saves the current figure at 300 dpi, in a color Encapsulated PostScript file named `picture1.eps`. The `-tiff` option creates a 72 dpi TIFF preview, which many word processor applications can display on screen after you import the EPS file. This enables you to view the picture on screen within your word processor and print the document to a PostScript printer using a resolution of 300 dpi.

## Alternatives

Select **File > Print** from the figure window to open the Print dialog box and **File > Print Preview** to open the Print Preview GUI. For details, see “How to Print or Export”.

# printopt

---

**Purpose** Configure printer defaults

**Syntax** [pcmd,dev] = printopt

**Description** [pcmd,dev] = printopt returns strings containing the current system-dependent printing command and output device. printopt is a file used by print to produce the hard-copy output. You can edit the file printopt.m to set your default printer type and destination.

pcmd and dev are platform-dependent strings. pcmd contains the command that print uses to send a file to the printer. dev contains the printer driver or graphics format option for the print command. Their defaults are platform dependent.

| Platform     | Print Command    | Driver or Format |
|--------------|------------------|------------------|
| Mac and UNIX | lpr -r           | -dps2            |
| Windows      | COPY /B %s LPT1: | -dwin            |

**See Also** printdlg | print

**Purpose** Print dialog box

**Syntax**

```
printdlg  
printdlg(fig)  
printdlg('-crossplatform',fig)  
printdlg('-setup',fig)
```

**Description**

`printdlg` prints the current figure.

`printdlg(fig)` creates a modal dialog box from which you can print the figure window identified by the handle `fig`. Note that `uimenu`s do not print.

`printdlg('-crossplatform',fig)` displays the standard cross-platform MATLAB printing dialog rather than the built-in printing dialog box for Microsoft Windows computers. Insert this option before the `fig` argument.

`printdlg('-setup',fig)` forces the printing dialog to appear in a setup mode. If you want to set up a new printer, use the operating system printer management utilities. Restart MATLAB if you don't see the printer which is already setup.

---

**Note** It is `advprinter` on MATLAB

---

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

# printpreview

---

**Purpose** Preview figure to print

## **Contents**

“Description” on page 2-3560

“Right Pane Controls” on page 2-3561

“The Layout Tab” on page 2-3562

“The Lines/Text Tab” on page 2-3563

“The Color Tab” on page 2-3565

“The Advanced Tab” on page 2-3567

“Alternatives” on page 2-3568

**Syntax**  
`printpreview`  
`printpreview(f)`

**Description** `printpreview` displays a dialog box showing the figure in the currently active figure window as it will print. A scaled version of the figure displays in the right-hand pane of the GUI.

`printpreview(f)` displays a dialog box showing the figure having the handle `f` as it will print.

Use the Print Preview dialog box, shown below, to control the layout and appearance of figures before sending them to a printer or print file. Controls are grouped into four tabbed panes: **Layout**, **Lines/Text**, **Color**, and **Advanced**.

## Right Pane Controls

You can position and scale plots on the printed page using the rulers in the right-hand pane of the Print Preview dialog. Use the outer ruler handlebars to change margins. Moving them changes plot proportions. Use the center ruler handlebars to change the position of the plot on the page. Plot proportions do not change, but you can move portions of

the plot off the paper. The buttons on that pane let you refresh the plot, close the dialog (preserving all current settings), print the page immediately, or obtain context-sensitive help. Use the **Zoom** box and scroll bars to view and position page elements more precisely.

## The Layout Tab

Use the **Layout** tab, shown above, to control the paper format and placement of the plot on printed pages. The following table summarizes the **Layout** options:

| Group       | Option                          | Description                                           |
|-------------|---------------------------------|-------------------------------------------------------|
| Placement   | <b>Auto</b>                     | Let MATLAB decide placement of plot on page*          |
|             | <b>Use manual...</b>            | Specify position parameters for plot on page*         |
|             | <b>Top, Left, Width, Height</b> | Standard position parameters in current units         |
|             | <b>Use defaults</b>             | Revert to default position                            |
|             | <b>Fill page</b>                | Expand figure to fill printable area (see note below) |
|             | <b>Fix aspect ratio</b>         | Correct height/width ratio                            |
|             | <b>Center</b>                   | Center plot on printed page                           |
| Paper       | <b>Format</b>                   | U.S. and ISO® sheet size selector                     |
|             | <b>Width, Height</b>            | Sheet size in current units                           |
| Units       | <b>Inches</b>                   | Use inches as units for dimensions and positions      |
|             | <b>Centimeters</b>              | Use centimeters as units for dimensions and positions |
|             | <b>Points</b>                   | Use points as units for dimensions and positions      |
| Orientation | <b>Portrait</b>                 | Upright paper orientation                             |

| Group | Option           | Description                            |
|-------|------------------|----------------------------------------|
|       | <b>Landscape</b> | Sideways paper orientation             |
|       | <b>Rotated</b>   | Currently the same as <b>Landscape</b> |

\* Selecting **Auto** in the Placement group sets the figure PaperPositionMode to 'auto' and disables the controls in that panel. Selecting **Use manual size and position** sets the figure PaperPositionMode to 'manual' and enables the controls. If you set PaperPositionMode programmatically, the print preview Placement controls respond accordingly.

