB COM Automation Server Interface”
- “Controlling the Server Window”

# minres

---

## Purpose

Minimum residual method

## Syntax

```
x = minres(A,b)
minres(A,b,tol)
minres(A,b,tol,maxit)
minres(A,b,tol,maxit,M)
minres(A,b,tol,maxit,M1,M2)
minres(A,b,tol,maxit,M1,M2,x0)
[x,flag] = minres(A,b,...)
[x,flag,relres] = minres(A,b,...)
[x,flag,relres,iter] = minres(A,b,...)
[x,flag,relres,iter,resvec] = minres(A,b,...)
[x,flag,relres,iter,resvec,resveccg] = minres(A,b,...)
```

## Description

`x = minres(A,b)` attempts to find a minimum norm residual solution  $x$  to the system of linear equations  $A*x=b$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be symmetric but need not be positive definite. It should be large and sparse. The column vector  $b$  must have length  $n$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x)` returns  $A*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `minres` converges, a message to that effect is displayed. If `minres` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual norm  $\|b-A*x\|/\|b\|$  and the iteration number at which the method stopped or failed.

`minres(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `minres` uses the default,  $1e-6$ .

`minres(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `minres` uses the default,  $\min(n,20)$ .

`minres(A,b,tol,maxit,M)` and `minres(A,b,tol,maxit,M1,M2)` use symmetric positive definite preconditioner  $M$  or  $M = M1*M2$  and effectively solve the system  $\text{inv}(\text{sqrt}(M))*A*\text{inv}(\text{sqrt}(M))*y =$

$\text{inv}(\text{sqrt}(M)) * b$  for  $y$  and then return  $x = \text{inv}(\text{sqrt}(M)) * y$ . If  $M$  is  $[]$  then `minres` applies no preconditioner.  $M$  can be a function handle `mfun`, such that `mfun(x)` returns  $M \backslash x$ .

`minres(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If  $x_0$  is  $[]$ , then `minres` uses the default, an all-zero vector.

`[x,flag] = minres(A,b,...)` also returns a convergence flag.

| Flag | Convergence                                                                                                             |
|------|-------------------------------------------------------------------------------------------------------------------------|
| 0    | minres converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.                        |
| 1    | minres iterated <code>maxit</code> times but did not converge.                                                          |
| 2    | Preconditioner $M$ was ill-conditioned.                                                                                 |
| 3    | minres stagnated. (Two consecutive iterates were the same.)                                                             |
| 4    | One of the scalar quantities calculated during <code>minres</code> became too small or too large to continue computing. |

Whenever `flag` is not 0, the solution  $x$  returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = minres(A,b,...)` also returns the relative residual  $\text{norm}(b - A * x) / \text{norm}(b)$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = minres(A,b,...)` also returns the iteration number at which  $x$  was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = minres(A,b,...)` also returns a vector of estimates of the `minres` residual norms at each iteration, including  $\text{norm}(b - A * x_0)$ .

`[x,flag,relres,iter,resvec,resvecg] = minres(A,b,...)` also returns a vector of estimates of the Conjugate Gradients residual norms at each iteration.

## Examples

### Using minres with a Matrix Input

```
n = 100; on = ones(n,1);
A = spdiags([-2*on 4*on -2*on],-1:1,n,n);
b = sum(A,2);
tol = 1e-10;
maxit = 50;
M1 = spdiags(4*on,0,n,n);

x = minres(A,b,tol,maxit,M1);
minres converged at iteration 49 to a solution with relative
residual 4.7e-014
```

### Using minres with a Function Handle

This example replaces the matrix A in the previous example with a handle to a matrix-vector product function `afun`. The example is contained in a file `run_minres` that

- Calls `minres` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_minres` are available to `afun`.

The following shows the code for `run_minres`:

```
function x1 = run_minres
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -2*on],-1:1,n,n);
b = sum(A,2);
tol = 1e-10;
maxit = 50;
M = spdiags(4*on,0,n,n);
x1 = minres(@afun,b,tol,maxit,M);

function y = afun(x)
y = 4 * x;
y(2:n) = y(2:n) - 2 * x(1:n-1);
y(1:n-1) = y(1:n-1) - 2 * x(2:n);
```

```
        end
    end
```

When you enter

```
x1=run_minres;
```

MATLAB software displays the message

```
minres converged at iteration 49 to a solution with relative
residual 4.7e-014
```

### Using minres instead of pcg

Use a symmetric indefinite matrix that fails with pcg.

```
A = diag([20:-1:1, -1:-1:-20]);
b = sum(A,2);           % The true solution is the vector of all ones.
x = pcg(A,b);          % Errors out at the first iteration.
```

displays the following message:

```
pcg stopped at iteration 1 without converging to the desired
tolerance 1e-006 because a scalar quantity became too small or
too large to continue computing.
The iterate returned (number 0) has relative residual 1
```

However, minres can handle the indefinite matrix A.

```
x = minres(A,b,1e-6,40);
minres converged at iteration 39 to a solution with relative
residual 1.3e-007
```

**Purpose**

Minus

**Syntax**

```
c = a-b  
c = minus(a,b)
```

**Description**

`c = a-b` subtracts array `b` from array `a` and returns the result in `c`. Inputs `a` and `b` must have the same size unless one is a scalar value (1-by-1 matrix).

`c = minus(a,b)` is called for the syntax `a-b` when `a` or `b` is an object.

**See Also**

`plus`

# mislocked

---

**Purpose** Determine if function is locked in memory

**Syntax** `mislocked`  
`mislocked(fun)`

**Description** `mislocked` by itself returns logical 1 (`true`) if the currently running function is locked in memory, and logical 0 (`false`) otherwise. Functions that are locked cannot be removed with the `clear` function unless you first unlock them using the `munlock` function. You can use locking on functions that reside in MATLAB `.m` files or `.mex` files.

`mislocked(fun)` returns logical 1 (`true`) if the function named *fun* is locked in memory, and logical 0 (`false`) otherwise.

**See Also** `mlock` | `munlock` | `inmem`

**Purpose** Make new folder

**Alternatives** As an alternative to `mkdir`, use the Current Folder browser.

**Syntax**

```
mkdir('folderName')
mkdir('parentFolder','folderName')
status = mkdir(...)
[status,message,messageid] = mkdir(...)
```

**Description**

`mkdir('folderName')` creates the folder `folderName`, where `folderName` can be an absolute or a relative path.

`mkdir('parentFolder','folderName')` creates the folder `folderName` in `parentFolder`, where `parentFolder` is an absolute or relative path. If `parentFolder` does not exist, MATLAB attempts to create it. See the Tips section.

`status = mkdir(...)` creates the specified folder. When the operation is successful, it returns a `status` of logical 1. When the operation is unsuccessful, it returns logical 0.

`[status,message,messageid] = mkdir(...)` creates the specified folder, and returns the `status`, message string, and MATLAB message ID. The value given to `status` is logical 1 for success, and logical 0 for error.

**Tips**

If an argument specifies a path that includes one or more nonexistent folders, MATLAB attempts to create the nonexistent folder. For example, for

```
mkdir('myFolder\folder1\folder2\targetFolder')
```

if `folder1` does not exist, MATLAB creates `folder1`, creates `folder2` within `folder1`, and creates `targetFolder` within `folder2`.

**Examples** **Creating a Subfolder in the Current Folder**

Create a subfolder called `newdir` in the current folder:

```
mkdir('newdir')
```

## Creating a Subfolder in the Specified Parent Folder

Create a subfolder called `newFolder` in the folder `testdata`, using a relative path, where `newFolder` is at the same level as the current folder:

```
mkdir('../testdata','newFolder')
```

## Returning Status When Creating a Folder

In this example, the first attempt to create `newFolder` succeeds, returning a status of 1, and no error or warning message or message identifier:

```
[s, mess, messid] = mkdir('../testdata', 'newFolder')
s =
    1
mess =
    ''
messid =
    ''
```

Attempt to create the same folder again. `mkdir` again returns a success status, and also a warning and message identifier informing you that the folder exists:

```
[s,mess,messid] = mkdir('../testdata','newFolder')
s =
    1
mess =
    Directory "newFolder" already exists.
messid =
    MATLAB:MKDIR:DirectoryExists
```

## See Also

`copyfile` | `cd` | `dir` | `ls` | `movefile` | `rmdir`

## How To

- “Working with Files and Folders”

**Purpose** Create folder on FTP server

**Syntax** `mkdir(ftpobj, folder)`

**Description** `mkdir(ftpobj, folder)` creates the specified folder on the FTP server associated with `ftpobj`.

**Input Arguments**

**ftpobj**  
FTP object created by `ftp`.

**folder**  
String enclosed in single quotation marks that specifies a path relative to the current folder on the FTP server.

**Examples** Suppose that a hypothetical host, `ftp.testsite.com`, contains a folder named `testfolder`. Connect to the server and add a subfolder:

```
test=ftp('ftp.testsite.com');
mkdir(test, 'testfolder/newfolder');
close(test);
```

**See Also** `dir` | `ftp` | `rmdir`

**Purpose** Make piecewise polynomial

**Syntax**  
`pp = mkpp(breaks,coefs)`  
`pp = mkpp(breaks,coefs,d)`

**Description** `pp = mkpp(breaks,coefs)` builds a piecewise polynomial `pp` from its `breaks` and coefficients. `breaks` is a vector of length  $L+1$  with strictly increasing elements which represent the start and end of each of  $L$  intervals. `coefs` is an  $L$ -by- $k$  matrix with each row `coefs(i,:)` containing the coefficients of the terms, from highest to lowest exponent, of the order  $k$  polynomial on the interval `[breaks(i),breaks(i+1)]`.

`pp = mkpp(breaks,coefs,d)` indicates that the piecewise polynomial `pp` is  $d$ -vector valued, i.e., the value of each of its coefficients is a vector of length  $d$ . `breaks` is an increasing vector of length  $L+1$ . `coefs` is a  $d$ -by- $L$ -by- $k$  array with `coefs(r,i,:)` containing the  $k$  coefficients of the  $i$ th polynomial piece of the  $r$ th component of the piecewise polynomial.

Use `ppval` to evaluate the piecewise polynomial at specific points. Use `unmkpp` to extract details of the piecewise polynomial.

**Note.** The *order* of a polynomial tells you the number of coefficients used in its description. A  $k$ th order polynomial has the form

$$c_1x^{k-1} + c_2x^{k-2} + \dots + c_{k-1}x + c_k$$

It has  $k$  coefficients, some of which can be 0, and maximum exponent  $k - 1$ . So the order of a polynomial is usually one greater than its degree. For example, a cubic polynomial is of order 4.

**Examples** The first plot shows the quadratic polynomial

$$1 - \left(\frac{x}{2} - 1\right)^2 = \frac{-x^2}{4} + x$$

shifted to the interval `[-8,-4]`. The second plot shows its negative

$$\left(\frac{x}{2} - 1\right)^2 - 1 = \frac{x^2}{4} - x$$

but shifted to the interval [-4,0].

The last plot shows a piecewise polynomial constructed by alternating these two quadratic pieces over four intervals. It also shows its first derivative, which was constructed after breaking the piecewise polynomial apart using `unmkpp`.

```
subplot(2,2,1)
cc = [-1/4 1 0];
pp1 = mkpp([-8 -4],cc);
xx1 = -8:0.1:-4;
plot(xx1,ppval(pp1,xx1),'k-')

subplot(2,2,2)
pp2 = mkpp([-4 0],-cc);
xx2 = -4:0.1:0;
plot(xx2,ppval(pp2,xx2),'k-')

subplot(2,1,2)
pp = mkpp([-8 -4 0 4 8],[cc;-cc;cc;-cc]);
xx = -8:0.1:8;
plot(xx,ppval(pp,xx),'k-')
[breaks,coefs,l,k,d] = unmkpp(pp);
dpp = mkpp(breaks,repmat(k-1:-1:1,d*1,1).*coefs(:,1:k-1),d);
hold on, plot(xx,ppval(dpp,xx),'r-'), hold off
```

## See Also

`ppval` | `spline` | `unmkpp`

**Purpose**

Solve systems of linear equations  $Ax = B$  for  $x$

**Syntax**

```
x = A\B  
x = mldivide(A,B)
```

**Description**

$x = A\B$  solves the system of linear equations  $A^*x = B$ . The matrices  $A$  and  $B$  must have the same number of rows. MATLAB displays a warning message if  $A$  is badly scaled or nearly singular, but performs the calculation regardless.

- If  $A$  is a scalar,  $A\B$  performs element-wise division of  $A$  into  $B$ .
- If  $A$  is a square  $n$ -by- $n$  matrix and  $B$  is a column vector with  $n$  elements or a matrix with  $n$  rows, then  $x = A\B$  is a solution to the equation  $A^*x = B$ , if it exists.
- If  $A$  is a rectangular  $m$ -by- $n$  matrix with  $m \neq n$ , and  $B$  is a column vector with  $m$  elements or a matrix with  $m$  rows, then  $A\B$  returns a least-squares solution to the system of equations  $A^*x = B$ .

$x = \text{mldivide}(A,B)$  is an alternative way to execute  $x = A\B$ , but is rarely used. It enables operator overloading for classes.

**Input Arguments****A - Coefficient matrix**

vector | full matrix | sparse matrix

Coefficient matrix, specified as a vector, full matrix, or sparse matrix. If  $A$  has  $m$  rows, then  $B$  must have  $m$  rows.

**Data Types**

single | double

**Complex Number Support:** Yes

**B - Right-hand side**

vector | full matrix | sparse matrix

Right-hand side, specified as a vector, full matrix, or sparse matrix. If  $B$  has  $m$  rows, then  $A$  must have  $m$  rows.

# mldivide

---

## Data Types

single | double

**Complex Number Support:** Yes

## Output Arguments

### x - Solution

vector | full matrix | sparse matrix

Solution, specified as a vector, full matrix, or sparse matrix. If A is an m-by-n matrix and B is an m-by-p matrix, then x is an n-by-p matrix, including the case when p==1.

x is sparse only if both A and B are sparse matrices.

## Examples

### System of Equations

Solve a simple system of linear equations,  $A*x = B$ .

```
A = magic(3);  
B = [15; 15; 15];  
x = A\B
```

```
x =
```

```
1.0000  
1.0000  
1.0000
```

### Linear System with Singular Matrix

Solve a linear system of equations involving a singular matrix, C.

```
C = magic(4);  
D = [34; 34; 34; 34];  
x = C\D
```

```
Warning: Matrix is close to singular or badly scaled. Results may be inaccurate.  
1.306145e-17.
```

```
x =
```

```

1.5000
2.5000
-0.5000
0.5000

```

MATLAB issues a warning but proceeds with the calculation. MATLAB might give a valid solution even when working with a singular matrix. These solutions are often not unique.

### Least-Squares Solution of Underdetermined System

Solve a system of linear equations,  $A*x = b$ .

```

A = [1 2 0; 0 4 3];
b = [8; 18];
x = A\b

```

ans =

```

      0
4.0000
0.6667

```

### Linear System with Sparse Matrix

Solve a simple system of linear equations using sparse matrices.

Consider the matrix equation  $A*x = B$ .

```

A = sparse([0 2 0 1 0; 4 -1 -1 0 0; 0 0 0 3 -6; -2 0 0 0 2; 0 0 4 2 0]);
B = sparse([8; -1; -18; 8; 20]);
x = A\B

```

x =

```

(1,1)      1.0000
(2,1)      2.0000
(3,1)      3.0000
(4,1)      4.0000

```

# mldivide

---

(5,1)      5.0000

## Tips

- If  $A$  is a square matrix,  $A \setminus B$  is roughly equal to  $\text{inv}(A) * B$ , but MATLAB processes  $A \setminus B$  differently and more robustly.
- If the rank of  $A$  is less than the number of columns in  $A$ , then  $x = A \setminus B$  is not necessarily the minimum norm solution. The more computationally expensive  $x = \text{pinv}(A) * B$  computes the minimum norm least-squares solution.
- For full singular inputs, you can compute the least-squares solution using the function `linsolve`.

| `linsolve` | `ldl`

## Concepts

- “Systems of Linear Equations”
- “Implementing Operators for Your Class”

**Purpose** Solve systems of linear equations  $xA = B$  for  $x$

**Syntax**  
 $x = B/A$   
 $x = \text{mrdivide}(B,A)$

**Description**  $x = B/A$  solves the system of linear equations  $x*A = B$  for  $x$ . The matrices **A** and **B** must contain the same number of columns. MATLAB displays a warning message if **A** is badly scaled or nearly singular, but performs the calculation regardless.

- If **A** is a scalar, **B/A** performs element-wise division of **B** by **A**.
- If **A** is a square  $n$ -by- $n$  matrix and **B** is a row vector with  $n$  elements or a matrix with  $n$  columns, then  $x = B/A$  is a solution to the equation  $x*A = B$ , if it exists.
- If **A** is a rectangular  $m$ -by- $n$  matrix with  $m \neq n$ , and **B** is a row vector with  $n$  elements or a matrix with  $n$  columns, then  $x = B/A$  returns a least-squares solution of the system of equations  $x*A = B$ .

$x = \text{mrdivide}(B,A)$  is an alternative way to execute  $x = B/A$ , but is rarely used. It enables operator overloading for classes.

## Input Arguments

**A - Coefficient matrix**  
 vector | full matrix | sparse matrix

Coefficient matrix, specified as a vector, full matrix, or sparse matrix. If **A** has  $n$  columns, then **B** must have  $n$  columns.

**Data Types**  
 single | double

**Complex Number Support:** Yes

**B - Right-hand side**  
 vector | full matrix | sparse matrix

Right-hand side, specified as a vector, full matrix, or sparse matrix. If **B** has  $n$  columns, then **A** must have  $n$  columns.

## Data Types

single | double

**Complex Number Support:** Yes

## Output Arguments

### x - Solution

vector | full matrix | sparse matrix

Solution, specified as a vector, full matrix, or sparse matrix. If A is an m-by-n matrix and B is a p-by-n matrix, then x is a p-by-m matrix.

x is sparse only if both A and B are sparse matrices.

## Examples

### System of Equations

Solve a system of equations that has a unique solution,  $x*A = B$ .

```
A = [1 1 3; 2 0 4; -1 6 -1];
```

```
B = [2 19 8];
```

```
x = B/A
```

```
x =
```

```
    1.0000    2.0000    3.0000
```

### Least-Squares on an Underdetermined System

Solve an underdetermined system,  $x*C = D$ .

```
C = [1 0; 2 0; 1 0];
```

```
D = [1 2];
```

```
x = D/C
```

```
Warning: Rank deficient, rank = 1, tol = 6.280370e-16.
```

```
x =
```

```
    0    0.5000    0
```

MATLAB issues a warning but proceeds with calculation.

Verify that  $x$  is not an exact solution.

$x * C - D$

ans =

0     -2

**Tips**

- The operators `/` and `\` are related to each other by the equation  $B/A = (A' \setminus B')'$ .
- If  $A$  is a square matrix,  $B/A$  is roughly equal to  $B * \text{inv}(A)$ , but MATLAB processes  $B/A$  differently and more robustly.

**Concepts**

- “Systems of Linear Equations”

# mlint

---

**Purpose** Check MATLAB code files for possible problems

---

**Note** `mlint` is not recommended. Use `checkcode` instead.

---

**Alternatives** For information on using the graphical user interface to the Code Analyzer, see “Check Code for Errors and Warnings”.

**Syntax**

```
mlint('filename')
mlint('filename', '-config=settings.txt')
mlint('filename', '-config=factory')
inform=mlint('filename', '-struct')
msg=mlint('filename', '-string')
[inform, filepaths]=mlint('filename')
inform=mlint('filename', '-id')
inform=mlint('filename', '-fullpath')
inform=mlint('filename', '-notok')
mlint('filename', '-cyc')
mlint('filename', '-codegen')
mlint('filename', '-eml')
```

**Description** `mlint('filename')` displays Code Analyzer messages about `filename`, where the message reports potential problems and opportunities for code improvement. The line number in the message is a hyperlink that opens the file in the Editor, scrolled to that line. If `filename` is a cell array, information is displayed for each file. For `mlint(F1,F2,F3,...)`, where each input is a character array, MATLAB software displays information about each input file name. You cannot combine cell arrays and character arrays of file names. Note that the exact text of the `mlint` messages is subject to some change between versions.

`mlint('filename', '-config=settings.txt')` overrides the default active settings file with the settings that enable or suppress messages as indicated in the specified `settings.txt` file.

---

**Note** If used, you must specify the full path to the `settings.txt` file specified with the `-config` option.

---

For information about creating a `settings.txt` file, see “Save and Reuse Code Analyzer Message Settings”. If you specify an invalid file, `mlint` returns a message indicating that it cannot open or read the file you specified. In that case, `mlint` uses the factory default settings.

`mlint('filename', '-config=factory')` ignores all settings files and uses the factory default preference settings.

`inform=mlint('filename', '-struct')` returns the information in a structure array whose length is the number of messages found. The structure has the fields that follow.

| Field                | Description                                                                                                                                                                                                                                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>message</code> | Message describing the suspicious construct that code analysis caught.                                                                                                                                                                                                                                                                          |
| <code>line</code>    | Vector of file line numbers to which the message refers.                                                                                                                                                                                                                                                                                        |
| <code>column</code>  | Two-column array of file columns (column extents) to which the message applies. The first column of the array specifies the column in the Editor where the message begins. The second column of the array specifies the column in the Editor where the message ends. There is one row in the two-column array for each occurrence of a message. |

If you specify multiple file names as input, or if you specify a cell array as input, `inform` contains a cell array of structures.

`msg=mlint('filename', '-string')` returns the information as a string to the variable `msg`. If you specify multiple file names as input, or if you specify a cell array as input, `msg` contains a string where each

file's information is separated by 10 equal sign characters (=), a space, the file name, a space, and 10 equal sign characters.

If you omit the **-struct** or **-string** argument and you specify an output argument, the default behavior is **-struct**. If you omit the argument and there are no output arguments, the default behavior is to display the information to the command line.

`[inform,filepath]=mlint('filename')` additionally returns `filepath`, the absolute paths to the file names, in the same order as you specified them.

`inform=mlint('filename','-id')` requests the message ID, where ID is a string of the form ABC... When returned to a structure, the output also has the `id` field, which is the ID associated with the message.

`inform=mlint('filename','-fullpath')` assumes that the input file names are absolute paths, so that `mlint` does not try to locate them.

`inform=mlint('filename','-notok')` runs `mlint` for all lines in `filename`, even those lines that end with the `mlint` suppression directive, `##ok`.

`mlint('filename','-cyc')` displays the McCabe complexity (also referred to as cyclomatic complexity) of each function in the file. Higher McCabe complexity values indicate higher complexity, and there is some evidence to suggest that programs with higher complexity values are more likely to contain errors. Frequently, you can lower the complexity of a function by dividing it into smaller, simpler functions. In general, smaller complexity values indicate programs that are easier to understand and modify. Some people advocate splitting up programs that have a complexity rating over 10.

`mlint('filename','-codegen')` enables code generation messages for display in the Command Window.

`mlint('filename','-eml')` `-eml` is not recommended. Use `-codegen` instead.

## Examples

The following examples use `lengthofline.m`, which is a sample file with MATLAB code that can be improved. You can find it in

*matlabroot/help/techdoc/matlab\_env/examples*. If you want to run the examples, save a copy of *lengthofline.m* to a location on your MATLAB path.

## Running mlint on a File with No Options

To run `mlint` on the example file, *lengthofline.m*, run

```
mlint('lengthofline')
```

MATLAB displays the M-Lint messages for *lengthofline.m* in the Command Window:

```
L 22 (C 1-9): The value assigned here to variable 'nothandle' might never be used.
L 23 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 24 (C 5-11): 'notline' might be growing inside a loop. Consider preallocating for speed.
L 24 (C 44-49): Use STRCMP(str1,str2) instead of using LOWER in a call to STRCMP.
L 28 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 34 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 34 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD.
                Type 'doc struct' for more information.
L 38 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 40 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 43 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 45 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 48 (C 52): There may be a parenthesis imbalance around here.
L 48 (C 53): There may be a parenthesis imbalance around here.
L 48 (C 54): There may be a parenthesis imbalance around here.
L 48 (C 55): There may be a parenthesis imbalance around here.
L 49 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 49 (C 23): Use of brackets [] is unnecessary. Use parentheses to group, if needed.
```

For details about these messages and how to improve the code, see “Changing Code Based on Code Analyzer Messages” in the MATLAB Desktop Tools and Development Environment documentation.

## Running mlint with Options to Show IDs and Return Results to a Structure

To store the results to a structure and include message IDs, run

```
inform=mlint('lengthofline', '-id')
```

MATLAB returns

```
inform =
```

```
19x1 struct array with fields:
```

```
    message  
     line  
   column  
     id
```

To see values for the first message, run

```
inform(1)
```

MATLAB displays

```
ans =
```

```
message: 'The value assigned here to variable 'nohandle' might never be used.'  
   line: 22  
column: [1 9]  
   id: 'NASGU'
```

Here, the message is for the value that appears on line 22 that extends from column 1–9 in the file.NASGU is the ID for the message 'The value assigned here to variable 'nohandle' might never be used.'.

## Displaying McCabe Complexity with mlint

To display the McCabe complexity of a MATLAB code file, run `mlint` with the `-cyc` option, as shown in the following example (assuming you have saved `lengthofline.m` to a local folder).

```
mlint lengthofline.m -cyc
```

Results displayed in the Command Window show the McCabe complexity of the file, followed by the M-Lint messages, as shown here:

```
L 1 (C 23-34): The McCabe complexity of 'lengthofline' is 12.
L 22 (C 1-9): The value assigned here to variable 'nohandle' might never be used.
L 23 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 24 (C 5-11): 'notline' might be growing inside a loop. Consider preallocating for speed.
L 24 (C 44-49): Use STRCMP(str1,str2) instead of using UPPER/LOWER in a call to STRCMP.
L 28 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 34 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 34 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD. Type 'doc struct' for mo
L 38 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 40 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 43 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 45 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 48 (C 52): There may be a parenthesis imbalance around here.
L 48 (C 53): There may be a parenthesis imbalance around here.
L 48 (C 54): There may be a parenthesis imbalance around here.
L 48 (C 55): There may be a parenthesis imbalance around here.
L 49 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 49 (C 23): Use of brackets [] is unnecessary. Use parentheses to group, if needed.
```

## See Also

mlintrpt, profile

## How To

- For information on the suppression directive, `%#ok`, and suppressing messages from within your program, see “Adjust Code Analyzer Message Indicators and Messages”.

# mlintrpt

---

**Purpose** Run checkcode for file or folder, reporting results in browser

**Syntax**

```
mlintrpt
mlintrpt('filename','file')
mlintrpt('dirname','dir')
mlintrpt('filename','file','settings.txt')
mlintrpt('dirname','dir','settings.txt')
```

**Description** `mlintrpt` scans all files with an `.m` file extension in the current folder for Code Analyzer messages and reports the results in a MATLAB Web browser.

`mlintrpt('filename','file')` scans `filename` for Code Analyzer messages and reports results. You can omit `'file'` in this form of the syntax because it is the default.

`mlintrpt('dirname','dir')` scans the specified folder. Here, `dirname` can be in the current folder or can be a full path.

`mlintrpt('filename','file','settings.txt')` applies the Code Analyzer preference settings to enable or suppress messages as indicated in the specified `settings.txt` file.

`mlintrpt('dirname','dir','settings.txt')` applies the settings indicated in the specified `settings.txt` file.

---

**Note** If you specify a `settings.txt` file, you must specify the full path to the file.

---

**Examples** `lengthofline.m` is an example file with code that can be improved. It is found in `matlabroot/matlab/help/techdoc/matlab_env/examples`.

## Run Report for All Files in a Folder

Run

```
mlintrpt(fullfile(matlabroot,'help','techdoc','matlab_env','examples'),'dir')
```

and MATLAB displays a report of potential problems and improvements for all files with an `.m` file extension in the `examples` folder.

For details about these messages and how to improve the code, see “Changing Code Based on Code Analyzer Messages”.

### Run Report Using Code Analyzer Preference Settings

You can save preference settings to a text file by clicking the **Preferences** button in the **Environment** section on the **Home** tab and selecting **Code Analyzer** in the left pane. To save a preferences file, select **Save as** under the  drop-down list. To apply those settings when you run `mlintrpt`, use the `file` option and supply the full path to the settings file name as shown in this example:

```
mlintrpt('lengthofline.m', 'file', ...
'C:\WINNT\Profiles\me\Application Data\MathWorks\MATLAB\R2012b\mymlint.txt')
```

Alternatively, use `fullfile` if the settings file is stored in the preferences folder:

```
mlintrpt('lengthofline.m', 'file', fullfile(prefdir, 'mymlint.txt'))
```

Assuming that in that example `mymlint.txt` file, the setting for **Terminate statement with semicolon to suppress output** has been disabled, the results of `mlintrpt` for `lengthofline` do not show that message for line 49.

When `mlintrpt` cannot locate the settings file, the first message in the report is

```
0: Unable to open or read the configuration file 'mymlint.txt'--using default settings.
```

## See Also

`checkcode`

## Concepts

- “Check Code for Errors and Warnings”

# mlock

---

**Purpose** Prevent clearing function from memory

**Syntax** `mlock`

**Description** `mlock` locks the currently running function in memory so that subsequent `clear` functions do not remove it. Locking a function in memory also prevents any persistent variables defined in the file from getting reinitialized.

Use the `munlock` function to return the file to its normal, clearable state.

**Examples** The function `testfun` begins with an `mlock` statement.

```
function testfun
mlock
.
.
```

When you execute this function, it becomes locked in memory. You can check this using the `mislocked` function.

```
testfun

mislocked('testfun')
ans =
     1
```

Using `munlock`, you unlock the `testfun` function in memory. Checking its status with `mislocked` shows that it is indeed unlocked at this point.

```
munlock('testfun')

mislocked('testfun')
ans =
     0
```

**See Also** `mislocked` | `munlock` | `inmem` | `persistent`

**Purpose** Information about multimedia file

**Syntax** `info = mmfileinfo(filename)`

**Description** `info = mmfileinfo(filename)` returns a structure, *info*, with fields containing information about the contents of the multimedia file identified by *filename*. The *filename* input is a string enclosed in single quotation marks.

If *filename* is a URL, `mmfileinfo` might take a long time to return because it must first download the file. For large files, downloading can take several minutes. To avoid blocking the MATLAB command line while this processing takes place, download the file before calling `mmfileinfo`.

The *info* structure contains the following fields, listed in the order they appear in the structure.

| Field    | Description                                                                                                                                        |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| Filename | String indicating the name of the file.                                                                                                            |
| Path     | String indicating the absolute path to the file.                                                                                                   |
| Duration | Length of the file in seconds.                                                                                                                     |
| Audio    | Structure containing information about the audio data in the file. See “Audio Data” on page 2-2926 for more information about this data structure. |
| Video    | Structure containing information about the video data in the file. See “Video Data” on page 2-2926 for more information about this data structure. |

## Audio Data

The Audio structure contains the following fields, listed in the order they appear in the structure. If the file does not contain audio data, the fields in the structure are empty.

| Field            | Description                               |
|------------------|-------------------------------------------|
| Format           | Text string, indicating the audio format. |
| NumberOfChannels | Number of audio channels.                 |

## Video Data

The Video structure contains the following fields, listed in the order they appear in the structure. If the file does not contain video data, the fields in the structure are empty.

| Field  | Description                               |
|--------|-------------------------------------------|
| Format | Text string, indicating the video format. |
| Height | Height of the video frame.                |
| Width  | Width of the video frame.                 |

## Examples

Display information about the example file `xylophone.mpg`:

```
info = mmfileinfo('xylophone.mpg')
audio = info.Audio
video = info.Video
```

MATLAB returns:

```
info =
  Filename: 'xylophone.mpg'
  Path: [1x75 char]
  Duration: 4.7020
  Audio: [1x1 struct]
  Video: [1x1 struct]
```

```
audio =  
    Format: 'MPEG'  
    NumberOfChannels: 2
```

```
video =  
    Format: 'MPEG1'  
    Height: 240  
    Width: 320
```

where Path is system-dependent.

## See Also

[get | VideoReader](#)

# mmreader

---

**Purpose** Create object for reading video files

---

**Note** mmreader will be removed in a future release. Use VideoReader instead. The mmreader class has been renamed VideoReader.

---

**Description** Use mmreader with the read method to read video data from a multimedia file into the MATLAB workspace.

The file formats that mmreader supports vary by platform, as follows (with no restrictions on file extensions):

|               |                                                                                                                                                                                                                                                                                        |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| All Platforms | Motion JPEG 2000 (.mj2)                                                                                                                                                                                                                                                                |
| Windows       | AVI (.avi),<br>MPEG-1 (.mpg),<br>Windows Media Video (.wmv, .asf, .asx),<br>and any format supported by Microsoft DirectShow.                                                                                                                                                          |
| Macintosh     | AVI (.avi),<br>MPEG-1 (.mpg),<br>MPEG-4 (.mp4, .m4v),<br>Apple QuickTime Movie (.mov),<br>and any format supported by QuickTime as listed on<br><a href="http://support.apple.com/kb/HT3775">http://support.apple.com/kb/HT3775</a> .                                                  |
| Linux         | Any format supported by your installed plug-ins<br>for GStreamer 0.10 or above, as listed on<br><a href="http://gstreamer.freedesktop.org/documentation/plugins.html">http://gstreamer.freedesktop.org/documentation/plugins.html</a> ,<br>including AVI (.avi) and Ogg Theora (.ogg). |

For more information, see “Supported Video File Formats” in the MATLAB Data Import and Export documentation.

**Construction** *obj* = mmreader(*filename*) constructs *obj* to read video data from the file named *filename*. The mmreader constructor searches for the file on the MATLAB path. If it cannot construct the object for any reason, mmreader generates an error.

```
obj = mmreader(filename, 'PropertyName', PropertyValue)
```

constructs the object using options, specified as property name/value pairs. Property name/value pairs can be in any format that the `set` method supports: name/value string pairs, structures, or name/value cell array pairs.

## Properties

### **BitsPerPixel**

Bits per pixel of the video data. (Read-only)

### **Duration**

Total length of the file in seconds. (Read-only)

### **FrameRate**

Frame rate of the video in frames per second. (Read-only)

### **Height**

Height of the video frame in pixels. (Read-only)

### **Name**

Name of the file associated with the object. (Read-only)

### **NumberOfFrames**

Total number of frames in the video stream. (Read-only)

Some files store video at a variable frame rate, including many Windows Media Video files. For these files, `mmreader` cannot determine the number of frames until you read the last frame. When you construct the object, `mmreader` returns a warning and does not set the `NumberOfFrames` property.

To count the number of frames in a variable frame rate file, use the `read` method to read the last frame of the file. For example:

```
vidObj = mmreader('varFrameRateFile.wmv');  
lastFrame = read(vidObj, inf);  
numFrames = vidObj.NumberOfFrames;
```

# mmreader

---

For more information, see “Reading Variable Frame Rate Video” in the MATLAB Data Import and Export documentation.

## **Path**

String containing the full path to the file associated with the reader. (Read-only)

## **Tag**

User-defined string to identify the object.

**Default:** ''

## **Type**

Class name of the object: 'mmreader'. (Read-only)

## **UserData**

Generic field for user-defined data.

**Default:** []

## **VideoFormat**

String indicating the MATLAB representation of the video format, such as 'RGB24'. (Read-only)

## **Width**

Width of the video frame in pixels. (Read-only)

## **Methods**

For backward compatibility, mmreader supports the following VideoReader methods:

|                |                                               |
|----------------|-----------------------------------------------|
| get            | Query property values for video reader object |
| getFileFormats | File formats that VideoReader supports        |

|      |                                             |
|------|---------------------------------------------|
| read | Read video frame data from file             |
| set  | Set property values for video reader object |

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB Programming Fundamentals documentation.

## Examples

Construct an `mmreader` object for the example movie file `xylophone.mpg` and view its properties:

```
xyloObj = mmreader('xylophone.mpg', 'Tag', 'My reader object');  
get(xyloObj)
```

---

Read and play back the movie file `xylophone.mpg`:

```
xyloObj = mmreader('xylophone.mpg');  
  
nFrames = xyloObj.NumberOfFrames;  
vidHeight = xyloObj.Height;  
vidWidth = xyloObj.Width;  
  
% Preallocate movie structure.  
mov(1:nFrames) = ...  
    struct('cdata', zeros(vidHeight, vidWidth, 3, 'uint8'),...  
          'colormap', []);  
  
% Read one frame at a time.  
for k = 1 : nFrames  
    mov(k).cdata = read(xyloObj, k);  
end  
  
% Size a figure based on the video's width and height.  
hf = figure;  
set(hf, 'position', [150 150 vidWidth vidHeight])
```

# mmreader

---

```
% Play back the movie once at the video's frame rate.  
movie(hf, mov, 1, xyloObj.FrameRate);
```

## How To

- “Read Video Files”

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Modulus after division                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Syntax</b>      | <code>M = mod(X,Y)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | <p><code>M = mod(X,Y)</code> if <code>Y ~= 0</code>, returns <code>X - n.*Y</code> where <code>n = floor(X./Y)</code>. If <code>Y</code> is not an integer and the quotient <code>X./Y</code> is within roundoff error of an integer, then <code>n</code> is that integer. The inputs <code>X</code> and <code>Y</code> must be real arrays of the same size, or real scalars.</p> <p>The following are true by convention:</p> <ul style="list-style-type: none"> <li>• <code>mod(X,0)</code> is <code>X</code></li> <li>• <code>mod(X,X)</code> is <code>0</code></li> <li>• <code>mod(X,Y)</code> for <code>X~=Y</code> and <code>Y~=0</code> has the same sign as <code>Y</code>.</li> </ul> |
| <b>Tips</b>        | <p><code>rem(X,Y)</code> for <code>X~=Y</code> and <code>Y~=0</code> has the same sign as <code>X</code>.</p> <p><code>mod(X,Y)</code> and <code>rem(X,Y)</code> are equal if <code>X</code> and <code>Y</code> have the same sign, but differ by <code>Y</code> if <code>X</code> and <code>Y</code> have different signs.</p> <p>The <code>mod</code> function is useful for congruence relationships: <i>x</i> and <i>y</i> are congruent (mod <i>m</i>) if and only if <code>mod(x,m) == mod(y,m)</code>.</p>                                                                                                                                                                                |
| <b>Examples</b>    | <pre>mod(13,5) ans =      3  mod([1:5],3) ans =      1     2     0     1     2  mod(magic(3),3) ans =      2     1     0      0     2     1      1     0     2</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

# mod

---

## See Also

rem

**Purpose** Most frequent values in array

**Syntax**

```
M = mode(X)
M = mode(X, dim)
[M,F] = mode(X, ...)
[M,F,C] = mode(X, ...)
```

**Description** `M = mode(X)` for vector `X` computes the sample mode `M`, (i.e., the most frequently occurring value in `X`). If `X` is a matrix, then `M` is a row vector containing the mode of each column of that matrix. If `X` is an `N`-dimensional array, then `M` is the mode of the elements along the first nonsingleton dimension of that array.

When there are multiple values occurring equally frequently, `mode` returns the smallest of those values. For complex inputs, this is taken to be the first value in a sorted list of values.

`M = mode(X, dim)` computes the mode along the dimension `dim` of `X`.

`[M,F] = mode(X, ...)` also returns array `F`, each element of which represents the number of occurrences of the corresponding element of `M`. The `M` and `F` output arrays are of equal size.

`[M,F,C] = mode(X, ...)` also returns cell array `C`, each element of which is a sorted vector of all values that have the same frequency as the corresponding element of `M`. All three output arrays `M`, `F`, and `C` are of equal size.

**Tips** The `mode` function is most useful with discrete or coarsely rounded data. The mode for a continuous probability distribution is defined as the peak of its density function. Applying the `mode` function to a sample from that distribution is unlikely to provide a good estimate of the peak; it would be better to compute a histogram or density estimate and calculate the peak of that estimate. Also, the `mode` function is not suitable for finding peaks in distributions having multiple modes.

**Examples** **Example 1**

Find the mode of the 3-by-4 matrix shown here:

# mode

---

```
X = [3 3 1 4; 0 0 1 1; 0 1 2 4]
```

```
X =  
     3     3     1     4  
     0     0     1     1  
     0     1     2     4
```

```
mode(X)  
ans =  
     0     0     1     4
```

Find the mode along the second (row) dimension:

```
mode(X, 2)  
ans =  
     3  
     0  
     0
```

## Example 2

Find the mode of a continuous variable grouped into bins:

```
rng(0,'twister');           % Reset the random number generator  
y = randn(1000,1);  
edges = -6:.25:6;  
[n,bin] = histc(y,edges);  
m = mode(bin)  
m =  
     26  
  
edges([m, m+1])  
ans =  
     0.2500     0.5000  
  
hist(y,edges+.125)
```

**See Also**

[mean](#) | [median](#) | [hist](#) | [histc](#)

# more

---

**Purpose** Control paged output for Command Window

**Syntax**

```
more on
more off
more(n)
A = more(state)
```

**Description** `more on` enables paging of the output in the MATLAB Command Window. MATLAB displays output one page at a time. Use the keys defined in the table below to control paging.

`more off` disables paging of the output in the MATLAB Command Window.

`more(n)` defines the length of a page to be `n` lines.

`A = more(state)` returns in `A` the number of lines that are currently defined to be a page. The `state` input can be one of the quoted strings `'on'` or `'off'`, or the number of lines to set as the new page length.

By default, the length of a page is equal to the number of lines available for display in the MATLAB Command Window. Manually changing the size of the command window adjusts the page length accordingly.

If you set the page length to a specific value, MATLAB uses that value for the page size, regardless of the size of the command window. To have MATLAB return to matching page size to window size, type `more off` followed by `more on`.

To see the status of `more`, type `get(0, 'More')`. MATLAB returns either `on` or `off`, indicating the `more` status.

When you have enabled `more` and are examining output, you can do the following.

| <b>Press the...</b> | <b>To...</b>                                                                                                                                 |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Return key          | Advance to the next line of output.                                                                                                          |
| Space bar           | Advance to the next page of output.                                                                                                          |
| Q (for quit) key    | Terminate display of the text. Do not use <b>Ctrl+C</b> to terminate <b>more</b> or you might generate error messages in the Command Window. |

**more** is in the **off** state, by default.

diary

# move

---

**Purpose** Move or resize control in parent window

**Syntax** `V = h.move(position)`  
`V = move(h, position)`

**Description** `V = h.move(position)` moves the control to the position specified by the `position` argument. When you use `move` with only the handle argument, `h`, it returns a four-element vector indicating the current position of the control.

`V = move(h, position)` is an alternate syntax.

The `position` argument is a four-element vector specifying the position and size of the control in the parent figure window. The elements of the vector are:

`[x, y, width, height]`

where `x` and `y` are offsets, in pixels, from the bottom left corner of the figure window to the same corner of the control, and `width` and `height` are the size of the control itself.

## Examples

This example moves the control:

```
f = figure('Position', [100 100 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.1', [0 0 200 200], f);
pos = h.move([50 50 200 200])
pos =
    50    50   200   200
```

The next example resizes the control to always be centered in the figure as you resize the figure window. Start by creating the script `resizectl.m` that contains

```
% Get the new position and size of the figure window
fpos = get(gcbo, 'position');

% Resize the control accordingly
```

```
h.move([0 0 fpos(3) fpos(4)]);
```

Now execute the following:

```
f = figure('Position', [100 100 200 200]);  
h = actxcontrol('mwsamp.mwsampctrl.1', [0 0 200 200]);  
set(f, 'ResizeFcn', 'resizectrl');
```

As you resize the figure window, notice that the circle moves so that it is always positioned in the center of the window.

set (COM) | get (COM)

# movefile

---

**Purpose** Move file or folder

**Alternatives** As an alternative to the `movefile` function, use the Current Folder browser. For more information, see “Working with Files and Folders”.

**Syntax**

```
movefile('source')  
movefile('source','destination')  
movefile('source','destination','f')  
[status,message,messageid]=movefile(...)
```

**Description** `movefile('source')` moves the file or folder named `source` to the current folder, where `source` is the absolute or relative path name for the folder or file. To move multiple files or folders, use one or more wildcard characters (\*) after the last file separator in `source`. The `source` argument permits a wildcard character in a path string. `movefile` does not preserve the archive attribute of `source`.

`movefile('source','destination')` moves the file or folder named `source` to the location `destination`, where `source` and `destination` are the absolute or relative paths for the folder or file. To move multiple files or folders, you can use one or more wildcard characters (\*) after the last file separator in `source`. You cannot use a wildcard character in `destination`. To rename a file or folder when moving it, make `destination` a different name than `source`, and specify only one file for `source`. When `source` and `destination` have the same location, `movefile` renames `source` to `destination`.

`movefile('source','destination','f')` moves the file or folder named `source` to the location `destination`, regardless of the read-only attribute of `destination`.

`[status,message,messageid]=movefile(...)` moves the file or folder named `source` to the location `destination`, returning the status, a message, and the MATLAB message ID. Here, `status` is logical 1 for success or logical 0 for error. `movefile` requires only one output argument.

## Examples

### Moving a File to the Current Folder

Assuming `myfiles` is a subfolder within the current folder, move the file `myfunction.m` to the current folder:

```
movefile('myfiles/myfunction.m')
```

Assuming `projects/testcases` is the current folder, move `projects/myfiles` and its contents to the current folder:

```
movefile('../myfiles')
```

### Renaming a File in the Current Folder

In the current folder, rename `myfunction.m` to `oldfunction.m`:

```
movefile('myfunction.m','oldfunction.m')
```

### Using a Wildcard to Move All Matching Files

Assuming `myfiles` is a subfolder of the current folder, move all files whose names that begin with `my` from the `myfiles` folder, to the current folder:

```
movefile('myfiles/my*')
```

### Moving a File to a Different Folder

Assuming `projects` and the current folder are at the same level, move the file `myfunction.m` from the current folder to the folder `projects`:

```
movefile('myfunction.m','../projects')
```

### Moving a Folder Down One Level

Assuming `projects` is a subfolder of the current folder, move the folder `projects/testcases` and all its contents down a level in `projects` into `projects/myfiles`:

```
movefile('projects/testcases','projects/myfiles/')
```

## Moving a File to a Read-Only Folder and Renaming the File

Move the file `myfile.m` from the current folder to `d:/work/restricted`, assigning it the name `test1.m`, where `restricted` is a read-only folder:

```
movefile('myfile.m','d:/work/restricted/test1.m','f')
```

The read-only file `myfile.m` is no longer in the current folder. The file `test1.m` is in `d:/work/restricted` and is read only.

## Returning Status When Moving Files

Move all files in the folder `myfiles` whose names start with `new` to the current folder, when there is an error. You mistype `new*` as `nex*` and no items in the current folder start with `nex*`:

```
[s,mess,messid]=movefile('myfiles/nex*')
```

```
s =  
    0
```

```
mess =
```

```
No matching files were found.
```

```
messid =
```

```
MATLAB:MOVEFILE:FileDoesNotExist
```

## How To

- “Creating, Opening, Changing, and Deleting Files and Folders”

**Purpose** Move GUI figure to specified location on screen

**Syntax**

```
movegui(h, 'position')  
movegui(position)  
movegui(h)  
movegui
```

**Description** `movegui(h, 'position')` moves the figure identified by handle `h` to the specified screen location, preserving the figure's size. The `position` argument is a string or a two-element vector, as defined in the following tables.

`movegui(position)` moves the callback figure (`gcbf`) or the current figure (`gcf`) to the specified position.

`movegui(h)` moves the figure identified by the handle `h` to the onscreen position.

`movegui` moves the callback figure (`gcbf`) or the current figure (`gcf`) to the onscreen position. You can specify 'movegui' as a `CreateFcn` callback for a figure. It ensures after you save it, the figure appears on screen when you reload it, regardless of its saved position. See the following example.

When it is a string, `position` is one of the following descriptors.

| Position String | Description                   |
|-----------------|-------------------------------|
| north           | Top center edge of screen     |
| south           | Bottom center edge of screen  |
| east            | Right center edge of screen   |
| west            | Left center edge of screen    |
| northeast       | Top right corner of screen    |
| northwest       | Top left corner of screen     |
| southeast       | Bottom right corner of screen |

| Position String | Description                                                     |
|-----------------|-----------------------------------------------------------------|
| southwest       | Bottom left corner                                              |
| center          | Centered on screen                                              |
| onscreen        | Nearest location to current location that is entirely on screen |

You can also specify the *position* argument as a two-element vector,  $[h, v]$ . Depending on sign,  $h$  specifies the figure's offset from the left or right edge of the screen, and  $v$  specifies the figure's offset from the top or bottom of the screen, in pixels. The following table summarizes the possible values.

|                       |                                                |
|-----------------------|------------------------------------------------|
| $h$ (for $h \geq 0$ ) | Offset of left side from left edge of screen   |
| $h$ (for $h < 0$ )    | Offset of right side from right edge of screen |
| $v$ (for $v \geq 0$ ) | Offset of bottom edge from bottom of screen    |
| $v$ (for $v < 0$ )    | Offset of top edge from top of screen          |

When you apply `movegui` to a maximized figure window, the window can shrink in size by a few pixels. On Microsoft Windows platforms, using it to move a maximized window toward the Windows task bar creates a gap on the opposite side of the screen about as wide as the task bar.

`GUIDE` and `openfig` call `movegui` when loading figures to ensure they are visible.

## Examples

Use `movegui` to ensure that a saved GUI appears on screen you reload it, regardless of the target computer screen size and resolution. Create a figure that is off the screen, assign `movegui` as its `CreateFcn` callback, save it, and then reload the figure.

```
f = figure('Position', [10000, 10000, 400, 300]);
```

```
% The figure does not display because it is created offscreen
set(f,'CreateFcn','movegui')
hgsave(f,'onscreenfig')
close(f)
f2 = hgload('onscreenfig');
% The reloaded figure is now visible
```

- “Positioning Figures”

# movie

---

**Purpose** Play recorded movie frames

**Syntax**

```
movie(M)
movie(M,n)
movie(M,n,fps)
movie(h,...)
movie(h,M,n,fps,loc)
```

**Description** The `movie` function plays the movie defined by a matrix whose columns are movie frames (usually produced by `getframe`).

`movie(M)` plays the movie in matrix `M` once, using the current axes as the default target. If you want to play the movie in the figure instead of the axes, specify the figure handle (or `gcf`) as the first argument: `movie(figure_handle,...)`. `M` must be an array of movie frames (usually from `getframe`).

`movie(M,n)` plays the movie `n` times. If `n` is negative, each cycle is shown forward then backward. If `n` is a vector, the first element is the number of times to play the movie, and the remaining elements make up a list of frames to play in the movie.

For example, if `M` has four frames then `n = [10 4 4 2 1]` plays the movie ten times, and the movie consists of frame 4 followed by frame 4 again, followed by frame 2 and finally frame 1.

`movie(M,n,fps)` plays the movie at `fps` frames per second. The default is 12 frames per second. Computers that cannot achieve the specified speed play as fast as possible.

`movie(h,...)` plays the movie centered in the figure or axes identified by the handle `h`. Specifying the figure or axes enables MATLAB to fit the movie to the available size.

`movie(h,M,n,fps,loc)` specifies `loc`, a four-element location vector, `[x y 0 0]`, where the lower left corner of the movie frame is anchored (only the first two elements in the vector are used). The location is relative to the lower left corner of the figure or axes specified by handle `h` and in units of pixels, regardless of the object's `Units` property.

**Tips**

The `movie` function uses a default figure size of 560-by-420 and does not resize figures to fit movies with larger or smaller frames. To accommodate other frame sizes, you can resize the figure to fit the movie, as shown in the second example below.

`movie` only accepts 8-bit image frames; it does not accept 16-bit grayscale or 24-bit truecolor image frames.

Buffering the movie places all frames in memory. As a result, on Microsoft Windows and perhaps other platforms, a long movie (on the order of several hundred frames) can exhaust memory, depending on system resources. In such cases an error message is issued that says

```
??? Error using ==> movie
Could not create movie frame
```

You can abort a movie by typing **Ctrl-C**.

`movie` is not a built-in function. Therefore, you cannot call `movie` using the `builtin` function.

**Limitations with Renderer on Windows Systems**

Setting the figure `Renderer` property to `zbuffer` or `painters` works around limitations of using `getframe` with the OpenGL renderer on some Windows systems.

**Examples**

Animate the `peaks` function as you scale the values of `Z`:

```
figure('Renderer','zbuffer')
Z = peaks;
surf(Z);
axis tight
set(gca,'NextPlot','replaceChildren');
% Preallocate the struct array for the struct returned by getframe
F(20) = struct('cdata',[],'colormap',[]);
% Record the movie
for j = 1:20
    surf(.01+sin(2*pi*j/20)*Z,Z)
    F(j) = getframe;
```

# movie

---

```
end
```

Now play the movie ten times. The twelfth frame looks like the following plot.

```
movie(F,10)
```

With larger frames, first adjust the figure's size to fit the movie:

```
figure('Position',[100 100 850 600])
```

```
Z = peaks; surf(Z);
axis tight
set(gca, 'NextPlot', 'replacechildren');
% Record the movie
for j = 1:20
    surf(sin(2*pi*j/20)*Z,Z)
    F(j) = getframe;
end
% use 1st frame to get dimensions
[h, w, p] = size(F(1).cdata);
hf = figure;
% resize figure based on frame's w x h, and place at (150, 150)
set(hf, 'Position', [150 150 w h]);
axis off
% Place frames at bottom left
movie(hf,F,4,30,[0 0 0 0]);
```

**How To**

- [Example – Visualizing an FFT as a Movie](#)

# movie2avi

---

**Purpose** Create Audio/Video Interleaved (AVI) file from MATLAB movie

**Syntax** `movie2avi(mov, filename)`  
`movie2avi(mov, filename, ParameterName, ParameterValue)`

**Description** `movie2avi(mov, filename)` creates the AVI file `filename` from the MATLAB movie `mov`. The `filename` input is a string. The `mov` input is a 1-by- $n$  structure array, where  $n$  is the number of frames. Each frame is a structure with two fields: `cdata` and `colormap`. For more information, see `getframe`.

`movie2avi(mov, filename, ParameterName, ParameterValue)` accepts one or more comma-separated parameter name/value pairs. The following table lists the available parameters and values.

| Parameter Name | Value                                                                                                                                                                                                                                                                                                                                                | Default                                                     |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| 'colormap'     | An $m$ -by-3 matrix defining the colormap for indexed AVI movies, where $m$ is no more than 256 (236 for Indeo compression).<br><br>Valid only when the 'compression' is 'MSVC', 'RLE', or 'None'.                                                                                                                                                   | No default                                                  |
| 'compression'  | A text string specifying the compression codec to use. To create an uncompressed file, specify a value of 'None'.<br><br>On UNIX operating systems, the only valid value is 'None'.<br><br>On Windows systems, valid values include: <ul style="list-style-type: none"><li>• 'MSVC'</li><li>• 'RLE'</li><li>• 'Cinepak' on 32-bit systems.</li></ul> | 'Indeo5' on Windows systems.<br><br>'None' on UNIX systems. |

| Parameter Name | Value                                                                                                                                                                                                                                                                                                                                                     | Default                      |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|
|                | <ul style="list-style-type: none"> <li>'Indeo3' or 'Indeo5' on 32-bit Windows XP systems.</li> </ul> <p>Alternatively, specify a custom compression codec on Windows systems using the four-character code that identifies the codec (typically included in the codec documentation). If MATLAB cannot find the specified codec, it returns an error.</p> |                              |
| 'fps'          | A scalar value specifying the speed of the AVI movie in frames per second (fps).                                                                                                                                                                                                                                                                          | 15 fps                       |
| 'keyframe'     | For compressors that support temporal compression, the number of key frames per second.                                                                                                                                                                                                                                                                   | 2.1429 key frames per second |
| 'quality'      | A number from 0 through 100. Higher quality numbers result in higher video quality and larger file sizes. Lower quality numbers result in lower video quality and smaller file sizes.<br><br>Valid only for compressed movies.                                                                                                                            | 75                           |
| 'videoname'    | A descriptive name for the video stream, no more than 64 characters.                                                                                                                                                                                                                                                                                      | <i>filename</i>              |

**Tips**

- On some Windows systems, including all 64-bit systems, the default Indeo 5 codec is not available. MATLAB issues a warning, and creates an uncompressed file.
- On 32-bit Windows XP systems, MATLAB can create AVI files compressed with Indeo 3 and Indeo 5 codecs. However, Microsoft Windows XP Service Pack 3 (SP3) with Security Update 954157 disables playback of Indeo 3 and Indeo 5 codecs in Windows Media Player and Internet Explorer. Consider specifying a compression value of 'None'.

## Examples

Create a movie and write to an uncompressed AVI file, `myPeaks.avi`:

```
nFrames = 20;

% Preallocate movie structure.
mov(1:nFrames) = struct('cdata', [],...
                       'colormap', []);

% Create movie.
Z = peaks; surf(Z);
axis tight
set(gca, 'nextplot', 'replacechildren');
for k = 1:nFrames
    surf(sin(2*pi*k/20)*Z,Z)
    mov(k) = getframe(gcf);
end

% Create AVI file.
movie2avi(mov, 'myPeaks.avi', 'compression', 'None');
```

**Purpose** Matrix power

**Syntax**  
`c = a^b`  
`c = mpower(a,b)`

**Description** `c = a^b` computes `a` to the `b` power and returns the result in `c`. Inputs `a` and `b` must be one of the following:

- `a` is a square matrix and exponent `b` a scalar.
- `a` is a scalar and exponent `b` a square matrix.

`c = mpower(a,b)` is called for the syntax `a^b` when `a` or `b` is an object.

**See Also** `power`

# FTP.mput

---

**Purpose** Upload file or folder to FTP server

**Syntax** `mput(ftpobj,contents)`  
`paths = mput(ftpobj,contents)`

**Description** `mput(ftpobj,contents)` uploads the file or folder specified by `contents` to the current folder on an FTP server.

`paths = mput(ftpobj,contents)` returns a cell array that lists the paths to the uploaded files on the server.

**Input Arguments** **ftpobj**  
FTP object created by `ftp`.

**contents**  
String enclosed in single quotation marks that specifies either a file name or a folder name. Can include a wildcard character (\*).

**Output Arguments** **paths**  
Cell array that includes the paths to the uploaded files on the server.

**Examples** Suppose that your current MATLAB folder contains files `myfile1.m` through `myfile10.m`, and that you want to upload to a hypothetical FTP server, `ftp.testsite.com`. Connect to the server and upload the files:

```
test = ftp('ftp.testsite.com');  
mput(test, 'myfile*.m');  
close(test);
```

**See Also** `mget` | `ftp` | `mkdir` | `rename`

**Purpose** Create and open message box

**Syntax**

```
h = msgbox(Message)
h = msgbox(Message,Title)
h = msgbox(Message,Title,Icon)
h = msgbox(Message,Title,'custom',IconData,IconCMap)
h = msgbox(...,CreateMode)
```

**Description** `h = msgbox(Message)` creates a message dialog box that automatically wraps `Message` to fit an appropriately sized figure. `Message` is a string vector, string matrix, or cell array. `msgbox` returns the handle of the message box in `h`.

`h = msgbox(Message,Title)` specifies the title of the message box.

`h = msgbox(Message,Title,Icon)` specifies which icon to display in the message box. `Icon` is 'none', 'error', 'help', 'warn', or 'custom'. The default is 'none'.

Error Icon

Help Icon

Warning Icon

`h = msgbox(Message,Title,'custom',IconData,IconCMap)` defines a customized icon. `IconData` contains image data defining the icon. `IconCMap` is the colormap used for the image.

`h = msgbox(...,CreateMode)` specifies whether the message box is modal or nonmodal. Optionally, it can also specify an interpreter for `Message` and `Title`.

If `CreateMode` is a string, it must be one of the values shown in the following table.

| CreateMode Value      | Description                                                                                                                                                                                                                                                     |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'modal'               | Replaces the message box having the specified Title, that was last created or clicked on, with a modal message box as specified. All other message boxes with the same title are deleted. The message box which is replaced can be either modal or nonmodal.    |
| 'non-modal' (default) | Creates a new nonmodal message box with the specified parameters. Existing message boxes with the same title are not deleted.                                                                                                                                   |
| 'replace'             | Replaces the message box having the specified Title, that was last created or clicked on, with a nonmodal message box as specified. All other message boxes with the same title are deleted. The message box which is replaced can be either modal or nonmodal. |

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. To block MATLAB program execution as well, use the `uiwait` function.

If you open a dialog with `errorDlg`, `msgbox`, or `warndlg` using 'CreateMode', 'modal' and a non-modal dialog created with any of these functions is already present and *has the same name as the modal dialog*, the non-modal dialog closes when the modal one opens.

For more information about modal dialog boxes, see `WindowState` in the Figure Properties.

---

If `CreateMode` is a structure, it can have fields `WindowState` and `Interpreter`. The `WindowState` field must be one of the values in the

table above. Interpreter is one of the strings 'tex' or 'none'. The default value for Interpreter is 'none'.

## **See Also**

# mtimes

---

**Purpose** Matrix multiplication

**Syntax**  $C = A*B$

**Description**  $C = A*B$  is the linear algebraic product of the matrices  $A$  and  $B$ . If  $A$  is an  $m$ -by- $p$  and  $B$  is a  $p$ -by- $n$  matrix, the  $i, j$  entry of  $C$  is defined by

$$C(i, j) = \sum_{k=1}^p A(i, k)B(k, j).$$

The product  $C$  is an  $m$ -by- $n$  matrix. For nonscalar  $A$  and  $B$ , the number of columns of  $A$  must equal the number of rows of  $B$ . You can multiply a scalar by a matrix of any size.

The preceding definition says that  $C(i, j)$  is the inner product of the  $i$ th row of  $A$  with the  $j$ th column of  $B$ . You can write this definition using the MATLAB colon operator as

$$C(i, j) = A(i, :) * B(:, j)$$

where  $A(i, :)$  is the  $i$ th row of  $A$  and  $B(:, j)$  is the  $j$ th column of  $B$ .

---

**Note** If  $A$  is an  $m$ -by-0 empty matrix and  $B$  is a 0-by- $n$  empty matrix, where  $m$  and  $n$  are positive integers,  $A*B$  is an  $m$ -by- $n$  matrix of zeros.

---

## Examples

### Example 1

If  $A$  is a row vector and  $B$  is a column vector with the same number of elements as  $A$ ,  $A*B$  is the inner product of  $A$  and  $B$ . For example,

$$A = [5 \ 3 \ 2 \ 6]$$

$A =$

5      3      2      6

$$B = [-4 \ 9 \ 0 \ 1]'$$

$$B =$$

```

-4
 9
 0
 1

```

$$A*B$$

$$\text{ans} =$$

```

13

```

### Example 2

$$A = [1 \ 3 \ 5; \ 2 \ 4 \ 7]$$

$$A =$$

```

 1   3   5
 2   4   7

```

$$B = [-5 \ 8 \ 11; \ 3 \ 9 \ 21; \ 4 \ 0 \ 8]$$

$$B =$$

```

-5   8  11
 3   9  21
 4   0   8

```

The product of A and B is

$$C = A*B$$

$$C =$$

```

24   35  114
30   52  162

```

Note that the second row of A is

```
A(2, :)
```

```
ans =
```

```
     2     4     7
```

while the third column of B is

```
B(:, 3)
```

```
ans =
```

```
    11
```

```
    21
```

```
     8
```

The inner product of A(2, :) and B(:, 3) is

```
A(2, :)*B(:, 3)
```

```
ans =
```

```
    162
```

which is the same as C(2,3).

## See Also

Arithmetic Operators

**Purpose** Convert mu-law audio signal to linear

**Syntax** `y = mu2lin(mu)`

**Description** `y = mu2lin(mu)` converts mu-law encoded 8-bit audio signals, stored as “flints” in the range  $0 \leq \mu \leq 255$ , to linear signal amplitude in the range  $-s < Y < s$  where  $s = 32124/32768 \approx .9803$ . The input `mu` is often obtained using `fread(..., 'uchar')` to read byte-encoded audio files. “Flints” are MATLAB integers — floating-point numbers whose values are integers.

**See Also** `auread` | `lin2mu`

# multibandread

**Purpose** Read band-interleaved data from binary file

**Syntax**

```
X = multibandread(filename, size, precision, offset,  
                 interleave, byteorder)  
X = multibandread(...,subset1,subset2,subset3)
```

**Description** `X = multibandread(filename, size, precision, offset, interleave, byteorder)` reads band-sequential (BSQ), band-interleaved-by-line (BIL), or band-interleaved-by-pixel (BIP) data from the binary file `filename`. The `filename` input is a string enclosed in single quotes. This function defines *band* as the third dimension in a 3-D array, as shown in this figure.

You can use the parameters to `multibandread` to specify many aspects of the read operation, such as which bands to read. See “Parameters” on page 2-2965 for more information.

`X` is a 2-D array if only one band is read; otherwise it is 3-D. `X` is returned as an array of data type `double` by default. Use the `precision` parameter to map the data to a different data type.

`X = multibandread(...,subset1,subset2,subset3)` reads a subset of the data in the file. You can use up to three subsetting parameters to specify the data subset along row, column, and band dimensions. See “Subsetting Parameters” on page 2-2966 for more information.

---

**Note** In addition to BSQ, BIL, and BIP files, multiband imagery may be stored using the TIFF file format. In that case, use the `imread` function to import the data.

---

## Parameters

This table describes the arguments accepted by `multibandread`.

| Argument               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>filename</code>  | String containing the name of the file to be read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>size</code>      | Three-element vector of integers consisting of [height, width, N], where <ul style="list-style-type: none"> <li>• height is the total number of rows</li> <li>• width is the total number of elements in each row</li> <li>• N is the total number of bands.</li> </ul> <p>This will be the dimensions of the data if it is read in its entirety.</p>                                                                                                                                                                                                                                                                                                                                  |
| <code>precision</code> | String specifying the format of the data to be read, such as <code>'uint8'</code> , <code>'double'</code> , <code>'integer*4'</code> , or any of the other precisions supported by the <code>fread</code> function. <p>Note: You can also use the <code>precision</code> parameter to specify the format of the output data. For example, to read <code>uint8</code> data and output a <code>uint8</code> array, specify a precision of <code>'uint8=&gt;uint8'</code> (or <code>'*uint8'</code>). To read <code>uint8</code> data and output it in the MATLAB software in single precision, specify <code>'uint8=&gt;single'</code>. See <code>fread</code> for more information.</p> |

# multibandread

---

| Argument   | Description                                                                                                                                                                                                                                                                                                                               |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| offset     | Scalar specifying the zero-based location of the first data element in the file. This value represents the number of bytes from the beginning of the file to where the data begins.                                                                                                                                                       |
| interleave | String specifying the format in which the data is stored <ul style="list-style-type: none"><li>• 'bsq' — Band-Sequential</li><li>• 'bil' — Band-Interleaved-by-Line</li><li>• 'bip' — Band-Interleaved-by-Pixel</li></ul> <p>For more information about these interleave methods, see the <code>multibandwrite</code> reference page.</p> |
| byteorder  | String specifying the byte ordering (machine format) in which the data is stored, such as <ul style="list-style-type: none"><li>• 'ieee-le' — Little-endian</li><li>• 'ieee-be' — Big-endian</li></ul> <p>See <code>fopen</code> for a complete list of supported formats.</p>                                                            |

## Subsetting Parameters

You can specify up to three subsetting parameters. Each subsetting parameter is a three-element cell array, `{dim, method, index}`, where

| Parameter  | Description                                                                                                                                                       |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>dim</i> | Text string specifying the dimension to subset along. It can have any of these values: <ul style="list-style-type: none"><li>• 'Column'</li><li>• 'Row'</li></ul> |

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>method</i> | <ul style="list-style-type: none"><li>• 'Band'</li></ul> Text string specifying the subsetting method. It can have either of these values: <ul style="list-style-type: none"><li>• 'Direct'</li><li>• 'Range'</li></ul> If you leave out this element of the subset cell array, <code>multibandread</code> uses 'Direct' as the default.                                                                                             |
| <i>index</i>  | If <i>method</i> is 'Direct', <i>index</i> is a vector specifying the indices to read along the Band dimension.<br><br>If <i>method</i> is 'Range', <i>index</i> is a three-element vector of [start, increment, stop] specifying the range and step size to read along the dimension specified in <i>dim</i> . If <i>index</i> is a two-element vector, <code>multibandread</code> assumes that the value of <i>increment</i> is 1. |

## Examples

### Example 1

Setup initial parameters for a data set.

```
rows=3; cols=3; bands=5;  
filename = tempname;
```

Define the data set.

```
fid = fopen(filename, 'w', 'ieee-le');  
fwrite(fid, 1:rows*cols*bands, 'double');  
fclose(fid);
```

Read every other band of the data using the Band-Sequential format.

# multibandread

---

```
im1 = multibandread(filename, [rows cols bands], ...  
                      'double', 0, 'bsq', 'ieee-le', ...  
                      {'Band', 'Range', [1 2 bands]} )
```

Read the first two rows and columns of data using  
Band-Interleaved-by-Pixel format.

```
im2 = multibandread(filename, [rows cols bands], ...  
                      'double', 0, 'bip', 'ieee-le', ...  
                      {'Row', 'Range', [1 2]}, ...  
                      {'Column', 'Range', [1 2]} )
```

Read the data using Band-Interleaved-by-Line format.

```
im3 = multibandread(filename, [rows cols bands], ...  
                      'double', 0, 'bil', 'ieee-le')
```

Delete the file created in this example.

```
delete(filename);
```

## Example 2

Read int16 BIL data from the FITS file `tst0012.fits`, starting at  
byte 74880.

```
im4 = multibandread('tst0012.fits', [31 73 5], ...  
                    'int16', 74880, 'bil', 'ieee-be', ...  
                    {'Band', 'Range', [1 3]} );  
im5 = double(im4)/max(max(max(im4)));  
imagesc(im5);
```

## See Also

`fread` | `fwrite` | `imread` | `memmapfile` | `multibandwrite`

## Purpose

Write band-interleaved data to file

## Syntax

```
multibandwrite(data,filename,interleave)
multibandwrite(data,filename,interleave,start,totalsize)
multibandwrite(...,param,value...)
```

## Description

`multibandwrite(data,filename,interleave)` writes `data`, a two- or three-dimensional numeric or logical array, to the binary file specified by `filename`. The `filename` input is a string enclosed in single quotes. The length of the third dimension of `data` determines the number of bands written to the file. The bands are written to the file in the form specified by `interleave`. See “Interleave Methods” on page 2-2971 for more information about this argument.

If `filename` already exists, `multibandwrite` overwrites it unless you specify the optional `offset` parameter. See the last alternate syntax for `multibandwrite` for information about other optional parameters.

`multibandwrite(data,filename,interleave,start,totalsize)` writes `data` to the binary file `filename` in chunks. In this syntax, `data` is a subset of the complete data set.

`start` is a 1-by-3 array [`firstrow firstcolumn firstband`] that specifies the location to start writing data. `firstrow` and `firstcolumn` specify the location of the upper left image pixel. `firstband` gives the index of the first band to write. For example, `data(I,J,K)` contains the data for the pixel at [`firstrow+I-1, firstcolumn+J-1`] in the (`firstband+K-1`)-th band.

`totalsize` is a 1-by-3 array, [`totalrows,totalcolumns,totalbands`], which specifies the full, three-dimensional size of the data to be written to the file.

# multibandwrite

---

---

**Note** In this syntax, you must call `multibandwrite` multiple times to write all the data to the file. The first time it is called, `multibandwrite` writes the complete file, using the fill value for all values outside the data subset. In each subsequent call, `multibandwrite` overwrites these fill values with the data subset in `data`. The parameters `filename`, `interleave`, `offset`, and `totalsize` must remain constant throughout the writing of the file.

---

`multibandwrite(..., param, value...)` writes the multiband data to a file, specifying any of these optional parameter/value pairs.

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'precision' | String specifying the form and size of each element written to the file. See the help for <code>fwrite</code> for a list of valid values. The default precision is the class of the data.                                                                                                                                                                                                                                                                                                                |
| 'offset'    | The number of bytes to skip before the first data element. If the file does not already exist, <code>multibandwrite</code> writes ASCII null values to fill the space. To specify a different fill value, use the parameter <code>'fillvalue'</code> .<br><br>This option is useful when you are writing a header to the file before or after writing the data. When writing the header to the file after the data is written, open the file with <code>fopen</code> using <code>'r+'</code> permission. |

| Parameter   | Description                                                                                                                                                                                                                                                                                              |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'machfmt'   | String to control the format in which the data is written to the file. Typical values are 'ieee-le' for little endian and 'ieee-be' for big endian. See the help for <code>fopen</code> for a complete list of available formats. The default machine format is the local machine format.                |
| 'fillvalue' | A number specifying the value to use in place of missing data. 'fillvalue' can be a single number, specifying the fill value for all missing data, or a 1-by-Number-of-bands vector of numbers specifying the fill value for each band. This value is used to fill space when data is written in chunks. |

## Interleave Methods

`interleave` is a string that specifies how `multibandwrite` interleaves the bands as it writes data to the file. If data is two-dimensional, `multibandwrite` ignores the `interleave` argument. The following table lists the supported methods and uses this example multiband file to illustrate each method.

Supported methods of interleaving bands include those listed below.

# multibandwrite

---

| Method                    | String | Description                        | Example                                                                       |
|---------------------------|--------|------------------------------------|-------------------------------------------------------------------------------|
| Band-Interleaved-by-Line  | 'bil'  | Write an entire row from each band | AAAAABBBBBCCCC<br>AAAAABBBBBCCCC<br>AAAAABBBBBCCCC                            |
| Band-Interleaved-by-Pixel | 'bip'  | Write a pixel from each band       | ABCABCABCABC...                                                               |
| Band-Sequential           | 'bsq'  | Write each band in its entirety    | AAAAA<br>AAAAA<br>AAAAA<br>BBBBB<br>BBBBB<br>BBBBB<br>CCCCC<br>CCCCC<br>CCCCC |

## Examples

---

**Note** To run these examples successfully, you must be in a writable directory.

---

### Example 1

Write all data (interleaved by line) to the file in one call.

```
data = reshape(uint16(1:600), [10 20 3]);  
multibandwrite(data, 'data.bil', 'bil');
```

## Example 2

Write a single-band tiled image with one call for each tile. This is only useful if a subset of each band is available at each call to `multibandwrite`.

```
numBands = 1;
dataDims = [1024 1024 numBands];
data = reshape(uint32(1:(1024 * 1024 * numBands)), dataDims);

for band = 1:numBands
    for row = 1:2
        for col = 1:2

            subsetRows = ((row - 1) * 512 + 1):(row * 512);
            subsetCols = ((col - 1) * 512 + 1):(col * 512);

            upperLeft = [subsetRows(1), subsetCols(1), band];
            multibandwrite(data(subsetRows, subsetCols, band), ...
                'banddata.bsq', 'bsq', upperLeft, dataDims);

        end
    end
end
```

## See Also

`multibandread` | `fwrite` | `fread`

# munlock

---

**Purpose** Allow clearing functions from memory

**Syntax**

```
munlock
munlock fun
munlock('fun')
```

**Description** `munlock` unlocks the currently running `.m` or `.mex` function in memory so that subsequent `clear` functions can remove it.

`munlock fun` unlocks the `.m` or `.mex` file named `fun` from memory. By default, these files are unlocked so that changes to the file are picked up. Calls to `munlock` are needed only to unlock `.m` or `.mex` functions that have been locked with `mlock`.

`munlock('fun')` is the function form of `munlock`.

**Examples** The function `testfun` begins with an `mlock` statement.

```
function testfun
mlock
.
.
```

When you execute this function, it becomes locked in memory. You can check this using the `mislocked` function.

```
testfun

mislocked testfun
ans =
     1
```

Using `munlock`, you unlock the `testfun` function in memory. Checking its status with `mislocked` shows that it is indeed unlocked at this point.

```
munlock testfun

mislocked testfun
ans =
```

0

# namelengthmax

---

**Purpose** Maximum identifier length

**Syntax** `len = namelengthmax`

**Description** `len = namelengthmax` returns the maximum length allowed for MATLAB identifiers. MATLAB identifiers are

- Variable names
- Function and local function names
- Structure fieldnames
- Object names
- File names with a `.m`, `.mex`, or `.mdl` extension

Rather than hard-coding a specific maximum name length into your programs, use the `namelengthmax` function. This saves you the trouble of having to update these limits should the identifier length change in some future MATLAB release.

**Examples** Call `namelengthmax` to get the maximum identifier length:

```
maxid = namelengthmax
maxid =
    63
```

**See Also** `isvarname` | `genvarname`

**Purpose**

Not-a-Number

**Syntax**

```
NaN
NaN('double')
NaN('single')
NaN(n)
NaN(m,n)
NaN([m,n])
NaN(m,n,p,...)
NaN([m,n,p,...])
```

**Description**

NaN returns the IEEE arithmetic representation for Not-a-Number (NaN). These result from operations which have undefined numerical results.

NaN('double') is the same as NaN with no inputs.

NaN('single') is the single precision representation of NaN.

NaN(n) is an n-by-n matrix of NaNs.

NaN(m,n) or NaN([m,n]) is an m-by-n matrix of NaNs.

NaN(m,n,p,...) or NaN([m,n,p,...]) is an m-by-n-by-p-by-... array of NaNs.

---

**Note** The size inputs m, n, p, ... should be nonnegative integers. Negative integers are treated as 0.

---

NaN(...,classname) is an array of NaNs of class specified by classname. classname must be either 'single' or 'double'.

**Examples**

These operations produce NaN:

- Any arithmetic operation on a NaN, such as `sqrt(NaN)`
- Addition or subtraction, such as magnitude subtraction of infinities as `(+Inf)+(-Inf)`

# NaN

---

- Multiplication, such as  $0 \cdot \text{Inf}$
- Division, such as  $0/0$  and  $\text{Inf}/\text{Inf}$
- Remainder, such as `rem(x,y)` where  $y$  is zero or  $x$  is infinity

## Tips

Because two NaNs are not equal to each other, logical operations involving NaNs always return false, except `~=` (not equal). Consequently,

```
NaN ~= NaN
ans =
     1
NaN == NaN
ans =
     0
```

and the NaNs in a vector are treated as different unique elements.

```
unique([1 1 NaN NaN])
ans =
     1 NaN NaN
```

Use the `isnan` function to detect NaNs in an array.

```
isnan([1 1 NaN NaN])
ans =
     0     0     1     1
```

## See Also

`Inf` | `isnan`

**Purpose**

Validate number of input arguments

---

**Note** nargchk will be removed in a future version. Use narginchk instead.

---

**Syntax**

```
msgstring = nargchk(minargs, maxargs, numargs)
msgstring = nargchk(minargs, maxargs, numargs, 'string')
msgstruct = nargchk(minargs, maxargs, numargs, 'struct')
```

**Description**

Use nargchk inside a function to check that the desired number of input arguments is specified in the call to that function.

msgstring = nargchk(minargs, maxargs, numargs) returns an error message string msgstring if the number of inputs specified in the call numargs is less than minargs or greater than maxargs. If numargs is between minargs and maxargs (inclusive), nargchk returns an empty matrix.

It is common to use the nargin function to determine the number of input arguments specified in the call.

msgstring = nargchk(minargs, maxargs, numargs, 'string') is essentially the same as the command shown above, as nargchk returns a string by default.

msgstruct = nargchk(minargs, maxargs, numargs, 'struct') returns an error message structure msgstruct instead of a string. The fields of the return structure contain the error message string and a message identifier. If numargs is between minargs and maxargs (inclusive), nargchk returns an empty structure.

When too few inputs are supplied, the message string and identifier are

```
message: 'Not enough input arguments.'
identifier: 'MATLAB:nargchk:notEnoughInputs'
```

When too many inputs are supplied, the message string and identifier are

# nargchk

---

```
message: 'Too many input arguments.'  
identifier: 'MATLAB:nargchk:tooManyInputs'
```

## Tips

nargchk is often used together with the error function. The error function accepts either type of return value from nargchk: a message string or message structure. For example, this command provides the error function with a message string and identifier regarding which error was caught:

```
error(nargchk(2, 4, nargin, 'struct'))
```

If nargchk detects no error, it returns an empty string or structure. When nargchk is used with the error function, as shown here, this empty string or structure is passed as an input to error. When error receives an empty string or structure, it simply returns and no error is generated.

## Examples

Given the function CheckInputs,

```
function CheckInputs(x, y, z)  
error(nargchk(2, 3, nargin))
```

Then typing CheckInputs(1) produces

```
Not enough input arguments.
```

## See Also

```
narginchk | nargoutchk | nargin | nargout | varargin | varargout  
| error
```

**Purpose**

Number of function input arguments

**Syntax**

```
nargin  
nargin(fx)
```

**Description**

`nargin` returns the number of input arguments passed in the call to the currently executing function. Use this `nargin` syntax only in the body of a function.

`nargin(fx)` returns the number of input arguments that appear in the definition statement for function `fx`. If the function includes `varargin` in its definition, then `nargin` returns the negative of the number of inputs. For example, if function `foo` declares inputs `a`, `b`, and `varargin`, then `nargin('foo')` returns `-3`.

**Input Arguments****fx**

Either a function handle or a string in single quotes that specifies the name of a function.

**Examples****Inputs to Current Function**

Create a function in a file named `addme.m` that accepts up to two inputs, and identify the number of inputs with `nargin`.

```
function c = addme(a,b)
```

```
switch nargin  
    case 2  
        c = a + b;  
    case 1  
        c = a + a;  
    otherwise  
        c = 0;  
end
```

**Inputs Defined for a Function**

Determine how many inputs a function can accept.

# nargin

---

The function `addme` created in the previous example has two inputs in its declaration statement (`a` and `b`).

```
fx = 'addme';  
nargin(fx)
```

```
ans =  
    2
```

## Function with varargin Input

Determine how many inputs a function that uses `varargin` can accept.

Define a function in a file named `mynewplot.m` that accepts numeric inputs `x` and `y` and any number of additional plot inputs using `varargin`.

```
function mynewplot(x,y,varargin)  
    figure  
    plot(x,y,varargin{:})  
    title('My New Plot')
```

At the command line, query how many inputs `newplot` can accept.

```
fx = 'mynewplot';  
nargin(fx)
```

```
ans =  
   -3
```

The minus sign indicates that the third input is `varargin`. The `mynewplot` function can accept an indeterminate number of additional input arguments.

```
fx = 'subtract';  
nargout(fx)
```

```
ans =  
     2
```

## Function with varargout Output

Determine how many outputs a function that uses `varargout` can return.

Define a function in a file named `mysize.m` that returns a vector of dimensions from the `size` function and the individual dimensions using `varargout`.

```
function [sizeVector,varargout] = mysize(x)  
    sizeVector = size(x);  
    varargout = cell(1,nargout-1);  
    for k = 1:length(varargout)  
        varargout{k} = sizeVector(k);  
    end
```

At the command line, query how many outputs `mysize` can return.

```
fx = 'mysize';  
nargout(fx)
```

```
ans =  
    -2
```

The minus sign indicates that the second output is `varargout`. The `mysize` function can return an indeterminate number of additional outputs.

## Tips

- When you use a function as part of an expression, MATLAB calls the function with one output argument, so `nargout` within the function returns 1. For example, given the following `if` statement and the `subtract` function defined in the Examples section, the value of `nargout` within the `subtract` function is 1.

```
a = 1; b = 2;  
if subtract(a,b) < 0  
    disp('Result is negative')  
end
```

# nargoutchk

---

**Purpose** Validate number of output arguments

**Syntax** nargoutchk(minargs, maxargs)

**Description** nargoutchk(minargs, maxargs) throws an error if the number of outputs specified in the call is less than minargs or greater than maxargs. If the number of outputs is between minargs and maxargs (inclusive), nargoutchk does nothing.

When too few outputs are supplied, the identifier and message are:

```
identifier: 'MATLAB:nargoutchk:notEnoughOutputs'  
message: 'Not enough output arguments.'
```

When too many outputs are supplied, the identifier and message are:

```
identifier: 'MATLAB:nargoutchk:tooManyOutputs'  
message: 'Too many output arguments.'
```

## Examples

This function uses nargoutchk to verify that a minimum of 2 and maximum of 5 input arguments are passed back to the calling function:

```
function [varargout] = check_outputs(array_in)  
minargs=2; maxargs=5;  
  
% Number of outputs must be >=minargs and <=maxargs.  
nargoutchk(minargs, maxargs)  
  
for k=1:nargout  
    varargout{k} = array_in(k)*3;  
end
```

Initialize input array X to a vector of 6 elements:

```
X = 5:7:40  
X =  
    5    12    19    26    33    40
```

Call the example function with 1 output argument. This is less than the minimum (2) that was specified by `nargoutchk` and results in an error:

```
A = check_outputs(X);
```

```
Error using check_outputs  
Not enough output arguments.
```

Call the function with 4 output arguments. This is within the allowable bounds (2 to 5) specified by `nargoutchk`:

```
[A, B, C, D] = check_outputs(X);
```

```
[A, B, C, D]  
ans =  
    15    36    57    78
```

Call the function with 6 output arguments. This exceeds the maximum (5) that was specified by `nargoutchk` and results in an error:

```
[A, B, C, D, E, F] = check_outputs(X);
```

```
Error using check_outputs  
Too many output arguments.
```

# native2unicode

---

**Purpose** Convert numeric bytes to Unicode characters

**Syntax** `unicodestr = native2unicode(bytes)`  
`unicodestr = native2unicode(bytes, encoding)`

**Description** `unicodestr = native2unicode(bytes)` takes a vector containing numeric values in the range [0,255] and converts these values as a stream of 8-bit bytes to Unicode characters. The stream of bytes is assumed to be in the MATLAB default character encoding scheme. Return value `unicodestr` is a char vector that has the same general array shape as `bytes`.

`unicodestr = native2unicode(bytes, encoding)` does the conversion with the assumption that the byte stream is in the character encoding scheme specified by the string `encoding`. `encoding` must be the empty string ('') or a name or alias for an encoding scheme. Some examples are 'UTF-8', 'latin1', 'US-ASCII', and 'Shift\_JIS'. For common names and aliases, see the Web site <http://www.iana.org/assignments/character-sets>. If `encoding` is unspecified or is the empty string (''), the MATLAB default encoding scheme is used.

---

**Note** If `bytes` is a char vector, it is returned unchanged.

---

## Examples

This example begins with a vector of bytes in an unknown character encoding scheme. The user-written function `detect_encoding` determines the encoding scheme. If successful, it returns the encoding scheme name or alias as a string. If unsuccessful, it throws an error represented by an `MException` object, `ME`. The example calls `native2unicode` to convert the bytes to Unicode characters:

```
try
    enc = detect_encoding(bytes);
    str = native2unicode(bytes, enc);
    disp(str);
```

```
catch ME
    rethrow(ME);
end
```

Note that the computer must be configured to display text in a language represented by the detected encoding scheme for the output of `disp(str)` to be correct.

`unicode2native`

# nchoosek

---

**Purpose** Binomial coefficient or all combinations

**Syntax**  $C = \text{nchoosek}(n, k)$   
 $C = \text{nchoosek}(v, k)$

**Description**  $C = \text{nchoosek}(n, k)$  where  $n$  and  $k$  are nonnegative integers, returns  $n!/((n-k)! k!)$ . This is the number of combinations of  $n$  things taken  $k$  at a time.

$C = \text{nchoosek}(v, k)$ , where  $v$  is a row vector of length  $n$ , creates a matrix whose rows consist of all possible combinations of the  $n$  elements of  $v$  taken  $k$  at a time. Matrix  $C$  contains  $n!/((n-k)! k!)$  rows and  $k$  columns.

Inputs  $n$ ,  $k$ , and  $v$  support classes of `float double` and `float single`.

**Examples** The command `nchoosek(2:2:10,4)` returns the even numbers from two to ten, taken four at a time:

|   |   |   |    |
|---|---|---|----|
| 2 | 4 | 6 | 8  |
| 2 | 4 | 6 | 10 |
| 2 | 4 | 8 | 10 |
| 2 | 6 | 8 | 10 |
| 4 | 6 | 8 | 10 |

**Limitations** When  $C = \text{nchoosek}(n, k)$  has a large coefficient, a warning will be produced indicating possible inexact results. In such cases, the result is only accurate to 15 digits for double-precision inputs, or 8 digits for single-precision inputs.

$C = \text{nchoosek}(v, k)$  is only practical for situations where  $n$  is less than about 15.

| <b>Tips</b>             | <p>The <code>ndgrid</code> function is similar to <code>meshgrid</code>, however <code>ndgrid</code> supports 1-D to N-D while <code>meshgrid</code> is restricted to 2-D and 3-D. The coordinates output by each function are the same, but the shape of the output arrays in the first two dimensions are different. For grid vectors <math>x1gv</math>,</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

# ndgrid

---

`x2gv` and `x3gv` of length `M`, `N` and `P` respectively, `ndgrid(x1gv, x2gv)` will output arrays of size `M`-by-`N` while `meshgrid(x1gv, x2gv)` outputs arrays of size `N`-by-`M`. Similarly, `ndgrid(x1gv, x2gv, x3gv)` will output arrays of size `M`-by-`N`-by-`P` while `meshgrid(x1gv, x2gv, x3gv)` outputs arrays of size `N`-by-`M`-by-`P`. See “Grid Representation” in the MATLAB Mathematics documentation for more information.

## Examples

Evaluate the function  $x_1 e^{-x_1^2 - x_2^2}$  over the range  $-2 < x_1 < 2, -2 < x_2 < 2$ :

```
[X1,X2] = ndgrid(-2:.2:2, -2:.2:2);  
Z = X1 .* exp(-X1.^2 - X2.^2);  
mesh(X1,X2,Z)
```

## How To

- “Interpolating Gridded Data”

**Purpose**            Number of array dimensions

**Syntax**            `n = ndims(A)`

**Description**        `n = ndims(A)` returns the number of dimensions in the array `A`. The number of dimensions in an array is always greater than or equal to 2. Trailing singleton dimensions are ignored. A singleton dimension is any dimension for which `size(A,dim) = 1`.

**Algorithms**        `ndims(x)` is `length(size(x))`.

**See Also**            `size`

**Purpose** Test for inequality

**Syntax** `A ~= B`  
`ne(A, B)`

**Description** `A ~= B` compares each element of array `A` with the corresponding element of array `B`, and returns an array with elements set to logical 1 (**true**) where `A` and `B` are unequal, or logical 0 (**false**) where they are equal. Each input of the expression can be an array or a scalar value.

If both `A` and `B` are scalar (i.e., 1-by-1 matrices), then the MATLAB software returns a scalar value.

If both `A` and `B` are nonscalar arrays, then these arrays must have the same dimensions, and MATLAB returns an array of the same dimensions as `A` and `B`.

If one input is scalar and the other a nonscalar array, then the scalar input is treated as if it were an array having the same dimensions as the nonscalar input array. In other words, if input `A` is the number 100, and `B` is a 3-by-5 matrix, then `A` is treated as if it were a 3-by-5 matrix of elements, each set to 100. MATLAB returns an array of the same dimensions as the nonscalar input array.

`ne(A, B)` is called for the syntax `A ~= B` when either `A` or `B` is an object.

## Examples

Create two 6-by-6 matrices, `A` and `B`, and locate those elements of `A` that are not equal to the corresponding elements of `B`:

```
A = magic(6);  
B = repmat(magic(3), 2, 2);
```

```
A ~= B  
ans =  
     1     0     0     1     1     1  
     0     1     0     1     1     1  
     1     0     0     1     1     1

# DelaunayTri.nearestNeighbor

---

**Purpose** Point closest to specified location

**Syntax**  
PI = nearestNeighbor(DT,QX)  
PI = nearestNeighbor(DT,QX,QY)  
PI = nearestNeighbor(DT,QX,QY,QZ)  
[PI,D] = nearestNeighbor(DT,QX,...)

**Description** PI = nearestNeighbor(DT,QX) returns the index of the nearest point in DT.X for each query point location in QX.  
PI = nearestNeighbor(DT,QX,QY) and PI = nearestNeighbor(DT,QX,QY,QZ) allow the query points to be specified in column vector format when working in 2-D and 3-D.  
[PI,D] = nearestNeighbor(DT,QX,...) returns the index of the nearest point in DT.X for each query point location in QX. The corresponding Euclidean distances between the query points and their nearest neighbors are returned in D.

---

**Note** Note: nearestNeighbor is not supported for 2-D triangulations that have constrained edges.

---

**Input Arguments**

|    |                                                                                                                                           |
|----|-------------------------------------------------------------------------------------------------------------------------------------------|
| DT | Delaunay triangulation.                                                                                                                   |
| QX | The matrix QX is of size mpts-by-ndim, mpts being the number of query points and ndim the dimension of the space where the points reside. |

## Output Arguments

PI

PI is a column vector of point indices that index into the points DT.X. The length of PI is equal to the number of query points mpts.

D

D is a column vector of length mpts.

## Examples

Create a Delaunay triangulation:

```
x = rand(10,1);  
y = rand(10,1);  
dt = DelaunayTri(x,y);
```

Create query points:

```
qrypts = [0.25 0.25; 0.5 0.5];
```

Find the nearest neighbors to the query points:

```
pid = nearestNeighbor(dt, qrypts)
```

| <b>Description</b>      | <code>SN = neighbors(TR, SI)</code> returns the simplex neighbor information for the specified simplices <code>SI</code> .                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Input Arguments</b>  | <code>TR</code>                                                                                                                                  | Triangulation representation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                         | <code>SI</code>                                                                                                                                  | <code>SI</code> is a column vector of simplex indices that index into the triangulation matrix <code>TR.Triangulation</code> . If <code>SI</code> is not specified the neighbor information for the entire triangulation is returned, where the neighbors associated with simplex <code>i</code> are defined by the <code>i</code> 'th row of <code>SN</code> .                                                                                                                                                                          |
| <b>Output Arguments</b> | <code>SN</code>                                                                                                                                  | <code>SN</code> is an <code>m</code> -by- <code>n</code> matrix, where <code>m = length(SI)</code> , the number of specified simplices, and <code>n</code> is the number of neighbors per simplex. Each row <code>SN(i, :)</code> represents the neighbors of the simplex <code>SI(i)</code> .<br><br>By convention, the simplex opposite vertex <code>(j)</code> of simplex <code>SI(i)</code> is <code>SN(i, j)</code> . If a simplex has one or more boundary facets, the nonexistent neighbors are represented by <code>NaN</code> . |
| <b>Definitions</b>      | <i>A simplex</i> is a triangle/tetrahedron or higher-dimensional equivalent. A <i>facet</i> is an edge of a triangle or a face of a tetrahedron. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Examples</b>         | <b>Example 1</b>                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                         | Load a 3-D triangulation and use <code>TriRep</code> to compute the neighbors of all tetrahedra.<br><br><code>load tetmesh</code>                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

# TriRep.neighbors

---

```
trep = TriRep(tet, X)
nbrs = neighbors(trep)
```

## Example 2

Query a 2-D triangulation created using `DelaunayTri`.

```
x = rand(10,1)
y = rand(10,1)
dt = DelaunayTri(x,y)
```

Find the neighbors of the first triangle:

```
n1 = neighbors(dt, 1)
```

**Purpose**

Summary of functions in MATLAB .NET interface

**Description**

Use the following functions to bring assemblies from the Microsoft .NET Framework into the MATLAB environment. The functions are implemented as a package called NET. To use these functions, prefix the function name with package name NET.

|                           |                                                                                           |
|---------------------------|-------------------------------------------------------------------------------------------|
| BeginInvoke               | Initiate asynchronous .NET delegate call                                                  |
| bitnot                    | Bit-wise NOT                                                                              |
| cell                      | Create cell array                                                                         |
| Combine                   | Convenience function for static .NET System.Delegate Combine method                       |
| enableNETfromNetworkDrive | Enable access to .NET commands from network drive                                         |
| EndInvoke                 | Retrieve result of asynchronous call initiated by .NET System.Delegate BeginInvoke method |
| NET.addAssembly           | Make .NET assembly visible to MATLAB                                                      |
| NET.Assembly              | Members of .NET assembly                                                                  |
| NET.convertArray          | Convert numeric MATLAB array to .NET array                                                |
| NET.createArray           | Array for nonprimitive .NET types                                                         |
| NET.createGeneric         | Create instance of specialized .NET generic type                                          |

|                         |                                                                                                                   |
|-------------------------|-------------------------------------------------------------------------------------------------------------------|
| NET.disableAutoRelease  | Lock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB does not release COM object |
| NET.enableAutoRelease   | Unlock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB releases COM object       |
| NET.GenericClass        | Represent parameterized generic type definitions                                                                  |
| NET.invokeGenericMethod | Invoke generic method of object                                                                                   |
| NET.NetException        | Capture error information for .NET exception                                                                      |
| NET.setStaticProperty   | Static property or field name                                                                                     |
| Remove                  | Convenience function for static .NET System.Delegate Remove method                                                |
| RemoveAll               | Convenience function for static .NET System.Delegate RemoveAll method                                             |

## How To

- “.NET Libraries”

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Make .NET assembly visible to MATLAB                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Syntax</b>           | <pre>asmInfo = NET.addAssembly(globalName) asmInfo = NET.addAssembly(privateName)</pre>                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b>      | <p><code>asmInfo = NET.addAssembly(globalName)</code> loads a global .NET assembly into MATLAB.</p> <p><code>asmInfo = NET.addAssembly(privateName)</code> loads a private .NET assembly.</p>                                                                                                                                                                                                                                                               |
| <b>Tips</b>             | <ul style="list-style-type: none"><li>• MATLAB dynamically loads the <code>mscorlib.dll</code> and <code>system.dll</code> assemblies from the .NET Framework class library the first time you type "NET." or "System.". You do not need to call <code>NET.addAssembly</code> to access classes in these assemblies.</li><li>• Refer to your .NET product documentation for the name of the assembly and its deployment type (global or private).</li></ul> |
| <b>Limitations</b>      | <ul style="list-style-type: none"><li>• <code>NET.addAssembly</code> does not support assemblies generated by the MATLAB Builder NE product.</li></ul>                                                                                                                                                                                                                                                                                                      |
| <b>Input Arguments</b>  | <p><b>globalName</b></p> <p>One of the following:</p> <ul style="list-style-type: none"><li>• String representing the name of a global assembly.</li><li>• Instance of <code>System.Reflection.AssemblyName</code> class.</li></ul> <p><b>privateName</b></p> <p>String representing the full path of a private assembly.</p>                                                                                                                               |
| <b>Output Arguments</b> | <p><b>asmInfo</b></p> <p><code>NET.Assembly</code> object containing names of the members of the assembly.</p>                                                                                                                                                                                                                                                                                                                                              |

# NET.addAssembly

---

## Examples

Display today's date using `System.DateTime` in the `mscorlib` assembly.

```
System.DateTime.Now.ToLongDateString
```

---

Call the `System.Windows.Forms.MessageBox.Show` method in the global assembly `System.Windows.Forms`.

```
asm = NET.addAssembly('System.Windows.Forms');  
import System.Windows.Forms.*;  
MessageBox.Show('Simple Message Box')
```

---

Display classes in the private assembly `NetSample.dll`.

```
asm = NET.addAssembly('c:\work\NetSample.dll');  
asm.Classes
```

|                       | <b>Interfaces</b><br>nInterfacex1 cell array of interface names of the assembly, where nInterface is the number of interfaces      |
|                       | <b>Delegates</b><br>nDelegatex1 cell array of delegates of the assembly, where nDelegate is the number of delegates                |
| <b>Copy Semantics</b> | Handle. To learn how this affects your use of the class, see Copying Objects in the MATLAB Programming Fundamentals documentation. |

# NET.Assembly

---

## See Also

`NET.addAssembly`

## How To

- “What Classes Are in a .NET Assembly?”

**Purpose** Convert numeric MATLAB array to .NET array

---

**Note** MATLAB automatically converts arrays to .NET types. For information, see “Using Arrays with .NET Applications”.

---

**Syntax** `arrObj = NET.convertArray(V, 'arrType', [m,n])`

**Description** `arrObj = NET.convertArray(V, 'arrType', [m,n])` converts a MATLAB array `V` to a .NET array. Optional value `arrType` is a string representing a namespace-qualified .NET array type. Use optional values `m,n` to convert a MATLAB vector to a two-dimensional .NET array (either 1-by-`n` or `m`-by-1). If `V` is a MATLAB vector and you do not specify the number of dimensions and their sizes, the output `arrObj` is a one-dimensional .NET array.

If you do not specify `arrType`, MATLAB converts the type according to the “MATLAB Primitive Type Conversion Table”.

**Examples** Create a list `aList` of random `System.Int32` integers using the `System.Collections.Generic.List` class, and then sort the results:

```
%Create array R of random integers
nInt = 5;
R = randi(100,1,nInt);
%Create .NET array A
A = NET.convertArray(R, 'System.Int32');
%Put A into aList, a generic collections list
aList = NET.createGeneric(...
    'System.Collections.Generic.List',...
    {'System.Int32'},A.Length);
aList.AddRange(A);
%Sort the values in aList
aList.Sort;
```

# NET.createArray

---

**Purpose** Array for nonprimitive .NET types

**Syntax**  
array = NET.createArray(typeName,[m,n,p,...])  
array = NET.createArray(typeName,m,n,p,...)

**Description** array = NET.createArray(typeName,[m,n,p,...]) creates an m-by-n-by-p-by-... array of type typeName, which is either a fully qualified .NET array type name (namespace and array type name) or an instance of the NET.GenericClass class, in case of arrays of generic type. m,n,p,... are the number of elements in each dimension of the array.

array = NET.createArray(typeName,m,n,p,...) alternative syntax for creating an array.

You cannot specify the lower bound of an array.

## Examples **Create .NET Array of Generic Type**

This example creates a .NET array of List<Int32> generic type.

```
genType = NET.GenericClass('System.Collections.Generic.List',...  
    'System.Int32');  
arr = NET.createArray(genType, 5)
```

```
arr =
```

```
System.Collections.Generic.List<System*Int32>[] handle  
Package: System.Collections.Generic
```

```
Properties:
```

```
    Length: 5  
    LongLength: 5  
    Rank: 1  
    SyncRoot: [1x1 System.Collections.Generic.List<System*Int32>[]]  
    IsReadOnly: 0  
    IsFixedSize: 1  
    IsSynchronized: 0
```

Methods, Events, Superclasses

## Create and Initialize Jagged Array

This example creates a jagged .NET array of 3 elements.

```
jaggedArray = NET.createArray('System.Double[]', 3)
```

```
jaggedArray =  
  System.Double[][] handle  
  Package: System
```

Properties:

```
  Length: 3  
  LongLength: 3  
  Rank: 1  
  SyncRoot: [1x1 System.Double[][]]  
  IsReadOnly: 0  
  IsFixedSize: 1  
  IsSynchronized: 0  
  Methods, Events, Superclasses
```

Assign values:

```
jaggedArray(1) = [1, 3, 5, 7, 9];  
jaggedArray(2) = [0, 2, 4, 6];  
jaggedArray(3) = [11, 22];
```

Access first value of 3rd array:

```
jaggedArray(3,1)
```

```
ans =  
  11
```

## Create Jagged Array of Generic Type

This example creates a jagged array of List<Double> generic type.

# NET.createArray

---

```
genCls = NET.GenericClass('System.Collections.Generic.List[]',...  
    'System.Double');
```

Create the array, genArr.

```
genArr = NET.createArray(genCls,3)
```

```
genArr =
```

```
System.Collections.Generic.List<System*Double>[][] handle  
Package: System.Collections.Generic
```

Properties:

```
    Length: 3  
    LongLength: 3  
    Rank: 1  
    SyncRoot: [1x1 System.Collections.Generic.List`1[][]]  
    IsReadOnly: 0  
    IsFixedSize: 1  
    IsSynchronized: 0
```

Methods, Events, Superclasses

## Create Nested Jagged Array

This command creates a jagged array of type System.Double[][][].

```
netArr = NET.createArray('System.Double[][][]', 3)
```

```
netArr =
```

```
System.Double[][][] handle  
Package: System
```

Properties:

```
    Length: 3  
    LongLength: 3  
    Rank: 1  
    SyncRoot: [1x1 System.Double[][][]]  
    IsReadOnly: 0
```

IsFixedSize: 1  
IsSynchronized: 0  
Methods, Events, Superclasses

|                         | <code>paramTypes</code>                                                                                                                                          | Allowed cell types are: strings with fully qualified parameter type names and instances of the <code>NET.GenericClass</code> class when parameterization with another parameterized type is needed. |
|                         | <code>ctorArgs</code>                                                                                                                                            | Optional, variable length (0 to N) list of constructor arguments matching the arguments of the .NET generic class constructor intended to be invoked.                                               |
| <b>Output Arguments</b> | <code>genObj</code>                                                                                                                                              | Handle to the specialized generic class instance.                                                                                                                                                   |

## Examples **Create a List of System.Double Objects**

Create a strongly typed list `dblLst` of objects of type `System.Double`:

```
dblLst =  
NET.createGeneric('System.Collections.Generic.List',...  
{'System.Double'},10);
```

## Create a List with Key/Value Pairs

Create the `kvpType` generic association where `Key` is of `System.Int32` type and `Value` is a `System.String`:

```
kvpType =  
NET.GenericClass('System.Collections.Generic.KeyValuePair',...  
    'System.Int32','System.String');
```

Create the list `kvpList` with initial storage capacity for 10 key-value pairs:

```
kvpList =  
NET.createGeneric('System.Collections.Generic.List',...  
    {kvpType},10);
```

## Add an Item to the List

Create a `KeyValuePair` item.

```
kvpItem = NET.createGeneric('System.Collections.Generic.KeyValuePair',...  
    {'System.Int32','System.String'},42,'myString');
```

Add this item to the list `kvpList`.

```
kvpList.Add(kvpItem);
```

`NET.GenericClass`

# NET.disableAutoRelease

---

**Purpose** Lock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB does not release COM object

**Syntax** A = NET.disableAutoRelease(obj)

**Description** A = NET.disableAutoRelease(obj) locks a .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB does not release the COM object. obj is a .NET object representing a COM Wrapper.

Before passing a .NET object representing a COM Wrapper to another process, lock the object using this function so that MATLAB does not release it. After using the object, call NET.enableAutoRelease to release the COM object.

**Examples** The following user-defined function, GetComApp.m, has access to a COM object defined in the **pseudo-class** ComNamespace.ComClass. One of its methods is readData, with the signature:

```
System.StringRetVal readData(ComNamespace.ComClass this, System.String s)
```

The input argument is defined in the **pseudo-class** NetDocTest.MyClass, which has a property named MyApp.

```
function GetComApp(obj)
comObj = ComNamespace.ComClass;
obj.MyApp = comObj;
% To pass a COM object to another process, lock the object
NET.disableAutoRelease(comObj);
end
```

The example in NET.enableAutoRelease shows how to call the GetComApp function.

**See Also** NET.enableAutoRelease

**How To** • “How MATLAB Handles System.\_\_ComObject”

- Purpose** Unlock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB releases COM object
- Syntax** `A = NET.enableAutoRelease(obj)`
- Description** `A = NET.enableAutoRelease(obj)` releases the COM wrapper when the object goes out of scope, where `obj` is a .NET object representing a COM Wrapper.
- Call this function only if the object was locked using `NET.disableAutoRelease`.
- Examples** The following **pseudo-code** shows how to call a function (`GetComApp.m`, described in `NET.disableAutoRelease`) which returns a COM object. The object, `mainObj` of type `NetDocTest.MyClass`, has a property, `MyApp`. Call `GetComApp` to get a COM object, and use its `readData` method.
- ```
mainObj = NetDocTest.MyClass;
GetComApp(mainObj);
app = mainObj.MyApp;
app.readData('hello');
% Unlock the COM object
NET.enableAutoRelease(mainObj.MyApp);
```
- See Also** `NET.disableAutoRelease`
- How To**
- “How MATLAB Handles System.\_\_ComObject”

# NET.GenericClass

---

**Purpose** Represent parameterized generic type definitions

**Description** Instances of this class are used by the `NET.createGeneric` function when creation of generic specialization requires parameterization with another parameterized type.

**Construction** `genType = NET.GenericClass (className, paramTypes)`

## Input Arguments

### className

Fully qualified string containing the generic type name.

### paramTypes

Optional, variable length (1 to N) list of types for the generic class parameterization. Allowed argument types are:

- Fully qualified string containing the generic type name.
- Instance of the `NET.GenericClass` class when deeper nested parameterization with another parameterized type is needed.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB Programming Fundamentals documentation.

## Examples

Create an instance of `System.Collections.Generic.List` of `System.Collections.Generic.KeyValuePair` generic associations where `Key` is of `System.Int32` type and `Value` is a `System.String` class with initial storage capacity for 10 key-value pairs.

```
kvpType = NET.GenericClass('System.Collections.Generic.KeyValuePair',...  
    'System.Int32', 'System.String');  
kvpList = NET.createGeneric('System.Collections.Generic.List',...  
    { kvpType }, 10);
```

## See Also

`NET.createGeneric` | `NET.createArray` | `NET.invokeGenericMethod`

## How To

- “.NET Generic Classes in MATLAB”

# NET.invokeGenericMethod

---

## Purpose

Invoke generic method of object

## Syntax

```
[varargout] = NET.invokeGenericMethod(obj,  
    'genericMethodName', paramTypes, args, ...)
```

## Description

[varargout] = NET.invokeGenericMethod(obj, 'genericMethodName', paramTypes, args, ...) calls instance or static generic method *genericMethodName*.

## Input Arguments

obj

Allowed argument types are:

- Instances of class containing the generic method
- Strings with fully qualified class name, if calling static generic methods
- Instances of NET.GenericClass definitions, if calling static generic methods of a generic class

*genericMethodName*

Generic method name to invoke

paramTypes

Cell vector (1 to N) with the types for generic method parameterization, where allowed cell types are:

- Strings with fully qualified parameter type name.
- Instances of NET.GenericClass definitions, if using nested parameterization with another parameterized type

args

Optional, variable length (0 to N) list of method arguments

## Output Arguments

varargout

Variable-length output argument list, varargout, from method *genericMethodName*

## Examples

Use the following syntax to call a generic method that takes two parameterized types and returns a parameterized type:

```
a = NET.invokeGenericMethod(obj, ...  
    'myGenericSwapMethod', ...  
    {'System.Double', 'System.Double'}, ...  
    5, 6);
```

---

To display generic methods in MATLAB, see the example “Display .NET Generic Methods Using Reflection”.

# NET.NetException

---

<b>Purpose</b>	Capture error information for .NET exception
<b>Description</b>	Process information from a NET.NetException object to handle .NET errors. This class is derived from MException.
<b>Construction</b>	<code>e = NET.NetException(msgID, errMsg, netObj)</code> constructs instance <code>e</code> of NET.NetException class.
<b>Input Arguments</b>	<b>msgID</b> message identifier <b>errMsg</b> error message string <b>netObj</b> System.Exception object that caused the exception
<b>Properties</b>	<b>ExceptionObject</b> System.Exception class causing the error.
<b>Methods</b>	<b>Inherited Methods</b> See the methods of the base class MException.
<b>Copy Semantics</b>	Handle. To learn how this affects your use of the class, see Copying Objects in the MATLAB Programming Fundamentals documentation.
<b>Examples</b>	Display error information after trying to load an unknown assembly: <pre>try NET.addAssembly('C:\Work\invalidfile.dll') catch e e.message; if(isa(e, 'NET.NetException')) eObj = e.ExceptionObject</pre>

```
end  
end
```

MATLAB displays:

```
ans =  
Message: Could not load file or assembly  
         'file:///C:\Work\invalidfile.dll' or  
         one of its dependencies. The system cannot  
         find the file specified.  
Source: mscorlib  
HelpLink:
```

```
eObj =  
System.IO.FileNotFoundException handle  
Package: System.IO
```

Properties:

```
    Message: [1x1 System.String]  
    FileName: [1x1 System.String]  
    FusionLog: [1x1 System.String]  
    Data: [1x1 System.Collections.ListDictionaryInternal]  
    InnerException: []  
    TargetSite: [1x1 System.Reflection.RuntimeMethodInfo]  
    StackTrace: [1x1 System.String]  
    HelpLink: []  
    Source: [1x1 System.String]  
Methods, Events, Superclasses
```

## See Also

MException

## How To

- Class Attributes
- Property Attributes

# NET.setStaticProperty

---

**Purpose** Static property or field name

**Syntax** `NET.setStaticProperty('propName', value)`

**Description** `NET.setStaticProperty('propName', value)` sets the static property or field name specified in the string `propName` to the given value.

**Examples** To set the `myStaticProperty` in the given class and namespace, use the syntax:

```
NET.setStaticProperty('MyTestObject.MyClass.myStaticProperty', 5);
```

---

<b>Purpose</b>	Create variable in NetCDF file
<b>Syntax</b>	<code>nccreate(filename,varname)</code> <code>nccreate(filename,varname,Name,Value)</code>
<b>Description</b>	<p><code>nccreate(filename,varname)</code> creates a scalar double variable named <code>varname</code> in the NetCDF file <code>filename</code>. If <code>filename</code> does not exist, <code>nccreate</code> creates the file using the <code>netcdf4_classic</code> format. To create a nonscalar variable, use the <code>Dimensions</code> argument.</p> <p><code>nccreate(filename,varname,Name,Value)</code> creates a variable named <code>varname</code> with additional options specified by one or more <code>Name,Value</code> pair arguments.</p>
<b>Input Arguments</b>	<p><b>filename</b></p> <p>Text string specifying a NetCDF file, or the name you want to assign to a new NetCDF file.</p> <p><b>varname</b></p> <p>Text string specifying the name you want to assign to a variable in a NetCDF file.</p> <p><b>Name-Value Pair Arguments</b></p> <p>Specify optional comma-separated pairs of <code>Name,Value</code> arguments, where <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as <code>Name1,Value1,...,NameN,ValueN</code>.</p> <p><b>Dimensions</b></p> <p>Cell array specifying dimensions for the variable in the NetCDF file. The cell array lists the dimension name as a string followed by its numerical length: <code>{dname1,dlength1,dname2,dlength2,...}</code>. If a dimension exists, specifying its length is optional. Use <code>Inf</code> to specify an unlimited dimension.</p>

All formats other than `netcdf4` format files can have only one unlimited dimension per file and it has to be the last in the list specified. A `netcdf4` format file can have any number of unlimited dimensions in any order.

A single-dimension variable is always treated as a column vector.

## Datatype

Text string specifying a MATLAB data type. When `nccreate` creates the variable in the NetCDF file, it uses a corresponding NetCDF datatype. The following table describes how MATLAB datatypes map to NetCDF datatypes.

<b>MATLAB Data Type</b>	<b>Corresponding NetCDF Variable Type</b>
<code>double</code>	<code>NC_DOUBLE</code>
<code>single</code>	<code>NC_FLOAT</code>
<code>int64</code>	<code>NC_INT64*</code>
<code>uint64</code>	<code>NC_UINT64*</code>
<code>int32</code>	<code>NC_INT</code>
<code>uint32</code>	<code>NC_UINT*</code>
<code>int16</code>	<code>NC_SHORT</code>
<code>uint16</code>	<code>NC_USHORT*</code>
<code>int8</code>	<code>NC_BYTE</code>
<code>uint8</code>	<code>NC_UBYTE*</code>
<code>char</code>	<code>NC_CHAR</code>

\* These data types are only available when the file is a `netcdf4` format file.

## Format

Text string specifying the type of NetCDF file you want to create.

Format String	Description
classic	NetCDF 3
64bit	NetCDF 3, with 64-bit offsets
netcdf4_classic	NetCDF 4 classic model
netcdf4	NetCDF 4 model (Use this to enable group hierarchy)

If varname specifies a group (e.g., '/grid3/temperature'), nccreate sets the value of format to 'netcdf4'.

**Default:** netcdf4\_classic

### FillValue

A scalar specifying the value to use for missing values. To disable fill values, set FillValue to the text string 'disable'. (Available for netcdf4 or netcdf4\_classic formats only.)

**Default:** Value specified by the NetCDF library

### ChunkSize

Vector specifying the size of the chunk along each dimension, [num\_rows,num\_cols,..., num\_ndims]. (Available for netcdf4 or netcdf4\_classic formats only.)

**Default:** Set by the NetCDF library

### DeflateLevel

Numeric value between 0 (least) and 9 (most) specifying the compression setting for the deflate filter, or the text string disable. (Available for netcdf4 or netcdf4\_classic formats only.)

**Default:** Disabled

## Shuffle

Boolean flag to turn on the shuffle filter. (Available for netcdf4 or netcdf4\_classic formats only.)

**Default:** False

## Examples

Create a new 2-D variable in a classic format file. Write data to this variable

```
nccreate('myncclassic.nc', 'peaks', ...
        'Dimensions', {'r' 200 'c' 200}, ...
        'Format', 'classic');
ncwrite('myncclassic.nc', 'peaks', peaks(200));
ncdisp('myncclassic.nc');
```

## Tutorials

- “Exporting to Network Common Data Form (NetCDF) Files”

**Purpose** Display contents of NetCDF data source in Command Window

**Syntax**  
 ncdisp(source)  
 ncdisp(source,location)  
 ncdisp(source,location,modestr)

**Description** ncdisp(source) displays as text in the Command Window, all the groups, dimensions, variable definitions, and all attributes in the NetCDF data source source, which can be the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

ncdisp(source,location) displays information about the variable or group specified by location in source

ncdisp(source,location,modestr) displays the contents of the location in source according to the value of modestr.

## Input Arguments

### source

Text string specifying the name of the NetCDF file.

### location

Text string specifying the location of the variable or group in the NetCDF file. Set location to / (forward slash) to display the entire contents of the file.

**Default:** /

### modestr

Specifies the type of display.

min	Display group hierarchy and variable definitions.
full	Display group hierarchy with dimensions, attributes, and variable definitions.

**Default:** full

# ncdisp

---

## Examples

Visually inspect a NetCDF file.

```
ncdisp('example.nc');
```

---

Visually inspect a NetCDF file, hiding the attributes.

```
ncdisp('example.nc', '/', 'min');
```

---

Visually inspect the full details of a variable.

```
ncdisp('example.nc', 'peaks');
```

## Tutorials

- “Importing Network Common Data Form (NetCDF) Files and OPeNDAP Data”

**Purpose** Return information about NetCDF data source

**Syntax**

```
finfo = ncinfo(source)
vinfo = ncinfo(source,varname)
ginfo = ncinfo(source,groupname)
```

**Description**

`finfo = ncinfo(source)` returns information in the structure `finfo` about the entire NetCDF data source specified by `source`, where `source` can be the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

`vinfo = ncinfo(source,varname)` returns information in the structure `vinfo` about the variable `varname` in `source`.

`ginfo = ncinfo(source,groupname)` returns information in the structure `ginfo` about the group `groupname` in `source` (only NetCDF4 data sources).

---

**Note** Use `ncdisp` for visual inspection of a NetCDF source.

---

## Input Arguments

### **source**

Text string specifying the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

### **varname**

Text string specifying the name of a variable in a NetCDF file or OPeNDAP data source.

### **groupname**

Text string specifying the name of a group in a NetCDF file or OPeNDAP data source.

## Output Arguments

### finfo

A structure with the following fields.

Field	Description	
Filename	NetCDF file name or OPeNDAP URL	
Name	' / ', indicating the full file	
Dimensions	An array of structures with these fields:	
	Name	Dimension name
	Length	Current length of dimension
	Unlimited	Boolean flag, true for unlimited dimensions
Variables	An array of structures with these fields:	
	Name	Variable name
	Dimensions	Associated dimensions
	Size	Current variable size
	Datatype	MATLAB datatype
	Attributes	Associated variable attributes
	ChunkSize	Chunk size, if defined. [ ] otherwise
	FillValue	Fill value of the variable.
	DeflateLevel	Deflate filter level, if enabled.
	Shuffle	Shuffle filter enabled flag
Attributes	An array of global attributes with these fields:	
	Name	Attribute name
	Value	Attribute value

Field	Description	
Groups	An array of groups present in the file, for netcdf4 files; An empty array ([]) for all other NetCDF file formats.	
Format	The format of the NetCDF file	

**vinfo**

A structure containing only the variable fields from `finfo`.

Field	Description
Filename	NetCDF file name
Name	Name of the variable
Dimensions	Dimensions of the variable
Size	Size of the current variable
Datatype	MATLAB datatype
Attributes	Attributes associated with the variable
ChunkSize	Chunk size, if defined. [] otherwise.
FillValue	Fill value used in the variable.
DeflateLevel	Deflate filter level, if enabled.
Shuffle	Shuffle filter enabled flag
Format	The format of the NetCDF file

**ginfo**

A structure containing only the group fields from `finfo`.

Field	Description
Filename	NetCDF file name
Name	Name of the group

Field	Description
Dimensions	Only dimensions defined in the specified group
Variables	Only variables defined in the specified group
Attributes	Attributes associated with the variable
Groups	Names of groups, if defined. [] otherwise.
Format	The format of the NetCDF file

## Examples

Search for dimensions with names that start with the character x in the file.

```
finfo = ncinfo('example.nc');
disp(finfo);
dimNames = {finfo.Dimensions.Name};
dimMatch = strncmpi(dimNames,'x',1);
disp(finfo.Dimensions(dimMatch));
```

---

Obtain the size of a variable and check if it has any unlimited dimensions.

```
vinfos = ncinfo('example.nc','peaks');
varSize = vinfos.Size;
disp(vinfos);
hasUnLimDim = any([vinfos.Dimensions.Unlimited]);
```

---

Find all unlimited dimensions defined in a group.

```
ginfo = ncinfo('example.nc','/grid2/');
unlimDims = [ginfo.Dimensions.Unlimited];
disp(ginfo.Dimensions(unlimDims));
```

- “Importing Network Common Data Form (NetCDF) Files and OPeNDAP Data”

# ncread

---

**Purpose** Read data from variable in NetCDF data source

**Syntax**  
`vardata = ncread(source,varname)`  
`vardata = ncread(source,varname,start,count,stride)`

**Description** `vardata = ncread(source,varname)` reads data from the variable `varname` in `source`, which can be either the name of a NetCDF file or an OPeNDAP NetCDF data source.

`vardata = ncread(source,varname,start,count,stride)` reads data from the variable `varname` in `source` beginning at the location given by `start`. `count` specifies the number of elements to read along the corresponding dimension. The optional argument `stride` specifies the inter-element spacing along each dimension.

## Input Arguments

### **source**

Text string specifying the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

### **varname**

Text string specifying the name of a variable in the NetCDF file or OPeNDAP NetCDF data source.

### **start**

For an  $N$ -dimensional variable, `start` is a vector of length  $N$  of indices specifying the starting location. Indices are 1-based.

### **count**

Vector of length  $N$  specifying the number of elements to read along the corresponding dimensions. If a particular element of `count` is `Inf`, `ncread` reads data until the end of the corresponding dimension.

### **stride**

Optional argument that specifies the inter-element spacing along each dimension.

**Default:** Vector of 1s (ones)

## Output Arguments

### vardata

The data in the variable. `ncread` uses the MATLAB datatype that is the closest type to the corresponding NetCDF datatype, except when at least one of `_FillValue`, `scale_offset`, and `add_offset` variables attribute is present. `ncread` applies the following attribute conventions, in sequence, to `vardata` if the corresponding attribute exists for this variable:

- If the `_FillValue` attribute exists, `ncread` replaces values in `vardata` equal to value of `_FillValue` with NaNs. If the `_FillValue` attribute does not exist, `ncread` queries the NetCDF library for the variable's fill value.
- If the `scale_factor` attribute exists, `ncread` multiplies `vardata` by the value of the `scale_factor` attribute.
- If the `add_offset` attribute exists, `ncread` adds the value of the `add_offset` attribute to `vardata`.

## Examples

Read and display the data in the `peaks` variable in the example file.

```
ncdisp('example.nc','peaks');  
peaksData = ncread('example.nc','peaks');  
peaksDesc = ncreadatt('example.nc','peaks','description');  
surf(double(peaksData));  
title(peaksDesc);
```

Subsample the `peaks` data by a factor of 2 (read every other value along each dimension).

```
subsetdata = ncread('example.nc','peaks',...  
                  [1 1], [Inf Inf], [2 2]);
```

# ncread

---

```
surf(double(subsetdata));
```

- “Importing Network Common Data Form (NetCDF) Files and OPeNDAP Data”

---

<b>Purpose</b>	Read attribute value from NetCDF data source
<b>Syntax</b>	<code>attvalue = ncreadatt(source,location,attname)</code>
<b>Description</b>	<code>attvalue = ncreadatt(source,location,attname)</code> reads the attribute <code>attname</code> from the group or variable specified by <code>location</code> in <code>source</code> , where <code>source</code> is the name of a NetCDF file or the URL of a NetCDF data source.
<b>Input Arguments</b>	<p><b>source</b></p> <p>Text string specifying the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.</p> <p><b>location</b></p> <p>Text string specifying a group or variable in the NetCDF data source. To read global attributes, set <code>location</code> to <code>'/'</code> (forward slash).</p> <p><b>attname</b></p> <p>Text string specifying the name of an attribute that you want to read in the NetCDF data source.</p>
<b>Output Arguments</b>	<p><b>attvalue</b></p> <p>Data associated with the attribute.</p>
<b>Examples</b>	<p>Read a global attribute.</p> <pre>creation_date = ncreadatt('example.nc','/','creation_date'); disp(creation_date);</pre> <hr/> <p>Read an attribute associated with a variable.</p> <pre>scale_factor = ncreadatt('example.nc','temperature','scale_factor'); disp(scale_factor);</pre>

# ncreadatt

---

---

Read an attribute associated with a group (netcdf4 format files only).