---

**Note** Selecting the **Fill page** option changes the PaperPosition property to fill the page, allowing objects in normalized units to expand to fill the space. If an object within the figure has an absolute size, for example a table, it can overflow the page when objects with normalized units expand. To avoid having objects fall off the page, do not use **Fill page** under such circumstances.

---

### The Lines/Text Tab

Use the **Lines/Text** tab, shown below, to control the line weights, font characteristics, and headers for printed pages. The following table summarizes the **Lines/Text** options:

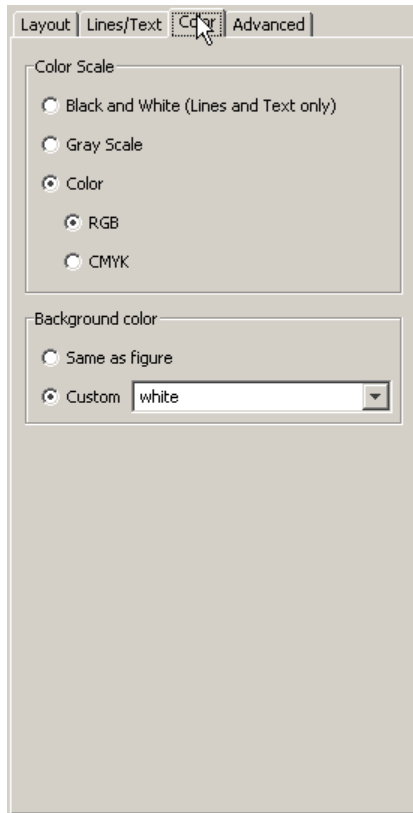

| Group | Option            | Description                                                                                                                                         |
|-------|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Lines | <b>Line Width</b> | Scale all lines by a percentage from 0 upward (100 being no change), print lines at a specified point size, or default line widths used on the plot |
|       | <b>Min Width</b>  | Smallest line width (in points) to use when printing; defaults to 0.5 point                                                                         |
| Text  | <b>Font Name</b>  | Select a system font for all text on plot, or default to fonts currently used on the plot                                                           |

| Group  | Option             | Description                                                                                                                   |
|--------|--------------------|-------------------------------------------------------------------------------------------------------------------------------|
|        | <b>Font Size</b>   | Scale all text by a percentage from 0 upward (100 being no change), print text at a specified point size, or default to this  |
|        | <b>Font Weight</b> | Select Normal ... Bold font styling for all text from drop-down menu or default to the font weights used on the plot          |
|        | <b>Font Angle</b>  | Select Normal, Italic or Oblique font styling for all text from drop-down menu or default to the font angles used on the plot |
| Header | <b>Header Text</b> | Type the text to appear on the header at the upper left of printed pages, or leave blank for no header                        |
|        | <b>Date Style</b>  | Select a date format to have today's date appear at the upper left of printed pages, or none for no date                      |

### The Color Tab

Use the **Color** tab, shown below, to control how colors are printed for lines and backgrounds. The following table summarizes the **Color** options:

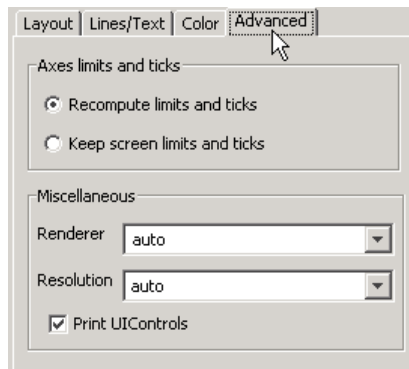

| Group       | Option                 | Description                                                                                    |
|-------------|------------------------|------------------------------------------------------------------------------------------------|
| Color Scale | <b>Black and White</b> | Select to print lines and text in black and white, but use color for patches and other objects |
|             | <b>Gray Scale</b>      | Convert colors to shades of gray on printed pages                                              |

| Group            | Option                | Description                                                                                                                      |
|------------------|-----------------------|----------------------------------------------------------------------------------------------------------------------------------|
|                  | <b>Color</b>          | Print everything in color, matching colors on plot; select RGB (default) or CMYK color model for printing                        |
| Background Color | <b>Same as figure</b> | Print the figure's background color as it is                                                                                     |
|                  | <b>Custom</b>         | Select a color name, or type a colorspec for the background; white (default) implies no background color, even on colored paper. |