```
desc_value = ncreadatt('example.nc', '/grid2', 'description');  
disp(desc_value);
```

## Tutorials

- “Importing Network Common Data Form (NetCDF) Files and OPeNDAP Data”

---

<b>Purpose</b>	Write data to NetCDF file
<b>Syntax</b>	<code>ncwrite(filename,varname,vardata)</code> <code>ncwrite(filename,varname,vardata,start, stride)</code>
<b>Description</b>	<p><code>ncwrite(filename,varname,vardata)</code> writes the numerical or char data in <code>vardata</code> to an existing variable <code>varname</code> in the NetCDF file <code>filename</code>. <code>ncwrite</code> writes the data in <code>vardata</code> starting at the beginning of the variable and extends unlimited dimensions automatically, if needed.</p> <p>If the NetCDF file or the variable do not exist, use <code>nccreate</code> to create them first.</p> <p><code>ncwrite(filename,varname,vardata,start, stride)</code> writes <code>vardata</code> to an existing variable <code>varname</code> in file <code>filename</code> beginning at the location given by <code>start</code>. <code>stride</code> is an optional argument that specifies the inter-element spacing of the data written. Use this syntax to append data to an existing variable or write partial data.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• If the variable <code>varname</code> already exists, <code>ncwrite</code> expects the datatype of <code>vardata</code> to match the NetCDF variable data type.</li><li>• If the variable <code>varname</code> has a <code>_FillValue</code>, <code>scale_factor</code> or <code>add_offset</code> attribute, <code>ncwrite</code> expects data in double format and casts <code>vardata</code> to the NetCDF data type, after applying the following attribute conventions in sequence:<ol style="list-style-type: none"><li>1 Subtract the value of the <code>add_offset</code> attribute from <code>vardata</code>.</li><li>2 Divide <code>vardata</code> by the value of the <code>scale_factor</code> attribute.</li><li>3 Replace NaNs in <code>vardata</code> by the value of the <code>_FillValue</code> attribute. If this attribute does not exist, <code>ncwrite</code> tries to use the fill value for this variable as reported by the NetCDF library.</li></ol></li></ul>
<b>Input Arguments</b>	<p><b>filename</b></p> <p>Text string specifying the name of a NetCDF file. If the file does not exist, use <code>nccreate</code> to create it first.</p>

**varname**

Text string specifying the name of a variable in a NetCDF file. If the variable does not exist, use `nccreate` to create it first.

**vardata**

Data to write to the variable in the NetCDF file.

**start**

For an  $N$ -dimensional variable, `start` is a vector of indices of length  $N$  specifying the starting location. Indices are 1-based.

**stride**

(Optional) Vector of length  $N$ , specifying the inter-element spacing.

**Default:** Vector of ones

## Examples

Create a new `netcdf4_classic` file, and write a scalar variable with no dimensions. Add the creation time as a global attribute.

```
nccreate('myfile.nc','pi');
ncwrite('myfile.nc','pi',3.1);
ncwriteatt('myfile.nc','/','creation_time',datestr(now));
% overwrite existing data
ncwrite('myfile.nc','pi',3.1416);
ncdisp('myfile.nc');
```

---

Create a `netcdf4_classic` file with a variable defined on an unlimited dimension. Write data incrementally to the variable.

```
nccreate('myncfile.nc','vmark',...
        'Dimensions', {'time', inf, 'cols', 6},...
        'ChunkSize', [3 3],...
        'DeflateLevel', 2);
ncwrite('myncfile.nc','vmark', eye(3),[1 1]);
```

```
varData = ncread('myncfile.nc','vmark');  
disp(varData);  
ncwrite('myncfile.nc','vmark',fliplr(eye(3)),[1 4]);  
varData = ncread('myncfile.nc','vmark');  
disp(varData);
```

- “Exporting to Network Common Data Form (NetCDF) Files”

# ncwriteatt

---

## Purpose

Write attribute to NetCDF file

## Syntax

```
ncwriteatt(filename,location,attname,attvalue)
```

## Description

`ncwriteatt(filename,location,attname,attvalue)` creates or modifies the attribute specified by `attname` in the group or variable specified by `location`, in the NetCDF file specified by `filename`. `attvalue` can be a numeric vector or a string.

## Input Arguments

### **filename**

Text string specifying the name of a NetCDF file

### **location**

Text string specifying a group or variable in the NetCDF file. To write global attributes, set `location` to `'/'` (forward slash).

### **attname**

Text string specifying the name of an existing attribute in a NetCDF file or the name of the attribute that you want to create.

### **attvalue**

Numeric vector or a string.

## Examples

Create a global attribute.

```
copyfile(which('example.nc'),'myfile.nc');  
fileattrib('myfile.nc','+w');  
ncdisp('myfile.nc');  
ncwriteatt('myfile.nc','/','creation_date',datestr(now));  
ncdisp('myfile.nc');
```

---

Modify an existing attribute.

```
copyfile(which('example.nc'),'myfile.nc');  
fileattrib('myfile.nc','+w');  
ncdisp('myfile.nc','peaks');  
ncwriteatt('myfile.nc','peaks','description','Output of PEAKS');  
ncdisp('myfile.nc','peaks');
```

**Tutorials**

- “Exporting to Network Common Data Form (NetCDF) Files”

# ncwritescema

---

**Purpose** Add NetCDF schema definitions to NetCDF file

**Syntax** `ncwritescema(filename,schema)`

**Description** `ncwritescema(filename,schema)` creates or adds attributes, dimensions, variable definitions and group structure defined in `schema` to the file `filename`.

Use `ncwritescema` in combination with `ncinfo` to create a new NetCDF file based on the schema of an existing file. You can also use `ncwritescema` to add variable definitions, attributes, dimensions, or group structure to an existing file.

---

**Note** `ncwritescema` does not write variable data. Use `ncwrite` to write data to the created variables. Created unlimited dimensions will have an initial size of 0 until you write data.

---

---

**Note** `ncwritescema` cannot change the format of an existing file. It cannot redefine existing variables and dimensions in `filename`. If your schema contains attributes, dimensions, variable definitions, or a group structure that already exist in the file, `writeschema` issues a warning but continues processing.

---

## Input Arguments

### **filename**

Text string specifying the name of a NetCDF file. If `filename` does not exist, `ncwritescema` creates a new file using the `netcdf4_classic` format, unless the `Format` field in `schema` specifies another format.

### **schema**

A structure, or array of structures, representing either a dimension, variable, an entire NetCDF file, or a `netcdf4` group. A group or file schema can contain a dimension or variable schema, or both. You can

use the output returned by `ncinfo` as a schema structure. The following table lists the fields in the various types of schema structures. Optional fields are marked with asterisk (\*).

Schema Type	Structure Field	Description
Group/File Schema	Name	Text string identifying the group name. Use '/' to indicate the entire file.
	Dimensions*	Dimension schema
	Variables*	Variable schema
	Attributes*	Structure array of group/global attributes with Name and Value fields
	Format*	Text string identifying a NetCDF file format
Dimension schema	Name	Text string identifying the dimension
	Length	Length of the dimension. Can be Inf.
	Unlimited*	Boolean flag indicating if the dimension is unlimited
	Format*	Text string identifying a NetCDF file format
Variable schema	Name	Text string identifying a variable name
	Dimensions	Variable's dimension schema
	Datatype	Text string identifying a MATLAB datatype
	Attributes*	Structure array of variable attributes with Name and Value fields

Schema Type	Structure Field	Description
	ChunkSize*	Numeric value specifying chunk size of the variable
	FillValue*	Character or numeric fill value
	DeflateValue*	Deflate compression level
	Shuffle*	Boolean flag to turn on the Shuffle filter
	Format*	Text string identifying a NetCDF file format

## Examples

Create a classic format file with two dimension definitions.

```
mySchema.Name = '/';
mySchema.Format = 'classic';
mySchema.Dimensions(1).Name = 'time';
mySchema.Dimensions(1).Length = Inf;
mySchema.Dimensions(2).Name = 'rows';
mySchema.Dimensions(2).Length = 10;
ncwritschema('emptyFile.nc', mySchema);
ncdisp('emptyFile.nc');
```

---

Create a netcdf4\_classic format file to store a single variable from an existing file. First use `ncinfo` to get the schema of the peaks variable from the file. Then use `ncwritschema` to create a NetCDF file, defining the peaks variable. Use `ncread` to get the data associated with the peaks variable and then use `ncwrite` to write the data to the variable in the new NetCDF file.

```
myVarSchema = ncinfo('example.nc','peaks');
ncwritschema('peaksFile.nc',myVarSchema);
peaksData = ncread('example.nc','peaks');
ncwrite('peaksFile.nc','peaks',peaksData);
ncdisp('peaksFile.nc');
```

**Tutorials**

- “Exporting to Network Common Data Form (NetCDF) Files”

**Purpose** Summary of MATLAB Network Common Data Form (NetCDF) capabilities

**Description** MATLAB provides both high- and low-level access to NetCDF files:

- High-level access functions make it easy to read a data set from a NetCDF file or write a variable from the MATLAB workspace into a NetCDF file
- Low-level access functions provide interfaces to dozens of functions in the NetCDF library

---

**Note** For information about MATLAB support for the Common Data Format (CDF), which is a completely separate and incompatible format, see `cdflib`.

---

## High-Level Access

These functions provide high-level access to NetCDF files.

<code>nccreate</code>	Create variable in NetCDF file
<code>ncdisp</code>	Display contents of NetCDF data source in Command Window
<code>ncinfo</code>	Return information about NetCDF data source
<code>ncread</code>	Read data from variable in NetCDF data source
<code>ncreadatt</code>	Read attribute value from NetCDF data source
<code>ncwrite</code>	Write data to NetCDF file
<code>ncwriteatt</code>	Write attribute to NetCDF file
<code>ncwritschema</code>	Add NetCDF schema definitions to NetCDF file

## Low-Level Access

The MATLAB low-level functions provide an API that you can use to enable reading data from and writing data to NetCDF files (known as *data sets* in NetCDF terminology). To use these functions, you should be familiar with the information about NetCDF contained in the [NetCDF C Interface Guide](#).

MATLAB supports NetCDF version 4.1.3.

In most cases, the syntax of the MATLAB function matches the syntax of the NetCDF library function. The functions are implemented as a package called `netcdf`. To use these functions, prefix the function name with package name `netcdf`. For example, to call the NetCDF library routine used to open existing NetCDF files, use the following MATLAB syntax:

```
ncid = netcdf.open(ncfile, mode);
```

## Library Functions

<code>netcdf</code>	Summary of MATLAB Network Common Data Form (NetCDF) capabilities
<code>netcdf.getChunkCache</code>	Retrieve chunk cache settings for NetCDF library
<code>netcdf.inqLibVers</code>	Return NetCDF library version information
<code>netcdf.setChunkCache</code>	Set default chunk cache settings for NetCDF library
<code>netcdf.setDefaultFormat</code>	Change default netCDF file format

## File Operations

<code>netcdf.abort</code>	Revert recent netCDF file definitions
<code>netcdf.close</code>	Close netCDF file

<code>netcdf.create</code>	Create new NetCDF dataset
<code>netcdf.endDef</code>	End netCDF file define mode
<code>netcdf.inq</code>	Return information about netCDF file
<code>netcdf.inqFormat</code>	Determine format of NetCDF file
<code>netcdf.inqGrps</code>	Retrieve array of child group IDs
<code>netcdf.inqUnlimDims</code>	Return list of unlimited dimensions in group
<code>netcdf.open</code>	Open NetCDF data source
<code>netcdf.reDef</code>	Put open netCDF file into define mode
<code>netcdf.setFill</code>	Set netCDF fill mode
<code>netcdf.sync</code>	Synchronize netCDF file to disk
<b>Dimensions</b>	
<code>netcdf.defDim</code>	Create netCDF dimension
<code>netcdf.inqDim</code>	Return netCDF dimension name and length
<code>netcdf.inqDimID</code>	Return dimension ID
<code>netcdf.renameDim</code>	Change name of netCDF dimension
<b>Variables</b>	
<code>netcdf.defVar</code>	Create NetCDF variable
<code>netcdf.defVarChunking</code>	Define chunking behavior for NetCDF variable
<code>netcdf.defVarDeflate</code>	Define compression parameters for NetCDF variable
<code>netcdf.defVarFill</code>	Define fill parameters for NetCDF variable

---

netcdf.defVarFletcher32	Define checksum parameters for NetCDF variable
netcdf.getVar	Return data from netCDF variable
netcdf.inqVar	Return information about variable
netcdf.inqVarChunking	Determine chunking settings for NetCDF variable
netcdf.inqVarDeflate	Determine compression settings for NetCDF variable
netcdf.inqVarFill	Determine values of fill parameters for NetCDF variable
netcdf.inqVarFletcher32	Fletcher32 checksum setting for NetCDF variable
netcdf.inqVarID	Return ID associated with variable name
netcdf.putVar	Write data to netCDF variable
netcdf.renameVar	Change name of netCDF variable

**Attributes**

netcdf.copyAtt	Copy attribute to new location
netcdf.delAtt	Delete netCDF attribute
netcdf.getAtt	Return netCDF attribute
netcdf.inqAtt	Return information about netCDF attribute
netcdf.inqAttID	Return ID of netCDF attribute
netcdf.inqAttName	Return name of netCDF attribute
netcdf.putAtt	Write netCDF attribute
netcdf.renameAtt	Change name of attribute

## Utilities

`netcdf.getConstant`

Return numeric value of named constant

`netcdf.getConstantNames`

Return list of constants known to netCDF library

<b>Purpose</b>	Revert recent netCDF file definitions
<b>Syntax</b>	<code>netcdf.abort(ncid)</code>
<b>Description</b>	<p><code>netcdf.abort(ncid)</code> reverts a netCDF file to its previous state, backing out any definitions made since the file last entered define mode. A file enters define mode when you create it (using <code>netcdf.create</code>) or when you explicitly enter define mode (using <code>netcdf.redef</code>). Once you leave define mode (using <code>netcdf.endDef</code>), you cannot revert the definitions you made while in define mode. <code>ncid</code> is a netCDF file identifier returned by <code>netcdf.create</code> or <code>netcdf.open</code>. A call to <code>netcdf.abort</code> closes the file.</p> <p>This function corresponds to the <code>nc_abort</code> function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See <code>netcdf</code> for more information.</p>
<b>Examples</b>	<p>This example creates a new file, performs an operation on the file, and then reverts the file back to its original state. To run this example, you must have write permission in your current directory.</p> <pre>% Create a netCDF file ncid = netcdf.create('foo.nc','NC_NOCLlobber');  % Perform an operation, such as defining a dimension. dimid = netcdf.defDim(ncid, 'lat', 50);  % Revert the file back to its previous state. netcdf.abort(ncid)  % Verify that the file is now closed. dimid = netcdf.defDim(ncid, 'lat', 50); % should fail ??? Error using ==&gt; netcdflib NetCDF: Not a valid ID  Error in ==&gt; defDim at 22 dimid = netcdflib('def_dim', ncid,dimname,dimlen);</pre>

# netcdf.abort

---

## See Also

[netcdf.create](#) | [netcdf.endDef](#) | [netcdf.reDef](#)

<b>Purpose</b>	Close netCDF file
<b>Syntax</b>	<code>netcdf.close(ncid)</code>
<b>Description</b>	<p><code>netcdf.close(ncid)</code> terminates access to the netCDF file identified by <code>ncid</code>.</p> <p><code>ncid</code> is a netCDF file identifier returned by <code>netcdf.create</code> or <code>netcdf.open</code>.</p> <p>This function corresponds to the <code>nc_close</code> function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See <code>netcdf</code> for more information.</p>
<b>Examples</b>	<p>This example creates a new netCDF file, and then closes the file. You must have write permission in your current directory to run this example.</p> <pre>ncid = netcdf.open('foo.nc', 'NC_WRITE')  netcdf.close(ncid)</pre>
<b>See Also</b>	<code>netcdf.create</code>   <code>netCDF.open</code>

# netcdf.copyAtt

---

<b>Purpose</b>	Copy attribute to new location
<b>Syntax</b>	<code>netcdf.copyAtt(ncid_in,varid_in,attname,ncid_out,varid_out)</code>
<b>Description</b>	<p><code>netcdf.copyAtt(ncid_in,varid_in,attname,ncid_out,varid_out)</code> copies an attribute from one variable to another, possibly across files. <code>ncid_in</code> and <code>ncid_out</code> are netCDF file identifiers returned by <code>netcdf.create</code> or <code>netcdf.open</code>. <code>varid_in</code> identifies the variable with an attribute that you want to copy. <code>varid_out</code> identifies the variable to which you want to associate a copy of the attribute.</p> <p>This function corresponds to the <code>nc_copy_att</code> function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See <code>netcdf</code> for more information.</p>

## Examples

This example makes a copy of the attribute associated with the first variable in the netCDF example file, `example.nc`, in a new file. To run this example, you must have write permission in your current directory.

```
% Open example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get identifier for a variable in the file.
varid = netcdf.inqVarID(ncid,'avagadros_number');

% Create new netCDF file.
ncid2 = netcdf.create('foo.nc','NC_NOCLlobber');

% Define a dimension in the new file.
dimid2 = netcdf.defDim(ncid2,'x',50);

% Define a variable in the new file.
varid2 = netcdf.defVar(ncid2,'myvar','double',dimid2);

% Copy the attribute named 'description' into the new file,
% associating the attribute with the new variable.
netcdf.copyAtt(ncid,varid,'description',ncid2,varid2);
```

```
%  
% Check the name of the attribute in new file.  
attname = netcdf.inqAttName(ncid2,varid2,0)  
  
attname =  
  
description
```

## See Also

```
netcdf.inqAtt | netcdf.inqAttID | netcdf.inqAttName |  
netcdf.putAtt | netcdf.renameAtt
```

# netcdf.create

---

**Purpose** Create new NetCDF dataset

**Syntax**

```
ncid = netcdf.create(filename, mode)
[chunksize_out, ncid]=netcdf.create(filename,mode,initsz,
    chunksize)
```

**Description** `ncid = netcdf.create(filename, mode)` creates a new NetCDF file according to the file creation mode. The return value `ncid` is a file ID. The mode parameter is a text string that describes the type of file access, which can have any of the following values.

Value	Description
NOGLOBBER	Prevent overwriting of existing file with the
GLOBBER	Overwrite any existing file with the same name.
SHARE	Allow synchronous file updates.
64BIT_OFFSET	Allow easier creation of files and variables which are larger than two gigabytes.
NETCDF4	Create a NetCDF-4/HDF5 file
CLASSIC_MODEL	Enforce the classic model; has no effect unless used in a bitwise-or with NETCDF4

---

**Note** You can specify the mode as a numeric value, retrieved using the `netcdf.getConstant` function. To specify more than one mode, use a bitwise-OR of the numeric values of the modes.

---

`[chunksize_out, ncid]=netcdf.create(filename,mode,initsz,chunksize)` creates a new netCDF file, but with additional performance tuning parameters. `initsz` sets the initial size of the file. `chunksize` can affect I/O performance. The actual value chosen by the NetCDF library might not correspond to the input value.

This function corresponds to the `nc_create` and `nc__create` functions in the NetCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example creates a NetCDF dataset named `foo.nc`, only if no other file with the same name exists in the current directory. To run this example, you must have write permission in your current directory.

```
ncid = netcdf.create('foo.nc', 'NOCLOBBER');
```

## See Also

`netcdf.getConstant` | `netcdf.open`

# netcdf.defDim

---

**Purpose** Create netCDF dimension

**Syntax** `dimid = netcdf.defDim(ncid,dimname,dimlen)`

**Description** `dimid = netcdf.defDim(ncid,dimname,dimlen)` creates a new dimension in the netCDF file specified by `ncid`, where `dimname` is a character string that specifies the name of the dimension and `dimlen` is a numeric value that specifies its length. To define an unlimited dimension, specify the predefined constant `'NC_UNLIMITED'` for `dimlen`, using `netcdf.getConstant` to retrieve the value.

`netcdf.defDim` returns `dimid`, a numeric ID corresponding to the new dimension.

This function corresponds to the `nc_def_dim` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

**Examples** Create a new file and define two dimensions in the file. One dimension is an unlimited dimension. To run this example, you must have write permission in your current folder.

```
% Create a netCDF file.
ncid = netcdf.create('foo.nc','NC_NOCLlobber')

% Define a dimension.
lat_dimID = netcdf.defDim(ncid,'latitude',360);

% Define an unlimited dimension.
long_dimID = netcdf.defDim(ncid,'longitude',netcdf.getConstant('NC_UNLIMITED'))
```

**See Also** `netcdf.getConstant`

<b>Purpose</b>	Create group in NetCDF file
<b>Syntax</b>	<code>childGrpID = netcdf.defGrp(parentGroupId,childGroupName)</code>
<b>Description</b>	<code>childGrpID = netcdf.defGrp(parentGroupId,childGroupName)</code> creates a child group with the name specified by <code>childGroupName</code> , that is the child of the parent group specified by <code>parentGroupId</code>
<b>Input Arguments</b>	<p><b>parentGroupId</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code>, or of a NetCDF group, returned by <code>netcdf.defGrp</code>.</p> <p><b>childGroupName</b> Text string specifying the name that you want to assign to the group.</p>
<b>Output Arguments</b>	<p><b>childGrpID</b> Identifier of a NetCDF group.</p>
<b>Examples</b>	<p>This example creates a NetCDF dataset and then defines a group.</p> <pre>ncid = netcdf.create('myfile.nc','netcdf4'); childGroupId = netcdf.defGrp(ncid,'mygroup'); netcdf.close(ncid);</pre>
<b>References</b>	<p>This function corresponds to the <code>nc_def_grp</code> function in the NetCDF library C API.</p> <p>For copyright information, read the files <code>netcdfcopyright.txt</code> and <code>mexnccopyright.txt</code>.</p>
<b>See Also</b>	<code>netcdf</code>   <code>netcdf.inqGrps</code>

# netcdf.defVar

---

## Purpose

Create NetCDF variable

## Syntax

```
varid = netcdf.defVar(ncid,varname,xtype,dimids)
```

## Description

`varid = netcdf.defVar(ncid,varname,xtype,dimids)` creates a new variable in the dataset identified by `ncid`.

`varname` is a character string that specifies the name of the variable. `xtype` can be either a character string specifying the data type of the variable, such as `'double'`, or it can be the numeric equivalent returned by the `netcdf.getConstant` function. `dimids` specifies a list of dimension IDs.

`netcdf.defVar` returns `varid`, a numeric identifier for the new variable.

This function corresponds to the `nc_def_var` function in the NetCDF library C API. Because MATLAB uses FORTRAN-style ordering, the fastest-varying dimension comes first and the slowest comes last. Any unlimited dimension is therefore last in the list of dimension IDs. This ordering is the reverse of that found in the C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example creates a new netCDF file, defines a dimension in the file, and then defines a variable on that dimension. (In netCDF files, you must create a dimension before you can create a variable.) To run this example, you must have write permission in your current directory.

```
% Create netCDF file.
ncid = netcdf.create('foo.nc','NC_NOCLlobber');
%
% Define a dimension in the new file.
dimid = netcdf.defDim(ncid,'x',50);

% Define a variable in the new file.
varid = netcdf.defVar(ncid,'myvar','double',dimid)
```

<b>Purpose</b>	Define chunking behavior for NetCDF variable
<b>Syntax</b>	<code>netcdf.defVarChunking(ncid,varid,storage,chunkDims)</code>
<b>Description</b>	<p><code>netcdf.defVarChunking(ncid,varid,storage,chunkDims)</code>. sets the chunk settings for the variable specified by <code>varid</code>. Chunking is a technique to improve performance. <code>storage</code> specifies the type of chunking to use and <code>chunkDims</code> specifies the extents of the chunk size. You must specify the chunk size used with a variable after creating the variable but before you write data to the variable.</p> <p>You cannot specify the chunk size for variables in a NetCDF file created with the netCDF-3 mode (<code>CLASSIC_MODEL</code>).</p>
<b>Input Arguments</b>	<p><b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code>, or of a NetCDF group, returned by <code>netcdf.defGrp</code>.</p> <p><b>varid</b> Identifier of a NetCDF variable, returned by <code>netcdf.defVar</code>.</p> <p><b>storage</b> Text string specifying whether NetCDF should break the variable into chunks when writing to a file. If set to <code>CHUNKED</code>, NetCDF breaks the variable into chunks; if set to <code>CONTIGUOUS</code>, NetCDF does not break the data into chunks.</p> <p><b>chunkDims</b> Array specifying the dimensions of the chunk. Because MATLAB uses FORTRAN-style ordering, the order of dimensions in <code>chunkdims</code> is reversed relative to what would be in the C API. If <code>storage</code> is <code>CONTIGUOUS</code>, you can omit <code>chunkDims</code>.</p>

# netcdf.defVarChunking

---

**Default:** Chunk size determined by the NetCDF library.

## Examples

This example creates a NetCDF file and specifies the chunking behavior of a variable.

```
ncid = netcdf.create('myfile.nc', 'NETCDF4');
latdimid = netcdf.defDim(ncid, 'lat', 1800);
londimid = netcdf.defDim(ncid, 'col', 3600);
varid = netcdf.defVar(ncid, 'earthgrid', 'double', [latdimid londimid]);
netcdf.defVarChunking(ncid, varid, 'CHUNKED', [180 360]);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_def_var_chunking` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

<b>Purpose</b>	Define compression parameters for NetCDF variable
<b>Syntax</b>	<code>netcdf.defVarDeflate(ncid, varid, shuffle, deflate, deflateLevel)</code>
<b>Description</b>	<code>netcdf.defVarDeflate(ncid, varid, shuffle, deflate, deflateLevel)</code> sets the compression parameters for the NetCDF variable specified by <code>varid</code> in the location specified by <code>ncid</code> .
<b>Input Arguments</b>	<p><b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code>, or of a NetCDF group, returned by <code>netcdf.defGrp</code>.</p> <p><b>varid</b> Identifier of a NetCDF variable, returned by <code>netcdf.defVar</code>.</p> <p><b>shuffle</b> Boolean value. To turn on the shuffle filter, set this argument to <code>true</code>. The shuffle filter can assist with the compression of integer data by changing the byte order in the data stream.</p> <p><b>deflate</b> Boolean value. To turn on compression, set this argument to <code>true</code> and set the <code>deflateLevel</code> argument to the desired compression level.</p> <p><b>deflateLevel</b> Numeric value between 0 and 9 specifying the amount of compression, where 0 is no compression and 9 is the most compression.</p>
<b>Examples</b>	<p>This example create a variable with dimensions [1800 3600] and a compression level of 5. This results in a chunked layout that is a 10-by-10 grid.</p> <pre>ncid = netcdf.create('myfile.nc', 'NETCDF4'); latdimid = netcdf.defDim(ncid, 'lat', 1800);</pre>

# netcdf.defVarDeflate

---

```
londimid = netcdf.defDim(ncid,'col',3600);  
varid = netcdf.defVar(ncid,'earthgrid','double',[latdimid londimid]);  
netcdf.defVarDeflate(ncid,varid,true,true,5);  
netcdf.close(ncid);
```

## References

<b>Purpose</b>	Define fill parameters for NetCDF variable
<b>Syntax</b>	<code>netcdf.defVarFill(ncid, varid, noFillMode, fillValue)</code>
<b>Description</b>	<p><code>netcdf.defVarFill(ncid, varid, noFillMode, fillValue)</code> sets the fill parameters for the NetCDF variable identified by <code>varid</code>. <code>ncid</code> specifies the location.</p> <p>For netCDF-4 files, you can only specify fill values when the NetCDF is in definition mode (before calling <code>netcdf.endDef</code>). For NetCDF files in classic and 64-bit offset modes, you can turn no-fill mode on and off at any time.</p>
<b>Input Arguments</b>	<p><b>ncid</b> Identifier of a NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code>, or of a NetCDF group, returned by <code>netcdf.defGrp</code>.</p> <p><b>varid</b> Identifier of a NetCDF variable, returned by <code>netcdf.defVar</code>.</p> <p><b>noFillMode</b> Boolean value. When set to <code>true</code>, turns off use of fill values for the variable, which can be helpful in high performance applications. When <code>true</code>, <code>netcdf.defVarFill</code> ignores the value of the <code>fillValue</code> argument. To use the fill value, set this to <code>false</code>.</p> <p><b>fillValue</b> Specifies the value to use in the variable when no other value is specified. The data type must be the same data type as the variable.</p>
<b>Examples</b>	<p>This example creates a NetCDF file and defines a fill value for a variable.</p> <pre>ncid = netcdf.create('myfile.nc', 'NETCDF4'); dimid = netcdf.defDim(ncid, 'latitude', 180);</pre>

# netcdf.defVarFill

---

```
varid = netcdf.defVar(ncid,'latitude','double',dimid);  
netcdf.defVarFill(ncid,varid,false,-999);  
netcdf.close(ncid);
```

**Purpose** Delete netCDF attribute

**Syntax** netcdf.delAtt(ncid,varid,attName)

**Description** netcdf.delAtt(ncid,varid,attName) deletes the attribute identified by the text string attName.

ncid is a netCDF file identifier returned by netcdf.create or netcdf.open.

varid is a numeric value that identifies the variable. To delete a global attribute, use netcdf.getConstant('GLOBAL') for the varid. You must be in define mode to delete an attribute.

This function corresponds to the nc\_del\_att function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See netcdf for more information.

**Examples** This example opens a local copy of the example netCDF file included with MATLAB, example.nc.

```
% Open a netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Determine number of global attributes in file.
[numdims numvars numatts unlimdimID] = netcdf.inq(ncid);

numatts =

    1

% Get name of attribute; it is needed for deletion.
attname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0)

% Put file in define mode to delete an attribute.
netcdf.reDef(ncid);

% Delete the global attribute in the netCDF file.
```

# netcdf.delAtt

---

```
netcdf.delAtt(ncid,netcdf.getConstant('GLOBAL'),attname);

% Verify that the global attribute was deleted.
[numdims numvars numatts unlimdimID] = netcdf.inq(ncid);

numatts =

    0
```

<b>Purpose</b>	End netCDF file define mode
<b>Syntax</b>	<pre>netcdf.endDef(ncid) netcdf.endDef(ncid,h_minfree,v_align,v_minfree,r_align)</pre>
<b>Description</b>	<p><code>netcdf.endDef(ncid)</code> takes a netCDF file out of define mode and into data mode. <code>ncid</code> is a netCDF file identifier returned by <code>netcdf.create</code> or <code>netcdf.open</code>.</p> <p><code>netcdf.endDef(ncid,h_minfree,v_align,v_minfree,r_align)</code> takes a netCDF file out of define mode, specifying four additional performance tuning parameters. For example, one reason for using the performance parameters is to reserve extra space in the netCDF file header using the <code>h_minfree</code> parameter:</p> <pre>ncid = netcdf.endDef(ncid,20000,4,0,4);</pre> <p>This reserves 20,000 bytes in the header, which can be used later when adding attributes. This can be extremely efficient when working with very large files. To understand how to use these performance tuning parameters, see the netCDF library documentation.</p> <p>This function corresponds to the <code>nc_enddef</code> and <code>nc__enddef</code> functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See <code>netcdf</code> for more information.</p>
<b>Examples</b>	<p>When you create a file using <code>netcdf.create</code>, the functions opens the file in define mode. This example uses <code>netcdf.endDef</code> to take the file out of define mode.</p> <pre>% Create a netCDF file. ncid = netcdf.create('foo.c','NC_NOCLlobber');  % Define a dimension. dimid = netcdf.defDim(ncid, 'lat', 50);  % Leave define mode. netcdf.endDef(ncid)</pre>

## netcdf.endDef

---

```
% Test if still in define mode.
dimid = netcdf.defDim(ncid, 'lon', 50); % should fail
??? Error using ==> netcdf.lib
NetCDF: Operation not allowed in data mode

Error in ==> defDim at 22
dimid = netcdf.lib('def_dim', ncid,dimname,dimlen);
```

[netcdf.create](#) | [netcdf.reDef](#)

**Purpose** Return netCDF attribute

**Syntax**

```
attrvalue = netcdf.getAtt(ncid,varid,attname)
attrvalue = netcdf.getAtt(ncid,varid,attname,output_datatype)
```

**Description** `attrvalue = netcdf.getAtt(ncid,varid,attname)` returns `attrvalue`, the value of the attribute specified by the text string `attname`. When it chooses the data type of `attrvalue`, MATLAB attempts to match the netCDF class of the attribute. For example, if the attribute has the netCDF data type `NC_INT`, MATLAB uses the `int32` class for the output data. If an attribute has the netCDF data type `NC_BYTE`, the class of the output data is `int8` value.

`attrvalue = netcdf.getAtt(ncid,varid,attname,output_datatype)` returns `attrvalue`, the value of the attribute specified by the text string `attname`, using the output class specified by `output_datatype`. You can specify any of the following strings for the output data type.

'int'	'double'	'int16'
'short'	'single'	'int8'
'float'	'int32'	'uint8'

This function corresponds to several attribute I/O functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example opens the example netCDF file included with MATLAB, `example.nc`, and gets the value of the attribute associated with the first variable. The example also gets the value of the global variable in the file.

```
% Open a netCDF file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get name of first variable.
```

## netcdf.getAtt

---

```
[varname vartype vardimIDs varatts] = netcdf.inqVar(ncid,0);

% Get ID of variable, given its name.
varid = netcdf.inqVarID(ncid,varname);

% Get attribute name, given variable id.
attname = netcdf.inqAttName(ncid,varid,0);

% Get value of attribute.
attval = netcdf.getAtt(ncid,varid,attname);

% Get name of global attribute
gattname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0);

% Get value of global attribute.
gattval = netcdf.getAtt(ncid,netcdf.getConstant('NC_GLOBAL'),gattname)

gattval =

09-Jun-2008
```

<b>Purpose</b>	Retrieve chunk cache settings for NetCDF library
<b>Syntax</b>	<code>[csize, nelems, premp] = netcdf.getChunkCache()</code>
<b>Description</b>	<code>[csize, nelems, premp] = netcdf.getChunkCache()</code> returns the default chunk cache settings.
<b>Output Arguments</b>	<p><b>csize</b></p> <p>Scalar double specifying the total size of the raw data chunk cache in bytes.</p> <p><b>nelems</b></p> <p>Scalar double specifying the number of chunk slots in the raw data chunk cache hash table.</p> <p><b>premp</b></p> <p>Double, between 0 and 1, inclusive, that specifies how the library handles preempting fully read chunks in the chunk cache. A value of zero means fully read chunks are treated no differently than other chunks, that is, preemption occurs solely based on the Least Recently Used (LRU) algorithm. A value of 1 means fully read chunks are always preempted before other chunks.</p>
<b>Examples</b>	<p>Determine information about the chunk cache size used by the NetCDF library.</p> <pre>[csize, nelems, premp] = netcdf.getChunkCache();</pre>
<b>References</b>	<p>This function corresponds to the <code>nc_get_chunk_cache</code> function in the NetCDF library C API.</p> <p>For copyright information, read the <code>netcdfcopyright.txt</code> and <code>mexnccopyright.txt</code> files.</p>
<b>See Also</b>	<code>netcdf</code>   <code>netcdf.setChunkCache</code>

# netcdf.getConstant

---

**Purpose** Return numeric value of named constant

**Syntax** `val = netcdf.getConstant(param_name)`

**Description** `val = netcdf.getConstant(param_name)` returns the numeric value corresponding to the name of a constant defined by the netCDF library. For example, `netcdf.getConstant('NC_NOGLOBBBER')` returns the numeric value corresponding to the netCDF constant `NC_NOGLOBBBER`.

The value for `param_name` can be either upper- or lowercase, and does not need to include the leading three characters `'NC_'`. To retrieve a list of all the names defined by the netCDF library, use the `netcdf.getConstantNames` function.

This function has no direct equivalent in the netCDF C interface. To find out more about NetCDF, see `netcdf`.

**Examples** This example opens the example netCDF file included with MATLAB, `example.nc`.

```
% Open example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Determine contents of the file.
[ndims nvars natts dimm] = netcdf.inq(ncid);

% Get name of global attribute.
% Note: You must use netcdf.getConstant to specify NC_GLOBAL.
attname = netcdf.inqattname(ncid,netcdf.getConstant('NC_GLOBAL'),0)

attname =

creation_date
```

**See Also** `netcdf.getConstantNames`

**Purpose** Return list of constants known to netCDF library

**Syntax** `val = netcdf.getConstantNames(param_name)`

**Description** `val = netcdf.getConstantNames(param_name)` returns a list of names of netCDF library constants, definitions, and enumerations. When these strings are supplied as actual parameters to MATLAB netCDF package functions, the functions automatically convert the constant to the appropriate numeric value.

This MATLAB function has no direct equivalent in the netCDF C interface. To find out more about netCDF, see `netcdf`.

**Examples** `nc_constants = netcdf.getConstantNames`

```
nc_constants =  
  
    'NC2_ERR'  
    'NC_64BIT_OFFSET'  
    'NC_BYTE'  
    'NC_CHAR'  
    'NC_CLOBBER'  
    'NC_DOUBLE'  
    'NC_EBADDIM'  
    'NC_EBADID'  
    'NC_EBADNAME'  
    'NC_EBADTYPE'  
    ...
```

**See Also** `netCDF.getConstantNames`

# netcdf.getVar

---

**Purpose** Return data from netCDF variable

**Syntax**

```
data = netcdf.getVar(ncid,varid)
data = netcdf.getVar(ncid,varid,start)
data = netcdf.getVar(ncid,varid,start,count)
data = netcdf.getVar(ncid,varid,start,count,stride)
data = netcdf.getVar(...,output_type)
```

**Description** `data = netcdf.getVar(ncid,varid)` returns data, the value of the variable specified by `varid`. MATLAB attempts to match the class of the output data to netCDF class of the variable.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`data = netcdf.getVar(ncid,varid,start)` returns a single value starting at the specified index, `start`.

`data = netcdf.getVar(ncid,varid,start,count)` returns a contiguous section of a variable. `start` specifies the starting point and `count` specifies the amount of data to return.

`data = netcdf.getVar(ncid,varid,start,count,stride)` returns a subset of a section of a variable. `start` specifies the starting point, `count` specifies the extent of the section, and `stride` specifies which values to return.

`data = netcdf.getVar(...,output_type)` specifies the data type of the return value `data`. You can specify any of the following strings for the output data type.

'int8'
'uint8'
'int16'
'int32'
'single'
'double'

This function corresponds to several functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

Open the example netCDF file and get the value of a variable in the file.

```
% Open example file.
ncid = netcdf.open('example.nc', 'NC_NOWRITE');

% Get the name of the first variable.
[varname, xtype, varDimIDs, varAtts] = netcdf.inqVar(ncid,0);

% Get variable ID of the first variable, given its name.
varid = netcdf.inqVarID(ncid,varname);

% Get the value of the first variable, given its ID.
data = netcdf.getVar(ncid,varid)

data =

    6.0221e+023

% Determine the data type of the output value
whos data
  Name      Size      Bytes  Class  Attributes

  data      1x1          8  double

% Get the value again, this time specifying the output data type
data = netcdf.getVar(ncid,varid,'single');

% Determine the data type of the output value
whos data
  Name      Size      Bytes  Class  Attributes

  data      1x1          4  single
```

# netcdf.getVar

# netcdf.inqDimIDs

---

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

**See Also**      `netcdf` | `netcdf.inqVarIDs`

**Purpose** Determine format of NetCDF file

**Syntax** `format = netcdf.inqFormat(ncid)`

**Description** `format = netcdf.inqFormat(ncid)` returns the format for the file specified by NetCDF file identifier, `ncid`.

**Input Arguments** **ncid**  
Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Output Arguments** **format**  
Text string that specifies the format of the NetCDF file. Values include:

Format String	Description
FORMAT_CLASSIC	Classic format — Original NetCDF format, used by all NetCDF files created between 1989 and 2004
FORMAT_64BIT	Classic format, 64-bit — Original format with 64-bit addressing capability to allow creation and access of much larger files.
FORMAT_NETCDF4	Enhanced model, HDF5-based — Introduced in 2008, NetCDF, version 4, extends the classic model and is based on HDF5.
FORMAT_NETCDF4_CLASSIC	Classic model, HDF5-based — Introduced in 2008, NetCDF, version 4, implements classic model but is based on HDF5.

**Examples** This example opens the sample NetCDF file and determines the format.

```
ncid = netcdf.open('example.nc', 'NOWRITE');
fmt = netcdf.inqFormat(ncid)
```

# netcdf.inqFormat

---

```
format =  
FORMAT_NETCDF4  
netcdf.close(ncid);
```

# netcdf.inqGrpNameFull

---

<b>Purpose</b>	Complete pathname of group
<b>Syntax</b>	<code>groupName = netcdf.inqGrpNameFull(ncid)</code>
<b>Description</b>	<code>groupName = netcdf.inqGrpNameFull(ncid)</code> returns the complete pathname of the group specified by <code>ncid</code> .
<b>Input Arguments</b>	<b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or of a NetCDF group, returned by <code>netcdf.defGrp</code> .
<b>Output Arguments</b>	<b>groupName</b> Text string specifying complete path of group.  The root group has the name <code>'/'</code> . The names of parent groups and child groups use the forward slash <code>'/'</code> separator, as in UNIX folder names, for example, <code>/group1/subgrp2/subsubgrp3</code> .
<b>Examples</b>	Open the NetCDF sample dataset and retrieve the names of all groups.  <pre>ncid = netcdf.open('example.nc', 'NOWRITE'); gid = netcdf.inqNcid(ncid, 'grid2'); fullName = netcdf.inqGrpNameFull(gid); netcdf.close(ncid);</pre>

# netcdf.inqGrps

---

<b>Purpose</b>	Retrieve array of child group IDs
<b>Syntax</b>	<code>childGrps = netcdf.inqGrps(ncid)</code>
<b>Description</b>	<code>childGrps = netcdf.inqGrps(ncid)</code> returns all the child group IDs in the parent group, specified by <code>ncid</code> .
<b>Input Arguments</b>	<b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or of a NetCDF group, returned by <code>netcdf.defGrp</code> .
<b>Output Arguments</b>	<b>childGrps</b> Array containing identifiers of child groups in the specified NetCDF file or group.
<b>Examples</b>	This example opens the sample NetCDF file and then gets information about the groups it contains.  <pre>ncid = netcdf.open('example.nc','nowrite'); childGroups = netcdf.inqGrps(ncid); netcdf.close(ncid);</pre>

# netcdf.inqUnlimDims

---

<b>Purpose</b>	Return list of unlimited dimensions in group
<b>Syntax</b>	<code>unlimdimIDs = netcdf.inqUnlimDims(ncid)</code>
<b>Description</b>	<code>unlimdimIDs = netcdf.inqUnlimDims(ncid)</code> returns the IDs of all unlimited dimensions in the group specified by <code>ncid</code> .
<b>Input Arguments</b>	<b>ncid</b> Identifier of a NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or group, returned by <code>netcdf.defGrp</code> .
<b>Output Arguments</b>	<b>unlimDimIDs</b> An array containing the identifiers of each unlimited dimension. <code>unlimDimIDs</code> is empty if there are no unlimited dimensions.
<b>Examples</b>	<p>This example opens the NetCDF sample dataset and gets the IDs of all the unlimited dimensions.</p> <pre>ncid = netcdf.open('example.nc', 'NOWRITE'); dimids = netcdf.inqUnlimDims(ncid)  dimids =       []  netcdf.close(ncid);</pre>
<b>References</b>	<p>This function corresponds to the <code>nc_inq_unlim_dims</code> function in the NetCDF library C API.</p> <p>For copyright information, read the <code>netcdfcopyright.txt</code> and <code>mexncccopyright.txt</code> files.</p>
<b>See Also</b>	<code>netcdf</code>   <code>netcdf.defDim</code>   <code>netcdf.inqDim</code>   <code>netcdf.inqDimID</code>   <code>netcdf.renameDim</code>   <code>netcdf.inqDimIDs</code>

<b>Purpose</b>	IDs of all variables in group
<b>Syntax</b>	<code>varids = netcdf.inqVarIDs(ncid)</code>
<b>Description</b>	<code>varids = netcdf.inqVarIDs(ncid)</code> returns IDs of the all the variables in the group specified by <code>ncid</code> .
<b>Input Arguments</b>	<b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or of a NetCDF group, returned by <code>netcdf.defGrp</code> .
<b>Output Arguments</b>	<b>varids</b> Array containing identifiers of variables in a NetCDF file or group.
<b>Examples</b>	<p>This example opens the NetCDF sample file and gets the IDs of all the variables in a group.</p> <pre>ncid = netcdf.open('example.nc', 'NOWRITE'); gid = netcdf.inqNcid(ncid, 'grid1'); varids = netcdf.inqVarIDs(gid); netcdf.close(ncid);</pre>
<b>References</b>	<p>This function corresponds to the <code>nc_inq_varids</code> function in the NetCDF library C API.</p> <p>For copyright information, read the <code>netcdfcopyright.txt</code> and <code>mexnccopyright.txt</code> files.</p>

# netcdf.inqVarChunking

---

<b>Purpose</b>	Determine chunking settings for NetCDF variable
<b>Syntax</b>	<code>[storage,chunkSizes] = netcdf.inqVarChunking(ncid,varid)</code>
<b>Description</b>	<code>[storage,chunkSizes] = netcdf.inqVarChunking(ncid,varid)</code> returns the type of chunking and the dimensions of a chunk for the NetCDF variable specified by <code>varid</code> , in the file or group specified by <code>ncid</code> .
<b>Input Arguments</b>	<b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or of a NetCDF group, returned by <code>netcdf.defGrp</code> .  <b>varid</b> Identifier of NetCDF variable, returned by <code>netcdf.defVar</code> .
<b>Output Arguments</b>	<b>storage</b> Text string specifying if NetCDF breaks the data into chunks when writing to a file. <code>CHUNKED</code> indicates the data is chunked; <code>CONTIGUOUS</code> indicates that the data is not chunked.  <b>chunkSizes</b> Array specifying the dimensions of the chunk.  Because MATLAB uses FORTRAN-style ordering, the order of dimensions in <code>chunkdims</code> is reversed relative to what would be in the NetCDF C API.  If the storage type specified is <code>CONTIGUOUS</code> , <code>netcdf.inqVarChunking</code> returns an empty array, <code>[]</code> .
<b>Examples</b>	This example opens the NetCDF sample dataset and gets the values of chunking parameters associated with a variable.  <pre>ncid = netcdf.open('example.nc','NOWRITE');</pre>

```
groupid = netcdf.inqNcid(ncid,'grid1');  
varid = netcdf.inqVarID(groupid,'temp');  
[storage,chunkSize] = netcdf.inqVarChunking(groupid,varid);  
netcdf.close(ncid);
```

## References

# netcdf.inqVarDeflate

---

<b>Purpose</b>	Determine compression settings for NetCDF variable
<b>Syntax</b>	<code>[shuffle,deflate,deflateLevel] = netcdf.inqVarDeflate(ncid, varid)</code>
<b>Description</b>	<code>[shuffle,deflate,deflateLevel] = netcdf.inqVarDeflate(ncid,varid)</code> returns the compression parameters for the NetCDF variable specified by <code>varid</code> in the location specified by <code>ncid</code> .
<b>Input Arguments</b>	<b>ncid</b> Identifier of a NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or of a NetCDF group, returned by <code>netcdf.defGrp</code> . <b>varid</b> Identifier of NetCDF variable, returned by <code>netcdf.defVar</code> .
<b>Output Arguments</b>	<b>shuffle</b> Boolean value. <code>true</code> indicates that the shuffle filter is enabled for the specified variable. The shuffle filter can assist with the compression of integer data by changing the byte order in the data stream. <b>deflate</b> Boolean value. <code>true</code> indicates that compression is enabled for this variable. The <code>deflateLevel</code> argument specifies the level of compression. <b>deflateLevel</b> Scalar value between 0 and 9 specifying the amount of compression, where 0 is no compression and 9 is the most compression
<b>Examples</b>	This example opens the NetCDF sample file and gets information about variable compression.

```
ncid = netcdf.open('example.nc', 'NOWRITE');
groupid = netcdf.inqNcid(ncid, 'grid1');
varid = netcdf.inqVarID(groupid, 'temp');
[shuffle, deflate, deflateLevel] = netcdf.inqVarDeflate(groupid, varid);
netcdf.close(ncid);
```

# netcdf.inqVarFill

---

<b>Purpose</b>	Determine values of fill parameters for NetCDF variable
<b>Syntax</b>	<code>[noFillMode,fillValue] = netcdf.inqVarFill(ncid,varid)</code>
<b>Description</b>	<code>[noFillMode,fillValue] = netcdf.inqVarFill(ncid,varid)</code> returns the fill mode and the fill value for the variable <code>varid</code> in the file or group specified by <code>ncid</code> .
<b>Input Arguments</b>	<b>ncid</b> Identifier of a NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or a NetCDF group, returned by <code>netcdf.defGrp</code> .  <b>varid</b> Identifier of NetCDF variable.
<b>Output Arguments</b>	<b>noFillMode</b> Boolean value. <code>true</code> indicates that use of the fill values for the variable has been disabled.  <b>fillValue</b> Specifies the value to use in the variable when no other value is specified and use of fill values has been enabled.
<b>Examples</b>	This example opens the NetCDF sample dataset and gets the fill mode and fill value used with a variable.  <pre>ncid = netcdf.open('example.nc','NOWRITE'); varid = netcdf.inqVarID(ncid,'temperature'); [noFillMode,fillValue] = netcdf.inqVarFill(ncid,varid); netcdf.close(ncid);</pre>

# netcdf.inqVarFletcher32

---

<b>Purpose</b>	Fletcher32 checksum setting for NetCDF variable
<b>Syntax</b>	<code>setting = netcdf.inqVarFletcher32(ncid,varid)</code>
<b>Description</b>	<code>setting = netcdf.inqVarFletcher32(ncid,varid)</code> returns the Fletcher32 checksum setting for the NetCDF variable specified by <code>varid</code> in the file or group specified by <code>ncid</code> .
<b>Input Arguments</b>	<b>ncid</b> Identifier for NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or group, returned by <code>netcdf.defGrp</code> .  <b>varid</b> Identifier of NetCDF variable.
<b>Output Arguments</b>	<b>setting</b> Text string specifying whether the Fletcher32 checksum is turned on for the specified variable. <code>netcdf.inqVarFletcher32</code> returns the text string <code>FLETCHER32</code> if the checksum is turned on for the variable; otherwise, <code>NOCHECKSUM</code> .
<b>Examples</b>	This example opens the sample NetCDF file and gets information about the checksum setting for a variable.  <pre>ncid = netcdf.open('example.nc', 'NOWRITE'); varid = netcdf.inqVarID(ncid, 'temperature'); setting = netcdf.inqVarFletcher32(ncid, varid); netcdf.close(ncid);</pre>
<b>References</b>	This function corresponds to the <code>nc_inq_var_fletcher32</code> function in the netCDF library C API.  For copyright information, read the <code>netcdfcopyright.txt</code> and <code>mexnccopyright.txt</code> for more information.

# netcdf.inqAtt

---

**Purpose** Return information about netCDF attribute

**Syntax** `[xtype,attlen] = netcdf.inqAtt(ncid,varid,attname)`

**Description** `[xtype,attlen] = netcdf.inqAtt(ncid,varid,attname)` returns the data type, `xtype`, and length, `attlen`, of the attribute identified by the text string `attname`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` identifies the variable that the attribute is associated with. To get information about a global attribute, specify `netcdf.getConstant('NC_GLOBAL')` in place of `varid`.

This function corresponds to the `nc_inq_att` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example opens the example netCDF file included with MATLAB, `example.nc`, and gets information about an attribute in the file.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NOWRITE');

% Get identifier of a variable in the file, given its name.
varid = netcdf.inqVarID(ncid,'avagadros_number');

% Get attribute name, given variable id and attribute number.
attname = netcdf.inqAttName(ncid,varid,0);

% Get information about the attribute.
[xtype,attlen] = netcdf.inqAtt(ncid,varid,'description')

xtype =
```

2

```
attlen =  
    31  
  
% Get name of global attribute  
gattname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0);  
  
% Get information about global attribute.  
[gxtype gattlen] = netcdf.inqAtt(ncid,netcdf.getConstant('NC_GLOBAL'));  
  
gxtype =  
    2  
  
gattlen =  
    11
```

## See Also

[netcdf.inqAttID](#) | [netcdf.inqAttName](#)

# netcdf.inqAttID

---

**Purpose** Return ID of netCDF attribute

**Syntax** `attnum = netcdf.inqAttID(ncid,varid,attname)`

**Description** `attnum = netcdf.inqAttID(ncid,varid,attname)` retrieves `attnum`, the identifier of the attribute specified by the text string `attname`.

`varid` specifies the variable the attribute is associated with.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_attid` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example opens the netCDF example file included with MATLAB, `example.nc`.

```
% Open the netCDF example file.  
ncid = netcdf.open('example.nc','NC_NOWRITE');
```

```
% Get the identifier of a variable in the file.  
varid = netcdf.inqVarID(ncid,'avagadros_number');
```

```
% Retrieve the identifier of the attribute associated with the variable.  
attid = netcdf.inqAttID(ncid,varid,'description');
```

**See Also** `netcdf.inqAtt` | `netcdf.inqAttName`

## Purpose

Return name of netCDF attribute

## Syntax

```
attname = netcdf.inqAttName(ncid,varid,attnum)
```

## Description

`attname = netcdf.inqAttName(ncid,varid,attnum)` returns `attname`, a text string specifying the name of an attribute.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` is a numeric identifier of a variable in the file. If you want to get the name of a global attribute in the file, use `netcdf.getConstant('NC_GLOBAL')` in place of `attnum` is a zero-based numeric value specifying the attribute, with 0 indicating the first attribute, 1 the second attribute, and so on.

This function corresponds to the `nc_inq_attname` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example opens the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get identifier of a variable in the file.
varid = netcdf.inqVarID(ncid,'avagadros_number')

% Get the name of the attribute associated with the variable.
attname = netcdf.inqAttName(ncid,varid,0)

attname =

description

% Get the name of the global attribute associated with the variable.
gattname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0)
```

# netcdf.inqAttName

netcdf.inqAtt | netcdf.inqAttID

<b>Purpose</b>	Return netCDF dimension name and length
<b>Syntax</b>	<code>[dimname, dimlen] = netcdf.inqDim(ncid,dimid)</code>
<b>Description</b>	<p><code>[dimname, dimlen] = netcdf.inqDim(ncid,dimid)</code> returns the name, <code>dimname</code>, and length, <code>dimlen</code>, of the dimension specified by <code>dimid</code>. If <code>ndims</code> is the number of dimensions defined for a netCDF file, each dimension has an ID between 0 and <code>ndims-1</code>. For example, the dimension identifier of the first dimension is 0, the second dimension is 1, and so on.</p> <p><code>ncid</code> is a netCDF file identifier returned by <code>netcdf.create</code> or <code>netcdf.open</code>.</p> <p>This function corresponds to the <code>nc_inq_dim</code> function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See <code>netcdf</code> for more information.</p>
<b>Examples</b>	<p>The example opens the example netCDF file include with MATLAB, <code>example.nc</code>.</p> <pre>ncid = netcdf.open('example.nc','NC_NOWRITE');  % Get name and length of first dimension [dimname, dimlen] = netcdf.inqDim(ncid,0)  dimname =  x  dimlen =      50</pre>
<b>See Also</b>	<code>netcdf.inqDimID</code>

# netcdf.inqDimID

---

**Purpose** Return dimension ID

**Syntax** `dimid = netcdf.inqDimID(ncid,dimname)`

**Description** `dimid = netcdf.inqDimID(ncid,dimname)` returns `dimid`, the identifier of the dimension specified by the character string `dimname`. You can use the `netcdf.inqDim` function to retrieve the dimension name. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_dimid` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example opens the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get name and length of first dimension
[dimname, dimlen] = netcdf.inqDim(ncid,0);

% Retrieve identifier of dimension.
dimid = netcdf.inqDimID(ncid,dimname)

dimid =

     0
```

**See Also** `netcdf.inqDim`

**Purpose** Return NetCDF library version information

**Syntax** `libvers = netcdf.inqLibVers`

**Description** `libvers = netcdf.inqLibVers` returns a string identifying the version of the NetCDF library.

This function corresponds to the `nc_inq_libvers` function in the NetCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** `libvers = netcdf.inqLibVers`

```
libvers =
```

```
4.1.3
```

# netcdf.inqVar

---

**Purpose** Return information about variable

**Syntax** [varname,xtype,dimids,natts] = netcdf.inqVar(ncid,varid)

**Description** [varname,xtype,dimids,natts] = netcdf.inqVar(ncid,varid) returns the name, data type, dimensions IDs, and the number of attributes associated with the variable identified by varid. Dimension IDs are zero-based.

ncid is a netCDF file identifier returned by netcdf.create or netcdf.open.

This function corresponds to the nc\_inq\_var function in the netCDF library C API. Because MATLAB uses FORTRAN-style ordering, however, the order of the dimension IDs is reversed relative to what would be obtained from the C API. To use this function, you should be familiar with the netCDF programming paradigm. See netcdf for more information.

**Examples** This example opens the example netCDF file included with MATLAB, example.nc, and gets information about a variable in the file.

```
% Open the example netCDF file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get information about third variable in the file.
[varname, xtype, dimids, numatts] = netcdf.inqVar(ncid,2)
```

```
varname =
```

```
peaks
```

```
xtype =
```

```
5
```

```
dimids =  
      0  1
```

```
numatts =  
      1  1
```

## See Also

[netcdf.create](#) | [netcdf.inqVarID](#) | [netcdf.open](#)

# netcdf.inqVarID

---

**Purpose** Return ID associated with variable name

**Syntax** `varid = netcdf.inqVarID(ncid,varname)`

**Description** `varid = netcdf.inqVarID(ncid,varname)` returns `varid`, the ID of a netCDF variable specified by the text string, `varname`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_varid` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example opens the example netCDF file included with MATLAB, `example.nc`, and uses several inquiry functions to get the ID of the first variable.

```
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get information about first variable in the file.
[varname, xtype, dimids, atts] = netcdf.inqVar(ncid,0);

% Get variable ID of the first variable, given its name
varid = netcdf.inqVarID(ncid,varname)

varid =

    0
```

**See Also** `netcdf.create` | `netcdf.inqVar` | `netcdf.open`

**Purpose**

Open NetCDF data source

**Syntax**

```
ncid = netcdf.open(source)
ncid = netcdf.open(source,mode)
[chosen_chunksize, ncid] = netcdf.open(source,mode,chunksize)
```

**Description**

`ncid = netcdf.open(source)` opens `source`, which can be the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source, for read-only access. Returns a NetCDF ID in `ncid`.

`ncid = netcdf.open(source,mode)` opens `source` with the type of access specified by `mode`, which can have any of the following values.

Value	Description
'WRITE'	Read-write access
'SHARE'	Synchronous file updates
'NOWRITE'	Read-only access (Default)

You can also specify `mode` as a numeric value that can be retrieved using `netcdf.getConstant`. Use these numeric values when you want to specify a bitwise-OR of several modes.

```
[chosen_chunksize, ncid] =
netcdf.open(source,mode,chunksize)
```

opens `source`, an existing netCDF data source, specifying the additional I/O performance tuning parameter, `chunksize`. The actual value used by the NetCDF library might not correspond to the input value you specify.

This function corresponds to the `nc_open` and `nc__open` functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples**

This example opens the example NetCDF file included with MATLAB, `example.nc`.

```
ncid = netcdf.open('example.nc','NOWRITE');
netcdf.close(ncid);
```

# netcdf.open

---

## See Also

[netcdf.close](#) | [netcdf](#) | [netcdf.getConstant](#)

**Purpose** Write netCDF attribute

**Syntax** `netcdf.putAtt(ncid,varid,attrname,attrvalue)`

**Description** `netcdf.putAtt(ncid,varid,attrname,attrvalue)` writes the attribute named `attrname` with value `attrvalue` to the netCDF variable specified by `varid`. To specify a global attribute, use `netcdf.getConstant('NC_GLOBAL')` for `varid`

`ncid` is a netCDF file identifier returned by `netCDF.create` or `netCDF.open`.

This function corresponds to several attribute I/O functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example creates a new netCDF file, defines a dimension and a variable, adds data to the variable, and then creates an attribute associated with the variable. To run this example, you must have `writer` permission in your current directory.

```
% Create a variable in the workspace.
my_vardata = linspace(0,50,50);

% Create a netCDF file.
ncid = netcdf.create('foo.nc','NC_WRITE');

% Define a dimension in the file.
dimid = netcdf.defDim(ncid,'my_dim',50);

% Define a new variable in the file.
varid = netcdf.defVar(ncid,'my_var','double',dimid);

% Leave define mode and enter data mode to write data.
netcdf.endDef(ncid);

% Write data to variable.
netcdf.putVar(ncid,varid,my_vardata);
```

## netcdf.putAtt

---

```
% Re-enter define mode.
netcdf.reDef(ncid);

% Create an attribute associated with the variable.
netcdf.putAtt(ncid,0,'my_att',10);

% Verify that the attribute was created.
[xtype xlen] = netcdf.inqAtt(ncid,0,'my_att')

xtype =

     6

xlen =

     1
```

### See Also

netcdf.getatt

**Purpose** Write data to netCDF variable

**Syntax**

```
netcdf.putVar(ncid,varid,data)
netcdf.putVar(ncid,varid,start,data)
netcdf.putVar(ncid,varid,start,count,data)
netcdf.putVar(ncid,varid,start,count,stride,data)
```

**Description**

`netcdf.putVar(ncid,varid,data)` writes data to a netCDF variable identified by `varid`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`netcdf.putVar(ncid,varid,start,data)` writes a single data value into the variable at the index specified by `start`.

`netcdf.putVar(ncid,varid,start,count,data)` writes a section of values into the netCDF variable at the index specified by the vector `start` to the extent specified by the vector `count`, along each dimension of the specified variable.

`netcdf.putVar(ncid,varid,start,count,stride,data)` writes the subsection specified by sampling interval, `stride`, of the values in the section of the variable beginning at the index `start` and to the extent specified by `count`.

This function corresponds to several variable I/O functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example creates a new netCDF file and writes a variable to the file.

```
% Create a 50 element vector for a variable.
my_vardata = linspace(0,50,50);

% Open netCDF file.
ncid = netcdf.create('foo.nc','NC_WRITE')

% Define the dimensions of the variable.
```

## netcdf.putVar

---

```
dimid = netcdf.defDim(ncid,'my_dim',50);

% Define a new variable in the file.
my_varID = netcdf.defVar(ncid,'my_var','double',dimid)

% Leave define mode and enter data mode to write data.
netcdf.endDef(ncid)

% Write data to variable.
netcdf.putVar(ncid,my_varID,my_vardata);

% Verify that the variable was created.
[varname xtype dimid natts ] = netcdf.inqVar(ncid,0)

varname =

my_var

xtype =

    6

dimid =

    0

natts =

    0
```

# netcdf.renameAtt

---

**Purpose** Change name of attribute

**Syntax** `netcdf.renameAtt(ncid,varid,oldName,newName)`

**Description** `netcdf.renameAtt(ncid,varid,oldName,newName)` changes the name of the attribute specified by the character string `oldName`.

`newName` is a character string that specifies the new name.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` identifies the variable to which the attribute is associated. To specify a global attribute, use `netcdf.getConstant('NC_GLOBAL')` for `varid`.

This function corresponds to the `nc_rename_att` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example modifies a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Get the ID of a variable the attribute is associated with.
varID = netcdf.inqVarID(ncid,'avagadros_number')

% Rename the attribute.
netcdf.renameAtt(ncid,varID,'description','Description');

% Verify that the name changed.
attname = netcdf.inqAttName(ncid,varID,0)

attname =

Description
```

**See Also**      `netcdf.inqAttName`

# netcdf.renameDim

---

**Purpose** Change name of netCDF dimension

**Syntax** `netcdf.renameDim(ncid,dimid,newName)`

**Description** `netcdf.renameDim(ncid,dimid,newName)` renames the dimension identified by the dimension identifier, `dimid`.

`newName` is a character string specifying the new name. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`

This function corresponds to the `nc_rename_dim` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This examples modifies a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Put file is define mode.
netcdf.reDef(ncid)

% Get the identifier of a dimension to rename.
dimid = netcdf.inqDimID(ncid,'x');

% Rename the dimension.
netcdf.renameDim(ncid,dimid,'Xdim')

% Verify that the name changed.
data = netcdf.inqDim(ncid,dimid)

data =

Xdim
```

**See Also** `netcdf.defDim`

**Purpose** Change name of netCDF variable

**Syntax** `netcdf.renameVar(ncid,varid,newName)`

**Description** `netcdf.renameVar(ncid,varid,newName)` renames the variable identified by `varid` in the netCDF file identified by `ncid`. `newName` is a character string specifying the new name.

This function corresponds to the `nc_rename_var` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example modifies a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Put file in define mode.
netcdf.redef(ncid)

% Get name of first variable
[varname, xtype, varDimIDs, varAtts] = netcdf.inqVar(ncid,0);

varname

varname =

avagadros_number

% Rename the variable, using a capital letter to start the name.
netcdf.renameVar(ncid,0,'Avagadros_number')

% Verify that the name of the variable changed.
[varname, xtype, varDimIDs, varAtts] = netcdf.inqVar(ncid,0);

varname
```

# netcdf.renameVar

---

varname =

Avagadros\_number

`netCDF.defVar` | `netCDF.inqVar` | `netCDF.putVar`

<b>Purpose</b>	Set default chunk cache settings for NetCDF library
<b>Syntax</b>	<code>netcdf.setChunkCache(csize, nelems, premp)</code>
<b>Description</b>	<p><code>netcdf.setChunkCache(csize, nelems, premp)</code> sets the default chunk cache settings used by the NetCDF library.</p> <p>Settings apply for subsequent file open or create operations, for the remainder of the MATLAB session or until you issue a <code>clear mex</code> call. This function does not change the chunk cache settings of files already open.</p>
<b>Input Arguments</b>	<p><b>csize</b></p> <p>Scalar double specifying the total size of the raw data chunk cache in bytes.</p> <p><b>nelems</b></p> <p>Scalar double specifying the number of chunk slots in the raw data chunk cache hash table.</p> <p><b>premp</b></p> <p>Scalar double, between 0 and 1, inclusive, that specifies how the library handles preempting fully read chunks in the chunk cache. A value of 0 means fully read chunks are treated no differently than other chunks, that is, preemption occurs solely based on the Least Recently Used (LRU) algorithm. A value of 1 means fully read chunks are always preempted before other chunks.</p>
<b>Examples</b>	<p>This example sets the cache chunk size used by the NetCDF library.</p> <pre>netcdf.setChunkCache(32000000, 2003, .75)</pre>
<b>References</b>	This function corresponds to the <code>nc_set_chunk_cache</code> function in the NetCDF library C API.

# netcdf.setChunkCache

---

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## **See Also**

`netcdf` | `netcdf.getChunkCache`

**Purpose** Change default netCDF file format

**Syntax** `oldFormat = netcdf.setDefaultFormat(newFormat)`

**Description** `oldFormat = netcdf.setDefaultFormat(newFormat)` changes the default format used by `netCDF.create` when creating new netCDF files, and returns the value of the old format. You can use this function to change the format used by a netCDF file without having to change the creation mode flag used in each call to `netCDF.create`.

`newFormat` can be either of the following values.

Value	Description
'NC_FORMAT_CLASSIC'	Original netCDF file format
'NC_FORMAT_64BIT'	64-bit offset format; relaxes limitations on creating very large files

You can also specify the numeric equivalent of these values, as retrieved by `netcdf.getConstant`.

This function corresponds to the `nc_set_default_format` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** `oldFormat = netcdf.setDefaultFormat('NC_FORMAT_64BIT');`

**See Also** `netcdf.create`

# netcdf.setFill

---

**Purpose** Set netCDF fill mode

**Syntax** `old_mode = netcdf.setFill(ncid,new_mode)`

**Description** `old_mode = netcdf.setFill(ncid,new_mode)` sets the fill mode for a netCDF file identified by `ncid`.

`new_mode` can be either 'FILL' or 'NOFILL' or their numeric equivalents, as retrieved by `netcdf.getConstant`. The default mode is 'FILL'. netCDF pre-fills data with fill values. Specifying 'NOFILL' can be used to enhance performance, because it avoids the duplicate writes that occur when the netCDF writes fill values that are later overwritten with data.

This function corresponds to the `nc_set_fill` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example creates a new file and specifies the fill mode used by netCDF with the file.

```
ncid = netcdf.open('foo.nc','NC_WRITE');  
  
% Set filling behavior  
old_mode = netcdf.setFill(ncid,'NC_NOFILL');
```

**See Also** `netcdf.getConstant`

**Purpose** Synchronize netCDF file to disk

**Syntax** `netcdf.sync(ncid)`

**Description** `netcdf.sync(ncid)` synchronizes the state of a netCDF file to disk. The netCDF library normally buffers accesses to the underlying netCDF file, unless you specify the `NC_SHARE` mode when you opened the file with `netcdf.open` or `netcdf.create`. To call `netcdf.sync`, the netCDF file must be in data mode.

This function corresponds to the `nc_sync` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example creates a new netCDF file for write access, performs an operation on the file, takes the file out of define mode, and then synchronizes the file to disk.

```
% Create a netCDF file.
ncid = netcdf.create('foo.nc','NC_WRITE');

% Perform an operation.
dimid = netcdf.defDim(ncid,'Xdim',50);

% Take file out of define mode.
netcdf.endDef(ncid);

% Synchronize the file to disk.
netcdf.sync(ncid)
```

**See Also** `netcdf.close` | `netcdf.create` | `netcdf.open` | `netcdf.endDef`

# newplot

---

**Purpose** Determine where to draw graphics objects

**Syntax**

```
newplot  
h = newplot  
h = newplot(hsave)
```

**Description** `newplot` prepares a figure and axes for subsequent graphics commands.

`h = newplot` prepares a figure and axes for subsequent graphics commands and returns a handle to the current axes.

`h = newplot(hsave)` prepares and returns an axes, but does not delete any objects whose handles you have assigned to the `hsave` argument, which can be a vector of handles. If `hsave` is not empty, the figure and axes containing `hsave` are prepared for plotting instead of the current axes of the current figure. If `hsave` is empty, `newplot` behaves as if it were called without any inputs.

**Tips** Use `newplot` at the beginning of high-level graphics code to determine which figure and axes to target for graphics output. Calling `newplot` can change the current figure and current axes. Basically, there are three options when you are drawing graphics in existing figures and axes:

- Add the new graphics without changing any properties or deleting any objects.
- Delete all existing objects whose handles are not hidden before drawing the new objects.
- Delete all existing objects regardless of whether or not their handles are hidden, and reset most properties to their defaults before drawing the new objects (refer to the following table for specific information).

The figure and axes `NextPlot` properties determine how `newplot` behaves. The following two tables describe this behavior with various property values.

First, `newplot` reads the current figure's `NextPlot` property and acts accordingly.

<b>NextPlot</b>	<b>What Happens</b>
new	Create a new figure and use it as the current figure.
add	Draw to the current figure without clearing any graphics objects already present.
replacechildren	Remove all child objects whose <code>HandleVisibility</code> property is set to <code>on</code> and reset figure <code>NextPlot</code> property to <code>add</code> .  This clears the current figure and is equivalent to issuing the <code>clf</code> command.
replace	Remove all child objects (regardless of the setting of the <code>HandleVisibility</code> property) and reset figure properties to their defaults, except <code>NextPlot</code> is reset to <code>add</code> regardless of user-defined defaults.  <ul style="list-style-type: none"> <li>• <code>Position</code>, <code>Units</code>, <code>PaperPosition</code>, and <code>PaperUnits</code> are not reset.</li> </ul> This clears and resets the current figure and is equivalent to issuing the <code>clf reset</code> command.

After `newplot` establishes which figure to draw in, it reads the current axes' `NextPlot` property and acts accordingly.

<b>NextPlot</b>	<b>Description</b>
<code>add</code>	Draw into the current axes, retaining all graphics objects already present.
<code>replacechildren</code>	Remove all child objects whose <code>HandleVisibility</code> property is set to <code>on</code> , but do not reset axes properties. This clears the current axes like the <code>cla</code> command.
<code>replace</code>	Remove all child objects (regardless of the setting of the <code>HandleVisibility</code> property) and reset axes properties to their defaults, except <code>Position</code> and <code>Units</code> .  This clears and resets the current axes like the <code>cla reset</code> command.

## How To

- Controlling Graphics Output

<b>Purpose</b>	Make next IFD current IFD
<b>Syntax</b>	<code>tiffobj.nextDirectory()</code>
<b>Description</b>	<code>tiffobj.nextDirectory()</code> makes the next image file directory (IFD) in the file the current IFD. <code>Tiff</code> object methods operate on the current IFD. Use this method to navigate among IFDs in a TIFF file containing multiple images.
<b>Examples</b>	<p>Open a <code>Tiff</code> object and change the current IFD to the next IFD in the file. Replace <code>myfile.tif</code> with the name of a TIFF file on your MATLAB path. The TIFF file should contain multiple images.</p> <pre>t = Tiff('myfile.tif', 'r'); t.nextDirectory();</pre>
<b>References</b>	This method corresponds to the <code>TIFFReadDirectory</code> function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at <a href="#">LibTIFF - TIFF Library and Utilities</a> .
<b>See Also</b>	<code>Tiff.setDirectory</code>
<b>Tutorials</b>	<ul style="list-style-type: none"><li>• “Exporting Image Data and Metadata to TIFF Files”</li><li>• “Reading Image Data and Metadata from TIFF Files”</li></ul>

# nextpow2

---

**Purpose** Next higher power of 2

**Syntax** `p = nextpow2(A)`

**Description** `p = nextpow2(A)` returns the smallest power of two that is greater than or equal to the absolute value of A. (That is, p that satisfies  $2^p \geq \text{abs}(A)$ ).

This function is useful for optimizing FFT operations, which are most efficient when sequence length is an exact power of two.

**Examples** For any integer n in the range from 513 to 1024, `nextpow2(n)` is 10.

For vector input, `nextpow2(n)` returns an element-by-element result:

```
A = [1 2 3 4 5 9 519]
nextpow2(A)
ans =
```

```
0    1    2    2    3    4   10
```

**See Also** `fft` | `log2` | `pow2`

---

<b>Purpose</b>	Number of nonzero matrix elements
<b>Syntax</b>	<code>n = nnz(X)</code>
<b>Description</b>	<code>n = nnz(X)</code> returns the number of nonzero elements in matrix <code>X</code> . The density of a sparse matrix is <code>nnz(X)/prod(size(X))</code> .
<b>Examples</b>	The matrix  <code>w = sparse(wilkinson(21));</code>  is a tridiagonal matrix with 20 nonzeros on each of three diagonals, so <code>nnz(w) = 60</code> .
<b>See Also</b>	<code>find</code>   <code>isa</code>   <code>nonzeros</code>   <code>nzmax</code>   <code>size</code>   <code>whos</code>

# noanimate

---

**Purpose** Change EraseMode of all objects to normal

---

**Note** noanimate will be removed in a future release.

---

**Syntax** noanimate(state, fig\_handle)  
noanimate(state)

**Description** noanimate(state, fig\_handle) sets the EraseMode of all image, line, patch, surface, and text graphics objects in the specified figure to normal. state can be the following strings:

- 'save' — Set the values of the EraseMode properties to normal for all the appropriate objects in the designated figure.
- 'restore' — Restore the EraseMode properties to the previous values (i.e., the values before calling noanimate with the 'save' argument).

noanimate(state) operates on the current figure.

noanimate is useful if you want to print the figure to a TIFF or JPEG format.

**See Also** print

**Purpose** Nonzero matrix elements

**Syntax** `s = nonzeros(A)`

**Description** `s = nonzeros(A)` returns a full column vector of the nonzero elements in A, ordered by columns.

This gives the s, but not the i and j, from `[i,j,s] = find(A)`.  
Generally,

`length(s) = nnz(A) <= nzmax(A) <= prod(size(A))`

**See Also** `find` | `isa` | `nnz` | `nzmax` | `size` | `whos`

# norm

---

## Purpose

Vector and matrix norms

## Syntax

```
n = norm(X,2)
n = norm(X)
n = norm(X,1)
n = norm(X,Inf)
n = norm(X,'fro')
n = norm(v,p)
n = norm(v,Inf)
n = norm(v,-Inf)
```

## Description

The `norm` function calculates several different types of matrix and vector norms. If the input is a vector or a matrix:

`n = norm(X,2)` returns the 2-norm of  $X$ .

`n = norm(X)` is the same as `n = norm(X,2)`.

`n = norm(X,1)` returns the 1-norm of  $X$ .

`n = norm(X,Inf)` returns the infinity norm of  $X$ .

`n = norm(X,'fro')` returns the Frobenius norm of  $X$ .

In addition, when the input is a vector  $v$ :

`n = norm(v,p)` returns the  $p$ -norm of  $v$ . The  $p$ -norm is  $\text{sum}(\text{abs}(v).^p)^{1/p}$ .

`n = norm(v,Inf)` returns the largest element of  $\text{abs}(v)$ .

`n = norm(v,-Inf)` returns the smallest element of  $\text{abs}(v)$ .

## Tips

By convention, `norm` returns NaN if the input matrix  $X$  or input vector  $v$  contains NaN values.

## See Also

`cond` | `condest` | `hypot` | `normest` | `rcond`

---

<b>Purpose</b>	2-norm estimate
<b>Syntax</b>	<pre>nrm = normest(S) nrm = normest(S,tol) [nrm,count] = normest(...)</pre>
<b>Description</b>	<p>This function is intended primarily for sparse matrices, although it works correctly and may be useful for large, full matrices as well.</p> <p><code>nrm = normest(S)</code> returns an estimate of the 2-norm of the matrix <code>S</code>.</p> <p><code>nrm = normest(S,tol)</code> uses relative error <code>tol</code> instead of the default tolerance <code>1.e-6</code>. The value of <code>tol</code> determines when the estimate is considered acceptable.</p> <p><code>[nrm,count] = normest(...)</code> returns an estimate of the 2-norm and also gives the number of power iterations used.</p>
<b>Algorithms</b>	<p>The power iteration involves repeated multiplication by the matrix <code>S</code> and its transpose, <code>S'</code>. The iteration is carried out until two successive estimates agree to within the specified relative tolerance.</p>
<b>See Also</b>	<code>cond</code>   <code>condest</code>   <code>norm</code>   <code>rcond</code>   <code>svd</code>

# not

---

**Purpose** Find logical NOT of array or scalar input

**Syntax** `~A`  
`not(A)`

**Description** `~A` performs a logical NOT of input array `A`, and returns an array containing elements set to either logical 1 (`true`) or logical 0 (`false`). An element of the output array is set to 1 if the input array contains a zero value element at that same array location. Otherwise, that element is set to 0.

The input of the expression can be an array or can be a scalar value. If the input is an array, then the output is an array of the same dimensions. If the input is scalar, then the output is scalar.

`not(A)` is called for the syntax `~A` when `A` is an object.

**Examples** If matrix `A` is

0	29	0	36	0
23	34	35	0	39
0	24	31	27	0
0	29	0	0	34

then

`~A`  
ans =

1	0	1	0	1
0	0	0	1	0
1	0	0	0	1
1	0	1	1	0

**How To**

- “Logical Operators”
- “Bit-Wise Functions”

- Purpose** Open MATLAB Notebook in Microsoft Word software (on Microsoft Windows platforms)
- Syntax**
- ```
notebook
notebook('filename')
notebook('-setup')
```
- Description**
- notebook starts Microsoft Word software and creates a new MATLAB Notebook titled Document 1.
- notebook('filename') starts Microsoft Word and opens the notebook filename, where filename is either in the MATLAB current folder or is a full path. If filename does not exist, MATLAB creates a new notebook titled filename. If the file name extension is not specified, MATLAB assumes .doc.
- notebook('-setup') runs an interactive setup function for MATLAB Notebook. It copies the notebook template, m-book.dot, to the Microsoft Word template folder, whose location MATLAB automatically determines from the Windows system registry. Upon completion, MATLAB displays a message indicating whether or not the setup was successful.
- How To**
- “Create a MATLAB Notebook with Microsoft Word”
  - “Publish MATLAB Code”

# notify (handle)

---

**Purpose** Notify listeners that event is occurring

**Syntax** `notify(Hobj, 'EventName')`  
`notify(Hobj, 'EventName', data)`

**Description** `notify(Hobj, 'EventName')` notifies listeners that the specified event is taking place on the specified handle objects.

`notify(Hobj, 'EventName', data)` includes user-defined event data.

## Input Arguments

**Hobj**  
Array of handle objects triggering the specified event.

**EventName**  
Name of the event.

**data**  
An `event.EventData` object encapsulating information about the event. You can define custom event data by subclassing `event.EventData` and passing an instance of your subclass as the data argument. See “Defining Event-Specific Data” for information on defining event data.

## See Also

See “Events and Listeners — Syntax and Techniques”

`handle`, `addlistener`

**Purpose** Current date and time

**Syntax** `t = now`

**Description** `t = now` returns the current date and time as a serial date number. To return the time only, use `rem(now, 1)`. To return the date only, use `floor(now)`.

**Examples** `t1 = now, t2 = rem(now, 1)`

`t1 =`

`7.2908e+05`

`t2 =`

`0.4013`

**See Also** `clock` | `date` | `datenum`

# nthroot

---

**Purpose** Real nth root of real numbers

**Syntax** `y = nthroot(X, n)`

**Description** `y = nthroot(X, n)` returns the real nth root of the elements of X. Both X and n must be real and n must be a scalar. If X has negative entries, n must be an odd integer.

**Examples** `nthroot(-2, 3)`

returns the real cube root of -2.

`ans =`

`-1.2599`

By comparison,

`(-2)^(1/3)`

returns a complex cube root of -2.

`ans =`

`0.6300 + 1.0911i`

**See Also** `power` | `sqrt`

**Purpose**

Null space

**Syntax**

```
Z = null(A)
Z = null(A, 'r')
```

**Description**

$Z = \text{null}(A)$  is an orthonormal basis for the null space of  $A$  obtained from the singular value decomposition. That is,  $A*Z$  has negligible elements, `size(Z,2)` is the nullity of  $A$ , and  $Z' * Z = I$ .

$Z = \text{null}(A, 'r')$  is a “rational” basis for the null space obtained from the reduced row echelon form.  $A*Z$  is zero, `size(Z,2)` is an estimate for the nullity of  $A$ , and, if  $A$  is a small matrix with integer elements, the elements of the reduced row echelon form (as computed using `rref`) are ratios of small integers.

The orthonormal basis is preferable numerically, while the rational basis may be preferable pedagogically.

**Examples****Example 1**

Compute the orthonormal basis for the null space of a matrix  $A$ .

```
A = [1    2    3
      1    2    3
      1    2    3];
```

```
Z = null(A);
A*Z
```

```
ans =
  1.0e-015 *
    0.2220    0.2220
    0.2220    0.2220
    0.2220    0.2220
```

```
Z' * Z
```

```
ans =
```

# null

---

```
1.0000 -0.0000
-0.0000 1.0000
```

## Example 2

Compute the 1-norm of the matrix  $A*Z$  and determine that it is within a small tolerance.

```
norm(A*Z,1) < 1e-12
ans =
     1
```

## Example 3

Compute the rational basis for the null space of the same matrix A.

```
ZR = null(A, 'r')
```

```
ZR =
    -2    -3
     1     0
     0     1
```

```
A*ZR
```

```
ans =
     0     0
     0     0
     0     0
```

**Purpose** Convert array to cell array with consistently sized cells

**Syntax**  
`C = num2cell(A)`  
`C = num2cell(A,dim)`

**Description** `C = num2cell(A)` converts array `A` into cell array `C` by placing each element of `A` into a separate cell in `C`. Array `A` need not be numeric.

`C = num2cell(A,dim)` splits the contents of `A` into separate cells of `C`, where `dim` specifies which dimensions of `A` to include in each cell. `dim` can be a scalar or a vector of dimensions. For example, if `A` has 2 rows and 3 columns, then:

- `num2cell(A,1)` creates a 1-by-3 cell array `C`, where each cell contains a 2-by-1 column of `A`.
- `num2cell(A,2)` creates a 2-by-1 cell array `C`, where each cell contains a 1-by-3 row of `A`.
- `num2cell(A,[1 2])` creates a 1-by-1 cell array `C`, where the cell contains the entire array `A`.

## Input Arguments

**A - Input**  
any type of multidimensional array

Input, specified as any type of multidimensional array.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | cell | function\_handle

### dim - Dimension of A

positive integer | positive vector of integers

Dimension of `A`, specified as a positive integer or a vector of positive integers. `dim` must be between 1 and `ndims(A)`.

# num2cell

Elements need not be in numeric order. However, `num2cell` permutes the dimensions of the arrays in each cell of `C` to match the order of the specified dimensions.

## Data Types

double

## Output Arguments

### C - Resulting array

cell array

Resulting array, returned as a cell array. The size of `C` depends on the size of `A` and the values of `dim`.

- If `dim` is not specified, then `C` is the same size as `A`.
- If `dim` is a scalar, then `C` contains `numel(A)/size(A,dim)` cells. If `dim` is 1 or 2, then each cell contains a column or row vector, respectively. If `dim > 2`, then each cell contains an array whose `dim`th dimensional length is `size(A,dim)`, and whose other dimensions are all singletons.

For example, given a 4-by-7-by-3 array, `A`, this figure shows how `num2cell` creates cells corresponding to `dim` values of 1, 2, and 3.

- If `dim` is a vector containing `N` values, then `C` has `numel(A)/prod([size(A,dim(1)), ..., size(A, dim(N))])` cells. Each cell contains an array whose `dim(i)`th dimension has a length of `size(A, dim(i))` and whose other dimensions are singletons.

For example, given a 4-by-7-by-3 array, you can specify `dim` as a positive integer vector to create cell arrays of different dimensions.

## Examples

### Convert Arrays to Cell Array

Place all elements of a numeric array into separate cells.

```
a = magic(3)
c = num2cell(a)
```

a =

```
8     1     6
3     5     7
4     9     2
```

c =

```
[8]    [1]    [6]
[3]    [5]    [7]
[4]    [9]    [2]
```

Place individual letters of a word into separate cells of an array.

```
a = ['four';'five';'nine']
c = num2cell(a)
```

a =

```
four
```

# num2cell

---

```
five  
nine
```

```
c =
```

```
    'f'    'o'    'u'    'r'  
    'f'    'i'    'v'    'e'  
    'n'    'i'    'n'    'e'
```

## Create Cell Array of Numeric Arrays

Generate a 4-by-3-by-2 numeric array, and then create a 1-by-3-by-2 cell array of 4-by-1 column vectors.

```
A = reshape(1:12,4,3);  
A(:,:,2) = A*10  
C = num2cell(A,1)
```

```
A(:,:,1) =
```

```
    1     5     9  
    2     6    10  
    3     7    11  
    4     8    12
```

```
A(:,:,2) =
```

```
   10   50   90  
   20   60  100  
   30   70  110  
   40   80  120
```

```
C(:,:,1) =
```

```
 [4x1 double]    [4x1 double]    [4x1 double]
```

```
C(:,:,2) =
    [4x1 double]    [4x1 double]    [4x1 double]
```

Each 4-by-1 vector contains elements from along the *first* dimension of A:

```
C{1}
```

```
ans =
```

```
    1
    2
    3
    4
```

Create a 4-by-1-by-2 cell array of 1-by-3 numeric arrays.

```
C = num2cell(A,2)
```

```
C(:,:,1) =
    [1x3 double]
    [1x3 double]
    [1x3 double]
    [1x3 double]
```

```
C(:,:,2) =
    [1x3 double]
    [1x3 double]
    [1x3 double]
    [1x3 double]
```

Each 1-by-3 row vector contains elements from along the *second* dimension of A:

## num2cell

---

```
C{1}
```

```
ans =
```

```
1 5 9
```

Finally, create a 4-by-3 cell array of 1-by-1-by-2 numeric arrays.

```
C = num2cell(A,3)
```

```
C =
```

```
 [1x1x2 double] [1x1x2 double] [1x1x2 double]
 [1x1x2 double] [1x1x2 double] [1x1x2 double]
 [1x1x2 double] [1x1x2 double] [1x1x2 double]
 [1x1x2 double] [1x1x2 double] [1x1x2 double]
```

Each 1-by-1-by-2 vector contains elements from along the *third* dimension of A:

```
C{1}
```

```
ans(:,:,1) =
```

```
1
```

```
ans(:,:,2) =
```

```
10
```

### Combine Across Multiple Dimensions

Create a cell array by combining elements into numeric arrays along several dimensions.

```
a = reshape(1:12,4,3);
```

```
a(:,:,2) = a*10
```

```
c = num2cell(A,[1 3])
```

```
a(:,:,1) =
```

```
    1    5    9
    2    6   10
    3    7   11
    4    8   12
```

```
a(:,:,2) =
```

```
   10   50   90
   20   60  100
   30   70  110
   40   80  120
```

```
c =
```

```
 [4x1x2 double] [4x1x2 double] [4x1x2 double]
```

Each 4-by-1-by-2 array contains elements from along the first and third dimension of A:

```
c{1}
```

```
ans(:,:,1) =
```

```
    1
    2
    3
    4
```

```
ans(:,:,2) =
```

```
   10
   20
```

# num2cell

---

```
30  
40
```

```
c = num2cell(A,[2 3])
```

```
c =
```

```
[1x3x2 double]  
[1x3x2 double]  
[1x3x2 double]  
[1x3x2 double]
```

## See Also

**Purpose** Convert singles and doubles to IEEE hexadecimal strings

**Syntax** num2hex(X)

**Description** If X is a single or double precision array with n elements, num2hex(X) is an n-by-8 or n-by-16 char array of the hexadecimal floating-point representation. The same representation is printed with format hex.

**Examples**

```
num2hex([1 0 0.1 -pi Inf NaN])

returns

ans =

3ff0000000000000
0000000000000000
3fb9999999999999a
c00921fb54442d18
7ff0000000000000
fff8000000000000
num2hex(single([1 0 0.1 -pi Inf NaN]))
```

returns

ans =

```
3f800000
00000000
3dcccccd
c0490fdb
7f800000
ffc00000
```

**See Also** hex2num | dec2hex | format

# num2str

---

**Purpose** Convert number to string

**Syntax**  
`str = num2str(A)`  
`str = num2str(A,precision)`  
`str = num2str(A,formatSpec)`

**Description** `str = num2str(A)` converts array `A` into a string representation `str`. When `A` contains floating-point numbers, the output format depends upon the magnitude of the original values and sometimes includes exponents.

`str = num2str(A,precision)` returns a string representation with the maximum number of digits specified by `precision`.

`str = num2str(A,formatSpec)` applies a format specified by `formatSpec` to all elements of `A`.

## Input Arguments

### **A - Input array**

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array of real or complex numbers.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**Complex Number Support:** Yes

### **precision - Numeric precision**

positive integer

Numeric precision of the output string, specified as a positive integer. This is the maximum number of digits in the output string.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**formatSpec - Format of the output fields**

string

Format of the output fields, specified as a string.

The string can include a percent sign followed by a conversion character. The following table lists the available conversion characters and subtypes.

| Value Type            | Conversion               | Details                                                                                             |
|-----------------------|--------------------------|-----------------------------------------------------------------------------------------------------|
| Integer, signed       | %d or %i                 | Base 10                                                                                             |
| Integer, unsigned     | %u                       | Base 10                                                                                             |
|                       | %o                       | Base 8 (octal)                                                                                      |
|                       | %x                       | Base 16 (hexadecimal), lowercase letters a–f                                                        |
|                       | %X                       | Same as %x, uppercase letters A–F                                                                   |
| Floating-point number | %f                       | Fixed-point notation                                                                                |
|                       | %e                       | Exponential notation, such as 3.141593e+00                                                          |
|                       | %E                       | Same as %e, but uppercase, such as 3.141593E+00                                                     |
|                       | %g                       | The more compact of %e or %f, with no trailing zeros                                                |
|                       | %G                       | The more compact of %E or %f, with no trailing zeros                                                |
|                       | %bx or %bX<br>%bo<br>%bu | Double-precision hexadecimal, octal, or decimal value<br>Example: %bx prints pi as 400921fb54442d18 |

| Value Type | Conversion               | Details                                                                                     |
|------------|--------------------------|---------------------------------------------------------------------------------------------|
|            | %tx or %tX<br>%to<br>%tu | Single-precision hexadecimal, octal, or decimal value<br>Example: %tx prints pi as 40490fdb |
| Characters | %c                       | Single character                                                                            |
|            | %s                       | String of characters                                                                        |

The string can include optional operators, which appear in the following order (includes spaces for clarity):

Optional operators include:

- Identifier

Order for processing inputs. Use the syntax `n$`, where `n` represents the position of the value in the input list.

For example, `'%3$s %2$s %1$s %2$s'` prints inputs 'A', 'B', 'C' as follows: C B A B.

- Flags

- ' ' Left-justify. Example: `%-5.2f`
- '+' Print sign character (+) for positive values. Example:  `%+5.2f`
- ' ' Pad to field width with spaces before the value. Example:  `% 5.2f`

'0' Pad to field width with zeros. Example: %05.2f

'#' Modify selected numeric conversions:

- For %o, %x, or %X, print 0, 0x, or 0X prefix.
- For %f, %e, or %E, print decimal point even when precision is 0.
- For %g or %G, do not remove trailing zeros or decimal point.

Example: %#5.0f

- Field width

Minimum number of characters to print. Can be a number, or an asterisk (\*) to refer to an argument in the input list. For example, the input list ('%12d', intmax) is equivalent to ('%\*d', 12, intmax).

- Precision

For %f, %e, or %E: Number of digits to the right of the decimal point.

Example: '%6.4f' prints pi as '3.1416'

For %g or %G: Number of significant digits.

Example: '%6.4g' prints pi as ' 3.142'

Can be a number, or an asterisk (\*) to refer to an argument in the input list. For example, the input list ('%6.4f', pi) is equivalent to ('%\*.\*f', 6, 4, pi).

The string can also include combinations of the following:

- Literal text to print.
- Escape characters, including:

' ' Single quotation mark

%% Percent character

|                  |                              |
|------------------|------------------------------|
| <code>\\</code>  | Backslash                    |
| <code>\a</code>  | Alarm                        |
| <code>\b</code>  | Backspace                    |
| <code>\f</code>  | Form feed                    |
| <code>\n</code>  | New line                     |
| <code>\r</code>  | Carriage return              |
| <code>\t</code>  | Horizontal tab               |
| <code>\v</code>  | Vertical tab                 |
| <code>\xN</code> | Hexadecimal number, <i>N</i> |
| <code>\N</code>  | Octal number, <i>N</i>       |

The following limitations apply to conversions:

- Numeric conversions print only the real component of complex numbers.
- If you specify a conversion that does not fit the data, such as a string conversion for a numeric value, MATLAB overrides the specified conversion, and uses %e.
- If you apply a string conversion (%s) to integer values, MATLAB converts values that correspond to valid character codes to characters. For example, '%s' converts [65 66 67] to ABC.

## Algorithms

num2str trims any leading spaces from a string, even when formatSpec includes a space character flag. For example, num2str(42.67, '%10.2f') returns a 1-by-5 character array '42.67'.

## Tips

- num2str is useful for labeling and titling plots with numeric values.

## Examples

### Default Conversions of Floating-Point Values

Convert pi and eps to text strings.

```
str = num2str(pi)
```

```
str =  
3.1416
```

```
str = num2str(eps)
```

```
str =  
2.2204e-16
```

### Specifying Precision

Specify the number of significant digits for floating-point values.

```
A = gallery('normaldata',[2,2],0);  
precision = 3;  
str = num2str(A,precision)
```

```
str =  
-0.433      0.125  
-1.67      0.288
```

### Specifying Formatting

Specify the width, precision, and other formatting for an array of floating-point values.

```
A = gallery('uniformdata',[2,3],0) * 9999;  
formatSpec = '%10.5e\n';  
str = num2str(A,formatSpec)
```

```
str =  
9.50034e+03  
6.06782e+03  
8.91210e+03  
2.31115e+03  
4.85934e+03  
7.62021e+03
```

## num2str

---

The format `'%10.5e'` prints each value in exponential format with five decimal places, and `'\n'` prints a new line character.

# Tiff.numberOfTiles

---

**Purpose** Total number of tiles in image

**Syntax** numTiles = tiffobj.numberOfTiles()

**Description** numTiles = tiffobj.numberOfTiles() returns the total number of tiles in the image.

**Examples** Open a Tiff object and determine the number of tiles in the image. Replace myfile.tif with the name of a TIFF file on your MATLAB path:

```
t = Tiff('myfile.tif', 'r');
%
% Check if image has a tiled organization
if t.isTiled()
    nTiles = t.numberOfTiles();
end
```

**References** This method corresponds to the TIFFNumberOfTiles function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**See Also** Tiff.numberOfStrips | Tiff.isTiled

**Tutorials**

- “Reading Image Data and Metadata from TIFF Files”

**Purpose** Number of elements in array or subscripted array expression

**Syntax**  
`n = numel(A)`  
`n = numel(A, index1, index2, ... indexn)`

**Description** `n = numel(A)` returns the number of elements, `n`, in array `A`.  
`n = numel(A, index1, index2, ... indexn)` returns the number of subscripted elements, `n`, in `A(index1, index2, ..., indexn)`. To handle the variable number of arguments, `numel` is typically written with the header function `n = numel(A, varargin)`, where `varargin` is a cell array with elements `index1, index2, ... indexn`.

The MATLAB software implicitly calls the `numel` built-in function whenever an expression generates a comma-separated list. This includes brace indexing (i.e., `A{index1, index2, ..., indexN}`), and dot indexing (i.e., `A.fieldname`).

**Tips** It is important to note the significance of `numel` with regards to the overloaded `subsref` and `subsasgn` functions. In the case of the overloaded `subsref` function for brace and dot indexing (as described in the last paragraph), `numel` is used to compute the number of expected outputs (`nargout`) returned from `subsref`. For the overloaded `subsasgn` function, `numel` is used to compute the number of expected inputs (`nargin`) to be assigned using `subsasgn`. The `nargin` value for the overloaded `subsasgn` function is the value returned by `numel` plus 2 (one for the variable being assigned to, and one for the structure array of subscripts).

As a class designer, you must ensure that the value of `n` returned by the built-in `numel` function is consistent with the class design for that object. If `n` is different from either the `nargout` for the overloaded `subsref` function or the `nargin` for the overloaded `subsasgn` function, then you need to overload `numel` to return a value of `n` that is consistent with the class' `subsref` and `subsasgn` functions. Otherwise, MATLAB produces errors when calling these functions.

# numel

---

## Examples

Create a 4-by-4-by-2 matrix. `numel` counts 32 elements in the matrix.

```
a = magic(4);
a(:,:,2) = a'

a(:,:,1) =
    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1

a(:,:,2) =
    16     5     9     4
     2    11     7    14
     3    10     6    15
    13     8    12     1

numel(a)
ans =
    32
```

[margin](#) | [nargout](#) | [prod](#) | [size](#) | [subsasgn](#) | [subsref](#)

**Purpose**

Amount of storage allocated for nonzero matrix elements

**Syntax**

`n = nzmax(S)`

**Description**

`n = nzmax(S)` returns the amount of storage allocated for nonzero elements.

If `S` is a sparse matrix...      `nzmax(S)` is the number of storage locations allocated for the nonzero elements in `S`.

If `S` is a full matrix...      `nzmax(S) = prod(size(S))`.

Often, `nnz(S)` and `nzmax(S)` are the same. But if `S` is created by an operation which produces fill-in matrix elements, such as sparse matrix multiplication or sparse LU factorization, more storage may be allocated than is actually required, and `nzmax(S)` reflects this. Alternatively, `sparse(i,j,s,m,n,nzmax)` or its simpler form, `spalloc(m,n,nzmax)`, can set `nzmax` in anticipation of later fill-in.

# ode15i

---

**Purpose** Solve fully implicit differential equations, variable order method

**Syntax**

```
[T,Y] = ode15i(odefun,tspan,y0,yp0)
[T,Y] = ode15i(odefun,tspan,y0,yp0,options)
[T,Y,TE,YE,IE] = ode15i(odefun,tspan,y0,yp0,options...)
sol = ode15i(odefun,[t0 tfinal],y0,yp0,...)
```

**Arguments** The following table lists the input arguments for `ode15i`.

|                      |                                                                                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>odefun</code>  | A function handle that evaluates the left side of the differential equations, which are of the form $f(t,y,y') = 0$ .                                                               |
| <code>tspan</code>   | A vector specifying the interval of integration, $[t_0, t_f]$ . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> . |
| <code>y0, yp0</code> | Vectors of initial conditions for $y$ and $y'$ respectively.                                                                                                                        |
| <code>options</code> | Optional integration argument created using the <code>odeset</code> function. See <code>odeset</code> for details.                                                                  |

The following table lists the output arguments for `ode15i`.

|                |                                                                                                                  |
|----------------|------------------------------------------------------------------------------------------------------------------|
| <code>T</code> | Column vector of time points                                                                                     |
| <code>Y</code> | Solution array. Each row in $y$ corresponds to the solution at a time returned in the corresponding row of $t$ . |

**Description** `[T,Y] = ode15i(odefun,tspan,y0,yp0)` with `tspan = [t0 tf]` integrates the system of differential equations  $f(t,y,y') = 0$  from time  $t_0$  to  $t_f$  with initial conditions  $y_0$  and  $yp_0$ . `odefun` is a function handle. Function `ode15i` solves ODEs and DAEs of index 1. The initial conditions must be consistent, meaning that  $f(t_0,y_0,yp_0) = 0$ . You can use the function `decic` to compute consistent initial conditions close to guessed values. Function `odefun(t,y,yp)`, for a scalar  $t$  and column vectors  $y$  and  $yp$ , must return a column vector corresponding to  $f(t,y,y')$ . Each row in the solution array  $Y$  corresponds to a time returned in the

column vector  $T$ . To obtain solutions at specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use  $tspan = [t_0, t_1, \dots, t_f]$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, if necessary.

`[T,Y] = ode15i(odefun,tspan,y0,yp0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used options include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components  $1e-6$  by default). See `odeset` for details.

`[T,Y,TE,YE,IE] = ode15i(odefun,tspan,y0,yp0,options...)` with the 'Events' property in `options` set to a function `events`, solves as above while also finding where functions of  $(t,y,y')$ , called event functions, are zero. The function `events` is of the form `[value,isterminal,direction] = events(t,y,yp)` and includes the necessary event functions. Code the function `events` so that the  $i$ th element of each output vector corresponds to the  $i$ th event. For the  $i$ th event function in `events`:

- `value(i)` is the value of the function.
- `isterminal(i) = 1` if the integration is to terminate at a zero of this event function and 0 otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Output `TE` is a column vector of times at which events occur. Rows of `YE` are the corresponding solutions, and indices in vector `IE` specify which event occurred. See “Integrator Options” in the MATLAB Mathematics documentation for more information.

`sol = ode15i(odefun,[t0 tfinal],y0,yp0,...)` returns a structure that can be used with `deval` to evaluate the solution at any point between `t0` and `tfinal`. The structure `sol` always includes these fields:

|                    |                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sol.x</code> | Steps chosen by the solver. If you specify the <code>Events</code> option and a terminal event is detected, <code>sol.x(end)</code> contains the end of the step at which the event occurred. |
| <code>sol.y</code> | Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .                                                                                                          |

If you specify the `Events` option and events are detected, `sol` also includes these fields:

|                     |                                                                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sol.xe</code> | Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.                           |
| <code>sol.ye</code> | Solutions that correspond to events in <code>sol.xe</code> .                                                                                       |
| <code>sol.ie</code> | Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected. |

## Options

`ode15i` accepts the following parameters in `options`. For more information, see `odeset` and [Changing ODE Integration Properties](#) in the MATLAB Mathematics documentation.

|                 |                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------|
| Error control   | <code>RelTol</code> , <code>AbsTol</code> , <code>NormControl</code>                       |
| Solver output   | <code>OutputFcn</code> , <code>OutputSel</code> , <code>Refine</code> , <code>Stats</code> |
| Event location  | <code>Events</code>                                                                        |
| Step size       | <code>MaxStep</code> , <code>InitialStep</code>                                            |
| Jacobian matrix | <code>Jacobian</code> , <code>JPattern</code> , <code>Vectorized</code>                    |

## Solver Output

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, and `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

## Jacobian Matrices

The Jacobian matrices  $\partial f/\partial y$  and  $\partial f/\partial y'$  are critical to reliability and efficiency. You can provide these matrices as one of the following:

- Function of the form `[dfdy,dfdyp] = FJAC(t,y,yp)` that computes the Jacobian matrices. If `FJAC` returns an empty matrix `[]` for either `dfdy` or `dfdyp`, then `ode15i` approximates that matrix by finite differences.
- Cell array of two constant matrices `{dfdy,dfdyp}`, either of which could be empty.

Use `odeset` to set the `Jacobian` option to the function or cell array. If you do not set the `Jacobian` option, `ode15i` approximates both Jacobian matrices by finite differences.

For `ode15i`, `Vectorized` is a two-element cell array. Set the first element to `'on'` if `odefun(t,[y1,y2,...],yp)` returns `[odefun(t,y1,yp),odefun(t,y2,yp),...]`. Set the second element to `'on'` if `odefun(t,y,[yp1,yp2,...])` returns `[odefun(t,y,yp1),odefun(t,y,yp2),...]`. The default value of `Vectorized` is `{'off','off'}`.

For `ode15i`, `JPattern` is also a two-element sparse matrix cell array. If  $\partial f/\partial y$  or  $\partial f/\partial y'$  is a sparse matrix, set `JPattern` to the sparsity patterns, `{SPDY, SPDYP}`. A sparsity pattern of  $\partial f/\partial y$  is a sparse matrix `SPDY` with `SPDY(i, j) = 1` if component `i` of `f(t, y, yp)` depends on component `j` of `y`, and 0 otherwise. Use `SPDY = []` to indicate that  $\partial f/\partial y$  is a full matrix. Similarly for  $\partial f/\partial y'$  and `SPDYP`. The default value of `JPattern` is `{[], []}`.

## Examples

### Example 1

This example uses a helper function `decic` to hold fixed the initial value for  $y(t_0)$  and compute a consistent initial value for  $y'(t_0)$  for the Weissinger implicit ODE. The Weissinger function evaluates the residual of the implicit ODE.

```
t0 = 1;  
y0 = sqrt(3/2);  
yp0 = 0;  
[y0, yp0] = decic(@weissinger, t0, y0, 1, yp0, 0);
```

The example uses `ode15i` to solve the ODE, and then plots the numerical solution against the analytical solution.

```
[t, y] = ode15i(@weissinger, [1 10], y0, yp0);  
ytrue = sqrt(t.^2 + 0.5);  
plot(t, y, t, ytrue, 'o');
```

### Other Examples

The files, `ihb1dae.m` and `iburgersode.m`, are examples of implicit ODEs.

**Purpose** Solve stiff differential equations and DAEs; variable order method

**Syntax**

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments** The following table describes the input arguments to the solvers.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>odefun</code> | A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).                                                                                                                                                                                                                                       |
| <code>tspan</code>  | A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .<br><br>For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing. |

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

|                 |                                                                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>T</code>  | Column vector of time points.                                                                                                          |
| <code>Y</code>  | Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> . |
| <code>TE</code> | The time at which an event occurs.                                                                                                     |
| <code>YE</code> | The solution at the time of the event.                                                                                                 |

|     |                                                         |
|-----|---------------------------------------------------------|
| IE  | The index <i>i</i> of the event function that vanishes. |
| sol | Structure to evaluate the solution.                     |

## Description

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0)$  with  $\text{tspan} = [t_0 \text{ tf}]$  integrates the system of differential equations  $y' = f(t, y)$  from time  $t_0$  to  $\text{tf}$  with initial conditions  $y_0$ . The first input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, \text{tf}$  (all increasing or all decreasing), use  $\text{tspan} = [t_0, t_1, \dots, \text{tf}]$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

$[T, Y, TE, YE, IE] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function  $[\text{value}, \text{isterminal}, \text{direction}] = \text{events}(t, y)$ . For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

|                         |                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------|
| <code>sol.x</code>      | Steps chosen by the solver.                                                          |
| <code>sol.y</code>      | Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> . |
| <code>sol.solver</code> | Solver name.                                                                         |

If you specify the `Events` option and events are detected, `sol` also includes these fields:

|                     |                                                                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sol.xe</code> | Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.                           |
| <code>sol.ye</code> | Solutions that correspond to events in <code>sol.xe</code> .                                                                                       |
| <code>sol.ie</code> | Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected. |

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the JPattern property or a sparse  $\partial f/\partial y$  using the Jacobian property.
- For strongly state-dependent  $M(t,y)$ , set MvPattern to a sparse matrix S with  $S(i, j) = 1$  if for any k, the (i, k) component of  $M(t,y)$  depends on component j of y, and 0 otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The ode15s and ode23t solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use odeset to set the MassSingular property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide  $yp_0$  as the value of the InitialSlope property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

| Solver | Problem Type | Order of Accuracy | When to Use                                                                        |
|--------|--------------|-------------------|------------------------------------------------------------------------------------|
| ode45  | Nonstiff     | Medium            | Most of the time. This should be the first solver you try.                         |
| ode23  | Nonstiff     | Low               | For problems with crude error tolerances or for solving moderately stiff problems. |

| <b>Solver</b> | <b>Problem Type</b> | <b>Order of Accuracy</b> | <b>When to Use</b>                                                                              |
|---------------|---------------------|--------------------------|-------------------------------------------------------------------------------------------------|
| ode113        | Nonstiff            | Low to high              | For problems with stringent error tolerances or for solving computationally intensive problems. |
| ode15s        | Stiff               | Low to medium            | If ode45 is slow because the problem is stiff.                                                  |
| ode23s        | Stiff               | Low                      | If using crude error tolerances to solve stiff systems and the mass matrix is constant.         |
| ode23t        | Moderately Stiff    | Low                      | For moderately stiff problems if you need a solution without numerical damping.                 |
| ode23tb       | Stiff               | Low                      | If using crude error tolerances to solve stiff systems.                                         |

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 2-3190 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

| Parameters                                | ode45 | ode23 | ode113 | ode15s | ode23s | ode23t | ode23tb |
|-------------------------------------------|-------|-------|--------|--------|--------|--------|---------|
| RelTol, AbsTol,<br>NormControl            | √     | √     | √      | √      | √      | √      | √       |
| OutputFcn,<br>OutputSel,<br>Refine, Stats | √     | √     | √      | √      | √      | √      | √       |
| NonNegative                               | √     | √     | √      | √ *    | —      | √ *    | √ *     |

| MassSingular                              | —     | —     | —      | √      | —      | √      | —       |
| InitialSlope                              | —     | —     | —      | √      | —      | √      | —       |
| MaxOrder, BDF                             | —     | —     | —      | √      | —      | —      | —       |

---

**Note** You can use the NonNegative parameter with ode15s, ode23t, and ode23tb only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.')
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned} y_1' &= y_2 & y_1(0) &= 2 \\ y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0 \end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

# ode15s

```
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

**Example 3**

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

# ode15s

---

```
title('Plot of y as a function of time');  
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

ode45 is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, ode45 is the best function to apply as a *first try* for most problems. [3]

ode23 is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than ode45 at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

**Purpose**

Solve nonstiff differential equations; low order method

**Syntax**

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments**

The following table describes the input arguments to the solvers.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>odefun</code> | A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).                                                                                                                                                                                                                                       |
| <code>tspan</code>  | A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .<br><br>For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing. |

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

|    |                                                                                                             |
|----|-------------------------------------------------------------------------------------------------------------|
| T  | Column vector of time points.                                                                               |
| Y  | Solution array. Each row in Y corresponds to the solution at a time returned in the corresponding row of T. |
| TE | The time at which an event occurs.                                                                          |
| YE | The solution at the time of the event.                                                                      |

|     |                                                         |
|-----|---------------------------------------------------------|
| IE  | The index <i>i</i> of the event function that vanishes. |
| sol | Structure to evaluate the solution.                     |

## Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations  $y' = f(t,y)$  from time `t0` to `tf` with initial conditions `y0`. The first input argument, `odefun`, is a function handle. The function, `f = odefun(t,y)`, for a scalar `t` and a column vector `y`, must return a column vector `f` corresponding to  $f(t,y)$ . Each row in the solution array `Y` corresponds to a time returned in column vector `T`. To obtain solutions at the specific times `t0`, `t1`, ..., `tf` (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[T,Y] = solver(odefun,tspan,y0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` (`1e-3` by default) and a vector of absolute error tolerances `AbsTol` (all components are `1e-6` by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)` solves as above while also finding where functions of  $(t,y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function `[value,isterminal,direction] = events(t,y)`. For the *i*th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i)` = 0 if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

|                         |                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------|
| <code>sol.x</code>      | Steps chosen by the solver.                                                          |
| <code>sol.y</code>      | Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> . |
| <code>sol.solver</code> | Solver name.                                                                         |

If you specify the `Events` option and events are detected, `sol` also includes these fields:

|                     |                                                                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sol.xe</code> | Points at which events, if any, occurred.<br><code>sol.xe(end)</code> contains the exact point of a terminal event, if any.                        |
| <code>sol.ye</code> | Solutions that correspond to events in <code>sol.xe</code> .                                                                                       |
| <code>sol.ie</code> | Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected. |

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MVPattern` to a sparse matrix `S` with `S(i,j) = 1` if for any `k`, the `(i,k)` component of  $M(t,y)$  depends on component `j` of `y`, and `0` otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

| Solver | Problem Type | Order of Accuracy | When to Use                                                                        |
|--------|--------------|-------------------|------------------------------------------------------------------------------------|
| ode45  | Nonstiff     | Medium            | Most of the time. This should be the first solver you try.                         |
| ode23  | Nonstiff     | Low               | For problems with crude error tolerances or for solving moderately stiff problems. |

| <b>Solver</b> | <b>Problem Type</b> | <b>Order of Accuracy</b> | <b>When to Use</b>                                                                              |
|---------------|---------------------|--------------------------|-------------------------------------------------------------------------------------------------|
| ode113        | Nonstiff            | Low to high              | For problems with stringent error tolerances or for solving computationally intensive problems. |
| ode15s        | Stiff               | Low to medium            | If ode45 is slow because the problem is stiff.                                                  |
| ode23s        | Stiff               | Low                      | If using crude error tolerances to solve stiff systems and the mass matrix is constant.         |
| ode23t        | Moderately Stiff    | Low                      | For moderately stiff problems if you need a solution without numerical damping.                 |
| ode23tb       | Stiff               | Low                      | If using crude error tolerances to solve stiff systems.                                         |

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 2-3205 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

# ode23

| Parameters                          | ode45 | ode23 | ode113 | ode15s | ode23s | ode23t | ode23tb |

---

**Note** You can use the NonNegative parameter with ode15s, ode23t, and ode23tb only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.'
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

```
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

## Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

```
title('Plot of y as a function of time');  
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

**Purpose** Solve stiff differential equations; low order method

**Syntax**

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments** The following table describes the input arguments to the solvers.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>odefun</code> | A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).                                                                                                                                                                                                                                       |
| <code>tspan</code>  | A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .<br><br>For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing. |

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

|                 |                                                                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>T</code>  | Column vector of time points.                                                                                                          |
| <code>Y</code>  | Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> . |
| <code>TE</code> | The time at which an event occurs.                                                                                                     |
| <code>YE</code> | The solution at the time of the event.                                                                                                 |

|     |                                                         |
|-----|---------------------------------------------------------|
| IE  | The index <i>i</i> of the event function that vanishes. |
| sol | Structure to evaluate the solution.                     |

## Description

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0)$  with  $\text{tspan} = [t_0 \text{ tf}]$  integrates the system of differential equations  $y' = f(t, y)$  from time  $t_0$  to  $\text{tf}$  with initial conditions  $y_0$ . The first input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, \text{tf}$  (all increasing or all decreasing), use  $\text{tspan} = [t_0, t_1, \dots, \text{tf}]$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

$[T, Y, TE, YE, IE] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function  $[\text{value}, \text{isterminal}, \text{direction}] = \text{events}(t, y)$ . For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

|                         |                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------|
| <code>sol.x</code>      | Steps chosen by the solver.                                                          |
| <code>sol.y</code>      | Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> . |
| <code>sol.solver</code> | Solver name.                                                                         |

If you specify the `Events` option and events are detected, `sol` also includes these fields:

|                     |                                                                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sol.xe</code> | Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.                           |
| <code>sol.ye</code> | Solutions that correspond to events in <code>sol.xe</code> .                                                                                       |
| <code>sol.ie</code> | Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected. |

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix `S` with  $S(i, j) = 1$  if for any  $k$ , the  $(i, k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

| <b>Solver</b> | <b>Problem Type</b> | <b>Order of Accuracy</b> | <b>When to Use</b>                                                                 |
|---------------|---------------------|--------------------------|------------------------------------------------------------------------------------|
| ode45         | Nonstiff            | Medium                   | Most of the time. This should be the first solver you try.                         |
| ode23         | Nonstiff            | Low                      | For problems with crude error tolerances or for solving moderately stiff problems. |

| <b>Solver</b> | <b>Problem Type</b> | <b>Order of Accuracy</b> | <b>When to Use</b>                                                                              |
|---------------|---------------------|--------------------------|-------------------------------------------------------------------------------------------------|
| ode113        | Nonstiff            | Low to high              | For problems with stringent error tolerances or for solving computationally intensive problems. |
| ode15s        | Stiff               | Low to medium            | If ode45 is slow because the problem is stiff.                                                  |
| ode23s        | Stiff               | Low                      | If using crude error tolerances to solve stiff systems and the mass matrix is constant.         |
| ode23t        | Moderately Stiff    | Low                      | For moderately stiff problems if you need a solution without numerical damping.                 |
| ode23tb       | Stiff               | Low                      | If using crude error tolerances to solve stiff systems.                                         |

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 2-3220 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

| Parameters                                | ode45 | ode23 | ode113 | ode15s | ode23s | ode23t | ode23tb |
|-------------------------------------------|-------|-------|--------|--------|--------|--------|---------|
| RelTol, AbsTol,<br>NormControl            | √     | √     | √      | √      | √      | √      | √       |
| OutputFcn,<br>OutputSel,<br>Refine, Stats | √     | √     | √      | √      | √      | √      | √       |
| NonNegative                               | √     | √     | √      | √ *    | —      | √ *    | √ *     |
| Events                                    | √     | √     | √      | √      | √      | √      | √       |

| MStateDependence                          | √     | √     | √      | √      | —      | √      | √       |
| MvPattern                                 | —     | —     | —      | √      | —      | √      | √       |
| MassSingular                              | —     | —     | —      | √      | —      | √      | —       |
| InitialSlope                              | —     | —     | —      | √      | —      | √      | —       |
| MaxOrder, BDF                             | —     | —     | —      | √      | —      | —      | —       |

---

**Note** You can use the NonNegative parameter with ode15s, ode23t, and ode23tb only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'-.')
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned} y_1' &= y_2 & y_1(0) &= 2 \\ y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0 \end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

# ode23s

```
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

### Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

```
title('Plot of y as a function of time');  
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

ode45 is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, ode45 is the best function to apply as a *first try* for most problems. [3]

ode23 is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than ode45 at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear’s method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

**Purpose**

Solve moderately stiff ODEs and DAEs; trapezoidal rule

**Syntax**

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments**

The following table describes the input arguments to the solvers.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>odefun</code> | A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).                                                                                                                                                                                                                        |
| <code>tspan</code>  | A vector specifying the interval of integration, $[t_0, t_f]$ . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .<br><br>For <code>tspan</code> vectors with two elements $[t_0 \ t_f]$ , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing. |

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

|    |                                                                                                             |
|----|-------------------------------------------------------------------------------------------------------------|
| T  | Column vector of time points.                                                                               |
| Y  | Solution array. Each row in Y corresponds to the solution at a time returned in the corresponding row of T. |
| TE | The time at which an event occurs.                                                                          |
| YE | The solution at the time of the event.                                                                      |

IE            The index *i* of the event function that vanishes.  
 sol          Structure to evaluate the solution.

## Description

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0)$  with  $\text{tspan} = [t_0 \text{ } t_f]$  integrates the system of differential equations  $y' = f(t, y)$  from time  $t_0$  to  $t_f$  with initial conditions  $y_0$ . The first input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use  $\text{tspan} = [t_0, t_1, \dots, t_f]$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

$[T, Y, TE, YE, IE] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function  $[\text{value}, \text{isterminal}, \text{direction}] = \text{events}(t, y)$ . For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i)` = 0 if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

|                         |                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------|
| <code>sol.x</code>      | Steps chosen by the solver.                                                          |
| <code>sol.y</code>      | Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> . |
| <code>sol.solver</code> | Solver name.                                                                         |

If you specify the `Events` option and events are detected, `sol` also includes these fields:

|                     |                                                                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sol.xe</code> | Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.                           |
| <code>sol.ye</code> | Solutions that correspond to events in <code>sol.xe</code> .                                                                                       |
| <code>sol.ie</code> | Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected. |

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MVPattern` to a sparse matrix `S` with `S(i,j) = 1` if for any `k`, the `(i,k)` component of  $M(t,y)$  depends on component `j` of `y`, and `0` otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

| Solver | Problem Type | Order of Accuracy | When to Use                                                                        |
|--------|--------------|-------------------|------------------------------------------------------------------------------------|
| ode45  | Nonstiff     | Medium            | Most of the time. This should be the first solver you try.                         |
| ode23  | Nonstiff     | Low               | For problems with crude error tolerances or for solving moderately stiff problems. |

| <b>Solver</b> | <b>Problem Type</b> | <b>Order of Accuracy</b> | <b>When to Use</b>                                                                              |
|---------------|---------------------|--------------------------|-------------------------------------------------------------------------------------------------|
| ode113        | Nonstiff            | Low to high              | For problems with stringent error tolerances or for solving computationally intensive problems. |
| ode15s        | Stiff               | Low to medium            | If ode45 is slow because the problem is stiff.                                                  |
| ode23s        | Stiff               | Low                      | If using crude error tolerances to solve stiff systems and the mass matrix is constant.         |
| ode23t        | Moderately Stiff    | Low                      | For moderately stiff problems if you need a solution without numerical damping.                 |
| ode23tb       | Stiff               | Low                      | If using crude error tolerances to solve stiff systems.                                         |

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 2-3235 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

| Parameters                          | ode45 | ode23 | ode113 | ode15s | ode23s | ode23t | ode23tb |
|-------------------------------------|-------|-------|--------|--------|--------|--------|---------|
| RelTol, AbsTol, NormControl         | √     | √     | √      | √      | √      | √      | √       |
| OutputFcn, OutputSel, Refine, Stats | √     | √     | √      | √      | √      | √      | √       |
| NonNegative                         | √     | √     | √      | √ *    | —      | √ *    | √ *     |
| Events                              | √     | √     | √      | √      | √      | √      | √       |
| MaxStep, InitialStep                | √     | √     | √      | √      | √      | √      | √       |
| Jacobian, JPattern, Vectorized      | —     | —     | —      | √      | √      | √      | √       |
| Mass                                | √     | √     | √      | √      | √      | √      | √       |
| MStateDependence                    | √     | √     | √      | √      | —      | √      | √       |
| MvPattern                           | —     | —     | —      | √      | —      | √      | √       |
| MassSingular                        | —     | —     | —      | √      | —      | √      | —       |
| InitialSlope                        | —     | —     | —      | √      | —      | √      | —       |
| MaxOrder, BDF                       | —     | —     | —      | √      | —      | —      | —       |

---

**Note** You can use the NonNegative parameter with ode15s, ode23t, and ode23tb only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1);    % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.')
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

```
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

## Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

```
title('Plot of y as a function of time');  
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

**Purpose** Solve stiff differential equations; low order method

**Syntax**

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments** The following table describes the input arguments to the solvers.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>odefun</code> | A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).                                                                                                                                                                                                                                       |
| <code>tspan</code>  | A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .<br><br>For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing. |

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

|                 |                                                                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>T</code>  | Column vector of time points.                                                                                                          |
| <code>Y</code>  | Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> . |
| <code>TE</code> | The time at which an event occurs.                                                                                                     |
| <code>YE</code> | The solution at the time of the event.                                                                                                 |

|     |                                                         |
|-----|---------------------------------------------------------|
| IE  | The index <i>i</i> of the event function that vanishes. |
| sol | Structure to evaluate the solution.                     |

## Description

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0)$  with  $\text{tspan} = [t_0 \text{ } t_f]$  integrates the system of differential equations  $y' = f(t, y)$  from time  $t_0$  to  $t_f$  with initial conditions  $y_0$ . The first input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use  $\text{tspan} = [t_0, t_1, \dots, t_f]$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

$[T, Y, TE, YE, IE] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function  $[\text{value}, \text{isterminal}, \text{direction}] = \text{events}(t, y)$ . For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

|                         |                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------|
| <code>sol.x</code>      | Steps chosen by the solver.                                                          |
| <code>sol.y</code>      | Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> . |
| <code>sol.solver</code> | Solver name.                                                                         |

If you specify the `Events` option and events are detected, `sol` also includes these fields:

|                     |                                                                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sol.xe</code> | Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.                           |
| <code>sol.ye</code> | Solutions that correspond to events in <code>sol.xe</code> .                                                                                       |
| <code>sol.ie</code> | Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected. |

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix `S` with  $S(i, j) = 1$  if for any  $k$ , the  $(i, k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

| <b>Solver</b> | <b>Problem Type</b> | <b>Order of Accuracy</b> | <b>When to Use</b>                                                                 |
|---------------|---------------------|--------------------------|------------------------------------------------------------------------------------|
| ode45         | Nonstiff            | Medium                   | Most of the time. This should be the first solver you try.                         |
| ode23         | Nonstiff            | Low                      | For problems with crude error tolerances or for solving moderately stiff problems. |

| <b>Solver</b> | <b>Problem Type</b> | <b>Order of Accuracy</b> | <b>When to Use</b>                                                                              |
|---------------|---------------------|--------------------------|-------------------------------------------------------------------------------------------------|
| ode113        | Nonstiff            | Low to high              | For problems with stringent error tolerances or for solving computationally intensive problems. |
| ode15s        | Stiff               | Low to medium            | If ode45 is slow because the problem is stiff.                                                  |
| ode23s        | Stiff               | Low                      | If using crude error tolerances to solve stiff systems and the mass matrix is constant.         |
| ode23t        | Moderately Stiff    | Low                      | For moderately stiff problems if you need a solution without numerical damping.                 |
| ode23tb       | Stiff               | Low                      | If using crude error tolerances to solve stiff systems.                                         |

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 2-3250 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

| Parameters                                | ode45 | ode23 | ode113 | ode15s | ode23s | ode23t | ode23tb |
|-------------------------------------------|-------|-------|--------|--------|--------|--------|---------|
| RelTol, AbsTol,<br>NormControl            | √     | √     | √      | √      | √      | √      | √       |
| OutputFcn,<br>OutputSel,<br>Refine, Stats | √     | √     | √      | √      | √      | √      | √       |
| NonNegative                               | √     | √     | √      | √ *    | —      | √ *    | √ *     |
| Events                                    | √     | √     | √      | √      | √      | √      | √       |
| MaxStep,<br>InitialStep                   | √     | √     | √      | √      | √      | √      | √       |

| Mass                                      | √     | √     | √      | √      | √      | √      | √       |
| MStateDependence                          | √     | √     | √      | √      | —      | √      | √       |
| MvPattern                                 | —     | —     | —      | √      | —      | √      | √       |
| MassSingular                              | —     | —     | —      | √      | —      | √      | —       |
| InitialSlope                              | —     | —     | —      | √      | —      | √      | —       |
| MaxOrder, BDF                             | —     | —     | —      | √      | —      | —      | —       |

---

**Note** You can use the NonNegative parameter with ode15s, ode23t, and ode23tb only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'-.')
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned} y_1' &= y_2 & y_1(0) &= 2 \\ y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0 \end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

## ode23tb

---

```
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

### Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

```
title('Plot of y as a function of time');  
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

ode45 is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, ode45 is the best function to apply as a *first try* for most problems. [3]

ode23 is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than ode45 at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear’s method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

**Purpose**

Solve nonstiff differential equations; medium order method

**Syntax**

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments**

The following table describes the input arguments to the solvers.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>odefun</code> | A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).                                                                                                                                                                                                                                       |
| <code>tspan</code>  | A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .<br><br>For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing. |

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

|                      |                                                                                                                     |
|----------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>y0</code>      | A vector of initial conditions.                                                                                     |
| <code>options</code> | Structure of optional parameters that change the default integration properties. This is the fourth input argument. |

`[t,y] = solver(odefun,tspan,y0,options)`

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

|                 |                                                                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>T</code>  | Column vector of time points.                                                                                                          |
| <code>Y</code>  | Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> . |
| <code>TE</code> | The time at which an event occurs.                                                                                                     |
| <code>YE</code> | The solution at the time of the event.                                                                                                 |

IE            The index *i* of the event function that vanishes.  
 sol          Structure to evaluate the solution.