### The Advanced Tab

Use the **Advanced** tab, shown below, to control finer details of printing, such as limits and ticks, renderer, resolution, and the printing of UIControls. The following table summarizes the **Advanced** options:

| Group                 | Option                            | Description                                                                                                           |
|-----------------------|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| Axes limits and ticks | <b>Recompute limits and ticks</b> | Redraw $x$ - and $y$ -axes ticks and limits based on printed plot size (default)                                      |
|                       | <b>Keep limits and ticks</b>      | Use the $x$ - and $y$ -axes ticks and limits shown on the plot when printing the previewed figure                     |
| Miscellaneous         | <b>Renderer</b>                   | Select a rendering algorithm for printing: painters, zbuffer, opengl, or auto (default)                               |
|                       | <b>Resolution</b>                 | Select resolution to print at in dots per inch: 150, 300, 600, or auto (default), or type in any other positive value |
|                       | <b>Print UIControls</b>           | Print all visible UIControls in the figure (default), or uncheck to exclude them from being printed                   |

## Alternatives

Use **File > Print Preview** on the figure window menu to access the Print Preview dialog box, described below. For details, see “Using Print Preview”.

printdlg | pagesetupdlg

## How To

- How to Print or Export

**Purpose**

Product of array elements

**Syntax**

```
B = prod(A)
B = prod(A,dim)
B = prod(A,'double')
B = prod(A,'native')
```

**Description**

`B = prod(A)` returns the products along different dimensions of an array. `A` can be `double` or `single`. `B` is multiplied natively, that is in the same class as `A`, and `B` has the same class as `A`.

If `A` is a vector, `prod(A)` returns the product of the elements.

If `A` is a matrix, `prod(A)` treats the columns of `A` as vectors, returning a row vector of the products of each column.

If `A` is a multidimensional array, `prod(A)` treats the values along the first non-singleton dimension as vectors, returning an array of row vectors.

`B = prod(A,dim)` takes the products along the dimension of `A` specified by scalar `dim`.

`B = prod(A,'double')` multiplies `B` in double and `B` has class `double`, even if `A` is `single`.

`B = prod(A,'native')` multiplies `B` natively and `B` has the same class as `A`.

**Examples**

The magic square of order 3 is

```
M = magic(3)
```

```
M =
     8     1     6
     3     5     7
     4     9     2
```

The product of the elements in each column is

# prod

---

```
prod(M) =
```

```
    96    45    84
```

The product of the elements in each row can be obtained by:

```
prod(M,2) =
```

```
    48  
   105  
    72
```

## See Also

cumprod | diff | sum
```

**Purpose**

Profile execution time for function

**Syntax**