## Description

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0)$  with  $\text{tspan} = [t_0 \text{ } t_f]$  integrates the system of differential equations  $y' = f(t, y)$  from time  $t_0$  to  $t_f$  with initial conditions  $y_0$ . The first input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use  $\text{tspan} = [t_0, t_1, \dots, t_f]$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

$[T, Y, TE, YE, IE] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function  $[\text{value}, \text{isterminal}, \text{direction}] = \text{events}(t, y)$ . For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i)` = 0 if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

|                         |                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------|
| <code>sol.x</code>      | Steps chosen by the solver.                                                          |
| <code>sol.y</code>      | Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> . |
| <code>sol.solver</code> | Solver name.                                                                         |

If you specify the `Events` option and events are detected, `sol` also includes these fields:

|                     |                                                                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sol.xe</code> | Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.                           |
| <code>sol.ye</code> | Solutions that correspond to events in <code>sol.xe</code> .                                                                                       |
| <code>sol.ie</code> | Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected. |

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MVPattern` to a sparse matrix `S` with `S(i,j) = 1` if for any `k`, the `(i,k)` component of  $M(t,y)$  depends on component `j` of `y`, and `0` otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

| Solver | Problem Type | Order of Accuracy | When to Use                                                                        |
|--------|--------------|-------------------|------------------------------------------------------------------------------------|
| ode45  | Nonstiff     | Medium            | Most of the time. This should be the first solver you try.                         |
| ode23  | Nonstiff     | Low               | For problems with crude error tolerances or for solving moderately stiff problems. |

| <b>Solver</b> | <b>Problem Type</b> | <b>Order of Accuracy</b> | <b>When to Use</b>                                                                              |
|---------------|---------------------|--------------------------|-------------------------------------------------------------------------------------------------|
| ode113        | Nonstiff            | Low to high              | For problems with stringent error tolerances or for solving computationally intensive problems. |
| ode15s        | Stiff               | Low to medium            | If ode45 is slow because the problem is stiff.                                                  |
| ode23s        | Stiff               | Low                      | If using crude error tolerances to solve stiff systems and the mass matrix is constant.         |
| ode23t        | Moderately Stiff    | Low                      | For moderately stiff problems if you need a solution without numerical damping.                 |
| ode23tb       | Stiff               | Low                      | If using crude error tolerances to solve stiff systems.                                         |

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 2-3265 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

# ode45

| Parameters                          | ode45 | ode23 | ode113 | ode15s | ode23s | ode23t | ode23tb |
|-------------------------------------|-------|-------|--------|--------|--------|--------|---------|
| RelTol, AbsTol, NormControl         | √     | √     | √      | √      | √      | √      | √       |
| OutputFcn, OutputSel, Refine, Stats | √     | √     | √      | √      | √      | √      | √       |
| NonNegative                         | √     | √     | √      | √ *    | —      | √ *    | √ *     |
| Events                              | √     | √     | √      | √      | √      | √      | √       |
| MaxStep, InitialStep                | √     | √     | √      | √      | √      | √      | √       |
| Jacobian, JPattern, Vectorized      | —     | —     | —      | √      | √      | √      | √       |
| Mass                                | √     | √     | √      | √      | √      | √      | √       |
| MStateDependence                    | √     | √     | √      | √      | —      | √      | √       |
| MvPattern                           | —     | —     | —      | √      | —      | √      | √       |
| MassSingular                        | —     | —     | —      | √      | —      | √      | —       |
| InitialSlope                        | —     | —     | —      | √      | —      | √      | —       |
| MaxOrder, BDF                       | —     | —     | —      | √      | —      | —      | —       |

---

**Note** You can use the NonNegative parameter with ode15s, ode23t, and ode23tb only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.')
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned} y_1' &= y_2 & y_1(0) &= 2 \\ y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0 \end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

```
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

## Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

```
title('Plot of y as a function of time');  
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

ode45 is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, ode45 is the best function to apply as a *first try* for most problems. [3]

ode23 is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than ode45 at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

**Purpose** Solve nonstiff differential equations; variable order method

**Syntax**

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments** The following table describes the input arguments to the solvers.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>odefun</code> | A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).                                                                                                                                                                                                                                       |
| <code>tspan</code>  | A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .<br><br>For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing. |

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

|                 |                                                                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>T</code>  | Column vector of time points.                                                                                                          |
| <code>Y</code>  | Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> . |
| <code>TE</code> | The time at which an event occurs.                                                                                                     |
| <code>YE</code> | The solution at the time of the event.                                                                                                 |

IE            The index *i* of the event function that vanishes.  
sol           Structure to evaluate the solution.

## Description

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0)$  with  $\text{tspan} = [t_0 \text{ } t_f]$  integrates the system of differential equations  $y' = f(t, y)$  from time  $t_0$  to  $t_f$  with initial conditions  $y_0$ . The first input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use  $\text{tspan} = [t_0, t_1, \dots, t_f]$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

$[T, Y, TE, YE, IE] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function  $[\text{value}, \text{isterminal}, \text{direction}] = \text{events}(t, y)$ . For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

|                         |                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------|
| <code>sol.x</code>      | Steps chosen by the solver.                                                          |
| <code>sol.y</code>      | Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> . |
| <code>sol.solver</code> | Solver name.                                                                         |

If you specify the `Events` option and events are detected, `sol` also includes these fields:

|                     |                                                                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sol.xe</code> | Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.                           |
| <code>sol.ye</code> | Solutions that correspond to events in <code>sol.xe</code> .                                                                                       |
| <code>sol.ie</code> | Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected. |

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix `S` with  $S(i, j) = 1$  if for any  $k$ , the  $(i, k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

| <b>Solver</b> | <b>Problem Type</b> | <b>Order of Accuracy</b> | <b>When to Use</b>                                                                 |
|---------------|---------------------|--------------------------|------------------------------------------------------------------------------------|
| ode45         | Nonstiff            | Medium                   | Most of the time. This should be the first solver you try.                         |
| ode23         | Nonstiff            | Low                      | For problems with crude error tolerances or for solving moderately stiff problems. |

| <b>Solver</b> | <b>Problem Type</b> | <b>Order of Accuracy</b> | <b>When to Use</b>                                                                              |
|---------------|---------------------|--------------------------|-------------------------------------------------------------------------------------------------|
| ode113        | Nonstiff            | Low to high              | For problems with stringent error tolerances or for solving computationally intensive problems. |
| ode15s        | Stiff               | Low to medium            | If ode45 is slow because the problem is stiff.                                                  |
| ode23s        | Stiff               | Low                      | If using crude error tolerances to solve stiff systems and the mass matrix is constant.         |
| ode23t        | Moderately Stiff    | Low                      | For moderately stiff problems if you need a solution without numerical damping.                 |
| ode23tb       | Stiff               | Low                      | If using crude error tolerances to solve stiff systems.                                         |

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 2-3280 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

---

**Note** You can use the NonNegative parameter with ode15s, ode23t, and ode23tb only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.')
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned} y_1' &= y_2 & y_1(0) &= 2 \\ y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0 \end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

# ode113

```
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

**Example 3**

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

```
title('Plot of y as a function of time');  
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear’s method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

`deval` | `ode15i` | `odeget` | `odeset` | `function_handle`

**Purpose**

Ordinary differential equation options parameters

**Syntax**

```
o = odeget(options,'name')  
o = odeget(options,'name',default)
```

**Description**

`o = odeget(options,'name')` extracts the value of the property specified by string `'name'` from integrator options structure `options`, returning an empty matrix if the property value is not specified in `options`. It is only necessary to type the leading characters that uniquely identify the property name. Case is ignored for property names. The empty matrix `[]` is a valid options argument.

`o = odeget(options,'name',default)` returns `o = default` if the named property is not specified in `options`.

**Examples**

Having constructed an ODE options structure,

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-3 2e-3 3e-3]);
```

you can view these property settings with `odeget`.

```
odeget(options,'RelTol')  
ans =
```

```
1.0000e-04
```

```
odeget(options,'AbsTol')  
ans =
```

```
0.0010    0.0020    0.0030
```

**See Also**

`odeset`

# odeset

---

**Purpose** Create or alter options structure for ordinary differential equation solvers

**Syntax**

```
options = odeset('name1',value1,'name2',value2,...)
options = odeset(olddopts,'name1',value1,...)
options = odeset(olddopts,newopts)
odeset
```

**Description** The `odeset` function lets you adjust the integration parameters of the following ODE solvers.

For solving fully implicit differential equations:

```
ode15i
```

For solving initial value problems:

```
ode23, ode45, ode113, ode15s, ode23s, ode23t, ode23tb
```

See below for information about the integration parameters.

`options = odeset('name1',value1,'name2',value2,...)` creates an options structure that you can pass as an argument to any of the ODE solvers. In the resulting structure, `options`, the named properties have the specified values. For example, 'name1' has the value `value1`. Any unspecified properties have default values. It is sufficient to type only the leading characters that uniquely identify a property name. Case is ignored for property names.

`options = odeset(olddopts,'name1',value1,...)` alters an existing options structure `olddopts`. This sets `options` equal to the existing structure `olddopts`, overwrites any values in `olddopts` that are respecified using name/value pairs, and adds any new pairs to the structure. The modified structure is returned as an output argument.

`options = odeset(olddopts,newopts)` alters an existing options structure `olddopts` by combining it with a new options structure `newopts`. Any new options not equal to the empty matrix overwrite corresponding options in `olddopts`.

odeset with no input arguments displays all property names as well as their possible and default values.

## ODE Properties

The following sections describe the properties that you can set using odeset. The available properties depend on the ODE solver you are using. There are several categories of properties:

- “Error Control Properties” on page 2-3285
- “Solver Output Properties” on page 2-3287
- “Step-Size Properties” on page 2-3290
- “Event Location Property” on page 2-3292
- “Jacobian Matrix Properties” on page 2-3293
- “Mass Matrix and DAE Properties” on page 2-3297
- “ode15s and ode15i-Specific Properties” on page 2-3299

---

**Note** This reference page describes the ODE properties for MATLAB, Version 7. The Version 5 properties are supported only for backward compatibility. For information on the Version 5 properties, type at the MATLAB command line: `more on`, `type odeset`, `more off`.

---

## Error Control Properties

At each step, the solver estimates the local error  $e$  in the  $i$ th component of the solution. This error must be less than or equal to the acceptable error, which is a function of the specified relative tolerance, `RelTol`, and the specified absolute tolerance, `AbsTol`.

$$|e(i)| \leq \max(\text{RelTol} * \text{abs}(y(i)), \text{AbsTol}(i))$$

For routine problems, the ODE solvers deliver accuracy roughly equivalent to the accuracy you request. They deliver less accuracy for problems integrated over "long" intervals and problems that are moderately unstable. Difficult problems may require tighter tolerances than the default values. For relative accuracy, adjust `RelTol`. For

the absolute error tolerance, the scaling of the solution components is important: if  $|y|$  is somewhat smaller than `AbsTol`, the solver is not constrained to obtain any correct digits in  $y$ . You might have to solve a problem more than once to discover the scale of solution components.

Roughly speaking, this means that you want `RelTol` correct digits in all solution components except those smaller than thresholds `AbsTol(i)`. Even if you are not interested in a component  $y(i)$  when it is small, you may have to specify `AbsTol(i)` small enough to get some correct digits in  $y(i)$  so that you can accurately compute more interesting components.

The following table describes the error control properties. Further information on each property is given following the table.

| Property                 | Value                               | Description                                                                               |
|--------------------------|-------------------------------------|-------------------------------------------------------------------------------------------|
| <code>RelTol</code>      | Positive scalar<br>{1e-3}           | Relative error tolerance that applies to all components of the solution vector $y$ .      |
| <code>AbsTol</code>      | Positive scalar<br>or vector {1e-6} | Absolute error tolerances that apply to the individual components of the solution vector. |
| <code>NormControl</code> | on   {off}                          | Control error relative to norm of solution.                                               |

## Description of Error Control Properties

**RelTol** — This tolerance is a measure of the error relative to the size of each solution component. Roughly, it controls the number of correct digits in all solution components, except those smaller than thresholds `AbsTol(i)`.

The default, `1e-3`, corresponds to 0.1% accuracy.

**AbsTol** — `AbsTol(i)` is a threshold below which the value of the  $i$ th solution component is unimportant. The absolute error tolerances determine the accuracy when the solution approaches zero.

If `AbsTol` is a vector, the length of `AbsTol` must be the same as the length of the solution vector `y`. If `AbsTol` is a scalar, the value applies to all components of `y`.

**NormControl** — Set this property on to request that the solvers control the error in each integration step with  $\text{norm}(e) \leq \max(\text{RelTol} \cdot \text{norm}(y), \text{AbsTol})$ . By default the solvers use a more stringent componentwise error control.

## Solver Output Properties

The following table lists the solver output properties that control the output that the solvers generate. Further information on each property is given following the table.

| Property    | Value              | Description                                                                                                            |
|-------------|--------------------|------------------------------------------------------------------------------------------------------------------------|
| NonNegative | Vector of integers | Specifies which components of the solution vector must be nonnegative. The default value is <code>[]</code> .          |
| OutputFcn   | Function handle    | A function for the solver to call after every successful integration step.                                             |
| OutputSel   | Vector of indices  | Specifies which components of the solution vector are to be passed to the output function.                             |
| Refine      | Positive integer   | Increases the number of output points by a factor of <code>Refine</code> .                                             |
| Stats       | on   {off}         | Determines whether the solver should display statistics about its computations. By default, <code>Stats</code> is off. |

### Description of Solver Output Properties

**NonNegative** — The `NonNegative` property is not available in `ode23s`, `ode15i`. In `ode15s`, `ode23t`, and `ode23tb`, `NonNegative` is not available for problems where there is a mass matrix.

**OutputFcn** — To specify an output function, set 'OutputFcn' to a function handle. For example,

```
options = odeset('OutputFcn',@myfun)
```

sets 'OutputFcn' to @myfun, a handle to the function myfun. See the [function\\_handle](#) reference page for more information.

The output function must be of the form

```
status = myfun(t,y,flag)
```

“Parameterizing Functions” explains how to provide additional parameters to myfun, if necessary.

The solver calls the specified output function with the following flags. Note that the syntax of the call differs with the flag. The function must respond appropriately:

| Flag | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| init | The solver calls <code>myfun(tspan,y0,'init')</code> before beginning the integration to allow the output function to initialize. <code>tspan</code> and <code>y0</code> are the input arguments to the ODE solver.                                                                                                                                                                                                                                                                                                                                                                                                             |
| {[]} | The solver calls <code>status = myfun(t,y,[])</code> after each integration step on which output is requested. <code>t</code> contains points where output was generated during the step, and <code>y</code> is the numerical solution at the points in <code>t</code> . If <code>t</code> is a vector, the <i>i</i> th column of <code>y</code> corresponds to the <i>i</i> th element of <code>t</code> .<br><br>When <code>length(tspan) &gt; 2</code> the output is produced at every point in <code>tspan</code> . When <code>length(tspan) = 2</code> the output is produced according to the <code>Refine</code> option. |

| Flag | Description                                                                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|      | myfun must return a status output value of 0 or 1. If status = 1, the solver halts integration. You can use this mechanism, for instance, to implement a <b>Stop</b> button. |
| done | The solver calls myfun([],[], 'done') when integration is complete to allow the output function to perform any cleanup chores.                                               |

You can use these general purpose output functions or you can edit them to create your own. Type `help` function at the command line for more information.

- `odeplot` — Time series plotting (default when you call the solver with no output arguments and you have not specified an output function)
- `odephas2` — Two-dimensional phase plane plotting
- `odephas3` — Three-dimensional phase plane plotting
- `odeprint` — Print solution as it is computed

---

**Note** If you call the solver with no output arguments, the solver does not allocate storage to hold the entire solution history.

---

**OutputSel** — Use `OutputSel` to specify which components of the solution vector you want passed to the output function. For example, if you want to use the `odeplot` output function, but you want to plot only the first and third components of the solution, you can do this using

```
options = ...
odeset('OutputFcn',@odeplot,'OutputSel',[1 3]);
```

By default, the solver passes all components of the solution to the output function.

**Refine** — If `Refine` is 1, the solver returns solutions only at the end of each time step. If `Refine` is  $n > 1$ , the solver subdivides each time step into  $n$  smaller intervals and returns solutions at each time point. `Refine` does not apply when `length(tspan) > 2`.

---

**Note** In all the solvers, the default value of `Refine` is 1. Within `ode45`, however, the default is 4 to compensate for the solver's large step sizes. To override this and see only the time steps chosen by `ode45`, set `Refine` to 1.

---

The extra values produced for `Refine` are computed by means of continuous extension formulas. These are specialized formulas used by the ODE solvers to obtain accurate solutions between computed time steps without significant increase in computation time.

**Stats** — By default, `Stats` is off. If it is on, after solving the problem the solver displays

- Number of successful steps
- Number of failed attempts
- Number of times the ODE function was called to evaluate  $f(t,y)$

Solvers based on implicit methods, including `ode23s`, `ode23t`, `ode15s`, and `ode15i`, also display

- Number of times that the partial derivatives matrix  $\partial f/\partial x$  was formed
- Number of LU decompositions
- Number of solutions of linear systems

## Step-Size Properties

The step-size properties specify the size of the first step the solver tries, potentially helping it to better recognize the scale of the problem. In addition, you can specify bounds on the sizes of subsequent time steps.

The following table describes the step-size properties. Further information on each property is given following the table.

| Property    | Value                               | Description                      |
|-------------|-------------------------------------|----------------------------------|
| InitialStep | Positive scalar                     | Suggested initial step size.     |
| MaxStep     | Positive scalar<br>{0.1*abs(t0-tf)} | Upper bound on solver step size. |

### Description of Step-Size Properties

**InitialStep** — InitialStep sets an upper bound on the magnitude of the first step size the solver tries. If you do not set InitialStep, the initial step size is based on the slope of the solution at the initial time `tspan(1)`, and if the slope of all solution components is zero, the procedure might try a step size that is much too large. If you know this is happening or you want to be sure that the solver resolves important behavior at the start of the integration, help the code start by providing a suitable InitialStep.

**MaxStep** — If the differential equation has periodic coefficients or solutions, it might be a good idea to set MaxStep to some fraction (such as 1/4) of the period. This guarantees that the solver does not enlarge the time step too much and step over a period of interest. Do *not* reduce MaxStep for any of the following purposes:

- To produce more output points. This can significantly slow down solution time. Instead, use `Refine` to compute additional outputs by continuous extension at very low cost.
- When the solution does not appear to be accurate enough. Instead, reduce the relative error tolerance `RelTol`, and use the solution you just computed to determine appropriate values for the absolute error tolerance vector `AbsTol`. See “Error Control Properties” on page 2-3285 for a description of the error tolerance properties.
- To make sure that the solver doesn’t step over some behavior that occurs only once during the simulation interval. If you know the time at which the change occurs, break the simulation interval into two pieces and call the solver twice. If you do not know the time at which the change occurs, try reducing the error tolerances `RelTol` and `AbsTol`. Use MaxStep as a last resort.

## Event Location Property

In some ODE problems the times of specific events are important, such as the time at which a ball hits the ground, or the time at which a spaceship returns to the earth. While solving a problem, the ODE solvers can detect such events by locating transitions to, from, or through zeros of user-defined functions.

The following table describes the Events property. Further information on each property is given following the table.

### ODE Events Property

| String | Value           | Description                                                     |
|--------|-----------------|-----------------------------------------------------------------|
| Events | Function handle | Handle to a function that includes one or more event functions. |

### Description of Event Location Properties

**Events** — The function is of the form

$$[\text{value}, \text{isterminal}, \text{direction}] = \text{events}(t, y)$$

`value`, `isterminal`, and `direction` are vectors for which the  $i$ th element corresponds to the  $i$ th event function:

- `value(i)` is the value of the  $i$ th event function.
- `isterminal(i) = 1` if the integration is to terminate at a zero of this event function, otherwise, 0.
- `direction(i) = 0` if all zeros are to be located (the default), +1 if only zeros where the event function is increasing, and -1 if only zeros where the event function is decreasing.

If you specify an events function and events are detected, the solver returns three additional outputs:

- A column vector of times at which events occur
- Solution values corresponding to these times

- Indices into the vector returned by the events function. The values indicate which event the solver detected.

If you call the solver as

```
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
```

the solver returns these outputs as TE, YE, and IE respectively. If you call the solver as

```
sol = solver(odefun,tspan,y0,options)
```

the solver returns these outputs as sol.xe, sol.ye, and sol.ie, respectively.

For examples that use an event function, see “Event Location” and “Advanced Event Location” in the MATLAB Mathematics documentation.

## Jacobian Matrix Properties

The stiff ODE solvers often execute faster if you provide additional information about the Jacobian matrix  $\partial f/\partial y$ , a matrix of partial derivatives of the function that defines the differential equations.

$$\frac{\partial f}{\partial y} = \begin{bmatrix} \frac{\partial f_1}{\partial y_1} & \frac{\partial f_1}{\partial y_2} & \dots \\ \frac{\partial f_2}{\partial y_1} & \frac{\partial f_2}{\partial y_2} & \dots \\ \vdots & \vdots & \ddots \end{bmatrix}$$

The Jacobian matrix properties pertain only to those solvers for stiff problems (`ode15s`, `ode23s`, `ode23t`, `ode23tb`, and `ode15i`) for which the Jacobian matrix  $\partial f/\partial y$  can be critical to reliability and efficiency. If you do not provide a function to calculate the Jacobian, these solvers approximate the Jacobian numerically using finite differences. In this case, you might want to use the `Vectorized` or `JPattern` properties.

The following table describes the Jacobian matrix properties for all implicit solvers except `ode15i`. Further information on each property is given following the table. See Jacobian Properties for `ode15i` on page 2-3296 for `ode15i`-specific information.

## Jacobian Properties for All Implicit Solvers Except `ode15i`

| Property   | Value                             | Description                                                              |
|------------|-----------------------------------|--------------------------------------------------------------------------|
| Jacobian   | Function handle   constant matrix | Matrix or function that evaluates the Jacobian.                          |
| JPattern   | Sparse matrix of {0,1}            | Generates a sparse Jacobian matrix numerically.                          |
| Vectorized | on   {off}                        | Allows the solver to reduce the number of function evaluations required. |

## Description of Jacobian Properties

**Jacobian** — Supplying an analytical Jacobian often increases the speed and reliability of the solution for stiff problems. Set this property to a function `FJac`, where `FJac(t,y)` computes  $\partial f/\partial y$ , or to the constant value of  $\partial f/\partial y$ .

The Jacobian for the “van der Pol Equation (Stiff)”, described in the MATLAB Mathematics documentation, can be coded as

```
function J = vdp1000jac(t,y)
J = [ 0          1
      (-2000*y(1)*y(2)-1)  (1000*(1-y(1)^2)) ];
```

**JPattern** — `JPattern` is a sparsity pattern with 1s where there might be nonzero entries in the Jacobian.

---

**Note** If you specify `Jacobian`, the solver ignores any setting for `JPattern`.

---

Set this property to a sparse matrix  $S$  with  $S(i,j) = 1$  if component  $i$  of  $f(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise. The solver uses this sparsity pattern to generate a sparse Jacobian matrix numerically. If the Jacobian matrix is large and sparse, this can greatly accelerate execution. For an example using the `JPattern` property, see Example: Large, Stiff, Sparse Problem in the MATLAB Mathematics documentation.

**Vectorized** — The `Vectorized` property allows the solver to reduce the number of function evaluations required to compute all the columns of the Jacobian matrix, and might significantly reduce solution time.

Set `on` to inform the solver that you have coded the ODE function `F` so that `F(t,[y1 y2 ...])` returns `[F(t,y1) F(t,y2) ...]`. This allows the solver to reduce the number of function evaluations required to compute all the columns of the Jacobian matrix, and might significantly reduce solution time.

---

**Note** If you specify `Jacobian`, the solver ignores a setting of `'on'` for `'Vectorized'`.

---

With the MATLAB array notation, it is typically an easy matter to vectorize an ODE function. For example, you can vectorize the “van der Pol Equation (Stiff)”, described in the MATLAB Mathematics documentation, by introducing colon notation into the subscripts and by using the array power (`.`<sup>`^`</sup>) and array multiplication (`.`<sup>`*`</sup>) operators.

```
function dydt = vdp1000(t,y)
dydt = [y(2,:); 1000*(1-y(1,:).^2).*y(2,:)-y(1,:)];
```

---

**Note** Vectorization of the ODE function used by the ODE solvers differs from the vectorization used by the boundary value problem (BVP) solver, `bvp4c`. For the ODE solvers, the ODE function is vectorized only with respect to the second argument, while `bvp4c` requires vectorization with respect to the first and second arguments.

---

The following table describes the Jacobian matrix properties for `ode15i`.

### Jacobian Properties for `ode15i`

| Property   | Value                                           | Description                                                              |
|------------|-------------------------------------------------|--------------------------------------------------------------------------|
| Jacobian   | Function handle   Cell array of constant values | Function that evaluates the Jacobian or a cell array of constant values. |
| JPattern   | Sparse matrices of {0,1}                        | Generates a sparse Jacobian matrix numerically.                          |
| Vectorized | on   {off}                                      | Vectorized ODE function                                                  |

### Description of Jacobian Properties for `ode15i`

**Jacobian** — Supplying an analytical Jacobian often increases the speed and reliability of the solution for stiff problems. Set this property to a function

$$[dFd_y, dFd_p] = Fjac(t, y, y_p)$$

or to a cell array of constant values  $[\partial F/\partial y, (\partial F/\partial y)']$ .

**JPattern** — `JPattern` is a sparsity pattern with 1's where there might be nonzero entries in the Jacobian.

Set this property to `{dFd_yPattern, dFd_pPattern}`, the sparsity patterns of  $\partial F/\partial y$  and  $\partial F/\partial y'$ , respectively.

**Vectorized** —

Set this property to {yVect, ypVect}. Setting yVect to 'on' indicates that

```
F(t, [y1 y2 ...], yp)
```

returns

```
[F(t,y1,yp), F(t,y2,yp) ...]
```

Setting ypVect to 'on' indicates that

```
F(t,y,[yp1 yp2 ...])
```

returns

```
[F(t,y,yp1) F(t,y,yp2) ...]
```

## Mass Matrix and DAE Properties

This section describes mass matrix and differential-algebraic equation (DAE) properties, which apply to all the solvers except `ode15i`. These properties are not applicable to `ode15i` and their settings do not affect its behavior.

The solvers of the ODE suite can solve ODEs of the form

$$M(t,y)y' = f(t,y) \quad (2-3)$$

with a mass matrix  $M(t,y)$  that can be sparse.

When  $M(t,y)$  is nonsingular, the equation above is equivalent to  $y' = M^{-1}f(t,y)$  and the ODE has a solution for any initial values  $y_0$  at  $t_0$ . The more general form (Equation 2-3) is convenient when you express a model naturally in terms of a mass matrix. For large, sparse  $M(t,y)$ , solving Equation 2-3 directly reduces the storage and run-time needed to solve the problem.

When  $M(t,y)$  is singular, then  $M(t,y)$  times  $M(t,y)y' = f(t,y)$  is a DAE. A DAE has a solution only when  $y_0$  is consistent; that is, there exists an initial slope  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . If  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve

the problem. For DAEs of index 1, solving an initial value problem with consistent initial conditions is much like solving an ODE.

The `ode15s` and `ode23t` solvers can solve DAEs of index 1. For examples of DAE problems, see Example: Differential-Algebraic Problem, in the MATLAB Mathematics documentation, and the examples `amp1dae` and `hb1dae`.

The following table describes the mass matrix and DAE properties. Further information on each property is given following the table.

## Mass Matrix and DAE Properties (Solvers Other Than `ode15i`)

| Property         | Value                    | Description                                                         |
|------------------|--------------------------|---------------------------------------------------------------------|
| Mass             | Matrix   function handle | Mass matrix or a function that evaluates the mass matrix $M(t,y)$ . |
| MStateDependence | none   {weak}   strong   | Dependence of the mass matrix on $y$ .                              |
| MvPattern        | Sparse matrix            | $\partial(M(t,y)v)/\partial y$ sparsity pattern.                    |
| MassSingular     | yes   no   {maybe}       | Indicates whether the mass matrix is singular.                      |
| InitialSlope     | Vector {zero vector}     | Vector representing the consistent initial slope $yp_0$ .           |

## Description of Mass Matrix and DAE Properties

**Mass** — For problems of the form  $M(t)y' = f(t,y)$ , set 'Mass' to a mass matrix  $M$ . For problems of the form  $M(t)y' = f(t,y)$ , set 'Mass' to a function handle `@Mfun`, where `Mfun(t,y)` evaluates the mass matrix  $M(t,y)$ . The `ode23s` solver can only solve problems with a constant mass matrix  $M$ . When solving DAEs, using `ode15s` or `ode23t`, it is advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semiexplicit DAE).

For example problems, see “Finite Element Discretization” in the MATLAB Mathematics documentation, or the examples `fem2ode` or `batonode`.

**MStateDependence** — Set this property to `none` for problems

$M(t)y' = f(t,y)$ . Both `weak` and `strong` indicate  $M(t,y)$ , but `weak` results in implicit solvers using approximations when solving algebraic equations.

**MvPattern** — Set this property to a sparse matrix  $S$  with  $S(i,j) = 1$  if, for any  $k$ , the  $(i,k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise. For use with the `ode15s`, `ode23t`, and `ode23tb` solvers when `MStateDependence` is `strong`. See `burgersode` as an example.

**MassSingular** — Set this property to `no` if the mass matrix is not singular and you are using either the `ode15s` or `ode23t` solver. The default value of `maybe` causes the solver to test whether the problem is a DAE, by testing whether  $M(t_0,y_0)$  is singular.

**InitialSlope** — Vector representing the consistent initial slope  $yp_0$ , where  $yp_0$  satisfies  $M(t_0,y_0) \cdot yp_0 = f(t_0,y_0)$ . The default is the zero vector.

This property is for use with the `ode15s` and `ode23t` solvers when solving DAEs.

## ode15s and ode15i-Specific Properties

`ode15s` is a variable-order solver for stiff problems. It is based on the numerical differentiation formulas (NDFs). The NDFs are generally more efficient than the closely related family of backward differentiation formulas (BDFs), also known as Gear’s methods. The `ode15s` properties let you choose among these formulas, as well as specifying the maximum order for the formula used.

`ode15i` solves fully implicit differential equations of the form

$$f(t,y,y') = 0$$

using the variable order BDF method.

The following table describes the `ode15s` and `ode15i`-specific properties. Further information on each property is given following the table. Use `odeset` to set these properties.

## ode15s and ode15i-Specific Properties

| Property             | Value               | Description                                                             |
|----------------------|---------------------|-------------------------------------------------------------------------|
| MaxOrder             | 1   2   3   4   {5} | Maximum order formula used to compute the solution.                     |
| BDF<br>(ode15s only) | on   {off}          | Specifies whether you want to use the BDFs instead of the default NDFs. |

## Description of ode15s and ode15i-Specific Properties

**MaxOrder** — Maximum order formula used to compute the solution.

**BDF** (ode15s only) — Set BDF on to have `ode15s` use the BDFs.

For both the NDFs and BDFs, the formulas of orders 1 and 2 are A-stable (the stability region includes the entire left half complex plane). The higher order formulas are not as stable, and the higher the order the worse the stability. There is a class of stiff problems (stiff oscillatory) that is solved more efficiently if `MaxOrder` is reduced (for example to 2) so that only the most stable formulas are used.

`deval` | `odeget` | `ode45` | `ode23` | `ode23t` | `ode23tb` | `ode113` | `ode15s` | `ode23s` | `function_handle`

**Purpose** Extend solution of initial value problem for ordinary differential equation

**Syntax**

```

solext = odextend(sol, odefun, tfinal)
solext = odextend(sol, [], tfinal)
solext = odextend(sol, odefun, tfinal, yinit)
solext = odextend(sol, odefun, tfinal, [yinit, ypinit])
solext = odextend(sol, odefun, tfinal, yinit, options)

```

**Description** `solext = odextend(sol, odefun, tfinal)` extends the solution stored in `sol` to an interval with upper bound `tfinal` for the independent variable. Specify `odefun` as a function handle. Specify `sol` as an ODE solution structure created using an ODE solver. The lower bound for the independent variable in `solext` is the same as in `sol`. If you created `sol` with an ODE solver other than `ode15i`, the function `odefun` computes the right-hand side of the ODE equation, which is of the form  $y' = f(t,y)$ . If you created `sol` using `ode15i`, the function `odefun` computes the left-hand side of the ODE equation, which is of the form  $f(t,y,y') = 0$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, if necessary.

`odextend` extends the solution by integrating `odefun` from the upper bound for the independent variable in `sol` to `tfinal`, using the same ODE solver that created `sol`. By default, `odextend` uses

- The initial conditions `y = sol.y(:,end)` for the subsequent integration
- The same integration properties and additional input arguments the ODE solver originally used to compute `sol`. This information is stored as part of the solution structure `sol` and is subsequently passed to `solext`. Unless you want to change these values, you do not need to pass them to `odextend`.

`solext = odextend(sol, [], tfinal)` uses the same ODE function that the ODE solver uses to compute `sol` to extend the solution. It is

# odextend

---

not necessary to pass in `odefun` explicitly unless it differs from the original ODE function.

`solext = odextend(sol, odefun, tfinal, yinit)` uses the column vector `yinit` as new initial conditions for the subsequent integration, instead of the vector `sol.y(end)`.

---

**Note** To extend solutions obtained with `ode15i`, use the following syntax, in which the column vector `ypinit` is the initial derivative of the solution:

---

```
solext = odextend(sol, odefun, tfinal, [yinit, ypinit])
```

---

`solext = odextend(sol, odefun, tfinal, yinit, options)` uses the integration properties specified in `options` instead of the options the ODE solver originally used to compute `sol`. The new options are then stored within the structure `solext`. See `odeset` for details on setting options properties. Set `yinit = []` as a placeholder to specify the default initial conditions.

## Examples

The following command

```
sol=ode45(@vdp1,[0 10],[2 0]);
```

uses `ode45` to solve the system  $y' = \text{vdp1}(t,y)$ , where `vdp1` is an example of an ODE function provided with MATLAB software, on the interval `[0 10]`. Then, the commands

```
sol=odextend(sol,@vdp1,20);  
plot(sol.x,sol.y(1,:));
```

extend the solution to the interval `[0 20]` and plot the first component of the solution on `[0 20]`.

|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Cleanup tasks upon function completion                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Syntax</b>      | <code>cleanupObj = onCleanup(cleanupFun)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | <p><code>cleanupObj = onCleanup(cleanupFun)</code> creates an object that, when destroyed, executes the function <code>cleanupFun</code>. MATLAB implicitly clears all local variables at the termination of a function, whether by normal completion, or a forced exit, such as an error, or <b>Ctrl+C</b>.</p> <p>If you reference or pass <code>cleanupObj</code> outside your function, then <code>cleanupFun</code> does not run when that function terminates. Instead, it runs whenever the MATLAB destroys the object.</p> |

## Input Arguments

### **cleanupFun - Clean-up task**

function handle

Clean-up task, specified as a function handle. Your clean-up function should never rely on variables that are defined outside of the scope of that function.

You can declare any number of `onCleanup` objects in a program file. However, if the clean-up tasks depend on the order of execution, then you should define only one object that calls a script or function, containing the relevant clean-up commands.

You should use an anonymous function handle to call your clean-up task. This allows you to pass arguments to your clean-up function.

**Example:** `@() fclose(file.m)`

**Example:** `@() user_script`

**Example:** `@() function(input)`

### **Data Types**

function\_handle

## Examples

### **Close a File After Executing Function**

Save the following code in `action.m` and type `action` in the Command Window.

```
function [] = action()
    file = fullfile(matlabroot,'help','techdoc','matlab_env',...
        'examples','collatz.m');
    fid = fopen(file);
    finishup = onCleanup(@() fclose(fid));
    disp('Execute code');
    disp('then close file')
end
```

```
Execute code
then close file
```

## Switch Directories After Executing Function

Pass your own script to the `onCleanup` object so that it executes. MATLAB destroys the cleanup object.

Save the following code in `cleanup.m`.

```
cd(matlabroot);
disp('You are now in the MATLAB root directory')
```

Save the following code in `youraction.m` and type `youraction` in the Command Window.

```
function [] = youraction
    changeup = onCleanup(@() cleanup);
    disp('Execute Code');
end
```

```
Execute Code
You are now in the MATLAB root directory
```

## Tips

- If your program contains multiple cleanup objects, MATLAB does not guarantee the order that it destroys these objects.
- If the order of your cleanup functions matters, define one `onCleanup` object for all the tasks.

**See Also**

`clear` | `clearvars` | `function_handle`

**Concepts**

- “Clean Up When Functions Complete”
- “Object Lifecycle”
- “Function Handles”
- “What Are Anonymous Functions?”

**Purpose** Create array of all ones

**Syntax**

```
Y = ones(n)
Y = ones(m,n)
Y = ones([m n])
Y = ones(m,n,p,...)
Y = ones([m n p ...])
Y = ones(size(A))
Y = ones
ones(m, n,...,classname)
ones([m,n,...],classname)
```

**Description** `Y = ones(n)` returns an  $n$ -by- $n$  matrix of 1s. An error message appears if  $n$  is not a scalar.

`Y = ones(m,n)` or `Y = ones([m n])` returns an  $m$ -by- $n$  matrix of ones.

`Y = ones(m,n,p,...)` or `Y = ones([m n p ...])` returns an  $m$ -by- $n$ -by- $p$ -by-... array of 1s.

---

**Note** The size inputs  $m$ ,  $n$ ,  $p$ , ... should be nonnegative integers. Negative integers are treated as 0.

---

`Y = ones(size(A))` returns an array of 1s that is the same size as  $A$ .

`Y = ones` with no arguments is the scalar 1.

`ones(m, n,...,classname)` or `ones([m,n,...],classname)` is an  $m$ -by- $n$ -by-... array of ones of data type `classname`. `classname` is a string specifying the data type of the output. `classname` can have the following values: 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', or 'uint64'.

**Examples** `x = ones(2,3,'int8');`

**See Also** `eye` | `zeros` | `complex` | `true`

**Purpose**

Open file in appropriate application

**Syntax**

```
open(name)  
output = open(name)
```

**Description**

`open(name)` opens the specified file or variable in the appropriate application.

`output = open(name)` returns an empty *output* ([]) for most cases. If opening a MAT-file, *output* is a structure that contains the variables in the file. If opening a figure, *output* is a handle to that figure.

**Tips**

The `open` function opens files based on their extension. You can extend the functionality of `open` by defining your own file handling function of the form `openxxx`, where `xxx` is a file extension. For example, if you create a function `openlog`, the `open` function calls `openlog` to process any files with the `.log` extension. The `open` function returns any single *output* defined by your function.

**Input Arguments****name**

Name of file or variable to open. If *name* does not include an extension, the `open` function:

- 1 Searches for a variable named *name*. If the variable exists, `open` opens it in the Variables editor.
- 2 Searches the MATLAB path for *name*.mdl, *name*.slx, or *name*.m. If *name*.mdl or *name*.slx exists, then `open` opens the model in Simulink. If only *name*.m exists, `open` opens the file in the MATLAB Editor.

If more than one file named *name* exists on the MATLAB path, the `open` function opens the file returned by `which(name)`.

The `open` function performs the following actions based on the file extension:

|               |                                                                                                          |
|---------------|----------------------------------------------------------------------------------------------------------|
| .m            | Open in MATLAB Editor.                                                                                   |
| .mat          | Return variables in structure <i>st</i> when called with the syntax:<br><br><code>st = open(name)</code> |
| .fig          | Open figure in Handle Graphics.                                                                          |
| .mdl or .slx  | Open model in Simulink.                                                                                  |
| .prj          | Open project in the MATLAB Compiler Deployment Tool.                                                     |
| .doc*         | Open document in Microsoft Word.                                                                         |
| .exe          | Run executable file (only on Windows systems).                                                           |
| .pdf          | Open document in Adobe® Acrobat®.                                                                        |
| .ppt*         | Open document in Microsoft PowerPoint.                                                                   |
| .xls*         | Start MATLAB Import Wizard.                                                                              |
| .htm or .html | Open document in MATLAB browser.                                                                         |
| .url          | Open file in your default Web browser.                                                                   |

## Examples

Open `Contents.m` in the MATLAB Editor by typing:

```
open Contents.m
```

Generally, MATLAB opens `matlabroot\toolbox\matlab\general\Contents.m`. However, if you have a file called `Contents.m` in a directory that is before `toolbox\matlab\general` on the MATLAB path, then `open` opens that file instead.

---

Open a file not on the MATLAB path by including the complete file specification:

```
open('D:\temp\data.mat')
```

If the file does not exist, MATLAB displays an error message.

---

Create a function called `opentxt` to handle files with extension `.txt`:

```
function opentxt(filename)

    fprintf('You have requested file: %s\n', filename);

    wh = which(filename);
    if exist(filename, 'file') == 2
        fprintf('Opening in MATLAB Editor: %s\n', filename);
        edit(filename);
    elseif ~isempty(wh)
        fprintf('Opening in MATLAB Editor: %s\n', wh);
        edit(wh);
    else
        warning('MATLAB:fileNotFound', ...
            'File was not found: %s', filename);
    end

end
```

Open the file `ngc6543a.txt` (a description of `ngc6543a.jpg`, located in `matlabroot\toolbox\matlab\demos`):

```
photo_text = 'ngc6543a.txt';
open(photo_text)
```

`open` calls your function with the following syntax:

```
opentxt(photo_text)
```

## See Also

`edit` | `load` | `openfig` | `openvar` | `path` | `uiopen` | `which` | `winopen`

# VideoWriter.open

---

**Purpose** Open file for writing video data

**Syntax** `open(writerObj)`

**Description** `open(writerObj)` opens the file associated with `writerObj` for writing. When you open the file, all properties of the object become read only. `open` discards any existing contents of the file.

**Input Arguments** **writerObj**  
VideoWriter object created by the `VideoWriter` function.

**Examples** Open a new AVI file:

```
myObj = VideoWriter('newfile.avi');  
open(myObj);
```

**See Also** `writeVideo` | `VideoWriter` | `close`

**Purpose**

Open new copy or raise existing copy of saved figure

**Syntax**

```
openfig('filename.fig')
openfig('filename.fig','new')
openfig('filename.fig','reuse')
openfig('filename.fig','new','invisible')
openfig('filename.fig','reuse','invisible')
openfig('filename.fig','new','visible')
openfig('filename.fig','reuse','visible')
figure_handle = openfig(...)
```

**Description**

`openfig('filename.fig')` and `openfig('filename.fig','new')` opens the figure contained in the FIG-file, `filename.fig`, and ensures it is visible and positioned completely on screen. You do not have to specify the full path to the FIG-file as long as it is on your MATLAB path. The `.fig` extension is optional.

`openfig('filename.fig','reuse')` opens the figure contained in the FIG-file only if a copy of the figure is not currently open. Otherwise, `openfig` brings the existing copy forward, making sure it is still visible and completely on screen.

`openfig('filename.fig','new','invisible')` or `openfig('filename.fig','reuse','invisible')` opens the figure as in the preceding example, while forcing the figure to be invisible.

`openfig('filename.fig','new','visible')` or `openfig('filename.fig','reuse','visible')` opens the figure, while forcing the figure to be visible.

`figure_handle = openfig(...)` returns the handle to the figure.

**Tips**

`openfig` is designed for use with GUI figures. Use this function to:

- Open the FIG-file creating the GUI and ensure it is displayed on screen. This provides compatibility with different screen sizes and resolutions.

# openfig

---

- Control whether the MATLAB software displays one or multiple instances of the GUI at any given time.
- Return the handle of the figure created, which is typically hidden for GUI figures.

If the FIG-file contains an invisible figure, `openfig` returns its handle and leaves it invisible. The caller should make the figure visible when appropriate.

Do not use `openfig` or double-click a FIG-file to open a GUI created with GUIDE. Instead open the GUI code file by typing its name in the command window or by right-clicking its name in the Current Folder Browser and selecting **Run File**. To open a GUIDE GUI, for example one called `guifile.m`, in an invisible state, specify the `Visible` property in your command:

```
guifile('Visible','off')
```

Your code should then make the figure visible at an appropriate time.

## See Also

`guide` | `guihandles` | `movegui` | `open` | `hgload` | `save`

**Purpose** Control OpenGL rendering

**Syntax**

```
opengl info
s = opengl('data')
opengl software
opengl hardware
opengl verbose
opengl quiet
opengl DriverBugWorkaround
opengl('DriverBugWorkaround',WorkaroundState)
```

**Description** The OpenGL autoselection mode applies when the `RendererMode` of the figure is `auto`. Possible values for `selection_mode` are

- `autoselect` – allows OpenGL to be automatically selected if OpenGL is available and if there is graphics hardware on the host machine.
- `neverselect` – disables autoselection of OpenGL.
- `advise` – prints a message to the command window if OpenGL rendering is advised, but `RenderMode` is set to `manual`.

`opengl`, by itself, returns the current autoselection state.

Note that the autoselection state only specifies whether OpenGL should or should not be considered for rendering; it does not explicitly set the rendering to OpenGL. You can do this by setting the `Renderer` property of the figure to `OpenGL`. For example,

```
set(figure_handle,'Renderer','OpenGL')
```

`opengl info` prints information with the version and vendor of the OpenGL on your system. Also indicates whether your system is currently using hardware or software OpenGL and the state of various driver bug workarounds. Note that calling `opengl info` loads the OpenGL Library.

For example, the following output is generated on a Windows XP computer that uses ATI Technologies graphics hardware:

```
>> opengl info
Version          = 1.3.4010 WinXP Release
Vendor           = ATI Technologies Inc.
Renderer         = RADEON 9600SE x86/SSE2
MaxTextureSize  = 2048
Visual           = 05 (RGB 16 bits(05 06 05 00) zdepth 16, Hardware
Accelerated, OpenGL, Double Buffered, Window)
Software         = false
# of Extensions = 85
Driver Bug Workarounds:
OpenGLBitmapZbufferBug   = 0
OpenGLWobbleTesselatorBug = 0
OpenGLLineSmoothingBug   = 0
OpenGLDockingBug         = 0
OpenGLClippedImageBug    = 0
```

Note that different computer systems may not list all OpenGL bugs.

`s = opengl('data')` returns a structure containing the same data that is displayed when you call `opengl info`, with the exception of the driver bug workaround state.

`opengl software` forces the MATLAB software to use software OpenGL rendering instead of hardware OpenGL. Note that Macintosh systems do not support software OpenGL.

`opengl hardware` reverses the `opengl software` command and enables MATLAB to use hardware OpenGL rendering if it is available. If your computer does not have OpenGL hardware acceleration, MATLAB automatically switches to software OpenGL rendering (except on Macintosh systems, which do not support software OpenGL).

Note that on UNIX systems, the `software` or `hardware` options with the `opengl` command works only if MATLAB has not yet used the OpenGL renderer or you have not issued the `opengl info` command (which attempts to load the OpenGL Library).

`opengl verbose` displays verbose messages about OpenGL initialization (if OpenGL is not already loaded) and other runtime messages.

`opengl quiet` disables verbose message setting.

`opengl DriverBugWorkaround` queries the state of the specified driver bug workaround. Use the command `opengl info` to see a list of all driver bug workarounds. See “Driver Bug Workarounds” on page 2-3315 for more information.

`opengl('DriverBugWorkaround',WorkaroundState)` sets the state of the specified driver bug workaround. You can set `WorkaroundState` to one of three values:

- 0 – Disable the specified *DriverBugWorkaround* (if enabled) and do not allow MATLAB to autoselect this workaround.
- 1 – Enable the specified *DriverBugWorkaround*.
- -1 – Set the specified *DriverBugWorkaround* to autoselection mode, which allows MATLAB to enable this workaround if the requisite conditions exist.

## Driver Bug Workarounds

The MATLAB software enables various OpenGL driver bug workarounds when it detects certain known problems with installed hardware. However, because there are many versions of graphics drivers, you might encounter situations when MATLAB does not enable a workaround that would solve a problem you are having with OpenGL rendering.

This section describes the symptoms that each workaround is designed to correct so you can decide if you want to try using one to fix an OpenGL rendering problem.

Use the `opengl info` command to see what driver bug workarounds are available on your computer.

---

**Note** These workarounds have not been tested under all driver combinations and therefore might produce undesirable results under certain conditions.

---

## **OpenGLBitmapZbufferBug**

Symptom: text with background color (including data tips) and text displayed on image, patch, or surface objects is not visible when using OpenGL renderer.

Possible side effect: text is always on top of other objects.

Command to enable:

```
opengl('OpenGLBitmapZbufferBug',1)
```

## **OpenGLWobbleTessellatorBug**

Symptom: Rendering complex patch object causes segmentation violation and returns a tessellator error message in the stack trace.

Command to enable:

```
opengl('OpenGLWobbleTessellatorBug',1)
```

## **OpenGLLineSmoothingBug**

Symptom: Lines with a LineWidth greater than 3 look bad.

Command to enable:

```
opengl('OpenGLLineSmoothingBug',1)
```

## **OpenGLDockingBug**

Symptom: MATLAB crashes when you dock a figure that has its Renderer property set to opengl.

Command to enable:

```
opengl('OpenGLDockingBug',1)
```

**OpenGLClippedImageBug**

Symptom: Images (as well as colorbar displays) do not display when the `Renderer` property is set to `opengl`.

Command to enable:

```
opengl('OpenGLClippedImageBug',1)
```

**OpenGLERaseModeBug**

Symptom: Graphics objects with `EraseMode` property set to non-normal erase modes (`xor`, `none`, or `background`) do not draw when the figure `Renderer` property is set to `opengl`.

Command to enable:

```
opengl('OpenGLERaseModeBug',1)
```

**See Also**

`Renderer`

# openvar

---

**Purpose** Open workspace variable in Variables editor or other graphical editing tool

**Syntax** `openvar(varname)`

**Description** `openvar(varname)` opens the workspace variable named by the string, `varname`, in the Variables editor for graphical editing. Changes that you make to variables in the Variables editor occur in the workspace as soon as you enter them.

In some toolboxes, `openvar` opens a tool appropriate for viewing or editing objects indicated by `varname` instead of opening the Variables editor.

MATLAB does not impose any limitation on the size of a variable that you can open in the Variables editor. However, your operating system or the amount of physical memory installed on your computer can impose such limits.

## Input Arguments

### **varname - Variable name**

string

Variable name, specified as a string. The named variable can be an array, character string, cell array, structure, or an object and its properties. If the named variable is a multidimensional array, then you can only view the array in the Variables editor, and not edit it.

**Example:** `'myVariable'`

**Example:** `'A'`

## Examples

### **Identify Outliers in a Linked Graph**

Use data brushing to identify observations in a vector or matrix that might warrant further analysis.

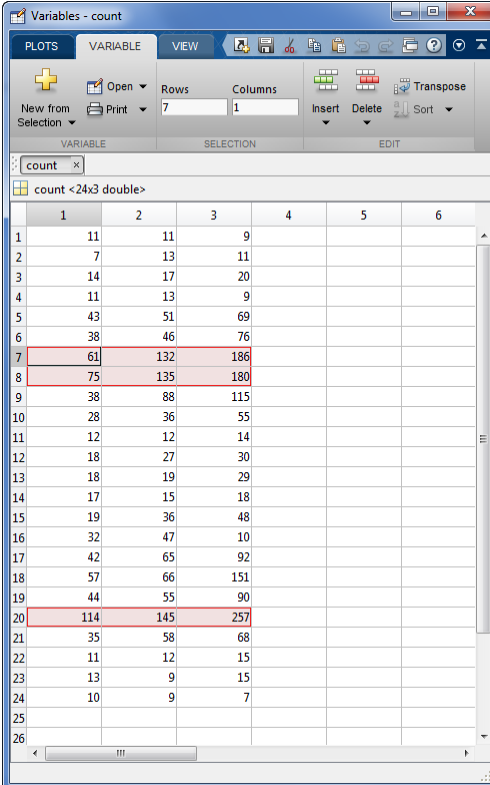

Make a scatter plot of data in the sample MAT-file `count.dat`, and open the variable `count` in the Variables editor.

```
load count.dat
```

```
scatter(count(:,1),count(:,2))  
openvar('count')
```

Right-click a cell in the Variables editor and select **Brushing > Brushing On**. This turns on data brushing in the Variables editor.

Select the rows 7, 8, and 20. (Select noncontiguous rows by holding down the **Ctrl** key and clicking in each row.)

|    | 1   | 2   | 3   | 4 | 5 | 6 |
|----|-----|-----|-----|---|---|---|
| 1  | 11  | 11  | 9   |   |   |   |
| 2  | 7   | 13  | 11  |   |   |   |
| 3  | 14  | 17  | 20  |   |   |   |
| 4  | 11  | 13  | 9   |   |   |   |
| 5  | 43  | 51  | 69  |   |   |   |
| 6  | 38  | 46  | 76  |   |   |   |
| 7  | 61  | 132 | 186 |   |   |   |
| 8  | 75  | 135 | 180 |   |   |   |
| 9  | 38  | 88  | 115 |   |   |   |
| 10 | 28  | 36  | 55  |   |   |   |
| 11 | 12  | 12  | 14  |   |   |   |
| 12 | 18  | 27  | 30  |   |   |   |
| 13 | 18  | 19  | 29  |   |   |   |
| 14 | 17  | 15  | 18  |   |   |   |
| 15 | 19  | 36  | 48  |   |   |   |
| 16 | 32  | 47  | 10  |   |   |   |
| 17 | 42  | 65  | 92  |   |   |   |
| 18 | 57  | 66  | 151 |   |   |   |
| 19 | 44  | 55  | 90  |   |   |   |
| 20 | 114 | 145 | 257 |   |   |   |
| 21 | 35  | 58  | 68  |   |   |   |
| 22 | 11  | 12  | 15  |   |   |   |
| 23 | 13  | 9   | 15  |   |   |   |
| 24 | 10  | 9   | 7   |   |   |   |
| 25 |     |     |     |   |   |   |
| 26 |     |     |     |   |   |   |

In the Figure window with the scatter plot, click **Brush/Select Data**  to enable data brushing, and **Link Plot**  to enable data linking.

The data observations you brushed in the Variables editor appear highlighted in the scatter plot.

As long as data linking is enabled in the figure, observations that you brush in the scatter plot are highlighted in the Variables editor. When a figure is not linked to its data sources, you can still brush its graphs and you can brush the same data in the Variables editor, but only the display that you brush responds by highlighting.

## Tips

- As an alternative to the `openvar` function, double-click a variable in the Workspace browser.

## Purpose

Optimization options values

## Syntax

```
val = optimget(options,'param')
val = optimget(options,'param',default)
```

## Description

`val = optimget(options,'param')` returns the value of the specified parameter in the optimization options structure `options`. You need to type only enough leading characters to define the parameter name uniquely. Case is ignored for parameter names.

`val = optimget(options,'param',default)` returns `default` if the specified parameter is not defined in the optimization options structure `options`. Note that this form of the function is used primarily by other optimization functions.

## Examples

This statement returns the value of the `Display` optimization options parameter in the structure called `my_options`.

```
val = optimget(my_options,'Display')
```

This statement returns the value of the `Display` optimization options parameter in the structure called `my_options` (as in the previous example) except that if the `Display` parameter is not defined, it returns the value `'final'`.

```
optnew = optimget(my_options,'Display','final');
```

## See Also

`optimset` | `fminbnd` | `fminsearch` | `fzero` | `lsqnonneg`

# optimset

---

**Purpose** Create or edit optimization options structure

**Syntax**

```
options = optimset('param1',value1,'param2',value2,...)
optimset
options = optimset
options = optimset(optimfun)
options = optimset(olddopts,'param1',value1,...)
options = optimset(olddopts,newopts)
```

**Description** The function `optimset` creates an options structure that you can pass as an input argument to the following four MATLAB optimization functions:

- `fminbnd`
- `fminsearch`
- `fzero`
- `lsqnonneg`

You can use the `options` structure to change the default parameters for these functions.

---

**Note** If you have an Optimization Toolbox™ license, you can also use `optimset` to create an expanded options structure containing additional options specifically designed for the functions provided in that toolbox. For more information about these additional options, see the reference page for the enhanced Optimization Toolbox `optimset` function.

---

`options = optimset('param1',value1,'param2',value2,...)` creates an optimization options structure called `options`, in which the specified parameters (`param`) have specified values. Any unspecified parameters are set to `[]` (parameters with value `[]` indicate to use the default value for that parameter when `options` is passed to the optimization function). It is sufficient to type only enough leading

characters to define the parameter name uniquely. Case is ignored for parameter names.

`optimset` with no input or output arguments displays a complete list of parameters with their valid values.

`options = optimset` (with no input arguments) creates an options structure `options` where all fields are set to `[]`.

`options = optimset(optimfun)` creates an options structure `options` with all parameter names and default values relevant to the optimization function `optimfun`.

`options = optimset(olddopts, 'param1', value1, ...)` creates a copy of `olddopts`, modifying the specified parameters with the specified values.

`options = optimset(olddopts, newopts)` combines an existing options structure `olddopts` with a new options structure `newopts`. Any parameters in `newopts` with nonempty values overwrite the corresponding old parameters in `olddopts`.

## Options

The following table lists the available options for the MATLAB optimization functions.

| Option  | Value                                          | Description                                                                                                                                                                                                | Solvers                                                                                            |
|---------|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| Display | 'off'  <br>'iter'  <br>{'final'}  <br>'notify' | Level of display. 'off' displays no output; 'iter' displays output at each iteration (not available for <code>lsqnonneg</code> ); 'final' displays just the final output; 'notify' displays output only if | <code>fminbnd</code> ,<br><code>fminsearch</code> , <code>fzero</code> ,<br><code>lsqnonneg</code> |

# optimset

| Option      | Value            | Description                                                                                                                                                                                                                                                                                                       | Solvers                    |
|-------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------|
|             |                  | the function does not converge.                                                                                                                                                                                                                                                                                   |                            |
| FunValCheck | 'off'   'on'     | Check whether objective function values are valid. 'on' displays an error when the objective function returns a value that is complex or NaN. 'off' displays no error.                                                                                                                                            | fminbnd, fminsearch, fzero |
| MaxFunEvals | positive integer | Maximum number of function evaluations allowed.                                                                                                                                                                                                                                                                   | fminbnd, fminsearch        |
| MaxIter     | positive integer | Maximum number of iterations allowed.                                                                                                                                                                                                                                                                             | fminbnd, fminsearch        |
| OutputFcn   | function   {}    | User-defined function that an optimization function calls at each iteration.                                                                                                                                                                                                                                      | fminbnd, fminsearch, fzero |
| PlotFcns    | function   {}    | User-defined or built-in plot function that an optimization function calls at each iteration.<br>Built-in functions: <ul style="list-style-type: none"> <li>• @optimplotx plots the current point</li> <li>• @optimplotfval plots the function value</li> <li>• @optimplotfunccount plots the function</li> </ul> | fminbnd, fminsearch, fzero |

| Option | Value           | Description                                       | Solvers                               |
|--------|-----------------|---------------------------------------------------|---------------------------------------|
|        |                 | count (not available for fzero)                   |                                       |
| TolFun | positive scalar | Termination tolerance on the function value.      | fminsearch                            |
| TolX   | positive scalar | Termination tolerance on $x$ , the current point. | fminbnd, fminsearch, fzero, lsqnonneg |

## Examples

This statement creates an optimization options structure called `options` in which the `Display` parameter is set to `'iter'` and the `TolFun` parameter is set to `1e-8`.

```
options = optimset('Display','iter','TolFun',1e-8)
```

This statement makes a copy of the options structure called `options`, changing the value of the `TolX` parameter and storing new values in `optnew`.