```
profile on
profile -history
profile -nohistory
profile -history -historysize integer
profile -timer clock
profile -history -historysize integer -timer clock
profile off
profile resume
profile clear
profile viewer
S = profile('status')
stats = profile('info')
```

**Description**

The `profile` function helps you debug and optimize MATLAB code files by tracking their execution time. For each MATLAB function, MATLAB local function, or MEX-function in the file, `profile` records information about execution time, number of calls, parent functions, child functions, code line hit count, and code line execution time. Some people use `profile` simply to see the child functions; see also `depfun` for that purpose. To open the Profiler graphical user interface, use the `profile viewer` syntax. By default, Profiler time is CPU time. The total time reported by the Profiler is not the same as the time reported using the `tic` and `toc` functions or the time you would observe using a stopwatch.

---

**Note** If your system uses Intel multi-core chips, you may want to restrict the active number of CPUs to 1 for the most accurate and efficient profiling. See “Intel Multi-Core Processors — Setting for Most Accurate Profiling on Windows Systems” or “Intel Multi-Core Processors — Setting for Most Accurate Profiling on Linux Systems” for details on how to do this.

---

`profile on` starts the Profiler, clearing previously recorded profile statistics. Note the following:

- You can specify all, none, or a subset, of the `history`, `historysize` and `timer` options with the `profile on` syntax.
- You can specify options in any order, including before or after `on`.
- If the Profiler is currently on and you specify `profile` with one of the options, MATLAB software returns an error message and the option has no effect. For example, if you specify `profile timer real`, MATLAB returns the following error: The profiler has already been started. `TIMER` cannot be changed.
- To change options, first specify `profile off`, and then specify `profile on` or `profile resume` with new options.

`profile -history` records the exact sequence of function calls. The `profile` function records, by default, up to 1,000,000 function entry and exit events. For more than 1,000,000 events, `profile` continues to record other profile statistics, but not the sequence of calls. To change the number of function entry and exit events that the `profile` function records, use the `historysize` option. By default, the `history` option is not enabled.

`profile -nohistory` disables further recording of the history (exact sequence of function calls). Use the `-nohistory` option after having previously set the `-history` option. All other profiling statistics continue to be collected.

`profile -history -historysize integer` specifies the number of function entry and exit events to record. By default, `historysize` is set to 1,000,000.

`profile -timer clock` specifies the type of time to use. Valid values for `clock` are:

- `'cpu'` — The Profiler uses computer time (the default).
- `'real'` — The Profiler uses wall-clock time.

For example, `cpu` time for the `pause` function is typically small, but `real` time accounts for the actual time paused, and therefore would be larger.

`profile -history -historysize integer -timer clock` specifies all of the options. Any order is acceptable, as is a subset.

`profile off` stops the Profiler.

`profile resume` restarts the Profiler without clearing previously recorded statistics.

`profile clear` clears the statistics recorded by `profile`.

`profile viewer` stops the Profiler and displays the results in the Profiler window. For more information, see [Profiling for Improving Performance in the Desktop Tools and Development Environment documentation](#).

`S = profile('status')` returns a structure containing information about the current status of the Profiler. The table lists the fields in the order that they appear in the structure.

| Field           | Values          | Default Value |
|-----------------|-----------------|---------------|
| ProfilerStatus  | 'on' or 'off'   | off           |
| DetailLevel     | 'mmex'          | 'mmex'        |
| Timer           | 'cpu' or 'real' | 'cpu'         |
| HistoryTracking | 'on' or 'off'   | 'off'         |
| HistorySize     | integer         | 1000000       |

`stats = profile('info')` displays a structure containing the results. Use this function to access the data generated by `profile`. The table lists the fields in the order that they appear in the structure.

| Field           | Description                                                      |
|-----------------|------------------------------------------------------------------|
| FunctionTable   | Structure array containing statistics about each function called |
| FunctionHistory | Array containing function call history                           |

| Field          | Description                                          |
|----------------|------------------------------------------------------|
| ClockPrecision | Precision of the profile function's time measurement |
| ClockSpeed     | Estimated clock speed of the CPU                     |
| Name           | Name of the profiler                                 |

The `FunctionTable` field is an array of structures, where each structure contains information about one of the functions or local functions called during execution. The following table lists these fields in the order that they appear in the structure.

| Field              | Description                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| CompleteName       | Full path to <code>FunctionName</code> , including local functions                                                                             |
| FunctionName       | Function name; includes local functions                                                                                                        |
| FileName           | Full path to <code>FunctionName</code> , with file extension, excluding local functions                                                        |
| Type               | MATLAB functions, MEX-functions, and many other types of functions including MATLAB local functions, nested functions, and anonymous functions |
| NumCalls           | Number of times the function was called                                                                                                        |
| TotalTime          | Total time spent in the function and its child functions                                                                                       |
| TotalRecursiveTime | No longer used.                                                                                                                                |
| Children           | <code>FunctionTable</code> indices to child functions                                                                                          |
| Parents            | <code>FunctionTable</code> indices to parent functions                                                                                         |

| Field         | Description                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ExecutedLines | <p>Array containing line-by-line details for the function being profiled.</p> <p>Column 1: Number of the line that executed. If a line was not executed, it does not appear in this matrix.</p> <p>Column 2: Number of times the line was executed</p> <p>Column 3: Total time spent on that line. Note: The sum of Column 3 entries does not necessarily add up to the function's TotalTime.</p> |
| IsRecursive   | BOOLEAN value: Logical 1 (true) if recursive, otherwise logical 0 (false)                                                                                                                                                                                                                                                                                                                         |
| PartialData   | BOOLEAN value: Logical 1 (true) if function was modified during profiling, for example by being edited or cleared. In that event, data was collected only up until the point when the function was modified.                                                                                                                                                                                      |

## Examples

### Profile, View Results, and Save Profile Data as HTML

This example profiles the MATLAB `magic` command and then displays the results in the Profiler window. The example then retrieves the profile data on which the HTML display is based and uses the `profsave` command to save the profile data in HTML form.

```
profile on
plot(magic(35))
profile viewer
p = profile('info');
profsave(p,'profile_results')
```

## Profile, Save Profile Data to a MAT-File, and View Results

Another way to save profile data is to store it in a MAT-file. This example stores the profile data in a MAT-file, clears the profile data from memory, and then loads the profile data from the MAT-file. This example also shows a way to bring the reloaded profile data into the Profiler graphical interface as live profile data, not as a static HTML page.

```
p = profile('info');
save myprofiledata p
clear p
load myprofiledata
profview(0,p)
```

## Profile and Show Results Including History

This example illustrates an effective way to view the results of profiling when the history option is enabled. The history data describes the sequence of functions entered and exited during execution. The `profile` command returns history data in the `FunctionHistory` field of the structure it returns. The history data is a 2-by-n array. The first row contains Boolean values, where 0 means entrance into a function and 1 means exit from a function. The second row identifies the function being entered or exited by its index in the `FunctionTable` field. This example reads the history data and displays it in the MATLAB Command Window.

```
profile on -history
plot(magic(4));
p = profile('info');

for n = 1:size(p.FunctionHistory,2)
    if p.FunctionHistory(1,n)==0
        str = 'entering function: ';
    else
        str = 'exiting function: ';
    end
    disp([str p.FunctionTable(p.FunctionHistory(2,n)).FunctionName])
end
```

end

## How To

- [Profiling for Improving Performance](#)
- [“Profiling Parallel Code”](#)

# profsave

---

**Purpose** Save profile report in HTML format

**Syntax**

```
profsave
profsave(profinfo)
profsave(profinfo,dirname)
```

**Description** `profsave` executes the `profile('info')` function and saves the results in HTML format. `profsave` creates a separate HTML file for each function listed in the `FunctionTable` field of the structure returned by `profile`. By default, `profsave` stores the HTML files in a subfolder of the current folder named `profile_results`.

`profsave(profinfo)` saves the profiling results, `profinfo`, in HTML format. `profinfo` is a structure of profiling information returned by the `profile('info')` function.

`profsave(profinfo,dirname)` saves the profiling results, `profinfo`, in HTML format. `profsave` creates a separate HTML file for each function listed in the `FunctionTable` field of `profinfo` and stores them in the folder specified by `dirname`.

**Examples** Run profile and save the results.

```
profile on
plot(magic(5))
profile off
profsave(profile('info'),'myprofile_results')
```

**See Also** `profile`

**How To**

- [Profiling for Improving Performance](#)

**Purpose** Open Property Editor

**Syntax**  
`propedit`  
`propedit(handle_list)`

**Description** `propedit` starts the Property Editor, a graphical user interface to the properties of graphics objects. If no current figure exists, `propedit` will create one.

`propedit(handle_list)` edits the properties for the object (or objects) in `handle_list`.

Starting the Property Editor enables plot editing mode for the figure.

| <b>Purpose</b>     | Class property names                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Syntax</b>      | <pre>properties('classname') properties(obj) p = properties(...)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | <p><code>properties('classname')</code> displays the names of the public properties for the MATLAB class named by <code>classname</code>. The <code>properties</code> function also displays inherited properties.</p> <p><code>properties(obj)</code> <code>obj</code> can be either a scalar object or an array of objects. When <code>obj</code> is scalar, <code>properties</code> also returns dynamic properties. See “Dynamic Properties — Adding Properties to an Instance” for information on using dynamic properties.</p> <p><code>p = properties(...)</code> returns the property names in a cell array of strings.</p> |
| <b>Definitions</b> | <p>A property is public when its <code>GetAccess</code> attribute value is <code>public</code> and its <code>Hidden</code> attribute value is <code>false</code> (default values for these attributes). See “Property Attributes” for a complete list of attributes.</p> <p><code>properties</code> is also a MATLAB class-definition keyword. See <code>classdef</code> for more information on class definition keywords.</p>                                                                                                                                                                                                     |
| <b>Examples</b>    | <p>Retrieve the names of the public properties of class <code>memmapfile</code> and store the result in a cell array of strings:</p> <pre>p = properties('memmapfile'); p ans =      'writable'     'offset'     'format'     'repeat'     'filename'</pre>                                                                                                                                                                                                                                                                                                                                                                         |

# properties

---

Construct an instance of the MException class and get its properties names:

```
me = MException('Msg:ID', 'MsgText');  
properties(me)  
Properties for class MException:
```

```
    identifier  
    message  
    cause  
    stack
```

## Tutorials

- “Properties”

**Purpose** Show or hide **Property Editor**

**Syntax**

```
propertyeditor('on')
propertyeditor('off')
propertyeditor
propertyeditor(figure_handle,...)
```

**Description** `propertyeditor('on')` displays the Property Editor tool on the current figure.

`propertyeditor('off')` hides the Property Editor on the current figure.

`propertyeditor` toggles the visibility of the Property Editor on the current figure. You can also use `propertyeditor('toggle')` instead for the same functionality.

`propertyeditor(figure_handle,...)` displays or hides the Property Editor on the figure specified by *figure\_handle*.

**Tips** If you call `propertyeditor` in a MATLAB program and subsequent lines depend on the Property Editor being fully initialized, follow it by `drawnow` to ensure complete initialization.

**Alternatives** To collectively enable **Plotting Tools**, use the large Plotting Tool icon  on the figure toolbar. To collectively disable the **Plotting Tools**, use the smaller icon . Open or close the **Property Editor** tool from the figure's **View** menu. For details, see “The Property Editor”.

# propertyeditor

---

## **See Also**

`plottools` | `plotbrowser` | `figurepalette` | `inspect`

**Purpose** Psi (polygamma) function

---

**Note** The syntax `Y = psi(k0:k1,X)` has been removed.

---

**Syntax**

```
Y = psi(X)
Y = psi(k,X)
Y = psi(k0:k1,X)
```

**Description** `Y = psi(X)` evaluates the  $\psi$  function for each element of array `X`. `X` must be real and nonnegative. The  $\psi$  function, also known as the digamma function, is the logarithmic derivative of the gamma function

$$\begin{aligned}\psi(x) &= \text{digamma}(x) \\ &= \frac{d(\log(\Gamma(x)))}{dx} \\ &= \frac{d(\Gamma(x)) / dx}{\Gamma(x)}\end{aligned}$$

`Y = psi(k,X)` evaluates the  $k$ th derivative of  $\psi$  at the elements of `X`. `psi(0,X)` is the digamma function, `psi(1,X)` is the trigamma function, `psi(2,X)` is the tetragamma function, etc.

`Y = psi(k0:k1,X)` evaluates derivatives of order `k0` through `k1` at `X`. `Y(k,j)` is the  $(k-1+k0)$ th derivative of  $\psi$ , evaluated at `X(j)`.

**Examples** **Example 1**

Use the `psi` function to calculate Euler's constant,  $\gamma$ .