```
optnew = optimset(options,'TolX',1e-4);
```

This statement returns an optimization options structure that contains all the parameter names and default values relevant to the function `fminbnd`.

```
optimset('fminbnd')
```

**Purpose** Find logical OR of array or scalar inputs

**Syntax** `A | B | ...`  
`or(A, B)`

**Description** `A | B | ...` performs a logical OR of all input arrays A, B, etc., and returns an array containing elements set to either logical 1 (true) or logical 0 (false). An element of the output array is set to 1 if any input arrays contain a nonzero element at that same array location. Otherwise, that element is set to 0.

Each input of the expression can be an array or can be a scalar value. All nonscalar input arrays must have equal dimensions. If one or more inputs are an array, then the output is an array of the same dimensions. If all inputs are scalar, then the output is scalar.

If the expression contains both scalar and nonscalar inputs, then each scalar input is treated as if it were an array having the same dimensions as the other input arrays. In other words, if input A is a 3-by-5 matrix and input B is the number 1, then B is treated as if it were a 3-by-5 matrix of ones.

`or(A, B)` is called for the syntax `A | B` when either A or B is an object.

---

**Note** The symbols `|` and `||` perform different operations in a MATLAB application. The element-wise OR operator described here is `|`. The short-circuit OR operator is `||`.

---

## Examples

If matrix A is

|        |        |        |        |        |
|--------|--------|--------|--------|--------|
| 0.4235 | 0.5798 | 0      | 0.7942 | 0      |
| 0.5155 | 0      | 0      | 0      | 0.8744 |
| 0      | 0      | 0      | 0.4451 | 0.0150 |
| 0.4329 | 0.6405 | 0.6808 | 0      | 0      |

and matrix B is

```
0 1 0 1 0
1 1 0 0 1
0 0 0 1 0
0 1 0 0 1
```

then

```
A | B
ans =
1 1 0 1 0
1 1 0 0 1
0 0 0 1 1
1 1 1 0 1
```

- logical operators

# ordeig

---

**Purpose** Eigenvalues of quasitriangular matrices

**Syntax** `E = ordeig(T)`  
`E = ordeig(AA,BB)`

**Description** `E = ordeig(T)` takes a quasitriangular Schur matrix `T`, typically produced by `schur`, and returns the vector `E` of eigenvalues in their order of appearance down the diagonal of `T`.

`E = ordeig(AA,BB)` takes a quasitriangular matrix pair `AA` and `BB`, typically produced by `qz`, and returns the generalized eigenvalues in their order of appearance down the diagonal of `AA -  $\lambda$ *BB`.

`ordeig` is an order-preserving version of `eig` for use with `ordschur` and `ordqz`. It is also faster than `eig` for quasitriangular matrices.

## Examples **Example 1**

```
T=diag([1 -1 3 -5 2]);
```

`ordeig(T)` returns the eigenvalues of `T` in the same order they appear on the diagonal.

```
ordeig(T)
```

```
ans =
```

```
    1  
   -1  
    3  
   -5  
    2
```

`eig(T)`, on the other hand, returns the eigenvalues in order of increasing magnitude.

```
eig(T)
```

```
ans =
```

```
-5
-1
 1
 2
 3
```

### Example 2

```
A = rand(10);
[U, T] = schur(A);
abs(ordeig(T))
```

```
ans =
```

```

schur | qz | ordschur | ordqz | eig

**Purpose** Order fields of structure array

**Syntax**

```
s = orderfields(s1)
s = orderfields(s1, s2)
s = orderfields(s1, c)
s = orderfields(s1, perm)
[s, perm] = orderfields(...)
```

**Description**

`s = orderfields(s1)` orders the fields in `s1` so that the new structure array `s` has field names in ASCII dictionary order.

`s = orderfields(s1, s2)` orders the fields in `s1` so that the new structure array `s` has field names in the same order as those in `s2`. Structures `s1` and `s2` must have the same fields.

`s = orderfields(s1, c)` orders the fields in `s1` so that the new structure array `s` has field names in the same order as those in the cell array of field name strings `c`. Structure `s1` and cell array `c` must contain the same field names.

`s = orderfields(s1, perm)` orders the fields in `s1` so that the new structure array `s` has fieldnames in the order specified by the indices in permutation vector `perm`.

If `s1` has `N` fieldnames, the elements of `perm` must be an arrangement of the numbers from 1 to `N`. This is particularly useful if you have more than one structure array that you would like to reorder in the same way.

`[s, perm] = orderfields(...)` returns a permutation vector representing the change in order performed on the fields of the structure array that results in `s`.

**Tips** `orderfields` only orders top-level fields. It is not recursive.

**Examples** Create a structure `s`. Then create a new structure from `s`, but with the fields ordered alphabetically:

```
s = struct('b', 2, 'c', 3, 'a', 1)
s =
```

# orderfields

---

```
b: 2  
c: 3  
a: 1
```

```
snew = orderfields(s)  
snew =  
  a: 1  
  b: 2  
  c: 3
```

Arrange the fields of `s` in the order specified by the second (cell array) argument of `orderfields`. Return the new structure in `snew` and the permutation vector used to create it in `perm`:

```
[snew, perm] = orderfields(s, {'b', 'a', 'c'})  
snew =  
  b: 2  
  a: 1  
  c: 3  
perm =  
  1  
  3  
  2
```

Now create a new structure, `s2`, having the same fieldnames as `s`. Reorder the fields using the permutation vector returned in the previous operation:

```
s2 = struct('b', 3, 'c', 7, 'a', 4)  
s2 =  
  b: 3  
  c: 7  
  a: 4  
  
snew = orderfields(s2, perm)  
snew =  
  b: 3  
  a: 4
```

c: 7

## How To

- dynamic field names

**Purpose** Reorder eigenvalues in QZ factorization

**Syntax**  
[AAS,BBS,QS,ZS] = ordqz(AA,BB,Q,Z,select)  
[...] = ordqz(AA,BB,Q,Z,keyword)  
[...] = ordqz(AA,BB,Q,Z,clusters)

**Description** [AAS,BBS,QS,ZS] = ordqz(AA,BB,Q,Z,select) reorders the QZ factorizations  $Q^*A^*Z = AA$  and  $Q^*B^*Z = BB$  produced by the qz function for a matrix pair (A,B). It returns the reordered pair (AAS,BBS) and the cumulative orthogonal transformations QS and ZS such that  $QS^*A^*ZS = AAS$  and  $QS^*B^*ZS = BBS$ . In this reordering, the selected cluster of eigenvalues appears in the leading (upper left) diagonal blocks of the quasitriangular pair (AAS,BBS), and the corresponding invariant subspace is spanned by the leading columns of ZS. The logical vector `select` specifies the selected cluster as  $E(\text{select})$  where E is the vector of eigenvalues as they appear along the diagonal of  $AA^{-1}BB$ .

---

**Note** To extract E from AA and BB, use `ordeig(BB)`, instead of `eig`. This ensures that the eigenvalues in E occur in the same order as they appear on the diagonal of  $AA^{-1}BB$ .

---

[...] = ordqz(AA,BB,Q,Z,keyword) sets the selected cluster to include all eigenvalues in the region specified by keyword:

| keyword | Selected Region                               |
|---------|-----------------------------------------------|
| 'lhp'   | Left-half plane ( $\text{real}(E) < 0$ )      |
| 'rhp'   | Right-half plane ( $\text{real}(E) > 0$ )     |
| 'udi'   | Interior of unit disk ( $\text{abs}(E) < 1$ ) |
| 'udo'   | Exterior of unit disk ( $\text{abs}(E) > 1$ ) |

[...] = ordqz(AA,BB,Q,Z,clusters) reorders multiple clusters at once. Given a vector `clusters` of cluster indices commensurate with  $E = \text{ordeig}(AA,BB)$ , such that all eigenvalues with the same `clusters`

value from one cluster, `ordqz` sorts the specified clusters in descending order along the diagonal of  $(AAS, BBS)$ . The cluster with highest index appears in the upper left corner.

**See Also**

`ordeig` | `ordschur` | `qz`

# ordschur

---

**Purpose** Reorder eigenvalues in Schur factorization

**Syntax**  
[US,TS] = ordschur(U,T,select)  
[US,TS] = ordschur(U,T,keyword)  
[US,TS] = ordschur(U,T,clusters)

**Description** [US,TS] = ordschur(U,T,select) reorders the Schur factorization  $X = U*U^*U'$  produced by the schur function and returns the reordered Schur matrix TS and the cumulative orthogonal transformation US such that  $X = US*TS*US'$ . In this reordering, the selected cluster of eigenvalues appears in the leading (upper left) diagonal blocks of the quasitriangular Schur matrix TS, and the corresponding invariant subspace is spanned by the leading columns of US. The logical vector `select` specifies the selected cluster as  $E(\text{select})$  where  $E$  is the vector of eigenvalues as they appear along  $T$ 's diagonal.

---

**Note** To extract  $E$  from  $T$ , use  $E = \text{ordeig}(T)$ , instead of  $\text{eig}$ . This ensures that the eigenvalues in  $E$  occur in the same order as they appear on the diagonal of  $TS$ .

---

[US,TS] = ordschur(U,T,keyword) sets the selected cluster to include all eigenvalues in one of the following regions:

| keyword | Selected Region                               |
|---------|-----------------------------------------------|
| 'lhp'   | Left-half plane ( $\text{real}(E) < 0$ )      |
| 'rhp'   | Right-half plane ( $\text{real}(E) > 0$ )     |
| 'udi'   | Interior of unit disk ( $\text{abs}(E) < 1$ ) |
| 'udo'   | Exterior of unit disk ( $\text{abs}(E) > 1$ ) |

[US,TS] = ordschur(U,T,clusters) reorders multiple clusters at once. Given a vector `clusters` of cluster indices, commensurate with  $E = \text{ordeig}(T)$ , and such that all eigenvalues with the same `clusters` value form one cluster, `ordschur` sorts the specified clusters

in descending order along the diagonal of  $TS$ , the cluster with highest index appearing in the upper left corner.

ordeig | ordqz | schur

# orient

---

**Purpose** Hardcopy paper orientation

**Alternatives** Use **File** → **Print Preview** on the figure window menu to directly manipulate print layout, paper size, headers, fonts and other properties when printing figures. For details, see Using Print Preview in the MATLAB Graphics documentation.

**Syntax**

```
orient
orient landscape
orient portrait
orient tall
orient(fig_handle), orient(simulink_model)
orient(fig_handle,orientation), orient(simulink_model,
    orientation)
```

**Description** `orient` returns a string with the current paper orientation: `portrait`, `landscape`, or `tall`.

`orient landscape` sets the paper orientation of the current figure to full-page landscape, orienting the longest page dimension horizontally. The figure is centered on the page and scaled to fit the page with a 0.25 inch border.

`orient portrait` sets the paper orientation of the current figure to portrait, orienting the longest page dimension vertically. The `portrait` option returns the page orientation to the MATLAB default. (Note that the result of using the `portrait` option is affected by changes you make to figure properties. See the "Algorithm" section for more specific information.)

`orient tall` maps the current figure to the entire page in portrait orientation, leaving a 0.25 inch border.

`orient(fig_handle)`, `orient(simulink_model)` returns the current orientation of the specified figure or Simulink model.

`orient(fig_handle,orientation)`,  
`orient(simulink_model,orientation)` sets the orientation for

the specified figure or Simulink model to the specified orientation (landscape, portrait, or tall).

## Algorithms

`orient` sets the `PaperOrientation`, `PaperPosition`, and `PaperUnits` properties of the current figure. Subsequent print operations use these properties. The result of using the `portrait` option can be affected by default property values as follows:

- If the current figure `PaperType` is the same as the default figure `PaperType` and the default figure `PaperOrientation` has been set to `landscape`, then the `orient portrait` command uses the current values of `PaperOrientation` and `PaperPosition` to place the figure on the page.
- If the current figure `PaperType` is the same as the default figure `PaperType` and the default figure `PaperOrientation` has been set to `landscape`, then the `orient portrait` command uses the default figure `PaperPosition` with the `x`, `y` and `width`, `height` values reversed (i.e., `[y,x,height,width]`) to position the figure on the page.
- If the current figure `PaperType` is different from the default figure `PaperType`, then the `orient portrait` command uses the current figure `PaperPosition` with the `x`, `y` and `width`, `height` values reversed (i.e., `[y,x,height,width]`) to position the figure on the page.

# orth

---

**Purpose** Range space of matrix

**Syntax** `B = orth(A)`

**Description** `B = orth(A)` returns an orthonormal basis for the range of A. The columns of B span the same space as the columns of A, and the columns of B are orthogonal, so that  $B' * B = \text{eye}(\text{rank}(A))$ . The number of columns of B is the rank of A.

**See Also** `null` | `svd` | `rank`

**Purpose** Optional keyword in switch statement

**Syntax**

```
switch switch_expression
    case case_expression
        statements
    case case_expression
        statements
    :
    otherwise
        statements
end
```

**Description** A switch block conditionally executes one set of statements from several choices. Each choice is a case.

An evaluated *switch\_expression* is a scalar or string. An evaluated *case\_expression* is a scalar, a string, or a cell array of scalars or strings. The switch block tests each case until one of the cases is true. A case is true when:

- For numbers, `eq(case_expression,switch_expression)`.
- For strings, `strcmp(case_expression,switch_expression)`.
- For objects that support the eq function, `eq(case_expression,switch_expression)`.
- For a cell array *case\_expression*, at least one of the elements of the cell array matches *switch\_expression*, as defined above for numbers, strings, and objects.

When a case is true, MATLAB executes the corresponding statements, and then exits the switch block.

*otherwise* is optional, and executes only when no case is true.

For more information, see the switch reference page.

# otherwise

---

## Examples

Decide which plot to create based on the value of the string `plottype`:

```
x = [12, 64, 24];
plottype = 'pie3';

switch plottype
    case 'bar'
        bar(x)
        title('Bar Graph')
    case {'pie', 'pie3'}
        pie3(x)
        title('Pie Chart')
        legend('First', 'Second', 'Third')
    otherwise
        warning('Unexpected plot type. No plot created.');
```

## See Also

`switch` | `end` | `if` | `for` | `while`

**Purpose**

Consolidate workspace memory

**Syntax**

```
pack
pack filename
pack('filename')
```

**Description**

`pack` frees up needed space by reorganizing information so that it only uses the minimum memory required. All variables from your base and global workspaces are preserved. Any persistent variables that are defined at the time are set to their default value (the empty matrix, `[]`).

The MATLAB software temporarily stores your workspace data in a file called `tp#####.mat` (where `#####` is a numeric value) that is located in your temporary folder. (You can use the command `dir(tempdir)` to see the files in this folder).

`pack filename` frees space in memory, temporarily storing workspace data in a file specified by `filename`. This file resides in your current working folder and, unless specified otherwise, has a `.mat` file extension.

`pack('filename')` is the function form of `pack`.

**Tips**

You can only run `pack` from the MATLAB command line.

If you specify a `filename` argument, that file must reside in a folder for which you have write permission.

The `pack` function does not affect the amount of memory allocated to the MATLAB process. You must quit MATLAB to free up this memory.

Since MATLAB uses a heap method of memory management, extended MATLAB sessions may cause memory to become fragmented. When memory is fragmented, there may be plenty of free space, but not enough contiguous memory to store a new large variable.

If you get the `Out of memory` message from MATLAB, the `pack` function may find you some free memory without forcing you to delete variables.

The `pack` function frees space by

- Saving all variables in the base and global workspaces to a temporary file.
- Clearing all variables and functions from memory.
- Reloading the base and global workspace variables back from the temporary file and then deleting the file.

If you use `pack` and there is still not enough free memory to proceed, you must clear some variables. If you run out of memory often, you can allocate larger matrices earlier in the MATLAB session and use these system-specific tips:

- When running MATLAB on The Open Group UNIX platforms, ask your system manager to increase your swap space.
- On Microsoft Windows platforms, increase virtual memory using the Windows Control Panel.

To maintain persistent variables when you run `pack`, use `mlock` in the function.

## Examples

Change the current folder to one that is writable, run `pack`, and return to the previous folder.

```
cwd = pwd;  
cd(tempdir);  
pack  
cd(cwd)
```

# pagesetupdlg

**Purpose** Page setup dialog box

**Syntax** `dlg = pagesetupdlg(fig)`

---

**Note** `pagesetupdlg` is not recommended. Use `printpreview` instead.

---

**Description** `dlg = pagesetupdlg(fig)` creates a dialog box from which a set of pagelayout properties for the figure window, `fig`, can be set.

`pagesetupdlg` implements the "Page Setup..." option in the **Figure File Menu**.

`pagesetupdlg` supports setting the layout for a single figure. `fig` must be a single figure handle, not a vector of figures or a simulink diagram.

# pan

---

**Purpose** Pan view of graph interactively

**Syntax**

```
pan on
pan xon
pan yon
pan off
pan
pan(figure_handle,...)
h = pan(figure_handle)
```

**Description**

`pan on` turns on mouse-based panning in the current figure.

`pan xon` turns on panning only in the *x* direction in the current figure.

`pan yon` turns on panning only in the *y* direction in the current figure.

`pan off` turns panning off in the current figure.

`pan` toggles the pan state in the current figure on or off.

`pan(figure_handle,...)` sets the pan state in the specified figure.

`h = pan(figure_handle)` returns the figure's pan *mode object* for the figure *figure\_handle* for you to customize the mode's behavior.

## Using Pan Mode Objects

Access the following properties of pan mode objects via `get` and modify some of them using `set`:

- *Enable* 'on' | 'off' — Specifies whether this figure mode is currently enabled on the figure
- *Motion* 'horizontal' | 'vertical' | 'both' — The type of panning enabled for the figure
- *FigureHandle* <handle> — The associated figure handle, a read-only property that cannot be set

## Pan Mode Callbacks

You can program the following callbacks for pan mode operations.

- **ButtonDownFilter** <function\_handle> — Function to intercept ButtonDown events

The application can inhibit the panning operation under circumstances the programmer defines, depending on what the callback returns. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function [res] = myfunction(obj,event_obj)
% obj          handle to the object that has been clicked on
% event_obj    event data (empty in this release)
% res [output] a logical flag to determine whether the pan
%              operation should take place(for 'res' set to 'false'
%              or the 'ButtonDownFcn' property of the object should
%              take precedence (when 'res' is 'true'))
```

- **ActionPreCallback** <function\_handle> — Function to execute before panning

Set this callback to if you need to execute code when a pan operation begins. The function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function myfunction(obj,event_obj)
% obj          handle to the figure that has been clicked on
% event_obj    object containing struct of event data
```

The event data struct has the following field:

|      |                                             |
|------|---------------------------------------------|
| Axes | The handle of the axes that is being panned |
|------|---------------------------------------------|

- **ActionPostCallback** <function\_handle> — Function to execute after panning

Set this callback if you need to execute code when a pan operation ends. The function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function myfunction(obj,event_obj)
% obj          handle to the figure that has been clicked on
% event_obj    object containing struct of event data (same as the
%              event data of the 'ActionPreCallback' callback)
```

## Pan Mode Utility Functions

The following functions in pan mode query and set certain of its properties.

- `flags = isAllowAxesPan(h,axes)` — Function querying permission to pan axes

Calling the function `isAllowAxesPan` on the pan object, `h`, with a vector of axes handles, `axes`, as input returns a logical array of the same dimension as the axes handle vector, which indicates whether a pan operation is permitted on the axes objects.

- `setAllowAxesPan(h,axes,flag)` — Function to set permission to pan axes

Calling the function `setAllowAxesPan` on the pan object, `h`, with a vector of axes handles, `axes`, and a logical scalar, `flag`, either allows or disallows a pan operation on the axes objects.

- `info = getAxesPanMotion(h,axes)` — Function to get style of pan operations

Calling the function `getAxesPanMotion` on the pan object, `h`, with a vector of axes handles, `axes`, as input will return a character cell array of the same dimension as the axes handle vector, which indicates the type of pan operation for each axes. Possible values for the type of operation are 'horizontal', 'vertical' or 'both'.

- `setAxesPanMotion(h,axes,style)` — Function to set style of pan operations

Calling the function `setAxesPanMotion` on the pan object, `h`, with a vector of axes handles, `axes`, and a character array, `style`, sets the style of panning on each axes.

## Examples

### Example 1 – Entering Pan Mode

Plot a graph and turn on Pan mode:

```
plot(magic(10));  
pan on  
% pan on the plot
```

### Example 2 – Constrained Pan

Constrain pan to  $x$ -axis using set:

```
plot(magic(10));  
h = pan;  
set(h,'Motion','horizontal','Enable','on');  
% pan on the plot in the horizontal direction.
```

### Example 3 – Constrained Pan in Subplots

Create four axes as subplots and give each one a different panning behavior:

```
ax1 = subplot(2,2,1);  
plot(1:10);  
h = pan;  
ax2 = subplot(2,2,2);  
plot(rand(3));  
setAllowAxesPan(h,ax2,false);  
ax3 = subplot(2,2,3);  
plot(peaks);  
setAxesPanMotion(h,ax3,'horizontal');  
ax4 = subplot(2,2,4);  
contour(peaks);  
setAxesPanMotion(h,ax4,'vertical');  
% pan on the plots.
```

### **Example 4 – Coding a ButtonDown Callback**

Create a `buttonDown` callback for pan mode objects to trigger. Copy the following code to a new file, execute it, and observe panning behavior:

```
function demo
% Allow a line to have its own 'ButtonDownFcn' callback.
hLine = plot(rand(1,10));
set(hLine,'ButtonDownFcn','disp(''This executes'')');
set(hLine,'Tag','DoNotIgnore');
h = pan;
set(h,'ButtonDownFilter',@mycallback);
set(h,'Enable','on');
% mouse click on the line
%
function [flag] = mycallback(obj,event_obj)
% If the tag of the object is 'DoNotIgnore', then return true.
% Indicate what the target is
disp(['Clicked ' get(obj,'Type') ' object'])
objTag = get(obj,'Tag');
if strcmpi(objTag,'DoNotIgnore')
    flag = true;
else
    flag = false;
end
```

### **Example 5 – Coding Pre- and Post-Callback Behavior**

Create callbacks for pre- and post-`ButtonDown` events for pan mode objects to trigger. Copy the following code to a new file, execute it, and observe panning behavior:

```
function demo
% Listen to pan events
plot(1:10);
h = pan;
set(h,'ActionPreCallback',@myprecallback);
set(h,'ActionPostCallback',@mypostcallback);
set(h,'Enable','on');
```

```
%  
function myprecallback(obj, evd)  
disp('A pan is about to occur.');
```

```
%  
function mypostcallback(obj, evd)  
newLim = get(evd.Axes, 'XLim');  
msgbox(sprintf('The new X-Limits are [%.2f %.2f].', newLim));
```

### Example 6 – Creating a Context Menu for Pan Mode

Coding a context menu that lets the user to switch to Zoom mode by right-clicking:

```
figure; plot(magic(10));  
hCM = uicontextmenu;  
hMenu = uimenu('Parent', hCM, 'Label', 'Switch to zoom', ...  
              'Callback', 'zoom(gcf, 'on')');
```

```
hPan = pan(gcf);  
set(hPan, 'UIContextMenu', hCM);  
pan('on')
```

You cannot add items to the built-in pan context menu, but you can replace it with your own.

### Tips

You can create a pan mode object once and use it to customize the behavior of different axes, as Example 3 illustrates. You can also change its callback functions on the fly.

---

**Note Do not change figure callbacks within an interactive mode.** While a mode is active (when panning, zooming, etc.), you will receive a warning if you attempt to change any of the figure’s callbacks and the operation will not succeed. The one exception to this rule is the figure `WindowButtonMotionFcn` callback, which can be changed from within a mode. Therefore, if you are creating a GUI that updates a figure’s callbacks, the GUI should some keep track of which interactive mode is active, if any, before attempting to do this.

---

When you assign different pan behaviors to different subplot axes via a mode object and then link them using the `linkaxes` function, the behavior of the axes you manipulate with the mouse carries over to the linked axes, regardless of the behavior you previously set for the other axes.

## Alternatives

Use the **Pan** tool  on the figure toolbar to enable and disable pan mode on a plot, or select **Pan** from the figure’s **Tools** menu. For details, see “Panning — Shifting Your View of the Graph”.

## See Also

`zoom` | `linkaxes` | `rotate3d`

**Purpose**

Pareto chart

**Syntax**

```
pareto(Y)
pareto(Y, names)
pareto(Y, X)
H = pareto(...)
```

**Description**

Pareto charts display the values in the vector `Y` as bars drawn in descending order. Values in `Y` must be nonnegative and not include NaNs. Only the first 95% of the cumulative distribution is displayed.

`pareto(Y)` labels each bar with its element index in `Y` and also plots a line displaying the cumulative sum of `Y`.

`pareto(Y, names)` labels each bar with the associated name in the string matrix or cell array `names`.

`pareto(Y, X)` labels each bar with the associated value from `X`.

`pareto(ax, ..)` plots a Pareto chart in existing axes `ax` rather than GCA.

`H = pareto(...)` returns a combination of patch and line object handles.

**Examples**

Examine the cumulative productivity of a group of programmers to see how normal its distribution is:

```
codelines = [200 120 555 608 1024 101 57 687];
coders = ...
{'Fred', 'Ginger', 'Norman', 'Max', 'Julia', 'Wally', 'Heidi', 'Pat'};
pareto(codelines, coders)
title('Lines of Code by Programmer')
```

# pareto

---

---

Generate a vector, X, representing diagnostic codes with values from 1 to 10 indicating various faults on devices emerging from a production line:

```
X = min(round(abs(randn(100,1)*4))+1,10);
```

Plot a Pareto chart showing the frequency of failure for each diagnostic code from the most to the least common:

```
pareto(hist(X))
```

### Tips

You can use `pareto` to display the output of `hist`, even for vectors that include negative numbers. Because only the first 95 percent of values are displayed, one or more of the smallest bars may not appear. If you extend the `Xlim` of your chart, you can display all the values, but the new bars will not be labeled.

You cannot place datatips (use the `Datacursor` tool) on graphs created with `pareto`.

# pareto

# inputParser.parse

---

|                        |                                                                                                                                                                                                             |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>         | Parse function inputs                                                                                                                                                                                       |
| <b>Syntax</b>          | parse(p, argList)                                                                                                                                                                                           |
| <b>Description</b>     | parse(p, argList) parses and validates the inputs in arglist.                                                                                                                                               |
| <b>Input Arguments</b> | <b>p</b><br>Object of class inputParser.<br><b>argList</b><br>Comma separated list of inputs to parse and validate for your custom function. The class of each input depends upon your function definition. |

## Examples **Input Parsing**

Parse and validate required and optional function inputs.

Create a custom function with required and optional inputs in the file findArea.m.

```
function a = findArea(width,varargin)
    p = inputParser;
    defaultHeight = 1;
    defaultUnits = 'inches';
    defaultShape = 'rectangle';
    expectedShapes = {'square','rectangle','parallelogram'};

    addRequired(p,'width',@isnumeric);
    addOptional(p,'height',defaultHeight,@isnumeric);
    addParamValue(p,'units',defaultUnits);
    addParamValue(p,'shape',defaultShape,...
        @(x) any(validatestring(x,expectedShapes)));

    parse(p,width,varargin{:});
    a = p.Results.width .* p.Results.height;
```

The input parser checks whether `width` and `height` are numeric, and whether the `shape` matches a string in cell array `expectedShapes`. `@` indicates a function handle, and the syntax `@(x)` creates an anonymous function with input `x`.

Call the function with inputs that do not match the scheme. For example, specify a nonnumeric value for the `width` input:

```
findArea('text')
```

```
Error using findArea (line 14)  
Argument 'width' failed validation isnumeric.
```

Specify an unsupported value for `shape`:

```
findArea(4, 'shape', 'circle')
```

```
Error using findArea (line 14)  
Argument 'shape' failed validation with error:  
Expected input to match one of these strings:
```

```
square, rectangle, parallelogram
```

The input, 'circle', did not match any of the valid strings.

# parseSoapResponse

---

**Purpose** Convert response string from SOAP server into MATLAB types

**Syntax** parseSoapResponse(response)

**Description** parseSoapResponse(response) extracts data from response a string returned by a SOAP server from the callSoapService function, and converts it to appropriate MATLAB classes (types).

**Examples** This example uses parseSoapResponse in conjunction with other SOAP functions to retrieve information about books from a library database, specifically, the author's name for a given book title.

---

**Note** The example does not use an actual endpoint; therefore, you cannot run it. The example only illustrates how to use the SOAP functions.

---

```
% Create the message:
message = createSoapMessage(...
    'urn:LibraryCatalog',...
    'getAuthor',...
    {'In the Fall'},...
    {'nameToLookUp'},...
    {'{http://www.w3.org/2001/XMLSchema}string'},...
    'rpc');
%
% Send the message to the service and get the response:
response = callSoapService(...
    'http://test/soap/services/LibraryCatalog',...
    'urn:LibraryCatalog#getAuthor',...
    message)
%
% Extract MATLAB data from the response
author = parseSoapResponse(response)
```

MATLAB returns:

```
author = Kate Alvin
```

where author is a char class (type).

# pascal

---

**Purpose** Pascal matrix

**Syntax**  
A = pascal(n)  
A = pascal(n,1)  
A = pascal(n,2)

**Description** A = pascal(n) returns the Pascal matrix of order n: a symmetric positive definite matrix with integer entries taken from Pascal's triangle. The inverse of A has integer entries.

A = pascal(n,1) returns the lower triangular Cholesky factor (up to the signs of the columns) of the Pascal matrix. It is *involutary*, that is, it is its own inverse.

A = pascal(n,2) returns a transposed and permuted version of pascal(n,1). A is a cube root of the identity matrix.

**Examples** pascal(4) returns

```
1    1    1    1
1    2    3    4
1    3    6   10
1    4   10   20
```

A = pascal(3,2) produces

```
A =
    1    1    1
   -2   -1    0
    1    0    0
```

**See Also** chol

**Purpose**

Create one or more filled polygons

**Syntax**

```
patch(X,Y,C)
patch(X,Y,Z,C)
patch(FV)
patch(X,Y,C, 'PropertyName',propertyvalue...)
patch('PropertyName',propertyvalue,...)
handle = patch(...)
```

**Properties**

For a list of properties, see [Patch Properties](#).

**Description**

`patch(X,Y,C)` adds a filled 2-D patch object to the current axes. A patch object is one or more polygons defined by the coordinates of its vertices. The elements of `X` and `Y` specify the vertices of a polygon. If `X` and `Y` are `m`-by-`n` matrices, MATLAB draws `n` polygons with `m` vertices. `C` determines the color of the patch. For more information on color input requirements, see “Coloring Patches” on page 2-3369.

MATLAB does not require each face to have the same number of vertices. In cases where they do not, pad the end of the `Faces` matrix with NaNs. To define a patch with faces that do not close, add one or more NaNs to the row in the `Vertices` matrix that defines the vertex you do not want connected.

See “Introduction to Patch Objects” for more information on using patch objects.

`patch(X,Y,Z,C)` creates a patch in 3-D coordinates. If the coordinate data does not define closed polygons, `patch` closes the polygons. The data can define concave or intersecting polygons. However, if the edges of an individual patch face intersect themselves, the resulting face might be only partly filled. In that case, it is better to divide the face into smaller polygons.

`patch(FV)` creates a patch using structure `FV`, which contains the fields `vertices`, `faces`, and optionally `facevertexcdata`. These fields correspond to the `Vertices`, `Faces`, and `FaceVertexCData` patch properties. Specifying only unique vertices and their connection matrix

can reduce the size of the data for patches having many faces. For an example of how to specify patches with this method, see “Specifying Patch Object Shapes” on page 2-3366.

`patch(X,Y,C,'PropertyName',propertyvalue...)` follows the `X`, `Y`, (`Z`), and `C` arguments with property name/property value pairs to specify additional patch properties. For a description of the properties, see [Patch Properties](#). You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see the [set](#) and [get](#) reference pages for examples of how to specify these data types).

`patch('PropertyName',propertyvalue,...)` specifies all properties using property name/property value pairs. This form lets you omit the color specification because MATLAB uses the default face color and edge color unless you explicitly assign a value to the `FaceColor` and `EdgeColor` properties. This form also lets you specify the patch using the `Faces` and `Vertices` properties instead of `x`-, `y`-, and `z`-coordinates. See “Specifying Patch Object Shapes” on page 2-3366 for more information.

`handle = patch(...)` returns the handle of the patch object it creates.

Unlike high-level area creation functions, such as `fill` or `area`, `patch` does not check the settings of the figure and axes `NextPlot` properties. It simply adds the patch object to the current axes.

## Examples

### Specifying Patch Object Shapes

The next two examples create a patch object using two methods:

- Specifying `x`-, `y`-, and `z`-coordinates and color data (`XData`, `YData`, `ZData`, and `CData` properties)
- Specifying vertices, the connection matrix, and color data (`Vertices`, `Faces`, and `FaceVertexCData` properties)

Create five triangular faces, each having three vertices, by specifying the `x`-, `y`-, and `z`-coordinates of each vertex:

```
xdata = [2 2 0 2 5;  
         2 8 2 4 5;
```

```

        8 8 2 4 8];
ydata = [4 4 4 2 0;
        8 4 6 2 2;
        4 0 4 0 0];
zdata = ones(3,5);

% Red numbers denote the vertex indices.
% For this example:
% xindices = [1 4 7 10 13;
%            2 5 8 11 14;
%            3 6 9 12 15];
% Blue numbers denote the face numbers.
patch(xdata,ydata,zdata,'w')

```

Create the five triangular faces, specifying faces and vertices:

% The Vertices property contains the coordinates of each

# patch

---

```
% unique vertex defining the patch. The Faces property
% specifies how to connect these vertices to form each
% face of the patch. More than one face may use a given vertex.
% For this example, five triangles have 11 total vertices,
% instead of 15. Each row contains the x- and y-coordinates
% of each vertex.
verts = [2 4; ...
         2 8; ...
         8 4; ...
         8 0; ...
         0 4; ...
         2 6; ...
         2 2; ...
         4 2; ...
         4 0; ...
         5 2; ...
         5 0 ];

% There are five faces, defined by connecting the
% vertices in the order indicated.
faces = [ ...
         1 2 3; ...
         1 3 4; ...
         5 6 1; ...
         7 8 9; ...
         11 10 4 ];

% Create the patch by specifying the Faces, Vertices,
% and FaceVertexCData properties as well as the
% FaceColor property. Red numbers denote the vertex
% numbers, as defined in faces. Blue indicate face numbers.
p = patch('Faces',faces,'Vertices',verts,'FaceColor','w');
```

```
% Using the previous values for verts and faces, you can
% create the same patch object using a structure:
patchinfo.Vertices = verts;
patchinfo.Faces = faces;
patchinfo.FaceColor = 'w';
```

```
patch(patchinfo);
```

### Coloring Patches

There are many ways to customize your patch objects using colors. The appropriate input depends on:

- Whether you want to change the edge colors
- How you specified the patch faces:
  - Using face/vertex values
  - Using  $x$ -,  $y$ -, and  $z$ -coordinates

The following sections present the various options available.

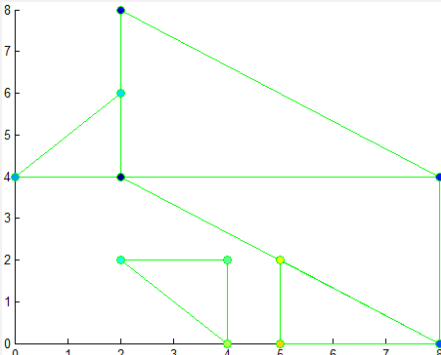

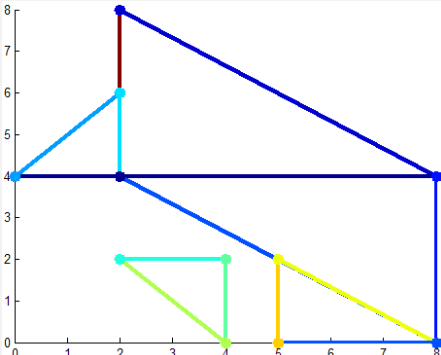

## Specifying Edge Colors

The following options apply to the edge colors of your patch object. The settings are independent of the face colors, but the colors themselves depend on the colors specified at each vertex. Markers show the color at each vertex. Specify the colors using the `EdgeColor` property. To explore the options using the Sample Input Code, create a base patch object:

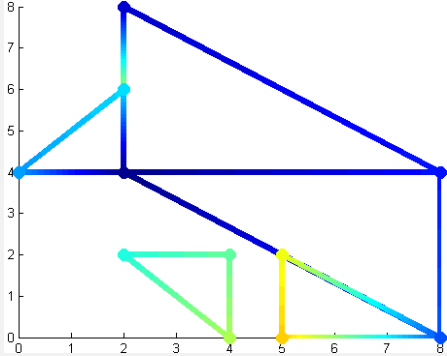

```
xdata = [2     2     0     2     5;  
         2     8     2     4     5;  
         8     8     2     4     8];  
ydata = [4     4     4     2     0;  
         8     4     6     2     2;  
         4     0     4     0     0];  
cdata = [15    0     4     6    10;  
         1     2     5     7     9;  
         2     3     0     8     3];  
p = patch(xdata,ydata,cdata,'Marker','o','MarkerFaceColor','flat','FaceColor','g');
```

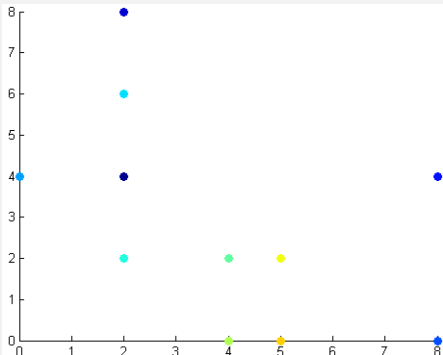

For more detailed information on how the `EdgeColor` property works, see the [Patch Properties](#) page.

| Desired Look                                                                                                    | EdgeColor Value        | Sample Code                           |

### Specifying Face Colors Using Face/Vertex Input Matrices

The following options apply to the face colors of your patch object when you specify the faces using face/vertex input matrices. To explore the options, start with a base patch object:

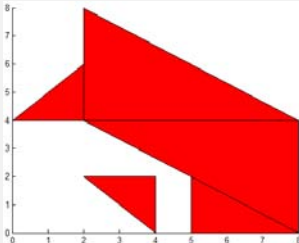

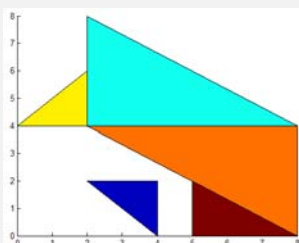

% For this example, there are five triangles ( $m = 5$ ) sharing  
 % eleven unique vertices ( $k = 11$ ).

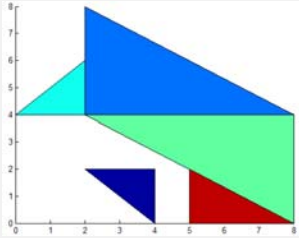

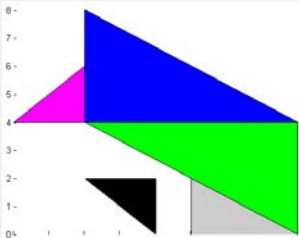

```
verts = [2 4; ...
         2 8; ...
         8 4; ...
         8 0; ...
         0 4; ...
         2 6; ...
         2 2; ...
         4 2; ...
         4 0; ...
         5 2; ...
         5 0 ];
faces = [1 2 3; ...
         1 3 4; ...
         5 6 1; ...
         7 8 9; ...
         11 10 4];
```

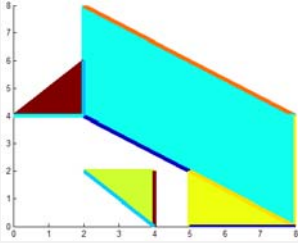

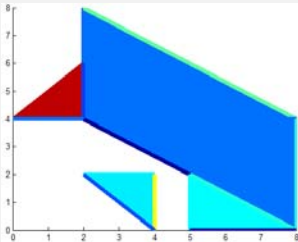

# patch

```
p = patch('Faces',faces,'Vertices',verts,'FaceColor','b');
```

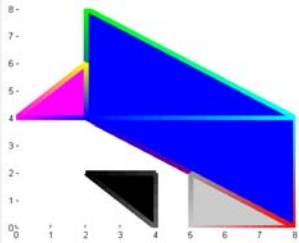

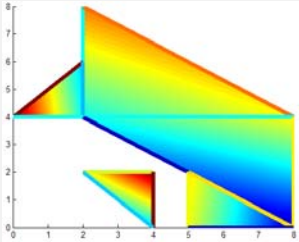

For more information on the relevant properties, see [FaceColor](#), [FaceVertexCData](#), and [CDataMapping](#).

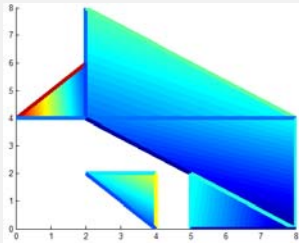

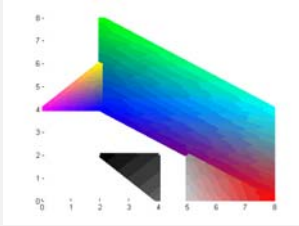

| Desired Look                                                                                                                                                                      | Parameter Values                                                                                                                                                                                                                                                                                                                                                                                                         | Sample Code                                                                                                                                                                          |

### Specifying Face Colors Using x-, y-, and z-Coordinate Input

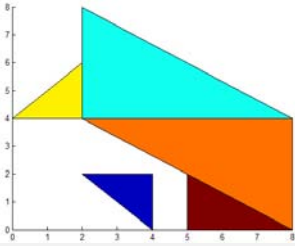

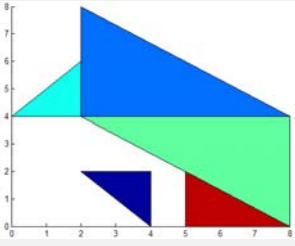

The following options apply to the face colors of your patch object when you specify the faces using x-, y-, and z-coordinates. To explore the options, start with a base patch object:

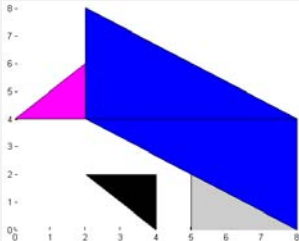

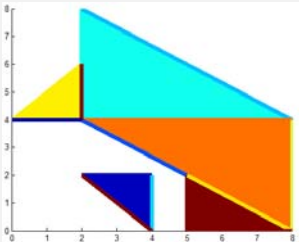

```
% For this example, there are five (m=5) triangles (n=3).
% The total number of vertices is mxn, or k = 15.
xdata = [2 2 0 2 5;
         2 8 2 4 5;
         8 8 2 4 8];
ydata = [4 4 4 2 0;
         8 4 6 2 2;
         4 0 4 0 0];
zdata = ones(3,5);
p = patch(xdata,ydata,zdata,'b')
```

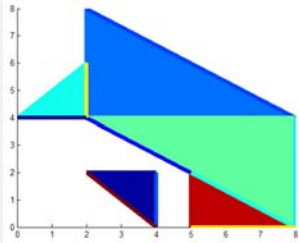

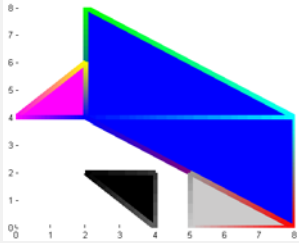

For more information on the relevant properties, see `FaceColor`, `CData`, and `CDataMapping`.

## Tutorials

- “Introduction to Patch Objects”

## Purpose

Patch properties

## Creating Patch Objects

Use patch to create patch objects.

## Modifying Properties

You can set and query graphics object properties in two ways:

- “The Property Editor” is an interactive tool that enables you to see and change object property values.
- The set and get commands enable you to set and query the values of properties.

To change the default values of properties, see “Setting Default Property Values”.

See “Core Graphics Objects” for general information about this type of object.

## Patch Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

AlphaDataMapping  
none | {scaled} | direct

*Transparency mapping method.* Determines how the MATLAB software interprets indexed alpha data.

- none — The transparency values of FaceVertexAlphaData are between 0 and 1 or are clamped to this range.
- scaled — Transform the FaceVertexAlphaData to span the portion of the alphamap indicated by the axes ALim property, linearly mapping data values to alpha values.
- direct — Use the FaceVertexAlphaData as indices directly into the alphamap. When not scaled, the data are usually integer values ranging from 1 to length(alphamap). MATLAB maps values less than 1 to the first alpha value in the

# Patch Properties

---

alphamap, and values greater than `length(alphamap)` to the last alpha value in the alphamap. Values with a decimal portion are fixed to the nearest lower integer. If `FaceVertexAlphaData` is an array of `uint8` integers, then the indexing begins at 0 (that is, MATLAB maps a value of 0 to the first alpha value in the alphamap).

## AmbientStrength

scalar  $\geq 0$  and  $\leq 1$

*Strength of ambient light.* Sets the strength of the ambient light, which is a nondirectional light source that illuminates the entire scene. You must have at least one visible light object in the axes for the ambient light to be visible. The axes `AmbientLightColor` property sets the color of the ambient light, which is therefore the same on all objects in the axes.

You can also set the strength of the diffuse and specular contribution of light objects. See the patch `DiffuseStrength` and `SpecularStrength` properties.

## Annotation

hg.Annotation object (read-only)

*Handle of Annotation object.* The Annotation property enables you to specify whether this patch object is represented in a figure legend.

Querying the Annotation property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the patch object is displayed in a figure legend:

| IconDisplayStyle Value | Purpose                                               |
|------------------------|-------------------------------------------------------|
| on                     | Represent this patch object in a legend (default)     |
| off                    | Do not include this patch object in a legend          |
| children               | Same as on because patch objects do not have children |

## Setting the IconDisplayStyle property

Set the IconDisplayStyle of a graphics object with handle `hobj` to off:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'off')
```

## Using the IconDisplayStyle property

See “Controlling Legends” for more information and examples.

## Selecting which objects to display in legend

Some graphics functions create multiple objects. For example, `contour3` uses patch objects to create a 3D contour graph. You can use the Annotation property set select a subset of the objects for display in the legend.

```
[X,Y] = meshgrid(-2:.1:2);  
[Cm hC] = contour3(X.*exp(-X.^2-Y.^2));  
hA = get(hC, 'Annotation');  
hLL = get([hA{:}], 'LegendInformation');  
% Set the IconDisplayStyle property to display  
% the first, fifth, and ninth patch in the legend  
set([hLL{:}], {'IconDisplayStyle'},...  
    {'on', 'off', 'off', 'off', 'on', 'off', 'off', 'off', 'on'})
```

# Patch Properties

---

```
% Assign DisplayNames for the three patch
that are displayed in the legend
set(hC([1,5,9]),{'DisplayName'},{'bottom','middle','top'})
legend show
```

BackFaceLighting  
unlit | lit | {reverselit}

*Face lighting control.* Determines how faces are lit when their vertex normals point away from the camera.

- unlit — Face not lit.
- lit — Face lit in normal way.
- reverselit — Face lit as if the vertex pointed towards the camera.

Use this property to discriminate between the internal and external surfaces of an object. See “Back Face Lighting” for an example.

BeingDeleted  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

BusyAction  
cancel | {queue}

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over the patch object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

Set this property to a function handle that references the callback. You can also use a string that is a valid MATLAB expression or the name of a MATLAB file. The expressions execute in the MATLAB workspace.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## `CData`

scalar | vector | matrix

# Patch Properties

*Patch colors.* Specifies the color of the patch. You can specify color for each vertex, each face, or a single color for the entire patch. The way MATLAB interprets CData depends on the type of data supplied. The data can be numeric values that are scaled to map linearly into the current colormap, integer values that are used directly as indices into the current colormap, or arrays of RGB values. RGB values are not mapped into the current colormap, but interpreted as the colors defined. On true color systems, MATLAB uses the actual colors defined by the RGB triples.

The following diagrams illustrate the dimensions of CData with respect to the coordinate data arrays, XData, YData, and ZData. The first diagram illustrates the use of indexed color.

The following diagram illustrates the use of true color. True color requires m-by-n-by-3 arrays to define red, green, and blue components for each color.

Note that if CData contains NaNs, MATLAB does not color the faces.

See the Faces, Vertices, and FaceVertexCData properties for an alternative method of patch definition.

CDataMapping  
 {scaled} | direct

*Direct or scaled color mapping.* Determines how MATLAB interprets indexed color data used to color the patch. If you use true color specification for CData or FaceVertexCData, this property has no effect.

- **scaled** — Transform the color data to span the portion of the colormap indicated by the axes CLim property, linearly mapping data values to colors. See the `caxis` command for more information on this mapping.
- **direct** — Use the color data as indices directly into the colormap. When not scaled, the data are usually integer values

# Patch Properties

---

ranging from 1 to `length(colormap)`. MATLAB maps values less than 1 to the first color in the colormap, and values greater than `length(colormap)` to the last color in the colormap. Values with a decimal portion are fixed to the nearest lower integer.

**Children**  
matrix of handles

Always the empty matrix; patch objects have no children.

**Clipping**  
{on} | off

*Clipping to axes rectangle.* When **Clipping** is on, MATLAB does not display any portion of the patch outside the axes rectangle.

**CreateFcn**  
string | function handle

*Callback routine executed during object creation.* Executes when MATLAB creates a patch object. You must define this property as a default value for patches or in a call to the patch function that creates a new object.

For example, the following statement creates a patch (assuming `x`, `y`, `z`, and `c` are defined), and executes the function referenced by the function handle `@myCreateFcn`.

```
patch(x,y,z,c,'CreateFcn',@myCreateFcn)
```

MATLAB executes the create function after setting all properties for the patch created. Setting this property on an existing patch object has no effect.

The handle of the object whose **CreateFcn** is being executed is accessible only through the root **CallbackObject** property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

**DeleteFcn**  
string | function handle

*Delete patch callback routine.* Executes when you delete the patch object (for example, when you issue a `delete` command or clear the axes (`cla`) or figure (`clf`) containing the patch). MATLAB executes the routine before deleting the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

**DiffuseStrength**  
scalar  $\geq 0$  and  $\leq 1$

*Intensity of diffuse light.* Sets the intensity of the diffuse component of the light falling on the patch. Diffuse light comes from light objects in the axes.

You can also set the intensity of the ambient and specular components of the light on the object. See the `AmbientStrength` and `SpecularStrength` properties.

**DisplayName**  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the patch object in the legend. The default is an empty string.

# Patch Properties

---

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

## EdgeAlpha

{scalar = 1} | flat | interp

*Transparency of the edges of patch faces.*

- `scalar` — A single non-`NaN` scalar value between 0 and 1 that controls the transparency of all the edges of the object. 1 (the default) means fully opaque and 0 means completely transparent.
- `flat` — The alpha data (`FaceVertexAlphaData`) of each vertex controls the transparency of the edge that follows it.
- `interp` — Linear interpolation of the alpha data (`FaceVertexAlphaData`) at each vertex determines the transparency of the edge.

Note that you cannot specify `flat` or `interp` `EdgeAlpha` without first setting `FaceVertexAlphaData` to a matrix containing one alpha value per face (`flat`) or one alpha value per vertex (`interp`).

## EdgeColor

{ColorSpec} | none | flat | interp

*Color of the patch edge.* Determines how MATLAB colors the edges of the individual faces that make up the patch.

- **ColorSpec** — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for edges. The default value is [0 0 0] (black). See the **ColorSpec** reference page for more information on specifying color.
- **none** — Edges not drawn.
- **flat** — The color of each vertex controls the color of the edge that follows it. This means **flat** edge coloring is dependent on the order in which you specify the vertices:

- **interp** — Linear interpolation of the **CData** or **FaceVertexCData** values at the vertices determines the edge color.

## EdgeLighting

{none} | flat | gouraud | phong

*Algorithm used for lighting calculations.* Selects the algorithm used to calculate the effect of light objects on patch edges.

- **none** — Lights do not affect the edges of this object.
- **flat** — The effect of light objects is uniform across each edge of the patch.

# Patch Properties

---

- `gouraud` — The effect of light objects is calculated at the vertices and then linearly interpolated across the edge lines.
- `phong` — The effect of light objects is determined by interpolating the vertex normals across each edge line and calculating the reflectance at each pixel. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

## EraseMode

{normal} | none | xor | background

*Erase mode.* Controls the technique MATLAB uses to draw and erase patch objects. Alternative erase modes are useful in creating animated sequences, where control of the way individual objects redraw is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the patch when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the patch by performing an exclusive OR (XOR) with each pixel index of the screen behind it. Erasing the patch does not damage the color of the objects behind it. However, patch color depends on the color of the screen behind it and is correctly colored only when over the axes background `Color`, or the figure background `Color` if the axes `Color` is `none`.
- `background` — Erase the patch by drawing it in the axes background `Color`, or the figure background `Color` if the axes

Color is none. This damages objects that are behind the erased patch, but the patch is always properly colored.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

### FaceAlpha

{scalar = 1} | flat | interp

*Transparency of the patch face.*

- `scalar` — A single non-NaN value between 0 and 1 that controls the transparency of all the faces of the object. 1 (the default) means fully opaque and 0 means completely transparent (invisible).
- `flat` — The values of the alpha data (`FaceVertexAlphaData`) determine the transparency for each face. The alpha data at the first vertex determines the transparency of the entire face.
- `interp` — Bilinear interpolation of the alpha data (`FaceVertexAlphaData`) at each vertex determines the transparency of each face.

Note that you cannot specify `flat` or `interp` `FaceAlpha` without first setting `FaceVertexAlphaData` to a matrix containing one alpha value per face (`flat`) or one alpha value per vertex (`interp`).

# Patch Properties

---

## FaceColor

{ColorSpec} | none | flat | interp

*Color of the patch face.*

- **ColorSpec** — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for faces. See the **ColorSpec** reference page for more information on specifying color.
- **none** — Do not draw faces. Note that edges are drawn independently of faces.
- **flat** — The **CData** or **FaceVertexCData** property must contain one value per face and determines the color for each face in the patch. The color data at the first vertex determines the color of the entire face.
- **interp** — Bilinear interpolation of the color at each vertex determines the coloring of each face. The **CData** or **FaceVertexCData** property must contain one value per vertex.

## FaceLighting

{none} | flat | gouraud | phong

*Algorithm used for lighting calculations.* Selects the algorithm used to calculate the effect of **light** objects on patch faces.

- **none** — Lights do not affect the faces of this object.
- **flat** — The effect of light objects is uniform across the faces of the patch. Select this choice to view faceted objects.
- **gouraud** — The effect of light objects is calculated at the vertices and then linearly interpolated across the faces. Select this choice to view curved surfaces.
- **phong** — The effect of light objects is determined by interpolating the vertex normals across each face and calculating the reflectance at each pixel. Select this choice to

view curved surfaces. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

## Faces

m-by-n matrix

*Vertex connection defining each face.* Specifies which vertices in the Vertices property are connected. The Faces matrix defines  $m$  faces with up to  $n$  vertices each. Each row designates the connections for a single face, and the number of elements in that row that are not NaN defines the number of vertices for that face.

The Faces and Vertices properties provide an alternative way to specify a patch that can be more efficient than using  $x$ ,  $y$ , and  $z$  coordinates in most cases. For example, consider the following patch. It is composed of eight triangular faces defined by nine vertices.

The corresponding Faces and Vertices properties are shown to the right of the patch. Note how some faces share vertices with other faces. For example, the fifth vertex (V5) is used six times, once each by faces one, two, and three and six, seven, and eight. Without sharing vertices, this same patch requires 24 vertex definitions.

# Patch Properties

---

## FaceVertexAlphaData

m-by-1 matrix

*Face and vertex transparency data.* Specifies the transparency of patches that have been defined by the `Faces` and `Vertices` properties. The interpretation of the values specified for `FaceVertexAlphaData` depends on the dimensions of the data.

`FaceVertexAlphaData` can be one of the following:

- A single value, which applies the same transparency to the entire patch. The `FaceAlpha` property must be set to `flat`.
- An m-by-1 matrix (where m is the number of rows in the `Faces` property), which specifies one transparency value per face. The `FaceAlpha` property must be set to `flat`.
- An m-by-1 matrix (where m is the number of rows in the `Vertices` property), which specifies one transparency value per vertex. The `FaceAlpha` property must be set to `interp`.

The `AlphaDataMapping` property determines how MATLAB interprets the `FaceVertexAlphaData` property values.

## FaceVertexCData

matrix

*Face and vertex colors.* Specifies the color of patches defined by the `Faces` and `Vertices` properties. You must also set the values of the `FaceColor`, `EdgeColor`, `MarkerFaceColor`, or `MarkerEdgeColor` appropriately. The interpretation of the values specified for `FaceVertexCData` depends on the dimensions of the data.

For indexed colors, `FaceVertexCData` can be:

- A single value, which applies a single color to the entire patch.
- An n-by-1 matrix, where n is the number of rows in the `Faces` property, which specifies one color per face.

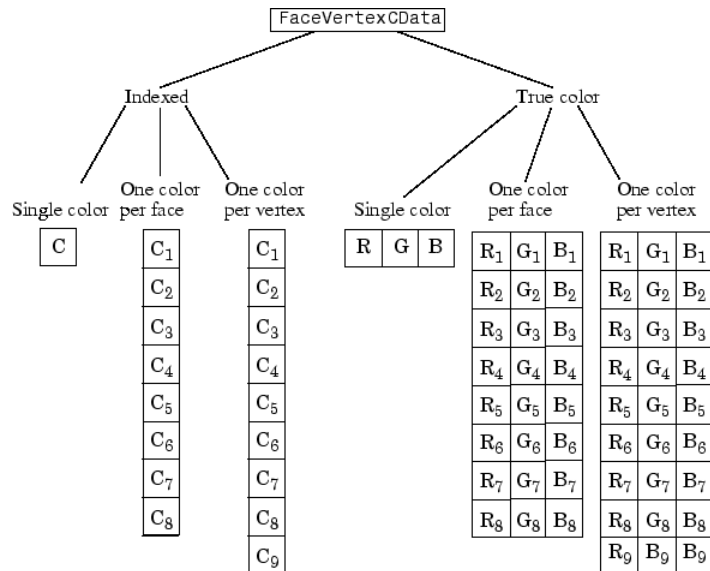

- An  $n$ -by-1 matrix, where  $n$  is the number of rows in the Vertices property, which specifies one color per vertex.

For true colors, FaceVertexCData can be:

- A 1-by-3 matrix, which applies a single color to the entire patch.
- An  $n$ -by-3 matrix, where  $n$  is the number of rows in the Faces property, which specifies one color per face.
- An  $n$ -by-3 matrix, where  $n$  is the number of rows in the Vertices property, which specifies one color per vertex.

The following diagram illustrates the various forms of the FaceVertexCData property for a patch having eight faces and nine vertices. The CDataMapping property determines how MATLAB interprets the FaceVertexCData property when you specify indexed colors.

# Patch Properties

---

HandleVisibility  
{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* Determines if the patch can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the patch. If `HitTest` is `off`, clicking the patch selects the object below it (which might be the axes containing it).

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- `'off'`, MATLAB finishes execution of the *running* callback without any interruptions
- `'on'`, these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.

# Patch Properties

---

- If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

BusyAction property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting Interruptible property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

LineStyle

{-} | -- | : | -. | none

*Line style of the patch edges.*

## Line Style Specifiers Table

| Specifier | Line Style           |
|-----------|----------------------|
| '-'       | Solid line (default) |
| '--'      | Dashed line          |
| ':'       | Dotted line          |

| Specifier | Line Style    |
|-----------|---------------|
| '-.'      | Dash-dot line |
| 'none'    | No line       |

Use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

#### `LineWidth`

width in points

*Edge line width.* The width, in points, of the patch edges 1 point =  $\frac{1}{72}$  inch. The default value is 0.5 points.

#### `Marker`

character (see table)

*Marker symbol.* Specifies marks that locate vertices. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

#### Marker Specifiers Table

| Specifier        | Marker Type |
|------------------|-------------|
| '+'              | Plus sign   |
| 'o'              | Circle      |
| '*'              | Asterisk    |
| '.'              | Point       |
| 'x'              | Cross       |
| 'square' or 's'  | Square      |
| 'diamond' or 'd' | Diamond     |

# Patch Properties

---

| Specifier            | Marker Type                   |
|----------------------|-------------------------------|
| '^'                  | Upward-pointing triangle      |
| 'v'                  | Downward-pointing triangle    |
| '>'                  | Right-pointing triangle       |
| '<'                  | Left-pointing triangle        |
| 'pentagram' or 'p'   | Five-pointed star (pentagram) |
| 'hexagram' or 'h' '' | Six-pointed star (hexagram)   |
| 'none'               | No marker (default)           |

## MarkerEdgeColor

ColorSpec | none | {auto} | flat

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — Defines the color to use.
- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Sets MarkerEdgeColor to the same color as the EdgeColor property.
- flat — The color of each vertex controls the color of the marker that denotes it.

## MarkerFaceColor

ColorSpec | {none} | auto | flat

*Marker face color.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — Defines the color to use.

- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Sets the fill color to the axes color, or the figure color, if the axes `Color` property is `none`.
- `flat` — The color of each vertex controls the color of the marker that denotes it.

## MarkerSize

scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

## NormalMode

{`auto`} | `manual`

*MATLAB generated or user-specified normal vectors.*

- `auto` — MATLAB calculates vertex normals based on the coordinate data
- `manual` — If you specify your own vertex normals, MATLAB sets this property to `manual` and does not generate its own data.

See also the `VertexNormals` property.

## Parent

handle of axes, `hggroup`, or `hgtransform`

*Parent of patch object.* Contains the handle of the patch object's parent. The parent of a patch object is the axes, `hggroup`, or `hgtransform` object that contains it. See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

# Patch Properties

---

## Selected

on | {off}

*Is object selected?* When this property is on, MATLAB displays selection handles or a dashed box (depending on the number of faces) if the `SelectionHighlight` property is also on. You can, for example, define the `ButtonDownFcn` to set this property, allowing users to select the object with the mouse.

## SelectionHighlight

{on} | off

*Objects are highlighted when selected.* When the `Selected` property is on, MATLAB indicates the selected state by:

- Drawing handles at each vertex for a single-faced patch
- Drawing a dashed bounding box for a multifaced patch

When `SelectionHighlight` is off, MATLAB does not draw the indicators.

## SpecularColorReflectance

scalar in the range 0 to 1

*Color of specularly-reflected light.* When this property is 0, the color of the specularly-reflected light depends on both the color of the object from which it reflects and the color of the light source. When set to 1, the color of the specularly-reflected light depends only on the color of the light source (that is, the light object `Color` property). The proportions vary linearly for values in between.

## SpecularExponent

scalar  $\geq 1$

*Harshness of specular reflection.* Controls the size of the specular spot. Most materials have exponents in the range of 5 to 20.

## SpecularStrength

scalar  $\geq 0$  and  $\leq 1$

*Intensity of specular light.* Sets the intensity of the specular component of the light falling on the patch. Specular light comes from light objects in the axes.