```
format long
-psi(1)
ans =
    0.57721566490153

-psi(0,1)
```

```
ans =  
    0.57721566490153
```

## Example 2

The trigamma function of 2,  $\psi(1,2)$ , is the same as  $(\pi^2/6) - 1$ .

```
format long  
psi(1,2)  
ans =  
    0.64493406684823
```

```
pi^2/6 - 1  
ans =  
    0.64493406684823
```

## Example 3

This code produces the first page of Table 6.1 in Abramowitz and Stegun [1].

```
x = (1:.005:1.250)';  
[x gamma(x) gammaln(x) psi(0:1,x)' x-1]
```

## Example 4

This code produces a portion of Table 6.2 in [1].

```
psi(2:3,1:.01:2)'
```

**Purpose** Generate view of MATLAB file in specified format

**Syntax**

```
publish(file)
publish(file,format)

publish(file,Name,Value)
publish(file,options)

my_doc = publish(file, __ )
```

**Description** `publish(file)` generates a view of the MATLAB file, `file`, in HTML format for sharing your code. For example, `publish('myfile.m')` executes the code in `myfile.m`, and saves the formatted code, MATLAB results, and comments in `/html/myfile.html`. The `html` subfolder is relative to the `file` folder.

`publish(file,format)` generates a view of a MATLAB file in the specified file format. The resulting files save to the `html` subfolder for all file formats.

`publish(file,Name,Value)` generates a view of the MATLAB file, `file`, with options specified by one or more name-value pair arguments.

`publish(file,options)` uses the `options` structure to customize the output, which is useful when you want to preconfigure and save your options for repeated use. The `options` structure fields and values correspond to names and values of name-value pair arguments, respectively.

`my_doc = publish(file, __ )` generates a view of the MATLAB file `file`, and returns the path of the resulting output file as `my_doc`.

## Input Arguments

### **file - MATLAB file**

string

Full or partial path of the MATLAB file for which you want to generate a presentation view, specified as a string. For example, 'myfile.m'

### **format - Output format of published file**

'html' (default) | 'doc' | 'latex' | 'ppt' | 'xml'

Output format of published MATLAB file, specified as a string.

**Example:** `publish('myfile.m','ppt');`

### **options - Options for published output**

MATLAB structure

Options for published output, specified as a structure. Use the options structure instead of name-value pair arguments when you want to reuse the same configuration for publishing multiple MATLAB code files.

The `options` structure field and values correspond to names and values of the name-value pair arguments, respectively.

For example, to specify the PDF output format and the output folder `C:\myPublishedOutput`, use:

```
options = struct('format','pdf','outputDir','C:\myPublishedOutput')
```

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'format','latex','showCode',false` specifies LaTeX output file format and excludes the code from the output.

### **Output Options**

#### **format - Published output file format**

'html' (default) | 'doc' | 'latex' | 'ppt' | 'xml' | 'pdf'

Published output file format, specified as the comma-separated pair consisting of 'format' and one of the following string values.

| Output Format              | String Value     |
|----------------------------|------------------|
| Hypertext Markup Language  | 'html' (default) |
| Microsoft Word             | 'doc'            |
| LaTeX                      | 'latex'          |
| Microsoft PowerPoint       | 'ppt'            |
| Extensible Markup Language | 'xml'            |
| Portable Document Format   | 'pdf'            |

### **outputDir - Output folder**

' ' (default) | full path

Output folder to which the published document is saved, specified as the comma-separated pair consisting of 'outputDir' and the full path. You must specify the full path as a string, for example 'C:\myPublishedOutput'.

The default value, ' ', specifies the html subfolder of the current folder.

### **stylesheet - Extensible Stylesheet language (XSL) file**

' ' (default) | full path to XSL file name

Extensible Stylesheet Language (XSL) file to use when publishing MATLAB code to HTML, XML, or LaTeX format, specified as the comma-separated pair consisting of 'stylesheet' and the full path to the XSL file. The full path must be a string, for example, 'C:\myStylesheet\stylesheet.xsl'

The default value, ' ', specifies the MATLAB default style sheet.

## Figure Options

### **createThumbnail - Thumbnail image creation**

true (default) | false

Thumbnail image creation for the published document, specified as the comma-separated pair consisting of 'createThumbnail' and either true or false. You can use this thumbnail to represent your file in HTML pages.

### **figureSnapMethod - Published figure window appearance**

'entireGUIWindow' (default) | 'print' | 'getframe' |  
'entireFigureWindow'

Appearance of published figure windows, including window decorations and background color, specified as the comma-separated pair consisting of 'figureSnapMethod' and one of the following string values.

| String Value                   | Window Decorations |          | Background Color |                |
|--------------------------------|--------------------|----------|------------------|----------------|
|                                | GUIs               | Figures  | GUIs             | Figures        |
| 'entireGUIWindow'<br>(default) | Included           | Excluded | Matches screen   | White          |
| 'print'                        | Excluded           | Excluded | White            | White          |
| 'getframe'                     | Excluded           | Excluded | Matches screen   | Matches screen |
| 'entireFigureWindow'           | Included           | Included | Matches screen   | Matches screen |

### **imageFormat - Published image file format**

'png' | 'epsc2' | 'jpg'

Published image file format, specified as the comma-separated pair consisting of 'imageFormat' and one of the following string values.

(Continued)

| 'format' Value | Valid 'imageFormat' Value                                                                                                                                                                                                                | Default 'imageFormat' Value                                                                                                                                                                                                             |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'doc'          | Any image format that your installed version of Microsoft Office can import, including 'png', 'jpg', 'bmp', and 'tiff'. If the 'figureSnapMethod' is 'print', then you can also specify 'eps', 'epsc', 'eps2', 'ill', 'meta', and 'pdf'. | 'png'                                                                                                                                                                                                                                   |
| 'html'         | Any format publishes successfully. Ensure that the tools you use to view and process the output files can display the output format you specify.                                                                                         | 'png'                                                                                                                                                                                                                                   |
| 'latex'        | Any format publishes successfully. Ensure that the tools you use to view and process the output files can display the output format you specify.                                                                                         | 'epsc2', except when 'figureSnapMethod' is any one of the following: <ul style="list-style-type: none"> <li>• 'getframe'</li> <li>• 'entireFigureWindow'</li> <li>• 'entireGUIWindow' and the snapped window is a GUI window</li> </ul> |

(Continued)

|       |                                                                                                                                                  | In these cases the default is 'png' |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| 'pdf' | 'bmp' or 'jpg'.                                                                                                                                  | 'bmp'                               |
| 'ppt' | Any format that your installed version of Microsoft Office can import, including 'png', 'jpg', 'bmp', and 'tiff'.                                | 'png'                               |
| 'xml' | Any format publishes successfully. Ensure that the tools you use to view and process the output files can display the output format you specify. | 'png'                               |

### **maxHeight - Maximum height of published images**

[ ] (default) | positive integer value

Maximum height of published images that the code generates, specified as the comma-separated pair consisting of 'maxHeight' and one of the following values:

- [ ] (default)—Unrestricted height. This value is always used when the 'format' value is 'pdf'.
- Positive integer value that specifies the image height in pixels.

### **maxWidth - Maximum width of published images**

' ' (default) | positive integer value

Maximum width of an image that the code generates, specified as the comma-separated pair consisting of 'maxWidth' and one of the following values:

- [ ] (default)—Unrestricted width. This value is always used when the 'format' value is 'pdf'.
- Positive integer value that specifies the image width in pixels.

### **useNewFigure - Create new figure**

true (default) | false

A logical value that determines if MATLAB creates a new Figure window for figures that the code generates, specified as the comma-separated pair consisting of 'useNewFigure' and one of the following:

- true (default)—If the code generates a figure, then MATLAB creates a Figure window with a white background, and at the default size before publishing.
- false—MATLAB does not create a figure window.

This value enables you to use a figure with different properties for publishing. For example, open a Figure window, change the size and background color, and then publish your code. Figures in your published document use the characteristics of the figure you opened before publishing.

## **Code Options**

### **evalCode - Option to run code**

true (default) | false

Option to evaluate code and include the MATLAB output in the published view, specified as a logical value.

### **catchError - Error handling during publishing**

true (default) | false

Error handling during publishing, specified as the comma-separated pair consisting of 'catchError' and one of the following logical values:

- true (default)—MATLAB continues publishing and includes the error in the published file.

- `false`—MATLAB displays the error at the command line and does not produce a published file.

## **codeToEvaluate - Additional code to evaluate during publishing**

string

Additional code to evaluate during publishing, specified as the comma-separated pair consisting of 'codeToEvaluate' and the string with the corresponding code. Use this option to specify code that does not appear in the MATLAB file, for example to set the value of an input argument for a function being published.

If this option is unspecified, MATLAB evaluates only the code in the MATLAB file you are publishing.

## **maxOutputLines - Maximum number of lines**

Inf (default) | Nonnegative integer value

Maximum number of lines in MATLAB output per cell evaluated during publishing, specified as the comma-separated pair consisting of 'maxOutputLines' and one of the following values:

- Inf (default)—MATLAB includes all output lines in the published output.
- Nonnegative integer—MATLAB truncates the number of lines in the output at the number of lines you specify.

## **showCode - Option to include code in published file**

true (default) | false

Option to include code in published file, specified as the comma-separated pair consisting of 'showCode' and a logical value.

## **Output Arguments**

### **my\_doc - Path of published output file**

Path of published output file, returned as a string.

## Tips

- If 'format' is 'html', MATLAB includes the code being published at the end of the published HTML file as comments, even when you set the 'showCode' option to false. Because MATLAB includes the code as comments, this code does not display in a Web browser. This enables you to use the grabcode function to extract the MATLAB code from an HTML file, even when the file does not display the code.
- MATLAB does not preserve syntax highlighting when you set 'format' to any of the following:
  - 'latex'
  - 'doc'
  - 'ppt'

## Definitions

### Window Decorations

Window decorations include window title bar, toolbar, menu bar, and window border.

### Syntax Highlighting

Syntax highlighting colors various elements in code to help you identify these elements while reading or editing code. By default, keywords are blue, strings are purple, and unterminated strings are maroon.

## Examples

### Generate HTML View of MATLAB Script

Generate an HTML view of the code, MATLAB results, and comments in a MATLAB script.

Copy the example file, fourier\_demo2.m, to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...  
'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Generate an HTML view of the MATLAB file.