You can also set the intensity of the ambient and diffuse components of the light on the patch object. See the `AmbientStrength` and `DiffuseStrength` properties. Also see the `material` function.

Tag

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, suppose you use patch objects to create borders for a group of `uicontrol` objects and want to change the color of the borders in a `uicontrol`'s callback routine. Specify a `Tag` with the patch definition:

```
patch(X,Y,'k','Tag','PatchBorder')
```

Then use `findobj` in the `uicontrol`'s callback routine to obtain the handle of the patch and set its `FaceColor` property.

```
set(findobj('Tag','PatchBorder'),'FaceColor','w')
```

Type

string (read-only)

*Class of the graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For patch objects, `Type` is always `'patch'`.

# Patch Properties

---

## UIContextMenu

handle of uicontextmenu object

*Associate a context menu with the patch.* Assign this property the handle of a uicontextmenu object created in the same figure as the patch. Use the uicontextmenu function to create the context menu. MATLAB displays the context menu whenever you right-click over the patch.

## UserData

matrix

*User-specified data.* Data you want to associate with the patch object. The default value is an empty array. MATLAB does not use this data, but you can access it using the set and get commands.

## VertexNormals

matrix

*Surface normal vectors.* Contains the vertex normals for the patch. MATLAB generates this data to perform lighting calculations. You can supply your own vertex normal data, even if it does not match the coordinate data. Use this property to produce interesting lighting effects.

## Vertices

matrix

*Vertex coordinates.* A matrix containing the  $x$ -,  $y$ -,  $z$ -coordinates for each vertex. See the Faces property for more information.

## Visible

{on} | off

*Patch object visibility.*

- on — All patches are visible.
- off — The patch is not visible, but still exists, and you can query and set its properties.

## XData

vector | matrix

*X-coordinates.* The  $x$ -coordinates of the patch vertices. If XData is a matrix, each column represents the  $x$ -coordinates of a single face of the patch. In this case, XData, YData, and ZData must have the same dimensions.

## YData

vector | matrix

*Y-coordinates.* The  $y$ -coordinates of the patch vertices. If YData is a matrix, each column represents the  $y$ -coordinates of a single face of the patch. In this case, XData, YData, and ZData must have the same dimensions.

## ZData

vector | matrix

*Z-coordinates.* The  $z$ -coordinates of the patch vertices. If ZData is a matrix, each column represents the  $z$ -coordinates of a single face of the patch. In this case, XData, YData, and ZData must have the same dimensions.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>      | View or change search path                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Alternatives</b> | As an alternative to the <code>path</code> function, use the Set Path dialog box.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Syntax</b>       | <pre>path path('newpath') path(<b>path</b>, 'newpath') path('newpath', <b>path</b>) p = path</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b>  | <p><code>path</code> displays the MATLAB search path, which is stored in <code>pathdef.m</code>.</p> <p><code>path('newpath')</code> changes the search path to <code>newpath</code>, where <code>newpath</code> is a string array of folders.</p> <p><code>path(<b>path</b>, 'newpath')</code> adds the <code>newpath</code> folder to the end of the search path. If <code>newpath</code> is already on the search path, then <code>path(<b>path</b>, 'newpath')</code> moves <code>newpath</code> to the end of the search path.</p> <p><code>path('newpath', <b>path</b>)</code> adds the <code>newpath</code> folder to the top of the search path. If <code>newpath</code> is already on the search path, then <code>path('newpath', <b>path</b>)</code> moves <code>newpath</code> to the top of the search path. To add multiple folders in one statement, instead use <code>addpath</code>.</p> <p><code>p = path</code> returns the search path to string variable <code>p</code>.</p> |
| <b>Examples</b>     | <p>Display the search path:</p> <pre>path</pre> <p>MATLAB returns, for example</p> <pre>MATLABPATH  H:\My Documents\MATLAB C:\Program Files\MATLAB\R200nn\toolbox\matlab\general C:\Program Files\MATLAB\R200nn\toolbox\matlab\ops C:\Program Files\MATLAB\R200nn\toolbox\matlab\lang C:\Program Files\MATLAB\R200nn\toolbox\matlab\elmat</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

```
C:\Program Files\MATLAB\R200nn\toolbox\matlab\elfun  
...
```

R200nn represents the folder for the MATLAB release, for example, R2009b.

Add a new folder to the search path on Microsoft Windows platforms:

```
path(path, 'c:/tools/goodstuff')
```

# path

---

Add a new folder to the search path on UNIX<sup>8</sup> platforms:

```
path(path, '/home/tools/goodstuff')
```

Temporarily add the folder `my_files` to the search path, run `my_function` in `my_files`, then restore the previous search path:

```
p = path
path(p, 'my_files')
my_function
path(p)
```

```

## How To

- “Using the MATLAB Search Path”
- “Making Files and Folders Accessible to MATLAB”

8. UNIX is a registered trademark of The Open Group in the United States and other countries.

**Purpose** Save current search path to pathdef.m file

**Syntax** path2rc

**Description** path2rc runs savepath. The savepath function is replacing path2rc. Use savepath instead of path2rc and replace instances of path2rc with savepath.

# pathsep

---

**Purpose** Search path separator for current platform

**Syntax** `c = pathsep`

**Description** `c = pathsep` returns the search path separator character for this platform. The search path separator is the character that separates path names in the `pathdef.m` file, as returned by the `path` function. The character is a semicolon (;). For versions of MATLAB software earlier than version 7.7 (R2008b), the character on UNIX<sup>9</sup> platforms was a colon (:). Use `pathsep` to work programmatically with the content of the search path file.

## How To

- “Using the MATLAB Search Path”

**Purpose** Halt execution temporarily

**Syntax**

```

pause
pause(n)
pause on
pause off
pause query
state = pause('query')
oldstate = pause(newstate)

```

**Description** `pause`, by itself, causes the currently executing function to stop and wait for you to press any key before continuing. Pausing must be enabled for this to take effect. (See `pause on`, below). `pause` without arguments also blocks execution of Simulink models, but not repainting of them.

`pause(n)` pauses execution for `n` seconds before continuing, where `n` is any nonnegative real number. Pausing must be enabled for this to take effect.

Typing `pause(inf)` puts you into an infinite loop. To return to the MATLAB prompt, type **Ctrl+C**.

`pause on` enables the pausing of MATLAB execution via the `pause` and `pause(n)` commands. Pausing remains enabled until you enter `pause off` in your function or at the command line.

`pause off` disables the pausing of MATLAB execution via the `pause` and `pause(n)` commands. This allows normally interactive scripts to run unattended. Pausing remains disabled until you enter `pause on` in your function or at the command line, or start a new MATLAB session.

`pause query` displays 'on' if pausing is currently enabled. Otherwise, it displays 'off'.

`state = pause('query')` returns 'on' in character array `state` if pausing is currently enabled. Otherwise, the value of `state` is 'off'.

`oldstate = pause(newstate)`, enables or disables pausing, depending on the 'on' or 'off' value in `newstate`, and returns the former setting (also either 'on' or 'off') in character array `oldstate`.

# pause

---

## Tips

The accuracy of `pause` is subject to the scheduling resolution of the operating system you are using, and also to other system activity. It cannot be guaranteed with 100% confidence. Asking for finer resolutions shows higher relative error.

While MATLAB is paused, the following continue to execute:

- Repainting of figure windows, Simulink block diagrams, and Java windows
- HG callbacks from figure windows
- Event handling from Java windows

`keyboard` | `input` | `drawnow`

**Purpose** Set or query plot box aspect ratio

**Syntax**

```
pbaspect
pbaspect([aspect_ratio])
pbaspect('mode')
pbaspect('auto')
pbaspect('manual')
pbaspect(axes_handle,...)
```

**Description** The plot box aspect ratio determines the relative size of the  $x$ -,  $y$ -, and  $z$ -axes.

`pbaspect` with no arguments returns the plot box aspect ratio of the current axes.

`pbaspect([aspect_ratio])` sets the plot box aspect ratio in the current axes to the specified value. Specify the aspect ratio as three relative values representing the ratio of the  $x$ -,  $y$ -, and  $z$ -axes size. For example, a value of `[1 1 1]` (the default) means the plot box is a cube (although with stretch-to-fill enabled, it may not appear as a cube). See [Tips](#).

`pbaspect('mode')` returns the current value of the plot box aspect ratio mode, which can be either `auto` (the default) or `manual`. See [Remarks](#).

`pbaspect('auto')` sets the plot box aspect ratio mode to `auto`.

`pbaspect('manual')` sets the plot box aspect ratio mode to `manual`.

`pbaspect(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. If you do not specify an axes handle, `pbaspect` operates on the current axes.

**Tips** `pbaspect` sets or queries values of the axes object `PlotBoxAspectRatio` and `PlotBoxAspectRatioMode` properties.

When the plot box aspect ratio mode is `auto`, the MATLAB software sets the ratio to `[1 1 1]`, but may change it to accommodate manual settings of the data aspect ratio, camera view angle, or axis limits. See the axes `DataAspectRatio` property for a table listing the interactions between various properties.

Setting a value for the plot box aspect ratio or setting the plot box aspect ratio mode to `manual` disables the MATLAB stretch-to-fill feature (stretching of the axes to fit the window). This means setting the plot box aspect ratio to its current value,

```
pbaspect(pbaspect)
```

can cause a change in the way the graphs look. See the Remarks section of the `axes` reference description, “Axes Aspect Ratio Properties” in the 3-D Visualization manual, and “Setting Aspect Ratio” in the MATLAB Graphics manual for a discussion of stretch-to-fill.

## Examples

The following surface plot of the function  $z = xe^{-x^2 - y^2}$  is useful to illustrate the plot box aspect ratio. First plot the function over the range  $-2 \leq x \leq 2$ ,  $-2 \leq y \leq 2$ ,

```
[x,y] = meshgrid([-2:.2:2]);  
z = x.*exp(-x.^2 - y.^2);  
surf(x,y,z)
```

Querying the plot box aspect ratio shows that the plot box is square.

```
pbaspect
ans =
    1    1    1
```

It is also interesting to look at the data aspect ratio selected by MATLAB.

```
daspect
ans =
    4    4    1
```

To illustrate the interaction between the plot box and data aspect ratios, set the data aspect ratio to `[1 1 1]` and again query the plot box aspect ratio.

```
daspect([1 1 1])
```

# pbaspect

---

```
pbaspect
ans =
     4     4     1
```

The plot box aspect ratio has changed to accommodate the specified data aspect ratio. Now suppose you want the plot box aspect ratio to be [1 1 1] as well.

```
pbaspect([1 1 1])
```

Notice how MATLAB changed the axes limits because of the constraints introduced by specifying both the plot box and data aspect ratios.

You can also use `pbaspect` to disable stretch-to-fill. For example, displaying two subplots in one figure can give surface plots a squashed appearance. Disabling stretch-to-fill,

```
upper_plot = subplot(211);
surf(x,y,z)
lower_plot = subplot(212);
surf(x,y,z)
pbaspect(upper_plot, 'manual')
```

## How To

- [Setting Aspect Ratio](#)
- [Axes Aspect Ratio Properties](#)

**Purpose** Preconditioned conjugate gradients method

**Syntax**

```
x = pcg(A,b)
pcg(A,b,tol)
pcg(A,b,tol,maxit)
pcg(A,b,tol,maxit,M)
pcg(A,b,tol,maxit,M1,M2)
pcg(A,b,tol,maxit,M1,M2,x0)
[x,flag] = pcg(A,b,...)
[x,flag,relres] = pcg(A,b,...)
[x,flag,relres,iter] = pcg(A,b,...)
[x,flag,relres,iter,resvec] = pcg(A,b,...)
```

**Description** `x = pcg(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be symmetric and positive definite, and should also be large and sparse. The column vector  $b$  must have length  $n$ . You also can specify  $A$  to be a function handle, `afun`, such that `afun(x)` returns  $A*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `pcg` converges, a message to that effect is displayed. If `pcg` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`pcg(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `pcg` uses the default,  $1e-6$ .

`pcg(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `pcg` uses the default,  $\min(n,20)$ .

`pcg(A,b,tol,maxit,M)` and `pcg(A,b,tol,maxit,M1,M2)` use symmetric positive definite preconditioner  $M$  or  $M = M1*M2$  and effectively solve the system  $\text{inv}(M)*A*x = \text{inv}(M)*b$  for  $x$ . If  $M$  is `[]`

then `pcg` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x)` returns  $M \backslash x$ .

`pcg(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `pcg` uses the default, an all-zero vector.

`[x,flag] = pcg(A,b,...)` also returns a convergence flag.

| Flag | Convergence                                                                                                          |
|------|----------------------------------------------------------------------------------------------------------------------|
| 0    | <code>pcg</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.           |
| 1    | <code>pcg</code> iterated <code>maxit</code> times but did not converge.                                             |
| 2    | Preconditioner <code>M</code> was ill-conditioned.                                                                   |
| 3    | <code>pcg</code> stagnated. (Two consecutive iterates were the same.)                                                |
| 4    | One of the scalar quantities calculated during <code>pcg</code> became too small or too large to continue computing. |

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = pcg(A,b,...)` also returns the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = pcg(A,b,...)` also returns the iteration number at which `x` was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = pcg(A,b,...)` also returns a vector of the residual norms at each iteration including  $\text{norm}(b-A*x0)$ .

## Examples

### Using `pcg` with Large Matrices

This example shows how to use `pcg` with a matrix input and with a function handle.

```
n1 = 21;  
A = gallery('moler',n1);  
b1 = sum(A,2);
```

```

tol = 1e-6;
maxit = 15;
M1 = spdiags((1:n1)',0,n1,n1);
[x1,flag1,rr1,iter1,rv1] = pcg(A,b1,tol,maxit,M1);

```

Alternatively, you can use the following function in place of the matrix A:

```

function y = applyMoler(x)
y = x;
y(end-1:-1:1) = y(end-1:-1:1) - cumsum(y(end:-1:2));
y(2:end) = y(2:end) - cumsum(y(1:end-1));

```

By using this function, you can solve larger systems more efficiently as there is no need to store the entire matrix A:

```

n2 = 21;
b2 = applyMoler(ones(n2,1));
tol = 1e-6;
maxit = 15;
M2 = spdiags((1:n2)',0,n2,n2);
[x2,flag2,rr2,iter2,rv2] = pcg(@applyMoler,b2,tol,maxit,M2);

```

### Using pcg with a Preconditioner

This example demonstrates how to use a preconditioner matrix with `pcg`.

#### 1

Create an input matrix and try to solve the system with `pcg`:

```

A = delsq(numgrid('S',100));
b = ones(size(A,1),1);
[x0,f10,rr0,it0,rv0] = pcg(A,b,1e-8,100);

```

`f10` is 1 because `pcg` does not converge to the requested tolerance of  $1e-8$  within the requested maximum 100 iterations. A preconditioner can make the system converge more quickly.

#### 2

Use `ichol` with only one input argument to construct an incomplete Cholesky factorization with zero fill:

```
L = ichol(A);  
[x1,f11,rr1,it1,rv1] = pcg(A,b,1e-8,100,L,L');
```

`f11` is 0 because `pcg` drives the relative residual to  $9.8e-09$  (the value of `rr1`) which is less than the requested tolerance of  $1e-8$  at the seventy-seventh iteration (the value of `it1`) when preconditioned by the zero-fill incomplete Cholesky factorization. `rv1(1) = norm(b)` and `rv1(78) = norm(b-A*x1)`.

The previous matrix represents the discretization of the Laplacian on a  $100 \times 100$  grid with Dirichlet boundary conditions. This means that a modified incomplete Cholesky preconditioner might perform even better.

### 3

Use the `michol` option to create a modified incomplete Cholesky preconditioner:

```
L = ichol(A,struct('michol','on'));  
[x2,f12,rr2,it2,rv2] = pcg(A,b,1e-8,100,L,L');
```

In this case you attain convergence in only forty-seven iterations.

### 4

You can see how the preconditioners affect the rate of convergence of `pcg` by plotting each of the residual histories starting from the initial estimate (iterate number 0):

```
figure;  
semilogy(0:it0,rv0/norm(b),'b.');
```

```
hold on;  
semilogy(0:it1,rv1/norm(b),'r.');
```

```
semilogy(0:it2,rv2/norm(b),'k.');
```

```
legend('No Preconditioner','IC(0)','MIC(0)');
```

```
xlabel('iteration number');
```

```
ylabel('relative residual');  
hold off;
```

# pchip

---

**Purpose** Piecewise Cubic Hermite Interpolating Polynomial (PCHIP)

**Syntax**  
`yi = pchip(x,y,xi)`  
`pp = pchip(x,y)`

**Description** `yi = pchip(x,y,xi)` returns vector `yi` containing elements corresponding to the elements of `xi` and determined by piecewise cubic interpolation within vectors `x` and `y`. The vector `x` specifies the points at which the data `y` is given. If `y` is a matrix, then the interpolation is performed for each column of `y` and `yi` is `length(xi)-by-size(y,2)`.

`pp = pchip(x,y)` returns a piecewise polynomial structure for use by `ppval`. `x` can be a row or column vector. `y` is a row or column vector of the same length as `x`, or a matrix with `length(x)` columns.

`pchip` finds values of an underlying interpolating function  $P(x)$  at intermediate points, such that:

- On each subinterval  $x_k \leq x \leq x_{k+1}$ ,  $P(x)$  is the cubic Hermite interpolant to the given values and certain slopes at the two endpoints.
- $P(x)$  interpolates  $y$ , i.e.,  $P(x_j) = y_j$ , and the first derivative  $P'(x)$  is continuous.  $P''(x)$  is probably not continuous; there may be jumps at the  $x_j$ .
- The slopes at the  $x_j$  are chosen in such a way that  $P(x)$  preserves the shape of the data and respects monotonicity. This means that, on intervals where the data are monotonic, so is  $P(x)$ ; at points where the data has a local extremum, so does  $P(x)$ .

---

**Note** If  $y$  is a matrix,  $P(x)$  satisfies the above for each column of  $y$ .

---

**Tips**

`spline` constructs  $S(x)$  in almost the same way `pchip` constructs  $P(x)$ . However, `spline` chooses the slopes at the  $x_j$  differently, namely to make even  $S''(x)$  continuous. This has the following effects:

- `spline` produces a smoother result, i.e.  $S''(x)$  is continuous.
- `spline` produces a more accurate result if the data consists of values of a smooth function.
- `pchip` has no overshoots and less oscillation if the data are not smooth.
- `pchip` is less expensive to set up.
- The two are equally expensive to evaluate.

**Examples**

```
x = -3:3;
y = [-1 -1 -1 0 1 1 1];
t = -3:.01:3;
p = pchip(x,y,t);
s = spline(x,y,t);
plot(x,y,'o',t,p,'- ',t,s,'- .')
legend('data','pchip','spline',4)
```

|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>         | Create protected function file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Syntax</b>          | <pre>pcode(fun) pcode(fun1,...,funN) pcode(fun, '-inplace')</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b>     | <p><code>pcode(fun)</code> encrypts the code in <code>fun.m</code> and produces a file called <code>fun.p</code>, known as a P-file. If <code>fun</code> is a folder, then all the script or function files in that folder are encrypted in P-files. MATLAB creates the P-files in the current folder. The original <code>.m</code> file or folder can be anywhere on the search path.</p> <p><code>pcode(fun1,...,funN)</code> creates N P-files from the listed files. If any inputs are folders, then MATLAB creates a P-file for every <code>.m</code> file the folders contain.</p> <p><code>pcode(fun, '-inplace')</code> creates P-files in the same folder as the script or function files.</p>                                         |
| <b>Tips</b>            | <ul style="list-style-type: none"><li>• The <code>pcode</code> algorithm was redesigned in MATLAB 7.5 (Release R2007b). You can run older P-files in any current version of MATLAB; however, upcoming releases will not run P-files created before version 7.5. Files generated in 7.5, or later versions, cannot run in MATLAB 7.4 or earlier.</li><li>• When encrypting all files in a folder, <code>pcode</code> does not encrypt any files within subfolders.</li><li>• A P-file takes precedence over the corresponding <code>.m</code> file for execution, even after modifications to the <code>.m</code> file.</li><li>• MATLAB does not display any of the help comments that might be in the original <code>.m</code> file.</li></ul> |
| <b>Input Arguments</b> | <p><b>fun</b></p> <p>MATLAB file or directory containing MATLAB files. If <code>fun</code> resides within a package and/or class folder, then <code>pcode</code> creates the same package and/or class structure to house the resulting P-files.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

An input argument with no file extension and that is not a folder must be a function in the MATLAB path or in the current folder.

When using wild cards \*, pcode ignores all files with extensions other than .m.

## Examples

### P-Coding Multiple Files

Convert selected files from the sparfun folder into P-files.

Create a temporary folder and define an existing path to .m files.

```
tmp = tempname;  
mkdir(tmp);  
cd(tmp);  
fun = fullfile(matlabroot,'toolbox','matlab','sparfun','spr*.m');
```

Create the P-files.

```
pcode(fun)  
dir(tmp)
```

```
.          ..          sprand.p      sprandn.p      sprandsym.p  sprank.p
```

The temporary folder now contains encoded P-files.

### P-Coding Files That Belong to a Package and/or Class

Generate P-files from input files that are part of a package and/or class.

Define funclass as an existing a class folder that contains .m files.

```
funclass = fullfile(matlabroot,'toolbox','matlab','datatypes','@char')  
dir(funclass)
```

```
funclass =
```

```
C:\Program Files\MATLAB\R2011b\toolbox\matlab\datatypes\@char
```

```
.          ..          superiorfloat.m
```

Create a temporary folder. This folder has no package or class structure at this time.

```
tmp = tempname;
mkdir(tmp);
cd(tmp);
dir(tmp)
```

```
.          ..
```

Create a P-file for every .m file in the path `funclass`. Because the input files are part of a package and/or class, MATLAB creates a folder structure so that the output file belongs to the same package and/or class.

```
pcode(funclass)
dir(tmp)
```

```
.          ..          @char
```

You see that the P-file resides in the same folder structure.

```
dir('@char')
```

```
.          ..          superiorfloat.p
```

### **P-Coding In Place**

Generate P-files in the same folder as the input files using the option `inplace`

Copy several MATLAB files to a temporary folder.

```
fun = fullfile(matlabroot,'toolbox','matlab','sparfun','spr*.m');
tmp = tempname;
mkdir(tmp);
copyfile(fun,tmp)
dir(tmp)
```

# pcode

---

```
.          ..          sprand.m    sprandn.m    sprandsym.m  sprank.m
```

Create P-files in the same folder as the original .m files.

```
pcode(tmp, '-inplace')
dir(tmp)
```

```
.          sprand.m    sprandn.m    sprandsym.m  sprank.m
..         sprand.p    sprandn.p    sprandsym.p  sprank.p
```

## Concepts

- “Protect Your Source Code”

**Purpose** Pseudocolor (checkerboard) plot

**Syntax**

```
pcolor(C)
pcolor(X,Y,C)
pcolor(axes_handles,...)
h = pcolor(...)
```

**Description** A pseudocolor plot is a rectangular array of cells with colors determined by **C**. MATLAB creates a pseudocolor plot using each set of four adjacent points in **C** to define a surface rectangle (i.e., cell).

The default shading is `faceted`, which colors each cell with a single color. The last row and column of **C** are not used in this case. With shading `interp`, each cell is colored by bilinear interpolation of the colors at its four vertices, using all elements of **C**.

The minimum and maximum elements of **C** are assigned the first and last colors in the colormap. Colors for the remaining elements in **C** are determined by a linear mapping from value to colormap element.

`pcolor(C)` draws a pseudocolor plot. The elements of **C** are linearly mapped to an index into the current colormap. The mapping from **C** to the current colormap is defined by `colormap` and `caxis`.

`pcolor(X,Y,C)` draws a pseudocolor plot of the elements of **C** at the locations specified by **X** and **Y**. The plot is a logically rectangular, two-dimensional grid with vertices at the points  $[X(i,j), Y(i,j)]$ . **X** and **Y** are vectors or matrices that specify the spacing of the grid lines. If **X** and **Y** are vectors, **X** corresponds to the columns of **C** and **Y** corresponds to the rows. If **X** and **Y** are matrices, they must be the same size as **C**.

`pcolor(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = pcolor(...)` returns a handle to a surface graphics object.

## Tips

A pseudocolor plot is a flat surface plot viewed from above. `pcolor(X,Y,C)` is the same as viewing `surf(X,Y,zeros(size(X)),C)` using `view([0 90])`.

When you use `shading faceted` or `shading flat`, the constant color of each cell is the color associated with the corner having the smallest  $x$ - $y$  coordinates. Therefore, `C(i,j)` determines the color of the cell in the  $i$ th row and  $j$ th column. The last row and column of `C` are not used.

When you use `shading interp`, each cell's color results from a bilinear interpolation of the colors at its four vertices, and all elements of `C` are used.

## Examples

A Hadamard matrix has elements that are +1 and -1. A colormap with only two entries is appropriate when displaying a pseudocolor plot of this matrix.

```
pcolor(hadamard(20))
colormap(gray(2))
axis ij
axis square
```

A simple color wheel illustrates a polar coordinate system.

```
n = 6;  
r = (0:n)'/n;  
theta = pi*(-n:n)/n;  
X = r*cos(theta);  
Y = r*sin(theta);  
C = r*cos(2*theta);  
pcolor(X,Y,C)
```

axis equal tight

## Algorithms

The number of vertex colors for `pcolor(C)` is the same as the number of cells for `image(C)`. `pcolor` differs from `image` in that `pcolor(C)` specifies the colors of vertices, which are scaled to fit the colormap; changing the axes `clim` property changes this color mapping. `image(C)` specifies the colors of cells and directly indexes into the colormap without scaling. Additionally, `pcolor(X,Y,C)` can produce parametric grids, which is not possible with `image`.

# pdepe

---

## Purpose

Solve initial-boundary value problems for parabolic-elliptic PDEs in 1-D

## Syntax

```
sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan)
sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan,options)
[sol,tsol,sole,te,ie] = pdepe(m,pdefun,icfun,bcfun,xmesh,
    tspan,options)
```

## Arguments

|         |                                                                                                                                                                                                                                          |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| m       | A parameter corresponding to the symmetry of the problem. m can be slab = 0, cylindrical = 1, or spherical = 2.                                                                                                                          |
| pdefun  | A handle to a function that defines the components of the PDE.                                                                                                                                                                           |
| icfun   | A handle to a function that defines the initial conditions.                                                                                                                                                                              |
| bcfun   | A handle to a function that defines the boundary conditions.                                                                                                                                                                             |
| xmesh   | A vector [x0, x1, ..., xn] specifying the points at which a numerical solution is requested for every value in tspan. The elements of xmesh must satisfy $x_0 < x_1 < \dots < x_n$ . The length of xmesh must be $\geq 3$ .              |
| tspan   | A vector [t0, t1, ..., tf] specifying the points at which a solution is requested for every value in xmesh. The elements of tspan must satisfy $t_0 < t_1 < \dots < t_f$ . The length of tspan must be $\geq 3$ .                        |
| options | Some options of the underlying ODE solver are available in pdepe: RelTol, AbsTol, NormControl, InitialStep, MaxStep, and Events. In most cases, default values for these options provide satisfactory solutions. See odeset for details. |

**Description**

`sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan)` solves initial-boundary value problems for systems of parabolic and elliptic PDEs in the one space variable  $x$  and time  $t$ . `pdefun`, `icfun`, and `bcfun` are function handles. See the `function_handle` reference page for more information. The ordinary differential equations (ODEs) resulting from discretization in space are integrated to obtain approximate solutions at times specified in `tspan`. The `pdepe` function returns values of the solution on a mesh provided in `xmesh`.

“Parameterizing Functions” explains how to provide additional parameters to the functions `pdefun`, `icfun`, or `bcfun`, if necessary.

`pdepe` solves PDEs of the form:

$$c\left(x,t,u,\frac{\partial u}{\partial x}\right)\frac{\partial u}{\partial t} = x^{-m}\frac{\partial}{\partial x}\left(x^m f\left(x,t,u,\frac{\partial u}{\partial x}\right)\right) + s\left(x,t,u,\frac{\partial u}{\partial x}\right) \quad (2-4)$$

The PDEs hold for  $t_0 \leq t \leq t_f$  and  $a \leq x \leq b$ . The interval  $[a,b]$  must be finite.  $m$  can be 0, 1, or 2, corresponding to slab, cylindrical, or spherical symmetry, respectively. If  $m > 0$ , then  $a$  must be  $\geq 0$ .

In Equation 2-4,  $f(x,t,u,\partial u/\partial x)$  is a flux term and  $s(x,t,u,\partial u/\partial x)$  is a source term. The coupling of the partial derivatives with respect to time is restricted to multiplication by a diagonal matrix  $c(x,t,u,\partial u/\partial x)$ . The diagonal elements of this matrix are either identically zero or positive. An element that is identically zero corresponds to an elliptic equation and otherwise to a parabolic equation. There must be at least one parabolic equation. An element of  $c$  that corresponds to a parabolic equation can vanish at isolated values of  $x$  if those values of  $x$  are mesh points. Discontinuities in  $c$  and/or  $s$  due to material interfaces are permitted provided that a mesh point is placed at each interface.

For  $t = t_0$  and all  $x$ , the solution components satisfy initial conditions of the form

$$u(x,t_0) = u_0(x) \quad (2-5)$$

For all  $t$  and either  $x = a$  or  $x = b$ , the solution components satisfy a boundary condition of the form

$$p(x,t,u) + q(x,t)f\left(x,t,u,\frac{\partial u}{\partial x}\right) = 0 \quad (2-6)$$

Elements of  $q$  are either identically zero or never zero. Note that the boundary conditions are expressed in terms of the flux  $f$  rather than  $\partial u/\partial x$ . Also, of the two coefficients, only  $p$  can depend on  $u$ .

In the call `sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan)`:

- $m$  corresponds to  $m$ .
- `xmesh(1)` and `xmesh(end)` correspond to  $a$  and  $b$ .
- `tspan(1)` and `tspan(end)` correspond to  $t_0$  and  $t_f$ .
- `pdefun` computes the terms  $c$ ,  $f$ , and  $s$  (Equation 2-4). It has the form

$$[c,f,s] = pdefun(x,t,u,dudx)$$

The input arguments are scalars  $x$  and  $t$  and vectors  $u$  and  $dudx$  that approximate the solution  $u$  and its partial derivative with respect to  $x$ , respectively.  $c$ ,  $f$ , and  $s$  are column vectors.  $c$  stores the diagonal elements of the matrix  $c$  (Equation 2-4).

- `icfun` evaluates the initial conditions. It has the form

$$u = icfun(x)$$

When called with an argument  $x$ , `icfun` evaluates and returns the initial values of the solution components at  $x$  in the column vector  $u$ .

- `bcfun` evaluates the terms  $p$  and  $q$  of the boundary conditions (Equation 2-6). It has the form

$$[p1,q1,pr,qr] = bcfun(xl,u1,xr,ur,t)$$

$u1$  is the approximate solution at the left boundary  $x1 = a$  and  $ur$  is the approximate solution at the right boundary  $xr = b$ .  $p1$  and  $q1$  are column vectors corresponding to  $p$  and  $q$  evaluated at  $x1$ , similarly  $pr$  and  $qr$  correspond to  $xr$ . When  $m > 0$  and  $a = 0$ , boundedness of the solution near  $x = 0$  requires that the flux  $f$  vanish at  $a = 0$ . `pdepe`

imposes this boundary condition automatically and it ignores values returned in `pl` and `ql`.

`pdepe` returns the solution as a multidimensional array `sol`.

$u_i = \text{ui} = \text{sol}(:, :, i)$  is an approximation to the  $i$ th component of the solution vector  $u$ . The element  $\text{ui}(j, k) = \text{sol}(j, k, i)$  approximates  $u_i$  at  $(t, x) = (\text{tspan}(j), \text{xmesh}(k))$ .

$\text{ui} = \text{sol}(j, :, i)$  approximates component  $i$  of the solution at time `tspan(j)` and mesh points `xmesh(:)`. Use `pdeval` to compute the approximation and its partial derivative  $\partial u_i / \partial x$  at points not included in `xmesh`. See `pdeval` for details.

`sol = pdepe(m, pdefun, icfun, bcfun, xmesh, tspan, options)` solves as above with default integration parameters replaced by values in `options`, an argument created with the `odeset` function. Only some of the options of the underlying ODE solver are available in `pdepe`: `RelTol`, `AbsTol`, `NormControl`, `InitialStep`, and `MaxStep`. The defaults obtained by leaving off the input argument `options` will generally be satisfactory. See `odeset` for details.

`[sol, tsol, sole, te, ie] = pdepe(m, pdefun, icfun, bcfun, xmesh, tspan, options)` with the 'Events' property in `options` set to a function handle `Events`, solves as above while also finding where event functions  $g(t, u(x, t))$  are zero. For each function you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Three column vectors are returned by events: `[value, isterminal, direction] = events(m, t, xmesh, umesh)`. `xmesh` contains the spatial mesh and `umesh` is the solution at the mesh points. Use `pdeval` to evaluate the solution between mesh points. For the  $I$ -th event function, `value(i)` is the value of the function, `ISTERMINAL(I) = 1` if the integration is to terminate at a zero of this event function and 0 otherwise. `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only zeros where the event function is increasing, and `-1` if only zeros where the event function is decreasing. Output `tsol` is a column vector of times specified in `tspan`, prior to first terminal event. `SOL(j, :, :)` is the solution at `T(j)`. `TE` is a vector of

times at which events occur. `SOLE(j, :, :)` is the solution at `TE(j)` and indices in vector `IE` specify which event occurred.

If `UI = SOL(j, :, i)` approximates component `i` of the solution at time `TSPAN(j)` and mesh points `XMESH`, `pdeval` evaluates the approximation and its partial derivative  $\partial u_i / \partial x$  at the array of points `XOUT` and returns them in `UOUT` and `DUOUTDX`: `[UOUT, DUOUTDX] = PDEVAL(M, XMESH, UI, XOUT)`

---

**Note** The partial derivative  $\partial u_i / \partial x$  is evaluated here rather than the flux. The flux is continuous, but at a material interface the partial derivative may have a jump.

---

## Tips

- The arrays `xmesh` and `tspan` play different roles in `pdepe`.  
**tspan** – The `pdepe` function performs the time integration with an ODE solver that selects both the time step and formula dynamically. The elements of `tspan` merely specify where you want answers and the cost depends weakly on the length of `tspan`.  
**xmesh** – Second order approximations to the solution are made on the mesh specified in `xmesh`. Generally, it is best to use closely spaced mesh points where the solution changes rapidly. `pdepe` does *not* select the mesh in  $x$  automatically. You must provide an appropriate fixed mesh in `xmesh`. The cost depends strongly on the length of `xmesh`. When  $m > 0$ , it is not necessary to use a fine mesh near  $x = 0$  to account for the coordinate singularity.
- The time integration is done with `ode15s`. `pdepe` exploits the capabilities of `ode15s` for solving the differential-algebraic equations that arise when Equation 2-4 contains elliptic equations, and for handling Jacobians with a specified sparsity pattern.
- After discretization, elliptic equations give rise to algebraic equations. If the elements of the initial conditions vector that correspond to elliptic equations are not "consistent" with the discretization, `pdepe` tries to adjust them before beginning the time integration. For

this reason, the solution returned for the initial time may have a discretization error comparable to that at any other time. If the mesh is sufficiently fine, pdepe can find consistent initial conditions close to the given ones. If pdepe displays a message that it has difficulty finding consistent initial conditions, try refining the mesh.

No adjustment is necessary for elements of the initial conditions vector that correspond to parabolic equations.

## Examples

**Example 1.** This example illustrates the straightforward formulation, computation, and plotting of the solution of a single PDE.

$$\pi^2 \frac{\partial u}{\partial t} = \frac{\partial}{\partial x} \left( \frac{\partial u}{\partial x} \right)$$

This equation holds on an interval  $0 \leq x \leq 1$  for times  $t \geq 0$ .

The PDE satisfies the initial condition

$$u(x, 0) = \sin \pi x$$

and boundary conditions

$$u(0, t) = 0$$

$$\pi e^{-t} + \frac{\partial u}{\partial x}(1, t) = 0$$

It is convenient to use local functions to place all the functions required by pdepe in a single function.

```
function pdex1

m = 0;
x = linspace(0,1,20);
t = linspace(0,2,5);

sol = pdepe(m,@pdex1pde,@pdex1ic,@pdex1bc,x,t);
% Extract the first solution component as u.
```

```
u = sol(:,:,1);

% A surface plot is often a good way to study a solution.
surf(x,t,u)
title('Numerical solution computed with 20 mesh points.')
xlabel('Distance x')
ylabel('Time t')

% A solution profile can also be illuminating.
figure
plot(x,u(end,:))
title('Solution at t = 2')
xlabel('Distance x')
ylabel('u(x,2)')
% -----
function [c,f,s] = pdex1pde(x,t,u,DuDx)
c = pi^2;
f = DuDx;
s = 0;
% -----
function u0 = pdex1ic(x)
u0 = sin(pi*x);
% -----
function [pl,ql,pr,qr] = pdex1bc(xl,ul,xr,ur,t)
pl = ul;
ql = 0;
pr = pi * exp(-t);
qr = 1;
```

In this example, the PDE, initial condition, and boundary conditions are coded in local functions `pdex1pde`, `pdex1ic`, and `pdex1bc`.

The surface plot shows the behavior of the solution.

The following plot shows the solution profile at the final value of  $t$  (i.e.,  $t = 2$ ).

**Example 2.** This example illustrates the solution of a system of PDEs. The problem has boundary layers at both ends of the interval. The solution changes rapidly for small  $t$ .

The PDEs are

$$\frac{\partial u_1}{\partial t} = 0.024 \frac{\partial^2 u_1}{\partial x^2} - F(u_1 - u_2)$$

$$\frac{\partial u_2}{\partial t} = 0.170 \frac{\partial^2 u_2}{\partial x^2} + F(u_1 - u_2)$$

where  $F(y) = \exp(5.73y) - \exp(-11.46y)$ .

This equation holds on an interval  $0 \leq x \leq 1$  for times  $t \geq 0$ .

The PDE satisfies the initial conditions

$$u_1(x, 0) \equiv 1$$

$$u_2(x, 0) \equiv 0$$

and boundary conditions

$$\frac{\partial u_1}{\partial x}(0, t) \equiv 0$$

$$u_2(0, t) \equiv 0$$

$$u_1(1, t) \equiv 1$$

$$\frac{\partial u_2}{\partial x}(1, t) \equiv 0$$

In the form expected by pdepe, the equations are

$$\begin{bmatrix} 1 \\ 1 \end{bmatrix} \cdot * \frac{\partial}{\partial t} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \frac{\partial}{\partial x} \begin{bmatrix} 0.024(\partial u_1 / \partial x) \\ 0.170(\partial u_2 / \partial x) \end{bmatrix} + \begin{bmatrix} -F(u_1 - u_2) \\ F(u_1 - u_2) \end{bmatrix}$$

The boundary conditions on the partial derivatives of  $u$  have to be written in terms of the flux. In the form expected by pdepe, the left boundary condition is

$$\begin{bmatrix} 0 \\ u_2 \end{bmatrix} + \begin{bmatrix} 1 \\ 0 \end{bmatrix} \cdot * \begin{bmatrix} 0.024(\partial u_1 / \partial x) \\ 0.170(\partial u_2 / \partial x) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

and the right boundary condition is

$$\begin{bmatrix} u_1 - 1 \\ 0 \end{bmatrix} + \begin{bmatrix} 0 \\ 1 \end{bmatrix} \cdot * \begin{bmatrix} 0.024(\partial u_1 / \partial x) \\ 0.170(\partial u_2 / \partial x) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The solution changes rapidly for small  $t$ . The program selects the step size in time to resolve this sharp change, but to see this behavior in the plots, the example must select the output times accordingly. There are boundary layers in the solution at both ends of  $[0, 1]$ , so the example places mesh points near 0 and 1 to resolve these sharp changes. Often

some experimentation is needed to select a mesh that reveals the behavior of the solution.

```
function pdex4
m = 0;
x = [0 0.005 0.01 0.05 0.1 0.2 0.5 0.7 0.9 0.95 0.99 0.995 1];
t = [0 0.005 0.01 0.05 0.1 0.5 1 1.5 2];

sol = pdepe(m,@pdex4pde,@pdex4ic,@pdex4bc,x,t);
u1 = sol(:,:,1);
u2 = sol(:,:,2);

figure
surf(x,t,u1)
title('u1(x,t)')
xlabel('Distance x')
ylabel('Time t')

figure
surf(x,t,u2)
title('u2(x,t)')
xlabel('Distance x')
ylabel('Time t')
% -----
function [c,f,s] = pdex4pde(x,t,u,DuDx)
c = [1; 1];
f = [0.024; 0.17] .* DuDx;
y = u(1) - u(2);
F = exp(5.73*y) - exp(-11.47*y);
s = [-F; F];
% -----
function u0 = pdex4ic(x);
u0 = [1; 0];
% -----
function [pl,ql,pr,qr] = pdex4bc(xl,ul,xr,ur,t)
pl = [0; ul(2)];
ql = [1; 0];
```

```
pr = [ur(1)-1; 0];  
qr = [0; 1];
```

In this example, the PDEs, initial conditions, and boundary conditions are coded in local functions `pdex4pde`, `pdex4ic`, and `pdex4bc`.

The surface plots show the behavior of the solution components.

**Purpose** Evaluate numerical solution of PDE using output of pdepe

**Syntax** `[uout,duoutdx] = pdeval(m,x,ui,xout)`

### Arguments

|       |                                                                                                                                                                                                          |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| m     | Symmetry of the problem: slab = 0, cylindrical = 1, spherical = 2. This is the first input argument used in the call to pdepe.                                                                           |
| xmesh | A vector <code>[x0, x1, ..., xn]</code> specifying the points at which the elements of <code>ui</code> were computed. This is the same vector with which pdepe was called.                               |
| ui    | A vector <code>sol(j,:,i)</code> that approximates component <code>i</code> of the solution at time $t_j$ and mesh points <code>xmesh</code> , where <code>sol</code> is the solution returned by pdepe. |
| xout  | A vector of points from the interval <code>[x0,xn]</code> at which the interpolated solution is requested.                                                                                               |

### Description

`[uout,duoutdx] = pdeval(m,x,ui,xout)` approximates the solution  $u_i$  and its partial derivative  $\partial u_i / \partial x$  at points from the interval `[x0,xn]`. The pdeval function returns the computed values in `uout` and `duoutdx`, respectively.

---

**Note** pdeval evaluates the partial derivative  $\partial u_i / \partial x$  rather than the flux  $f$ . Although the flux is continuous, the partial derivative may have a jump at a material interface.

pdepe

# peaks

---

## Purpose

Example function of two variables

## Syntax

```
Z = peaks;  
Z = peaks(n);  
Z = peaks(V);  
Z = peaks(X,Y);
```

```
peaks;  
peaks(N);  
peaks(V);  
peaks(X,Y);
```

```
[X,Y,Z] = peaks;  
[X,Y,Z] = peaks(n);  
[X,Y,Z] = peaks(V);
```

## Description

`peaks` is a function of two variables, obtained by translating and scaling Gaussian distributions, which is useful for demonstrating `mesh`, `surf`, `pcolor`, `contour`, and so on.

`Z = peaks;` returns a 49-by-49 matrix.

`Z = peaks(n);` returns an n-by-n matrix.

`Z = peaks(V);` returns an n-by-n matrix, where `n = length(V)`.

`Z = peaks(X,Y);` evaluates `peaks` at the given `X` and `Y` (which must be the same size) and returns a matrix the same size.

`peaks(...)` (with no output argument) plots the peaks function with `surf`.

`[X,Y,Z] = peaks(...)`; returns two additional matrices, `X` and `Y`, for parametric plots, for example, `surf(X,Y,Z,de12(Z))`. If not given as input, the underlying matrices `X` and `Y` are

```
[X,Y] = meshgrid(V,V)
```

where `V` is a given vector, or `V` is a vector of length `n` with elements equally spaced from `-3` to `3`. If no input argument is given, the default `n` is `49`.

## Examples

This example creates a 5-by-5 matrix of peaks and displays the image:

```
peaks(5);
```

# peaks

---

See Examples section from `surf` for a more elaborate use case.

`meshgrid` | `surf`

**Purpose**

Call Perl script using appropriate operating system executable

**Syntax**

```
perl('perlfile')
perl('perlfile',arg1,arg2,...)
result = perl(...)
[result, status] = perl(...)
```

**Description**

`perl('perlfile')` calls the Perl script `perlfile`, using the appropriate operating system Perl executable. Perl is included with the MATLAB software on Microsoft Windows systems, and thus MATLAB users can run user-created MATLAB functions containing the `perl` function. On Linux and Macintosh systems, MATLAB calls the Perl interpreter available with the operating system.

`perl('perlfile',arg1,arg2,...)` calls the Perl script `perlfile`, using the appropriate operating system Perl executable, and passes the arguments `arg1`, `arg2`, and so on, to `perlfile`.

`result = perl(...)` returns the results of attempted Perl call to `result`.

`[result, status] = perl(...)` returns the results of attempted Perl call to `result` and its exit status to `status`.

It is sometimes beneficial to use Perl scripts instead of MATLAB code. The `perl` function allows you to run those scripts from MATLAB. Specific examples where you might choose to use a Perl script include:

- Perl script already exists
- Perl script preprocesses data quickly, formatting it in a way more easily read by MATLAB
- Perl has features not supported by MATLAB

**Examples**

Given the Perl script, `hello.pl`:

```
$input = $ARGV[0];
print "Hello $input.";
```

# perl

---

At the MATLAB command line, type:

```
perl('hello.pl','World')
```

MATLAB displays:

```
ans =  
Hello World.
```

## **See Also**

`dos` | `regexp` | `system` | `unix` | `!` (exclamation point)

**Purpose** All possible permutations

**Syntax**  $P = \text{perms}(v)$

**Description**  $P = \text{perms}(v)$ , where  $v$  is a row vector of length  $n$ , creates a matrix whose rows consist of all possible permutations of the  $n$  elements of  $v$ . Matrix  $P$  contains  $n!$  rows and  $n$  columns.

**Examples** The command `perms([2 4 6])` returns *all* the permutations of the numbers 2, 4, and 6:

|   |   |   |
|---|---|---|
| 6 | 4 | 2 |
| 6 | 2 | 4 |
| 4 | 6 | 2 |
| 4 | 2 | 6 |
| 2 | 4 | 6 |
| 2 | 6 | 4 |

**Limitations** This function is only practical for situations where  $n$  is less than about 11.

**See Also** `nchoosek` | `permute` | `randperm`

# permute

---

**Purpose** Rearrange dimensions of N-D array

**Syntax** `B = permute(A,order)`

**Description** `B = permute(A,order)` rearranges the dimensions of `A` so that they are in the order specified by the vector `order`. `B` has the same values of `A` but the order of the subscripts needed to access any particular element is rearranged as specified by `order`. All the elements of `order` must be unique.

**Tips** `permute` and `ipermute` are a generalization of transpose (`.'`) for multidimensional arrays.

**Examples** Given any matrix `A`, the statement

```
permute(A,[2 1])
```

is the same as `A.'`

For example:

```
A = [1 2; 3 4]; permute(A,[2 1])
ans =
     1     3
     2     4
```

The following code permutes a three-dimensional array:

```
X = rand(12,13,14);
Y = permute(X,[2 3 1]);
size(Y)
ans =
    13    14    12
```

**See Also** `ipermute` | `circshift` | `fliplr` | `flipud` | `reshape` | `shiftdim`

**Purpose** Define persistent variable

**Syntax** `persistent X Y Z`

**Description** `persistent X Y Z` defines X, Y, and Z as variables that are local to the function in which they are declared; yet their values are retained in memory between calls to the function. Persistent variables are similar to global variables because the MATLAB software creates permanent storage for both. They differ from global variables in that persistent variables are known only to the function in which they are declared. This prevents persistent variables from being changed by other functions or from the MATLAB command line.

Whenever you clear or modify a function that is in memory, MATLAB also clears all persistent variables declared by that function. To keep a function in memory until MATLAB quits, use `mlock`.

If the persistent variable does not exist the first time you issue the `persistent` statement, it is initialized to the empty matrix.

It is an error to declare a variable persistent if a variable with the same name exists in the current workspace. MATLAB also errors if you declare any of a function's input or output arguments as persistent within that same function. For example, the following persistent declaration is invalid:

```
function myfun(argA, argB, argC)
persistent argB
```

**Tips** There is no function form of the `persistent` command (i.e., you cannot use parentheses and quote the variable names).

**Examples** This function writes a large array to a spreadsheet file and then reads several rows from the same file. Because you only need to write the array to the spreadsheet one time, the program tests whether an array can be read from the file and, if so, does not waste time in repeating that task. By defining the `dblArray` variable as persistent, you can easily check whether the array has been read from the spreadsheet file.

Here is the arrayToXLS function:

```
function arrayToXLS(A, xlsfile, x1, x2)
persistent dblArray;

if isempty(dblArray)
    disp 'Writing spreadsheet file ...'
    xlswrite(xlsfile, A);
end

disp 'Reading array from spreadsheet ...'
dblArray = xlsread(xlsfile, 'Sheet1', [x1 ':' x2])
fprintf('\n');
```

Run the function three times and observe the time elapsed for each run. The second and third run take approximately one tenth the time of the first run in which the function must create the spreadsheet:

```
largeArray = rand(4000, 200);

tic, arrayToXLS(largeArray, 'myTest.xls','E254', 'J256'), toc
Writing spreadsheet file ...
Reading array from spreadsheet ...
dblArray =
    0.0982    0.3783    0.1264    0.7880    0.1902    0.5811
    0.2251    0.2704    0.5682    0.7271    0.8028    0.2834
    0.6453    0.5568    0.8254    0.4961    0.9096    0.5402
```

Elapsed time is 8.990525 seconds.

```
tic, arrayToXLS(largeArray, 'myTest.xls','E257', 'J258'), toc
Reading array from spreadsheet ...
dblArray =
    0.4620    0.3781    0.6386    0.5930    0.0946    0.4865
    0.1605    0.1251    0.8709    0.5188    0.6702    0.2138
```

Elapsed time is 0.912534 seconds.

```
tic, arrayToXLS(largeArray, 'myTest.xls','E259', 'J262'), toc
Reading array from spreadsheet ...
dblArray =
    0.7015    0.6588    0.4023    0.0359    0.4512    0.6097
    0.1308    0.6441    0.0431    0.6396    0.7481    0.8688
    0.8278    0.2686    0.5475    0.8550    0.5896    0.1080
    0.9437    0.1671    0.0505    0.1203    0.2461    0.7306
```

Elapsed time is 0.928843 seconds.

Now clear the arrayToXLS function from memory and observe that running it takes much longer again:

```
clear functions
```

```
tic, arrayToXLS(largeArray, 'myTest.xls','E263', 'J264'), toc
Writing spreadsheet file ...
Reading array from spreadsheet ...
dblArray =
    0.6292    0.7788    0.0732    0.6481    0.9299    0.8631
    0.7700    0.5181    0.9805    0.5092    0.8658    0.4070
```

Elapsed time is 7.603461 seconds.

## See Also

[global](#) | [clear](#) | [mislocked](#) | [mlock](#) | [munlock](#) | [isempty](#)

# pi

---

**Purpose** Ratio of circle's circumference to its diameter

**Syntax** `pi`

**Description** `pi` returns the floating-point number nearest the value of  $\pi$ . The expressions `4*atan(1)` and `imag(log(-1))` provide the same value.

**Examples** Find the sine of  $\pi$ :

```
sin(pi)
```

```
returns
```

```
ans =
```

```
1.2246e-16
```

The expression `sin(pi)` is not exactly zero because `pi` is not exactly  $\pi$ .

**Purpose**

Pie chart

**Syntax**

```
pie(X)
pie(X,explode)
pie(...,labels)
pie(axes_handle,...)
h = pie(...)
```

**Description**

`pie(X)` draws a pie chart using the data in `X`. Each element in `X` is represented as a slice in the pie chart.

`pie(X,explode)` offsets a slice from the pie. `explode` is a vector or matrix of zeros and nonzeros that correspond to `X`. A nonzero value offsets the corresponding slice from the center of the pie chart, so that `X(i,j)` is offset from the center if `explode(i,j)` is nonzero. `explode` must be the same size as `X`.

`pie(...,labels)` specifies text labels for the slices. The number of labels must equal the number of elements in `X`. For example,

```
pie(1:3,{'Taxes','Expenses','Profit'})
```

`pie(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = pie(...)` returns a vector of handles to patch and text graphics objects.

**Tips**

The values in `X` are normalized via  $X/\text{sum}(X)$  to determine the area of each slice of the pie. If  $\text{sum}(X) = 1$ , the values in `X` directly specify the area of the pie slices. MATLAB draws only a partial pie if  $\text{sum}(X) < 1$ .

**Examples**

Emphasize the second slice in the chart by setting its corresponding `explode` element to 1.

# pie

---

```
x = [1 3 0.5 2.5 2];  
explode = [0 1 0 0 0];  
pie(x,explode)  
colormap jet
```

## See Also

`pie3`

**Purpose**

3-D pie chart

**Syntax**

```
pie3(X)
pie3(X,explode)
pie3(...,labels)
pie3(axes_handle,...)
h = pie3(...)
```

**Description**

`pie3(X)` draws a three-dimensional pie chart using the data in `X`. Each element in `X` is represented as a slice in the pie chart.

`pie3(X,explode)` specifies whether to offset a slice from the center of the pie chart. `X(i,j)` is offset from the center of the pie chart if `explode(i,j)` is nonzero. `explode` must be the same size as `X`.

`pie3(...,labels)` specifies text labels for the slices. The number of labels must equal the number of elements in `X`. For example,

```
pie3(1:3,{'Taxes','Expenses','Profit'})
```

`pie3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = pie3(...)` returns a vector of handles to patch, surface, and text graphics objects.

**Tips**

The values in `X` are normalized via  $X/\text{sum}(X)$  to determine the area of each slice of the pie. If  $\text{sum}(X) = 1$ , the values in `X` directly specify the area of the pie slices. MATLAB draws only a partial pie if  $\text{sum}(X) < 1$ .

**Examples**

Offset a slice in the pie chart by setting the corresponding `explode` element to 1:

```
x = [1 3 0.5 2.5 2];
explode = [0 1 0 0 0];
```

# pie3

---

```
pie3(x,explode)  
colormap hsv
```

## See Also

[pie](#)

**Purpose**

Moore-Penrose pseudoinverse of matrix

**Syntax**

`B = pinv(A)`  
`B = pinv(A,tol)`

**Definitions**

The Moore-Penrose pseudoinverse is a matrix  $B$  of the same dimensions as  $A'$  satisfying four conditions:

$A*B*A = A$   
 $B*A*B = B$   
 $A*B$  is Hermitian  
 $B*A$  is Hermitian

The computation is based on `svd(A)` and any singular values less than `tol` are treated as zero.

**Description**

`B = pinv(A)` returns the Moore-Penrose pseudoinverse of  $A$ .

`B = pinv(A,tol)` returns the Moore-Penrose pseudoinverse and overrides the default tolerance, `max(size(A))*norm(A)*eps`.

**Examples**

If  $A$  is square and not singular, then `pinv(A)` is an expensive way to compute `inv(A)`. If  $A$  is not square, or is square and singular, then `inv(A)` does not exist. In these cases, `pinv(A)` has some of, but not all, the properties of `inv(A)`.

If  $A$  has more rows than columns and is not of full rank, then the overdetermined least squares problem

`minimize norm(A*x-b)`

does not have a unique solution. Two of the infinitely many solutions are

`x = pinv(A)*b`

and

`y = A\b`

These two are distinguished by the facts that  $\text{norm}(x)$  is smaller than the norm of any other solution and that  $y$  has the fewest possible nonzero components.

For example, the matrix generated by

```
A = magic(8); A = A(:,1:6)
```

is an 8-by-6 matrix that happens to have  $\text{rank}(A) = 3$ .

```
A =  
    64     2     3    61    60     6  
     9    55    54    12    13    51  
    17    47    46    20    21    43  
    40    26    27    37    36    30  
    32    34    35    29    28    38  
    41    23    22    44    45    19  
    49    15    14    52    53    11  
     8    58    59     5     4    62
```

The right-hand side is  $b = 260 \cdot \text{ones}(8, 1)$ ,

```
b =  
    260  
    260  
    260  
    260  
    260  
    260  
    260  
    260  
    260
```

The scale factor 260 is the 8-by-8 magic sum. With all eight columns, one solution to  $A \cdot x = b$  would be a vector of all 1's. With only six columns, the equations are still consistent, so a solution exists, but it is not all 1's. Since the matrix is rank deficient, there are infinitely many solutions. Two of them are

```
x = pinv(A)*b
```

which is

```
x =  
  1.1538  
  1.4615  
  1.3846  
  1.3846  
  1.4615  
  1.1538
```

and

```
y = A\b
```

which produces this result.

```
Warning: Rank deficient, rank = 3  tol = 1.8829e-013.
```

```
y =  
  4.0000  
  5.0000  
   0  
   0  
   0  
 -1.0000
```

Both of these are exact solutions in the sense that  $\text{norm}(A*x-b)$  and  $\text{norm}(A*y-b)$  are on the order of roundoff error. The solution  $x$  is special because

```
norm(x) = 3.2817
```

is smaller than the norm of any other solution, including

```
norm(y) = 6.4807
```

On the other hand, the solution  $y$  is special because it has only three nonzero components.

# planerot

---

**Purpose** Givens plane rotation

**Syntax** `[G,y] = planerot(x)`

**Description** `[G,y] = planerot(x)` where  $x$  is a 2-component column vector, returns a 2-by-2 orthogonal matrix  $G$  so that  $y = G*x$  has  $y(2) = 0$ .

**Examples**

```
x = [3 4];  
[G,y] = planerot(x')
```

```
G =  
    0.6000    0.8000  
   -0.8000    0.6000
```

```
y =  
    5  
    0
```

**See Also** `qrdelete` | `qrinsert`

**Purpose** Play audio from audioplayer object

**Syntax**

```
play(playerObj)
play(playerObj, start)
play(playerObj, [start, stop])
```

**Description**

`play(playerObj)` plays the audio associated with audioplayer object `playerObj` from beginning to end.

`play(playerObj, start)` plays audio from the sample indicated by `start` to the end.

`play(playerObj, [start, stop])` plays audio from the sample indicated by `start` to the sample indicated by `stop`.

## **Examples**      **Play with and without Blocking**

Play two audio samples with and without blocking using the `play` and `playblocking` methods.

Load data from example files `chirp.mat` and `gong.mat`.

```
chirpData = load('chirp.mat');
chirpObj = audioplayer(chirpData.y, chirpData.Fs);
```

```
gongData = load('gong.mat');
gongObj = audioplayer(gongData.y, gongData.Fs);
```

Play the samples with blocking, one after the other.

```
playblocking(chirpObj);
playblocking(gongObj);
```

Play without blocking. The audio can overlap.

```
play(chirpObj);
play(gongObj);
```

# audioplayer.play

---

## Starting Sample

Play audio from the example file `handel.mat` starting 4 seconds from the beginning.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = playerObj.SampleRate * 4;

play(playerObj,start);
```

## Sample Range

Play the first 3 seconds of audio from the example file `handel.mat`.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = 1;
stop = playerObj.SampleRate * 3;

play(playerObj,[start,stop]);
```

## See Also

## How To

- “Play Audio”

**Purpose** Play audio from audiorecorder object

**Syntax**

```
player = play(recObj)  
player = play(recObj, start)  
player = play(recObj, [start stop])
```

**Description**

*player* = play(*recObj*) plays the audio associated with audiorecorder object *recObj* from beginning to end, and returns an audioplayer object.

*player* = play(*recObj*, *start*) plays audio from the sample indicated by *start* to the end.

*player* = play(*recObj*, [*start stop*]) plays audio from the sample indicated by *start* to the sample indicated by *stop*.

**Examples** Record 5 seconds of your speech with a microphone, and play it back. Display the properties of the audioplayer object.

```
myVoice = audiorecorder;  
  
disp('Start speaking.');
```

---

```
recordblocking(myVoice, 5);  
disp('End of recording. Playing back ...');
```

```
playerObj = play(myVoice);  
  
disp('Properties of playerObj:');  
get(playerObj)
```

---

Play back only the first 3 seconds of the speech recorded in the previous example:

```
play(myVoice, [1 myVoice.SampleRate*3]);
```

**See Also** audioplayer | audiorecorder

# audioplayer.playblocking

---

**Purpose** Play audio from audioplayer object, holding control until playback completes

**Syntax**

```
playblocking(playerObj)
playblocking(playerObj,start)
playblocking(playerObj,[start,stop])
```

**Description**

`playblocking(playerObj)` plays the audio associated with audioplayer object `playerObj` from beginning to end. `playblocking` does not return control until playback completes.

`playblocking(playerObj,start)` plays audio from the sample indicated by `start` to the end.

`playblocking(playerObj,[start,stop])` plays audio from the sample indicated by `start` to the sample indicated by `stop`.

## **Examples**      **Play with and without Blocking**

Play two audio samples with and without blocking using the `play` and `playblocking` methods.

Load data from example files `chirp.mat` and `gong.mat`.

```
chirpData = load('chirp.mat');
chirpObj = audioplayer(chirpData.y,chirpData.Fs);
```

```
gongData = load('gong.mat');
gongObj = audioplayer(gongData.y,gongData.Fs);
```

Play the samples with blocking, one after the other.

```
playblocking(chirpObj);
playblocking(gongObj);
```

Play without blocking. The audio can overlap.

```
play(chirpObj);
play(gongObj);
```

## Starting Sample

Play audio from the example file `handel.mat` starting 4 seconds from the beginning.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = playerObj.SampleRate * 4;

playblocking(playerObj,start);
beep;
```

## Sample Range

Play the first 3 seconds of audio from the example file `handel.mat`.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = 1;
stop = playerObj.SampleRate * 3;

playblocking(playerObj,[start,stop]);
beep;
```

## See Also

[audioplayer](#) | [play](#)

## How To

- “Play Audio”

# plot

---

**Purpose** 2-D line plot

**Syntax**

```
plot(Y)
plot(X1,Y1,...,Xn,Yn)
plot(X1,Y1,LineStyle,...,Xn,Yn,LineStyle)
plot(...,'PropertyName',PropertyValue,...)
plot(axes_handle,...)
h = plot(...)
```

**Description** `plot(Y)` plots the columns of `Y` versus the index of each value when `Y` is a real number. For complex `Y`, `plot(Y)` is equivalent to `plot(real(Y), imag(Y))`.

`plot(X1,Y1,...,Xn,Yn)` plots each vector `Yn` versus vector `Xn` on the same axes. If one of `Yn` or `Xn` is a matrix and the other is a vector, it plots the vector versus the matrix row or column with a matching dimension to the vector. If `Xn` is a scalar and `Yn` is a vector, it plots discrete `Yn` points vertically at `Xn`. If `Xn` or `Yn` are complex, imaginary components are ignored. If `Xn` or `Yn` are matrices, they must be 2-D and the same size, and the columns of `Yn` are plotted against the columns of `Xn`. `plot` automatically chooses colors and line styles in the order specified by `ColorOrder` and `LineStyleOrder` properties of current axes.

`plot(X1,Y1,LineStyle,...,Xn,Yn,LineStyle)` plots lines defined by the `Xn,Yn,LineStyle` triplets, where `LineStyle` specifies the line type, marker symbol, and color. You can mix `Xn,Yn,LineStyle` triplets with `Xn,Yn` pairs: `plot(X1,Y1,X2,Y2,LineStyle,X3,Y3)`.

`plot(...,'PropertyName',PropertyValue,...)` manipulates plot characteristics by setting `lineseries` properties (of `lineseries` graphics objects created by `plot`). Enter properties as one or more name-value pairs. Property name-value pairs apply to all the lines plotted. You cannot specify name-value pairs for each set of data.

`plot(axes_handle,...)` plots using axes with the handle `axes_handle` instead of the current axes (`gca`).

`h = plot(...)` returns a column vector of handles to `lineseries` objects, one handle per line.

**Tips**

Plot data can include NaN and inf values, which cause breaks in the lines drawn. For example,

```
plot([1:5,NaN,6:10])
```

Skips the sixth element and resumes line drawing at the seventh element with the Y value of 6.

**Examples**

Plot a sine curve.

```
x = -pi:.1:pi;  
y = sin(x);  
plot(x,y)
```

# plot

---

---

Create line plot using specific line width, marker color, and marker size.

```
x = -pi:pi/10:pi;  
y = tan(sin(x)) - sin(tan(x));  
plot(x,y,'--rs','LineWidth',2,...  
      'MarkerEdgeColor','k',...  
      'MarkerFaceColor','g',...  
      'MarkerSize',10)
```

Modify axis tick marks and tick labels and annotate the graph.

```
x = -pi:.1:pi;  
y = sin(x);  
plot(x,y)  
set(gca,'XTick',-pi:pi/2:pi)  
set(gca,'XTickLabel',{'-pi','-pi/2','0','pi/2','pi'})
```

# plot

---

```
title('Sine Function');  
xlabel('Radians');  
ylabel('Function Value');
```

Add a plot title, axis labels, and annotations.

```
x = -pi:.1:pi;  
y = sin(x);  
p = plot(x,y)
```

```
set(gca,'XTick',-pi:pi/2:pi)
set(gca,'XTickLabel',{'-pi','-pi/2','0','pi/2','pi'})
xlabel('-\pi \leq \Theta \leq \pi')
ylabel('sin(\Theta)')
title('Plot of sin(\Theta)')
% \Theta appears as a Greek symbol (see String)
% Annotate the point (-pi/4, sin(-pi/4))
text(-pi/4,sin(-pi/4),'\leftarrow sin(-\pi\div4)',...
    'HorizontalAlignment','left')
% Change the line color to red and
% set the line width to 2 points
set(p,'Color','red','LineWidth',2)
```

# plot

---

Plot multiple line plots on the same axes.

```
plot(sin(x));  
% hold axes and all lineseries properties, such as  
% ColorOrder and LineStyleOrder, for the next plot  
hold all  
plot(sin(x+(pi/4)));
```

Set line color to be always black and line style order to cycle through solid, dash-dot, dash-dash, and dotted line styles.

```
set(0, 'DefaultAxesColorOrder', [0 0 0], ...  
      'DefaultAxesLineStyleOrder', '-|-|.|-|:|')  
plot(sin(x))  
hold all  
plot(cos(x))  
hold all
```

# plot

---

```
plot(log(abs(x)))
```

## How To

- [Editing Plot Characteristics](#)
- [Creating Line Plots](#)

- Annotating Graphs
- “Axes Objects — Defining Coordinate Systems for Graphs”

# plot3

---

**Purpose** 3-D line plot

**Syntax**

```
plot3(X1,Y1,Z1,...)
plot3(X1,Y1,Z1,LineStyle,...)
plot3(...,'PropertyName',PropertyValue,...)
h = plot3(...)
```

**Description** The `plot3` function displays a three-dimensional plot of a set of data points.

`plot3(X1,Y1,Z1,...)`, where  $X1$ ,  $Y1$ ,  $Z1$  are vectors or matrices, plots one or more lines in three-dimensional space through the points whose coordinates are the elements of  $X1$ ,  $Y1$ , and  $Z1$ .

`plot3(X1,Y1,Z1,LineStyle,...)` creates and displays all lines defined by the  $Xn, Yn, Zn, LineSpec$  quads, where  $LineSpec$  is a line specification that determines line style, marker symbol, and color of the plotted lines.

`plot3(...,'PropertyName',PropertyValue,...)` sets properties to the specified property values for all line graphics objects created by `plot3`. See `lineseries` properties for a description of the properties you can set.

`h = plot3(...)` returns a column vector of handles to `lineseries` graphics objects, with one handle per object.

**Tips** If one or more of  $X1$ ,  $Y1$ ,  $Z1$  is a vector, the vectors are plotted versus the rows or columns of the matrix, depending whether the vectors' lengths equal the number of rows or the number of columns.

You can mix  $Xn, Yn, Zn$  triples with  $Xn, Yn, Zn, LineSpec$  quads, for example,

```
plot3(X1,Y1,Z1,X2,Y2,Z2,LineStyle,X3,Y3,Z3)
```

See `LineStyle` and `plot` for information on line types and markers.

**Examples**

Plot a three-dimensional helix.

```
t = 0:pi/50:10*pi;
plot3(sin(t),cos(t),t)
xlabel('sin(t)')
ylabel('cos(t)')
zlabel('t')
grid on
axis square
```

## See Also

[axis](#) | [bar3](#) | [grid](#) | [line](#) | [LineStyle](#) | [lineseries](#) properties | [loglog](#) | [plot](#) | [scatter3](#) | [semilogx](#) | [semilogy](#) | [subplot](#)

**Purpose** Show or hide figure **Plot Browser**

**Syntax**

```
plotbrowser('on')
plotbrowser('off')
plotbrowser
plotbrowser(figure_handle,...)
```

**Description**

`plotbrowser('on')` displays the Plot Browser on the current figure.

`plotbrowser('off')` hides the Plot Browser on the current figure.

`plotbrowser` toggles the visibility of the Plot Browser on the current figure. You can use `plotbrowser('toggle')` instead for the same functionality.

`plotbrowser(figure_handle,...)` shows or hides the Plot Browser on the figure specified by `figure_handle`.

**Tips**

If you call `plotbrowser` in a MATLAB program and subsequent lines depend on the Plot Browser being fully initialized, follow it by `drawnow` to ensure complete initialization.

**Alternatives**

To collectively enable **Plotting Tools**, use the large Plotting Tool icon  on the figure toolbar. To collectively disable the **Plotting Tools**, use the smaller icon . Open or close the **Plot Browser** tool from the figure's **View** menu.

**See Also** `plottools` | `figurepalette` | `propertyeditor`

# plottedit

---

**Purpose** Interactively edit and annotate plots

**Syntax**

```
plottedit on
plottedit off
plottedit
plottedit(h)
plottedit('state')
plottedit(h, 'state')
```

**Description** `plottedit on` starts plot edit mode for the current figure, allowing you to use a graphical interface to annotate and edit plots easily. In plot edit mode, you can label axes, change line styles, and add text, line, and arrow annotations.

`plottedit off` ends plot mode for the current figure.

`plottedit` toggles the plot edit mode for the current figure.

`plottedit(h)` toggles the plot edit mode for the figure specified by figure handle `h`.

`plottedit('state')` specifies the `plottedit` state for the current figure. Values for `state` can be as shown.

| Value for state | Description                                     |
|-----------------|-------------------------------------------------|
| on              | Starts plot edit mode                           |
| off             | Ends plot edit mode                             |
| showtoolsmenu   | Displays the <b>Tools</b> menu in the menu bar  |
| hidetoolsmenu   | Removes the <b>Tools</b> menu from the menu bar |

---

**Note** `hidetoolsmenu` is intended for GUI developers who do not want the **Tools** menu to appear in applications that use the figure window.

---

`plottedit(h, 'state')` specifies the plottedit state for figure handle `h`.

## Tips

### Plot Editing Mode Graphical Interface Components

Use these toolbar buttons to add a legend, text, and arrows.

To start plot edit mode, click this button.

Use the Edit, Insert, and Tools menus to add objects or edit existing objects in a graph.

Double-click on an object to select it.

Position labels, legends, and other objects by clicking and dragging.

Access object-specific plot edit functions through context-sensitive pop-up menus.

## Examples

Start plot edit mode for figure 2.

```
plottedit(2)
```

End plot edit mode for figure 2.

```
plottedit(2, 'off')
```

Hide the **Tools** menu for the current figure:

# plottedit

---

```
plottedit('hidetoolsmenu')
```

## See Also

[axes](#) | [line](#) | [open](#) | [plot](#) | [print](#) | [saveas](#) | [text](#) | [propedit](#)

**Purpose**

Scatter plot matrix

**Syntax**

```
plotmatrix(X,Y)
plotmatrix(X)
plotmatrix(...,'LineStyle')
[H,AX,BigAx,P] = plotmatrix(...)
```

**Description**

`plotmatrix(X,Y)` scatter plots the columns of `X` against the columns of `Y`. If `X` is  $p$ -by- $m$  and `Y` is  $p$ -by- $n$ , `plotmatrix` produces an  $n$ -by- $m$  matrix of axes.

`plotmatrix(X)` is the same as `plotmatrix(X,X)`, except that the diagonal is replaced by `hist(X(:,i))`.

`plotmatrix(...,'LineStyle')` uses a `LineStyle` to create the scatter plot. The default is `'.'`.

`[H,AX,BigAx,P] = plotmatrix(...)` returns a matrix of handles to the objects created in `H`, a matrix of handles to the individual subaxes in `AX`, a handle to a big (invisible) axes that frames the subaxes in `BigAx`, and a matrix of handles for the histogram plots in `P`. `BigAx` is left as the current axes so that a subsequent `title`, `xlabel`, or `ylabel` command is centered with respect to the matrix of axes.

**Examples**

Generate plots of random data.

```
x = randn(50,3);
y = x*[-1 2 1;2 0 1;1 -2 3]';
plotmatrix(y,'*r')
```

# plotmatrix

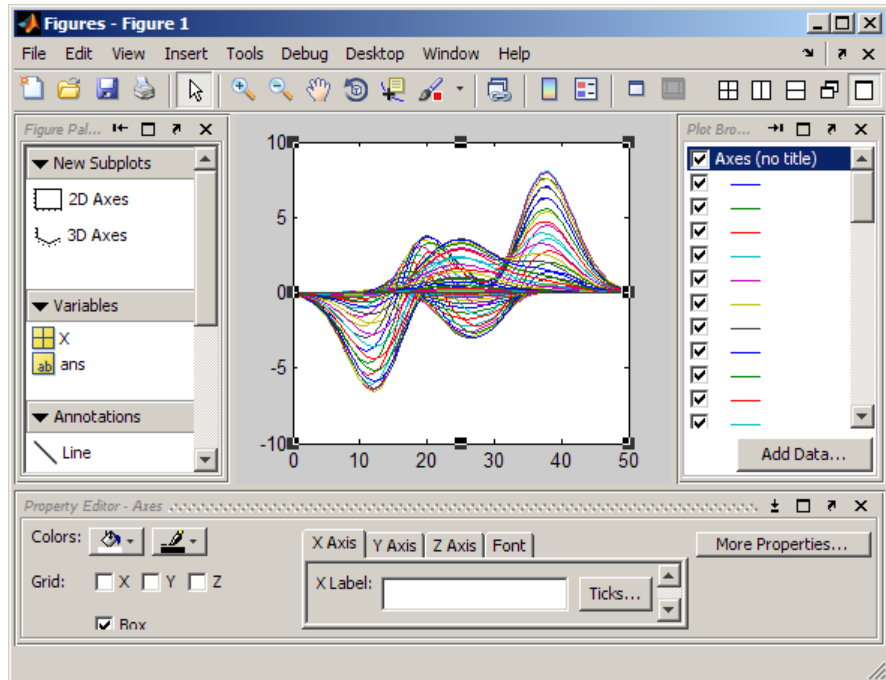

---

**Purpose** Show or hide plot tools

**Syntax**

```

plottools('on')
plottools('off')
plottools
plottools(figure_handle,...)
plottools(..., 'tool')

```

**Description**

`plottools('on')` displays the Figure Palette, Plot Browser, and Property Editor on the current figure, configured as you last used them.

`plottools('off')` hides the Figure Palette, Plot Browser, and Property Editor on the current figure.

`plottools` with no arguments, is the same as `plottools('on')`

`plottools(figure_handle, ...)` displays or hides the plot tools on the specified figure instead of on the current figure.

`plottools(..., 'tool')` operates on the specified tool only. *tool* can be one of the following strings:

- `figurepalette`
- `plotbrowser`
- `propertyeditor`

---

**Note** The first time you open the plotting tools, all three of them appear, grouped around the current figure as shown above. If you close, move, or undock any of the tools, MATLAB remembers the configuration you left them in and restores it when you invoke the tools for subsequent figures, both within and across MATLAB sessions.

---

## Alternatives

Click the larger **Plotting Tools** icon  on the figure toolbar to collectively enable plotting tools, and the smaller icon  to collectively disable them. Individually select the **Figure Palette**, **Plot Browser**, and **Property Editor** tools from the figure's **View** menu. For details, see “Plotting Tools — Interactive Plotting”.

## See Also

`figurepalette` | `plotbrowser` | `propertyeditor`

## Purpose

2-D line plots with y-axes on both left and right side

## Syntax

```
plotyy(X1,Y1,X2,Y2)
plotyy(X1,Y1,X2,Y2,function)
plotyy(X1,Y1,X2,Y2,'function1','function2')
[AX,H1,H2] = plotyy(...)
```

## Description

`plotyy(X1,Y1,X2,Y2)` plots  $X1$  versus  $Y1$  with  $y$ -axis labeling on the left and plots  $X2$  versus  $Y2$  with  $y$ -axis labeling on the right.

`plotyy(X1,Y1,X2,Y2,function)` uses the specified plotting function to produce the graph.

`function` can be either a function handle or a string specifying `plot`, `semilogx`, `semilogy`, `loglog`, `stem`, or any MATLAB function that accepts the syntax

```
h = function(x,y)
```

For example,

```
plotyy(x1,y1,x2,y2,@loglog) % function handle
plotyy(x1,y1,x2,y2,'loglog') % string
```

Function handles enable you to access user-defined local functions and can provide other advantages. See `@` for more information on using function handles.

`plotyy(X1,Y1,X2,Y2,'function1','function2')` uses `function1(X1,Y1)` to plot the data for the left axis and `function2(X2,Y2)` to plot the data for the right axis.

`[AX,H1,H2] = plotyy(...)` returns the handles of the two axes created in `AX` and the handles of the graphics objects from each plot in `H1` and `H2`. `AX(1)` is the left axes and `AX(2)` is the right axes.

## Examples

This example graphs two mathematical functions using `plot` as the plotting function. The two  $y$ -axes enable you to display both sets of data on one graph even though relative values of the data are quite different.

```
figure
x = 0:0.01:20;
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);
[AX,H1,H2] = plotyy(x,y1,x,y2,'plot');
```

You can use the handles returned by `plotyy` to label the axes and set the line styles used for plotting. With the axes handles you can specify the `YLabel` properties of the left- and right-side  $y$ -axis:

```
set(get(AX(1),'Ylabel'),'String','Slow Decay')
set(get(AX(2),'Ylabel'),'String','Fast Decay')
```

Use the `xlabel` and `title` commands to label the  $x$ -axis and add a title:

```
xlabel('Time (\musec)')
title('Multiple Decay Rates')
```

Use the line handles to set the `LineStyle` properties of the left- and right-side plots:

```
set(H1,'LineStyle','--')
set(H2,'LineStyle',':')
```

- “Using Multiple X- and Y-Axes”

# plus

---

**Purpose**

Plus

**Syntax**

```
c = a+b  
c = plus(a,b)
```

**Description**

`c = a+b` adds arrays `a` and `b` and returns the result in `c`. Inputs `a` and `b` must have the same size unless one is a scalar value (1-by-1 matrix). You can add a scalar value to any other value.

`c = plus(a,b)` is called for the syntax `a + b` when `a` or `b` is an object.

**See Also**

minus

## Purpose

Simplex containing specified location

## Syntax

```
SI = pointLocation(DT,QX)  
SI = pointLocation(DT,QX,QY)  
SI = pointLocation(DT,QX,QY,QZ)  
[SI, BC] = pointLocation(DT,...)
```

## Description

SI = pointLocation(DT,QX) returns the indices SI of the enclosing simplex (triangle/tetrahedron) for each query point location in QX. The enclosing simplex for point QX(k,:) is SI(k). pointLocation returns NaN for all points outside the convex hull.

SI = pointLocation(DT,QX,QY) and SI = pointLocation(DT,QX,QY,QZ) allow the query point locations to be specified in alternative column vector format when working in 2-D and 3-D.

[SI, BC] = pointLocation(DT,...) returns the barycentric coordinates BC.

## Input Arguments

|    |                                                                     |
|----|---------------------------------------------------------------------|
| DT | Delaunay triangulation.                                             |
| QX | Matrix of size mpts-by-ndim, mpts being the number of query points. |

## Output Arguments

|    |                                                                                                                                              |
|----|----------------------------------------------------------------------------------------------------------------------------------------------|
| SI | Column vector of length mpts containing the indices of the enclosing simplex for each query point. mpts is the number of query points.       |
| BC | BC is a mpts-by-ndim matrix, each row BC(i,:) represents the barycentric coordinates of QX(i,:) with respect to the enclosing simplex SI(i). |

# DelaunayTri.pointLocation

---

## Examples

### Example 1

Create a 2-D Delaunay triangulation:

```
X = rand(10,2);  
dt = DelaunayTri(X);
```

Find the triangles that contain specified query points:

```
qrypts = [0.25 0.25; 0.5 0.5];  
triids = pointLocation(dt, qrypts)
```

### Example 2

Create a 3-D Delaunay triangulation:

```
x = rand(10,1);  
y = rand(10,1);  
z = rand(10,1);  
dt = DelaunayTri(x,y,z);
```

Find the triangles that contain specified query points and evaluate the barycentric coordinates:

```
qrypts = [0.25 0.25 0.25; 0.5 0.5 0.5];  
[tetids, bcs] = pointLocation(dt, qrypts)
```

## See Also

[nearestNeighbor](#)

**Purpose** Transform polar or cylindrical coordinates to Cartesian

**Syntax**  
 $[X, Y] = \text{pol2cart}(\text{THETA}, \text{RHO})$   
 $[X, Y, Z] = \text{pol2cart}(\text{THETA}, \text{RHO}, Z)$

**Description**  $[X, Y] = \text{pol2cart}(\text{THETA}, \text{RHO})$  transforms the polar coordinate data stored in corresponding elements of THETA and RHO to two-dimensional Cartesian, or *xy*, coordinates. The arrays THETA and RHO must be the same size (or either can be scalar). The values in THETA must be in radians.

$[X, Y, Z] = \text{pol2cart}(\text{THETA}, \text{RHO}, Z)$  transforms the cylindrical coordinate data stored in corresponding elements of THETA, RHO, and Z to three-dimensional Cartesian, or *xyz* coordinates. The arrays THETA, RHO, and Z must be the same size (or any can be scalar). The values in THETA must be in radians.

**Algorithms** The mapping from polar and cylindrical coordinates to Cartesian coordinates is:

**Polar to Cartesian Mapping**  
 $x = \text{rho} * \cos(\text{theta})$   
 $y = \text{rho} * \sin(\text{theta})$

**Polar to Cartesian Mapping**  
 $x = \text{rho} * \cos(\text{theta})$   
 $y = \text{rho} * \sin(\text{theta})$   
 $z = z$

# pol2cart

---

## See Also

[cart2pol](#) | [cart2sph](#) | [sph2cart](#)

**Purpose**

Polar coordinate plot

**Syntax**

```
polar(theta,rho)
polar(theta,rho,LineStyle)
polar(axes_handle,...)
h = polar(...)
```

**Description**

The `polar` function accepts polar coordinates, plots them in a Cartesian plane, and draws the polar grid on the plane.

`polar(theta,rho)` creates a polar coordinate plot of the angle `theta` versus the radius `rho`. `theta` is the angle from the  $x$ -axis to the radius vector specified in radians; `rho` is the length of the radius vector specified in dataspace units.

`polar(theta,rho,LineStyle)` `LineStyle` specifies the line type, plot symbol, and color for the lines drawn in the polar plot.

`polar(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = polar(...)` returns the handle of a line object in `h`.

**Tips**

Negative  $r$  values reflect through the origin, rotating by  $\pi$  (since  $(\theta,r)$  transforms to  $(r\cos(\theta), r\sin(\theta))$ ). If you want different behavior, you can manipulate  $r$  prior to plotting. For example, you can make  $r$  equal to  $\max(0,r)$  or  $\text{abs}(r)$ .

**Examples**

Create a simple polar plot using a dashed red line:

```
figure
t = 0:.01:2*pi;
polar(t,sin(2*t).*cos(2*t),'--r')
```

## See Also

[cart2pol](#) | [compass](#) | [LineStyle](#) | [plot](#) | [pol2cart](#) | [rose](#)

**Purpose**

Polynomial with specified roots

**Syntax**

```
p = poly(A)
p = poly(r)
```

**Description**

$p = \text{poly}(A)$  where  $A$  is an  $n$ -by- $n$  matrix returns an  $n+1$  element row vector whose elements are the coefficients of the characteristic polynomial,  $\det(\lambda I - A)$ . The coefficients are ordered in descending powers: if a vector  $c$  has  $n+1$  components, the polynomial it represents is  $c_1 s^n + \dots + c_n s + c_n + 1$

$p = \text{poly}(r)$  where  $r$  is a vector returns a row vector whose elements are the coefficients of the polynomial whose roots are the elements of  $r$ .

**Tips**

Note the relationship of this command to

```
r = roots(p)
```

which returns a column vector whose elements are the roots of the polynomial specified by the coefficients row vector  $p$ . For vectors, `roots` and `poly` are inverse functions of each other, up to ordering, scaling, and roundoff error.

**Examples**

MATLAB displays polynomials as row vectors containing the coefficients ordered by descending powers. The characteristic equation of the matrix

```
A =
```

```
    1    2    3
    4    5    6
    7    8    0
```

is returned in a row vector by `poly`:

```
p = poly(A)
```

```
p =
    1    -6   -72   -27
```

The roots of this polynomial (eigenvalues of matrix A) are returned in a column vector by `roots`:

```
r = roots(p)
```

```
r =
```

```
    12.1229  
   -5.7345  
   -0.3884
```

## Algorithms

The algorithms employed for `poly` and `roots` illustrate an interesting aspect of the modern approach to eigenvalue computation. `poly(A)` generates the characteristic polynomial of A, and `roots(poly(A))` finds the roots of that polynomial, which are the eigenvalues of A. But both `poly` and `roots` use `eig`, which is based on similarity transformations. The classical approach, which characterizes eigenvalues as roots of the characteristic polynomial, is actually reversed.

If A is an n-by-n matrix, `poly(A)` produces the coefficients `c(1)` through `c(n+1)`, with `c(1) = 1`, in

$$\det(\lambda I - A) = c_1 \lambda^n + \dots + c_n \lambda + c_{n+1}$$

The algorithm is

```
z = eig(A);  
c = zeros(n+1,1); c(1) = 1;  
for j = 1:n  
    c(2:j+1) = c(2:j+1) - z(j)*c(1:j);  
end
```

This recursion is easily derived by expanding the product.

$$(\lambda - \lambda_1)(\lambda - \lambda_2)\dots(\lambda - \lambda_n)$$

It is possible to prove that `poly(A)` produces the coefficients in the characteristic polynomial of a matrix within roundoff error of A. This is

true even if the eigenvalues of  $A$  are badly conditioned. The traditional algorithms for obtaining the characteristic polynomial, which do not use the eigenvalues, do not have such satisfactory numerical properties.

`conv` | `polyval` | `residue` | `roots`

# polyarea

---

**Purpose** Area of polygon

**Syntax**  
`A = polyarea(X,Y)`  
`A = polyarea(X,Y,dim)`

**Description** `A = polyarea(X,Y)` returns the area of the polygon specified by the vertices in the vectors `X` and `Y`.

If `X` and `Y` are matrices of the same size, then `polyarea` returns the area of polygons defined by the columns `X` and `Y`.

If `X` and `Y` are multidimensional arrays, `polyarea` returns the area of the polygons in the first nonsingleton dimension of `X` and `Y`.

`A = polyarea(X,Y,dim)` operates along the dimension specified by scalar `dim`.

**Examples**

```
L = linspace(0,2.*pi,9); xv = 1.2*cos(L)';yv = 1.2*sin(L)';  
xv = [xv ; xv(1)]; yv = [yv ; yv(1)];  
A = polyarea(xv,yv);  
plot(xv,yv); title(['Area = ' num2str(A)]); axis image
```

**See Also**`convhull` | `inpolygon` | `rectint`

# polyder

---

**Purpose** Polynomial derivative

**Syntax**  
`k = polyder(p)`  
`k = polyder(a,b)`  
`[q,d] = polyder(b,a)`

**Description** The `polyder` function calculates the derivative of polynomials, polynomial products, and polynomial quotients. The operands `a`, `b`, and `p` are vectors whose elements are the coefficients of a polynomial in descending powers.

`k = polyder(p)` returns the derivative of the polynomial `p`.

`k = polyder(a,b)` returns the derivative of the product of the polynomials `a` and `b`.

`[q,d] = polyder(b,a)` returns the numerator `q` and denominator `d` of the derivative of the polynomial quotient `b/a`.

**Examples** The derivative of the product

$$(3x^2 + 6x + 9)(x^2 + 2x)$$

is obtained with

```
a = [3 6 9];  
b = [1 2 0];  
k = polyder(a,b)  
k =  
    12    36    42    18
```

This result represents the polynomial

$$12x^3 + 36x^2 + 42x + 18$$

**See Also** `conv` | `deconv`

**Purpose**

Polynomial eigenvalue problem

**Syntax**

```
[X,e] = polyeig(A0,A1,...,Ap)
e = polyeig(A0,A1,...,Ap)
[X, e, s] = polyeig(A0,A1,...,AP)
```

**Description**

`[X,e] = polyeig(A0,A1,...,Ap)` solves the polynomial eigenvalue problem of degree  $p$

$$(A_0 + \lambda A_1 + \dots + \lambda^p A_p)x = 0$$

where polynomial degree  $p$  is a non-negative integer, and  $A_0, A_1, \dots, A_p$  are input matrices of order  $n$ . The output consists of a matrix  $X$  of size  $n$ -by- $n \times p$  whose columns are the eigenvectors, and a vector  $e$  of length  $n \times p$  containing the eigenvalues.

If  $\lambda$  is the  $j$ th eigenvalue in  $e$ , and  $x$  is the  $j$ th column of eigenvectors in  $X$ , then  $(A_0 + \lambda A_1 + \dots + \lambda^p A_p)x$  is approximately 0.

$e = \text{polyeig}(A_0, A_1, \dots, A_p)$  is a vector of length  $n \times p$  whose elements are the eigenvalues of the polynomial eigenvalue problem.

`[X, e, s] = polyeig(A0,A1,...,AP)` also returns a vector  $s$  of length  $p \times n$  containing condition numbers for the eigenvalues. At least one of  $A_0$  and  $A_p$  must be nonsingular. Large condition numbers imply that the problem is close to a problem with multiple eigenvalues.

**Tips**

Based on the values of  $p$  and  $n$ , `polyeig` handles several special cases:

- $p = 0$ , or `polyeig(A)` is the standard eigenvalue problem: `eig(A)`.
- $p = 1$ , or `polyeig(A,B)` is the generalized eigenvalue problem: `eig(A,-B)`.
- $n = 1$ , or `polyeig(a0,a1,...,ap)` for scalars  $a_0, a_1, \dots, a_p$  is the standard polynomial problem: `roots([ap ... a1 a0])`.

If both  $A_0$  and  $A_p$  are singular the problem is potentially ill-posed. Theoretically, the solutions might not exist or might not be unique. Computationally, the computed solutions might be inaccurate. If one, but not both, of  $A_0$  and  $A_p$  is singular, the problem is well posed, but some of the eigenvalues might be zero or infinite.

Note that scaling  $A_0, A_1, \dots, A_p$  to have  $\text{norm}(A_i)$  roughly equal 1 may increase the accuracy of `polyeig`. In general, however, this cannot be achieved. (See Tisseur [3] for more detail.)

## Algorithms

The `polyeig` function uses the QZ factorization to find intermediate results in the computation of generalized eigenvalues. It uses these intermediate results to determine if the eigenvalues are well-determined. See the descriptions of `eig` and `qz` for more on this.

`condeig` | `eig` | `qz`

**Purpose** Polynomial curve fitting

**Syntax**

```
p = polyfit(x,y,n)
[p,S] = polyfit(x,y,n)
[p,S,mu] = polyfit(x,y,n)
```

**Description** `p = polyfit(x,y,n)` finds the coefficients of a polynomial  $p(x)$  of degree  $n$  that fits the data,  $p(x(i))$  to  $y(i)$ , in a least squares sense. The result `p` is a row vector of length  $n+1$  containing the polynomial coefficients in descending powers:

$$p(x) = p_1x^n + p_2x^{n-1} + \dots + p_nx + p_{n+1}.$$

`[p,S] = polyfit(x,y,n)` returns the polynomial coefficients `p` and a structure `S` for use with `polyval` to obtain error estimates or predictions. Structure `S` contains fields `R`, `df`, and `normr`, for the triangular factor from a QR decomposition of the Vandermonde matrix of `x`, the degrees of freedom, and the norm of the residuals, respectively. If the data `y` are random, an estimate of the covariance matrix of `p` is  $(R_{\text{inv}} * R_{\text{inv}}') * \text{normr}^2 / \text{df}$ , where `Rinv` is the inverse of `R`. If the errors in the data `y` are independent normal with constant variance, `polyval` produces error bounds that contain at least 50% of the predictions.

`[p,S,mu] = polyfit(x,y,n)` finds the coefficients of a polynomial in

$$\hat{x} = \frac{x - \mu_1}{\mu_2}$$

where  $\mu_1 = \text{mean}(x)$  and  $\mu_2 = \text{std}(x)$ . `mu` is the two-element vector  $[\mu_1, \mu_2]$ . This centering and scaling transformation improves the numerical properties of both the polynomial and the fitting algorithm.

**Examples** This example involves fitting the error function,  $\text{erf}(x)$ , by a polynomial in  $x$ . This is a risky project because  $\text{erf}(x)$  is a bounded function, while polynomials are unbounded, so the fit might not be very good.

First generate a vector of  $x$  points, equally spaced in the interval  $[0, 2.5]$ ; then evaluate  $\text{erf}(x)$  at those points.

```
x = (0: 0.1: 2.5)';  
y = erf(x);
```

The coefficients in the approximating polynomial of degree 6 are

```
p = polyfit(x,y,6)
```

```
p =
```

```
0.0084 -0.0983 0.4217 -0.7435 0.1471 1.1064 0.0004
```

There are seven coefficients, and the polynomial is

$$0.0084x^6 - 0.0983x^5 + 0.4217x^4 - 0.7435x^3 + 0.1471x^2 + 1.1064x + 0.0004$$

To see how good the fit is, evaluate the polynomial at the data points with:

```
f = polyval(p,x);
```

A table showing the data, fit, and error is

```
table = [x y f y-f]
```

```
table =
```

| 2.5000 | 0.9996 | 0.9994 | 0.0002  |

On this interval, the interpolated values and the actual values agree fairly closely. Outside this interval, the extrapolated values quickly diverge from the actual data values, as the following plot demonstrates.

```
x = (0: 0.1: 5)';  
y = erf(x);  
f = polyval(p,x);  
plot(x,y,'o',x,f,'-')  
axis([0 5 0 2])
```

## Algorithms

The polyfit MATLAB file forms the Vandermonde matrix,  $V$ , whose elements are powers of  $x$ .  $v_{i,j} = x_i^{n-j}$

# polyfit

---

It then uses the backslash operator, `\`, to solve the least squares problem  $Vp \cong y$ .

See “Programmatic Fitting” for information about fitting different functions of  $x$ .

## See Also

`poly` | `polyval` | `roots` | `lscov` | `cov`

**Purpose** Integrate polynomial analytically

**Syntax** `polyint(p,k)`  
`polyint(p)`

**Description** `polyint(p,k)` returns a polynomial representing the integral of polynomial `p`, using a scalar constant of integration `k`.  
`polyint(p)` assumes a constant of integration `k=0`.

**See Also** `polyder` | `polyval` | `polyvalm` | `polyfit`

# polyval

---

**Purpose** Polynomial evaluation

**Syntax**

```
y = polyval(p,x)
[y,delta] = polyval(p,x,S)
y = polyval(p,x,[],mu)
[y,delta] = polyval(p,x,S,mu)
```

**Description** `y = polyval(p,x)` returns the value of a polynomial of degree  $n$  evaluated at  $x$ . The input argument  $p$  is a vector of length  $n+1$  whose elements are the coefficients in descending powers of the polynomial to be evaluated.

$$y = p_1x^n + p_2x^{n-1} + \dots + p_nx + p_{n+1}$$

$x$  can be a matrix or a vector. In either case, `polyval` evaluates  $p$  at each element of  $x$ .

`[y,delta] = polyval(p,x,S)` uses the optional output structure  $S$  generated by `polyfit` to generate error estimates  $\delta$ .  $\delta$  is an estimate of the standard deviation of the error in predicting a future observation at  $x$  by  $p(x)$ . If the coefficients in  $p$  are least squares estimates computed by `polyfit`, and the errors in the data input to `polyfit` are independent, normal, and have constant variance, then  $y \pm \delta$  contains at least 50% of the predictions of future observations at  $x$ .

`y = polyval(p,x,[],mu)` or `[y,delta] = polyval(p,x,S,mu)` use  $\hat{x} = (x - \mu_1) / \mu_2$  in place of  $x$ . In this equation,  $\mu_1 = \text{mean}(x)$  and  $\mu_2 = \text{std}(x)$ . The centering and scaling parameters  $\text{mu} = [\mu_1, \mu_2]$  are optional output computed by `polyfit`.

**Tips** The `polyvalm(p,x)` function, with  $x$  a matrix, evaluates the polynomial in a matrix sense. See `polyvalm` for more information.

## Examples

The polynomial  $p(x) = 3x^2 + 2x + 1$  is evaluated at  $x = 5, 7,$  and  $9$  with

```
p = [3 2 1];  
polyval(p,[5 7 9])
```

which results in

```
ans =
```

```
86    162    262
```

For another example, see `polyfit`.

## See Also

`polyfit` | `polyvalm` | `polyder` | `polyint`

# polyvalm

---

**Purpose** Matrix polynomial evaluation

**Syntax** `Y = polyvalm(p,X)`

**Description** `Y = polyvalm(p,X)` evaluates a polynomial in a matrix sense. This is the same as substituting matrix `X` in the polynomial `p`.

Polynomial `p` is a vector whose elements are the coefficients of a polynomial in descending powers, and `X` must be a square matrix.

## Examples

The Pascal matrices are formed from Pascal's triangle of binomial coefficients. Here is the Pascal matrix of order 4.

```
X = pascal(4)
X =
     1     1     1     1
     1     2     3     4
     1     3     6    10
     1     4    10    20
```

Its characteristic polynomial can be generated with the `poly` function.

```
p = poly(X)
p =
     1    -29     72    -29     1
```

This represents the polynomial  $x^4 - 29x^3 + 72x^2 - 29x + 1$ .

Pascal matrices have the curious property that the vector of coefficients of the characteristic polynomial is palindromic; it is the same forward and backward.

Evaluating this polynomial at each element is not very interesting.

```
polyval(p,X)
ans =
     16     16     16     16
     16     15    -140    -563
     16    -140   -2549  -12089
```

```
16      -563  -12089  -43779
```

But evaluating it in a matrix sense is interesting.

```
polyvalm(p,X)
ans =
    0     0     0     0
    0     0     0     0
    0     0     0     0
    0     0     0     0
```

The result is the zero matrix. This is an instance of the Cayley-Hamilton theorem: a matrix satisfies its own characteristic equation.

# pow2

---

**Purpose** Base 2 power and scale floating-point numbers

**Syntax**  
`X = pow2(Y)`  
`X = pow2(F,E)`

**Description** `X = pow2(Y)` returns an array `X` whose elements are 2 raised to the power `Y`.  
`X = pow2(F,E)` computes  $x = f * 2^e$  for corresponding elements of `F` and `E`. The result is computed quickly by simply adding `E` to the floating-point exponent of `F`. Arguments `F` and `E` are real and integer arrays, respectively.

**Tips** This function corresponds to the ANSI C function `ldexp()` and the IEEE floating-point standard function `scalbn()`.

**Examples** For IEEE arithmetic, the statement `X = pow2(F,E)` yields the values:

| F       | E     | X       |
|---------|-------|---------|
| 1/2     | 1     | 1       |
| pi/4    | 2     | pi      |
| -3/4    | 2     | -3      |
| 1/2     | -51   | eps     |
| 1-eps/2 | 1024  | realmax |
| 1/2     | -1021 | realmin |

**See Also** `log2` | `exp` | `hex2num` | `realmax` | `realmin` | Arithmetic Operators `^` and `.^`

**Purpose** Array power

**Syntax**  $Z = X.^Y$

**Description**  $Z = X.^Y$  denotes element-by-element powers.  $X$  and  $Y$  must have the same dimensions unless one is a scalar. A scalar is expanded to an array of the same size as the other input.

$C = \text{power}(A,B)$  is called for the syntax ' $A .^ B$ ' when  $A$  or  $B$  is an object.

Note that for a negative value  $X$  and a non-integer value  $Y$ , if the  $\text{abs}(Y)$  is less than one, the `power` function returns the complex roots. To obtain the remaining real roots, use the `nthroot` function.

**See Also** `nthroot` | `realpow`

**Purpose** Evaluate piecewise polynomial

**Syntax** `v = ppval(pp,xx)`

**Description** `v = ppval(pp,xx)` returns the value of the piecewise polynomial  $f$ , contained in `pp`, at the entries of `xx`. You can construct `pp` using the functions `pchip`, `spline`, or the spline utility `mkpp`.

`v` is obtained by replacing each entry of `xx` by the value of  $f$  there. If  $f$  is scalar-valued, `v` is of the same size as `xx`. `xx` may be N-dimensional.

If `pp` was constructed by `pchip`, `spline`, or `mkpp` using the orientation of non-scalar function values specified for those functions, then:

If  $f$  is  $[D1, \dots, Dr]$ -valued, and `xx` is a vector of length  $N$ , then `V` has size  $[D1, \dots, Dr, N]$ , with `V(:, ..., :, J)` the value of  $f$  at `xx(J)`.

If  $f$  is  $[D1, \dots, Dr]$ -valued, and `xx` has size  $[N1, \dots, Ns]$ , then `V` has size  $[D1, \dots, Dr, N1, \dots, Ns]$ , with `V(:, ..., :, J1, ..., Js)` the value of  $f$  at `xx(J1, ..., Js)`.

**Examples** Compare the results of integrating the function `cos`

```
a = 0; b = 10;  
int1 = quad(@cos,a,b)
```

```
int1 =  
    -0.5440
```

with the results of integrating the piecewise polynomial `pp` that approximates the cosine function by interpolating the computed values `x` and `y`.

```
x = a:b;  
y = cos(x);  
pp = spline(x,y);  
int2 = quad(@(x)ppval(pp,x),a,b)
```

```
int2 =
```

-0.5485

`int1` provides the integral of the cosine function over the interval  $[a,b]$ , while `int2` provides the integral over the same interval of the piecewise polynomial `pp`.

**See Also**

`mkpp` | `spline` | `unmkpp`

# prefdir

---

**Purpose** Folder containing preferences, history, and layout files

**Syntax**

```
prefdir
folder = prefdir
folder = prefdir(1)
```

**Description** `prefdir` returns the folder that contains

- Preferences for MATLAB and related products (`matlab.prf`)
- Command history file (`history.m`)
- MATLAB shortcuts (`shortcuts_2.xml`)
- MATLAB desktop layout files (`MATLABDesktop.xml` and `Your_Saved_LayoutMATLABLayout.xml`)
- Other related files

`folder = prefdir` assigns to `folder` the name of the folder containing preferences and related files.

`folder = prefdir(1)` creates a folder for preferences and related files if one does not exist. If the folder does exist, the name is assigned to `folder`.

**Tips**

- You must have write access to the preferences folder. Otherwise, MATLAB generates an error in the Command Window when you try to change preferences. This can happen if the folder is hidden, for example: `myname/.matlab/R2009a`.

**Examples** View the location of the preferences folder:

```
prefdir
```

---

Make the preferences folder become the current folder:

```
cd(prefdir)
```

```
% Then, view the files for customizing MathWorks products:  
dir
```

On Windows platforms, go directly to the preferences folder in Microsoft Windows Explorer

```
winopen(prefdir)
```

**See Also**

preferences | getpref | setpref

**How To**

**Purpose** Generate list of prime numbers

**Syntax** `p = primes(n)`

**Description** `p = primes(n)` returns a row vector of the prime numbers less than or equal to `n`. A prime number is one that has no factors other than 1 and itself.

**Examples** `p = primes(37)`

```
p = 2 3 5 7 11 13 17 19 23 29 31 37
```

**See Also** `factor`

## Purpose

Print figure or save to file

## Syntax

```
print
print('argument1', 'argument2', ...)
print(handle, 'filename')
print argument1 argument2 ... argumentn
```

## Description

`print` sends the contents of the current figure, including bitmap representations of any user interface controls, to the printer using the device and system printing command defined by `printopt`.

`print('argument1', 'argument2', ...)` is the function form of `print`. It enables you to pass variables for any input arguments. This form is useful for passing file names and handles (for example, `print(handle, 'filename')`). See “Batch Processing” on page 2-3557 for an example. Also see “Specifying the Figure to Print” on page 2-3555 for further examples.

---

**Note** Print input only takes string variables and handles as inputs. Strings passed in as cell array or struct inputs are not accepted.

---

`print argument1 argument2 ... argumentn` prints the figure using the specified arguments.

The following arguments apply to both the function and the command form:

| <b>Argument</b>                | <b>Description</b>                                                                                                                                                                                                                                                                               |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>handle</code>            | Print the specified object.                                                                                                                                                                                                                                                                      |
| <code>filename</code>          | Direct the output to the PostScript file designated by <code>filename</code> . If <code>filename</code> does not include an extension, <code>print</code> appends an appropriate extension.                                                                                                      |
| <code>-ddriver</code>          | Print the figure using the specified printer <code>driver</code> , (such as color PostScript). If you omit <code>-ddriver</code> , <code>print</code> uses the default value stored in <code>printopt.m</code> . The table in “Printer Drivers” on page 2-3540 lists all supported device types. |
| <code>-dformat</code>          | Copy the figure to the system Clipboard (Microsoft Windows platforms only). To be valid, the <code>format</code> for this operation must be either <code>-dmeta</code> (Windows Enhanced Metafile) or <code>-dbitmap</code> (Windows Bitmap).                                                    |
| <code>-dformat filename</code> | Export the figure to the specified file using the specified graphics <code>format</code> (such as TIFF). The table of “Graphics Format Files” on page 2-3544 lists all supported graphics file formats.                                                                                          |
| <code>-smodelName</code>       | Print the current Simulink model <code>modelName</code> .                                                                                                                                                                                                                                        |
| <code>-options</code>          | Specify print options that modify the action of the <code>print</code> command. (For example, the <code>-noui</code> option suppresses printing of user interface controls.) “Printing Options” on page 2-3548 lists available options.                                                          |

## Printer Drivers

The following table shows the more widely used printer drivers supported by MATLAB software. If you do not specify a driver, the default setting shown in the previous table is used. For a list of all supported printer drivers, type `print -d` at the MATLAB prompt. Some things to remember:

- As indicated in “Description” on page 2-3538 the `-d` switch specifies a printer driver or a graphics file format:
  - Specifying a printer driver without a file name or printer name (the `-P` option) sends the output formatted by the specified driver to your default printer, which may not be what you want to do.

---

**Note** On Windows systems, when you use the `-P` option to identify a printer to use, if you specify any driver other than `-dwin` or `-dwinc`, MATLAB writes the output to a file with an appropriate extension but does not send it to the printer. You can then copy that file to a printer.

---

- Specifying a `-dmeta` or a `-dbitmap` graphics format without a file name places the graphic on the system Clipboard, if possible (Windows platforms only).
- Specifying any other graphics format without a file name creates a file in the current folder with a name such as `figureN.fmt`, where `N` is 1, 2, 3, ... and `fmt` indicates the format type, for example, `eps` or `png`.
- Several drivers come from a product called Ghostscript, which is shipped with MATLAB software. The last column indicates when Ghostscript is used.
- Not all drivers are supported on all platforms. Non support is noted in the first column of the table.
- If you specify a particular printer with the `-P` option and do not specify a driver, a default driver for that printer is selected, either by the operating system or by MATLAB, depending on the platform:

- On Windows, the driver associated with this particular printing device is used.
- On Macintosh and UNIX platforms, the driver specified in `printopt.m` is used

See *Selecting the Printer* in the Graphics documentation for more information.

**Note** MathWorks is planning to leverage existing operating system (OS) support for printer drivers and devices. As a result, the ability to specify certain print devices using the `print -d` command, and certain graphics formats using the `print -d` command and/or the `saveas` command, will be removed in a future release. In the following table, the affected formats have an asterisk (\*) next to the `print` command option string. The asterisks provide a link to the Web site which supplies a form for users to give feedback about these changes.

| <b>Printer Driver</b>                                              | <b>Print Command Option String</b> | <b>Ghostscript</b> |

---

**Tip** Generally, Level 2 PostScript files are smaller and are rendered more quickly when printing than Level 1 PostScript files. However, not all PostScript printers support Level 2, so determine the capabilities of your printer before using those drivers. Level 2 PostScript printing is the default for UNIX platforms. You can change this default by editing the `printopt.m` file. Likewise, if you want color PostScript printing to be the default instead of black-and-white PostScript printing, edit the line in the `printopt.m` file that reads `dev = '-dps2'`; to be `dev = '-dpsc2'`;

---

## Graphics Format Files

To save your figure as a graphics format file, specify a format switch and file name. To set the resolution of the output file for a built-in MATLAB format, use the `-r` switch. (For example, `-r300` sets the output resolution to 300 dots per inch.) The `-r` switch is also supported for Windows Enhanced Metafiles, JPEG, TIFF and PNG files, but is not supported for Ghostscript raster formats. For more information, see “Printing and Exporting without a Display” on page 2-3547 and “Resolution Considerations” on page 2-3550.

---

**Note** When you print to a file, the file name must have fewer than 128 characters, including path name. When you print to a file in your current folder, the filename must have fewer than 126 characters, because MATLAB places  `'./'` or  `'.\'` at the beginning of the filename when referring to it.

---

The following table shows the supported output formats for exporting from figures and the switch settings to use. In some cases, a format is available both as a MATLAB output filter and as a Ghostscript output filter. All formats except for EMF are supported on both Windows and UNIX platforms.

| <b>Graphics Format</b>                                               | <b>Bitmap or Vector</b> | <b>Print Command Option String</b> | <b>MATLAB or Ghostscript</b> |
|----------------------------------------------------------------------|-------------------------|------------------------------------|------------------------------|
| <b>BMP</b> monochrome BMP                                            | Bitmap                  | -dbmpmono                          | Ghostscript                  |
| <b>BMP</b> 24-bit BMP                                                | Bitmap                  | -dbmp16m                           | Ghostscript                  |
| <b>BMP</b> 8-bit (256-color) BMP (this format uses a fixed colormap) | Bitmap                  | -dbmp256                           | Ghostscript                  |
| <b>BMP</b> 24-bit                                                    | Bitmap                  | -dbmp                              | MATLAB                       |

| <b>PPM</b> Portable Pixmap (plain format)                      | Bitmap                  | -dppm                              | Ghostscript                  |
| <b>PPM</b> Portable Pixmap (raw format)                        | Bitmap                  | -dppmraw                           | Ghostscript                  |
| <b>SVG</b> Scalable Vector Graphics (For Simulink Models Only) | Vector                  | -dsvg                              | MATLAB                       |

| <b>Graphics Format</b>            | <b>Bitmap or Vector</b> | <b>Print Command Option String</b> | <b>MATLAB or Ghostscript</b> |
|-----------------------------------|-------------------------|------------------------------------|------------------------------|
| <b>TIFF 24-bit</b>                | Bitmap                  | -dtiff or -dtiffn                  | MATLAB                       |
| <b>TIFF preview for EPS files</b> | Bitmap                  | -tiff                              |                              |

The TIFF image format is supported on all platforms by almost all word processors for importing images. The `-dtiffn` variant writes an uncompressed TIFF. JPEG is a lossy, highly compressed format that is supported on all platforms for image processing and for inclusion into HTML documents on the Web. To create these formats, MATLAB renders the figure using the Z-buffer rendering method and the resulting bitmap is then saved to the specified file.

### **Printing and Exporting without a Display**

On a UNIX platform (including Macintosh), where you can start in MATLAB `nodisplay` mode (`matlab -nodisplay`), you can print using most of the drivers you can use with a display and export to most of the same file formats. The PostScript and Ghostscript devices all function in `nodisplay` mode on UNIX platforms. The graphic devices `-djpeg`, `-dpng`, `-dtiff` (compressed TIFF bitmaps), and `-tiff` (EPS with TIFF preview) work as well, but under `nodisplay` they use Ghostscript to generate output instead of using the drivers built into MATLAB. However, Ghostscript ignores the `-r` option when generating `-djpeg`, `-dpng`, `-dtiff`, and `-tiff` image files. This means that you cannot vary the resolution of image files when running in `nodisplay` mode.

Naturally, the Windows only `-dwin` and `-dwinc` output formats cannot be used on UNIX or Mac platforms with or without a display.

The same holds true on Windows platforms with the `-noFigureWindows` startup option. The `-dwin`, `-dwinc`, and `-dsetup` options operate as usual under `-noFigureWindows`. However, the `printpreview` GUI does not function in this mode.

The formats which you cannot generate in `nodisplay` mode on UNIX and Mac platforms are:

- `bitmap (-dbitmap)` — Windows bitmap file
- `bmp (-dbmp...)` — Monochrome and color bitmaps
- `hdf (-dhdf)` — Hierarchical Data Format
- `svg (-dsvg)` — Scalable Vector Graphics file
- `tiffn (-dtiffn)` — TIFF image file, no compression

In addition, `uicontrols` do not print or export in `nodisplay` mode.

## Printing Options

This table summarizes options that you can specify for `print`. The second column links to tutorials that provide operational details. Also see “Resolution Considerations” on page 2-3550 for information on controlling output resolution.

| Option                  | Description                                                                                                                           |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>-adobecset</code> | PostScript devices only. Use PostScript default character set encoding. See “Early PostScript 1 Printers”.                            |
| <code>-append</code>    | PostScript devices only. Append figure to existing PostScript file. See “Settings That Are Driver Specific”.                          |
| <code>-cmyk</code>      | PostScript devices only. Print with CMYK colors instead of RGB. See “Setting CMYK Color”.                                             |
| <code>-ddriver</code>   | Printing only. Printer driver to use. See “Printer Drivers” on page 2-3540 table.                                                     |
| <code>-dformat</code>   | Exporting only. Graphics format to use. See “Graphics Format Files” table.                                                            |
| <code>-dsetup</code>    | Windows printing only. Display the (platform-specific) Print Setup dialog. Settings you make in it are saved, but nothing is printed. |

| Option        | Description                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -fhandle      | Handle of figure to print. Note that you cannot specify both this option and the <i>-swindowtitle</i> option. See “Which Figure Is Printed”.                                                                                                                                                                                                                                                                            |
| -loose        | PostScript and Ghostscript printing only. Use loose bounding box for PostScript output. See “Producing Uncropped Figures”.                                                                                                                                                                                                                                                                                              |
| -noui         | Suppress printing of user interface controls. See “Excluding User Interface Controls”.                                                                                                                                                                                                                                                                                                                                  |
| -opengl       | Render using the OpenGL algorithm. Note that you cannot specify this method in conjunction with <i>-zbuffer</i> or <i>-painters</i> . See “Selecting a Renderer”.                                                                                                                                                                                                                                                       |
| -painters     | Render using the Painter’s algorithm. Note that you cannot specify this method in conjunction with <i>-zbuffer</i> or <i>-opengl</i> . See “Selecting a Renderer”.                                                                                                                                                                                                                                                      |
| -Pprinter     | Specify name of printer to use. See “Selecting the Printer”.                                                                                                                                                                                                                                                                                                                                                            |
| -rnumber      | PostScript and built-in raster formats, and Ghostscript vector format only. Specify resolution in dots per inch. Defaults to 90 for Simulink, 150 for figures in image formats and when printing in Z-buffer or OpenGL mode, screen resolution for metafiles, and 864 otherwise. Use <i>-r0</i> to specify screen resolution. For details, see “Resolution Considerations” on page 2-3550 and “Setting the Resolution”. |
| -swindowtitle | Specify name of Simulink system window to print. Note that you cannot specify both this option and the <i>-fhandle</i> option. See “Which Figure Is Printed”.                                                                                                                                                                                                                                                           |

| Option   | Description                                                                                                                                         |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| -v       | Windows printing only. Display the Windows Print dialog box. The v stands for “verbose mode.”                                                       |
| -zbuffer | Render using the Z-buffer algorithm. Note that you cannot specify this method in conjunction with -opengl or -painters. See “Selecting a Renderer”. |

## Resolution Considerations

Use *-rnumber* to specify the resolution of the generated output. In general, using a higher value will yield higher quality output but at the cost of larger output files. It affects the resolution and output size of all MATLAB built-in *raster* formats (which are identified in column four of the table in “Graphics Format Files” on page 2-3544).

---

**Note** Built-in graphics formats are generated directly from MATLAB without conversion through the Ghostscript library. Also, in headless (nodisplay) mode, writing to certain image formats is not done by built-in drivers, as it is when a display is being used. These formats are -djpeg, -dtiff, and -dpng. Furthermore, the -dhdf and -dbmp formats cannot be generated in headless mode (but you can substitute -dbmp16m for -dbmp). See “Printing and Exporting without a Display” on page 2-3547 for details on printing when not using a display.

---

Unlike the built-in MATLAB formats, graphic output generated via Ghostscript does not directly obey *-r* option settings. However, the intermediate PostScript file generated by MATLAB as input for the Ghostscript processor is affected by the *-r* setting and thus can indirectly influence the quality of the final Ghostscript generated output.

The effect of the *-r* option on output quality can be subtle at ordinary magnification when using the OpenGL or ZBuffer renderers and writing to one of the MATLAB built-in raster formats, or when generating vector

output that contains an embedded raster image (for example, PostScript or PDF). The effect of specifying higher resolution is more apparent when viewing the output at higher magnification or when printed, since a larger `-r` setting provides more data to use when scaling the image.

When generating fully vectorized output (as when using the Painters renderer to output a vector format such as PostScript or PDF), the resolution setting affects the degree of detail of the output; setting resolution higher generates crisper output (but small changes in the resolution may have no observable effect). For example, the gap widths of lines that do not use a solid ( ' - ' ) linestyle can be affected.

## Paper Sizes

MATLAB printing supports a number of standard paper sizes. You can select from the following list by setting the `PaperType` property of the figure or selecting a supported paper size from the Print dialog box.

| Property Value | Size (Width by Height) |
|----------------|------------------------|
| usletter       | 8.5 by 11 inches       |
| uslegal        | 8.5 by 14 inches       |
| tabloid        | 11 by 17 inches        |
| A0             | 841 by 1189 mm         |
| A1             | 594 by 841 mm          |
| A2             | 420 by 594 mm          |
| A3             | 297 by 420 mm          |
| A4             | 210 by 297 mm          |
| A5             | 148 by 210 mm          |
| B0             | 1029 by 1456 mm        |
| B1             | 728 by 1028 mm         |
| B2             | 514 by 728 mm          |
| B3             | 364 by 514 mm          |

| Property Value | Size (Width by Height) |
|----------------|------------------------|
| B4             | 257 by 364 mm          |
| B5             | 182 by 257 mm          |
| arch-A         | 9 by 12 inches         |
| arch-B         | 12 by 18 inches        |
| arch-C         | 18 by 24 inches        |
| arch-D         | 24 by 36 inches        |
| arch-E         | 36 by 48 inches        |
| A              | 8.5 by 11 inches       |
| B              | 11 by 17 inches        |
| C              | 17 by 22 inches        |
| D              | 22 by 34 inches        |
| E              | 34 by 43 inches        |

## Printing Tips

### Setting Default Printer

You can edit the file `printopt.m` to set the default printer type and destination. If you want to set up a new printer, use the operating system printer management utilities. Restart MATLAB if you do not see a printer which is already setup.

### Figures with Resize Functions

The `print` command produces a warning when you print a figure having a callback routine defined for the figure `ResizeFcn`. To avoid the warning, set the figure `PaperPositionMode` property to `auto` or select **Auto (Actual Size, Centered)** in the **File > Print Preview** dialog box.

## Troubleshooting Microsoft Windows Printing

If you encounter problems such as segmentation violations, general protection faults, or application errors, or the output does not appear as you expect when using Microsoft printer drivers, try the following:

- If your printer is PostScript compatible, print with one of the MATLAB built-in PostScript drivers. There are various PostScript device options that you can use with `print`, which all start with `-dps`.
- The behavior you are experiencing might occur only with certain versions of the print driver. Contact the print driver vendor for information on how to obtain and install a different driver.
- Try printing with one of the MATLAB built-in Ghostscript devices. These devices use Ghostscript to convert PostScript files into other formats, such as HP LaserJet, PCX, Canon BubbleJet, and so on.
- Copy the figure as a Windows Enhanced Metafile using the **Edit > Copy Figure** menu item on the figure window menu or the `print -dmeta` option at the command line. You can then import the file into another application for printing.

You can set copy options in the figure's **File > Preferences > Copying Options** dialog box. The Windows Enhanced Metafile Clipboard format produces a better quality image than Windows Bitmap.

## Printing MATLAB GUIs

You can generally obtain better results when printing a figure window that contains MATLAB uicontrols by setting these key properties:

- Set the figure `PaperPositionMode` property to `auto`. This ensures that the printed version is the same size as the on-screen version. With `PaperPositionMode` set to `auto` MATLAB, does not resize the figure to fit the current value of the `PaperPosition`. This is particularly important if you have specified a figure `ResizeFcn`, because if MATLAB resizes the figure during the print operation, `ResizeFcn` is automatically called.

To set `PaperPositionMode` on the current figure, use the command:

```
set(gcf, 'PaperPositionMode', 'auto')
```

- Set the figure `InvertHardcopy` property to `off`. By default, MATLAB changes the figure background color of printed output to white, but does not change the color of `uicontrols`. If you have set the background color, for example, to match the gray of the GUI devices, you must set `InvertHardcopy` to `off` to preserve the color scheme.

To set `InvertHardcopy` on the current figure, use the command:

```
set(gcf, 'InvertHardcopy', 'off')
```

- Use a color device if you want lines and text that are in color on the screen to be written to the output file as colored objects. Black and white devices convert colored lines and text to black or white to provide the best contrast with the background and to avoid dithering.
- Use the `print` command's `-loose` option to keep a bounding box from being too tightly wrapped around objects contained in the figure. This is important if you have intentionally used space between `uicontrols` or axes and the edge of the figure and you want to maintain this appearance in the printed output.

If you print or export in `nodisplay` mode, none of the `uicontrols` the figure has will be visible. If you run code that adds `uicontrols` to a figure when the figure is invisible, the controls will not print until the figure is made visible.

## Printing Interpolated Shading with PostScript Drivers

You can print MATLAB surface objects (such as graphs created with `surf` or `mesh`) using interpolated colors. However, only patch objects that are composed of triangular faces can be printed using interpolated shading.

Printed output is always interpolated in RGB space, not in the colormap colors. This means that if you are using indexed color and interpolated face coloring, the printed output can look different from what is displayed on screen.

PostScript files generated for interpolated shading contain the color information of the graphics object's vertices and require the printer to perform the interpolation calculations. This can take an excessive amount of time and in some cases, printers might time out before finishing the print job. One solution to this problem is to interpolate the data and generate a greater number of faces, which can then be flat shaded.

To ensure that the printed output matches what you see on the screen, print using the `-zbuffer` option. To obtain higher resolution (for example, to make text look better), use the `-r` option to increase the resolution. There is, however, a tradeoff between the resolution and the size of the created PostScript file, which can be quite large at higher resolutions. The default resolution of 150 dpi generally produces good results. You can reduce the size of the output file by making the figure smaller before printing it and setting the figure `PaperPositionMode` to `auto`, or by just setting the `PaperPosition` property to a smaller size.

## Examples

### Specifying the Figure to Print

Pass a figure handle as a variable to the function form of `print`. For example:

```
h = figure;  
plot(1:4,5:8)  
print(h)
```

Save the figure with the handle `h` to a PostScript file named `Figure2`, which can be printed later:

```
print(h, '-dps', 'Figure2.ps')
```

Pass in a file name as a variable:

```
filename = 'mydata';  
print(h, '-dpsc', filename);
```

(Because a file name is specified, the figure will be printed to a file.)

## Specifying the Model to Print

Print a noncurrent Simulink model using the `-s` option with the title of the window (in this case, `f14`):

```
print('-sf14')
```

If the window title includes any spaces, you must call the function form rather than the command form of `print`. For example, this command saves the Simulink window title `Thruster Control`:

```
print('-sThruster Control')
```

To print the current system, use:

```
print('-s')
```

For information about issues specific to printing Simulink windows, see the Simulink documentation.

## Printing Figures at Screen Size

This example prints a surface plot with interpolated shading. Setting the current figure's (`gcf`) `PaperPositionMode` to `auto` enables you to resize the figure window and print it at the size you see on the screen. See “Printing Options” on page 2-3548 and “Printing Interpolated Shading with PostScript Drivers” on page 2-3554 for information on the `-zbuffer` and `-r200` options.

```
surf(peaks)
shading interp
set(gcf,'PaperPositionMode','auto')
print('-dpsc2','-zbuffer','-r200')
```

For additional details, see “Printing Images” in the MATLAB Graphics documentation.

## Batch Processing

You can use the function form of `print` to pass variables containing file names. For example, this for loop uses file names stored in a cell array to create a series of graphs and prints each one with a different file name:

```
fnames = {'file1', 'file2', 'file3'};
for k=1:length(fnames)
    surf(peaks)
    print('-dtiff', '-r200', fnames{k}) % fnames is a cell of string array
                                        % each element is a string
```

## Tiff Preview

The command

```
print('-depsec', '-tiff', '-r300', 'picture1')
```