```
publish('fourier_demo2.m');
```

The `publish` command executes the code for each cell in `fourier_demo2.m`, and saves the file to `/html/fourier_demo2.html`.

View the HTML file.

```
web('html/fourier_demo2.html')
```

## **Generate View of MATLAB Script in Microsoft Word Format**

Generate a Microsoft Word view of the code, MATLAB results, and comments in a MATLAB script.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot, 'help', 'techdoc', ...  
'matlab_env', 'examples', 'fourier_demo2.m'), '.', 'f')
```

Publish the file in Microsoft Word format.

```
publish('fourier_demo2.m', 'doc');
```

View the published output.

```
winopen('html/fourier_demo2.doc')
```

## **Publish MATLAB Script Using Name-Value Pairs to Customize the Output**

Generate a Microsoft Word view of the code, MATLAB results, and comments in a MATLAB script. Use name-value pair arguments to include window decorations in the published output.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot, 'help', 'techdoc', ...  
'matlab_env', 'examples', 'fourier_demo2.m'), '.', 'f')
```

Publish the example MATLAB file to Microsoft Word format.

```
publish('fourier_demo2.m', 'figureSnapMethod', 'entireFigureWindow')
```

The 'figureSnapMethod', 'entireFigureWindow' name-value pair argument specifies to include the window decorations in the figures, and to match the figure background color to the screen color.

View the published output.

```
web('html/fourier_demo2.html')
```

### **Customize publish Output Using Options Structure**

Generate a Microsoft Word view of the code, MATLAB results, and comments in a MATLAB script. Use a structure to customize the published output.

Specifying options as a structure is useful when you want to preconfigure and save your options for repeated use.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...  
'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Define options to customize the published output as a structure, options\_doc\_nocode.

```
options_doc_nocode.format = 'doc';  
options_doc_nocode.showCode = false;
```

Publish the file, specifying the options structure.

```
publish('fourier_demo2.m',options_doc_nocode);
```

### **Save File Path of Published Script to Variable**

Generate an HTML view of a MATLAB script, and save the path of the published HTML file to a variable.

This example assumes that the current folder is C:\my\_MATLAB\_files.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...  
'matlab_env','examples','fourier_demo2.m'),'.','f');
```

# publish

---

```
'matlab_env', 'examples', 'fourier_demo2.m'), '.', 'f')
```

Publish the MATLAB file, and save the path of the resulting published HTML file to an output variable.

```
mydoc = publish('fourier_demo2.m')
```

```
mydoc =
```

```
C:\my_MATLAB_files\html\fourier_demo2.html
```

## Concepts

- “Publish MATLAB Code”
- “Publishing Markup”

## Purpose

Store character array in Automation server

## Syntax

### MATLAB Client

```
h.PutCharArray('varname', 'workspace', 'string')
PutCharArray(h, 'varname', 'workspace', 'string')
invoke(h, 'PutCharArray', 'varname', 'workspace', 'string')
```

### IDL Method Signature

```
PutCharArray([in] BSTR varname, [in] BSTR workspace,
[in] BSTR string)
```

### Microsoft Visual Basic Client

```
PutCharArray(varname As String, workspace As String,
string As String)
```

## Description

PutCharArray stores the character array in `string` in the specified workspace of the server attached to handle `h`, assigning to it the variable `varname`. The workspace argument can be either `base` or `global`.

## Tips

The character array specified in the `string` argument can have any dimensions. However, PutCharArray changes the dimensions to a 1-by-n column-wise representation, where n is the number of characters in the array. Executing the following commands in MATLAB illustrates this behavior:

```
h = actxserver('matlab.application');
chArr = ['abc'; 'def'; 'ghk']
chArr =
abc
def
ghk

h.PutCharArray('Foo', 'base', chArr)
tstArr = h.GetCharArray('Foo', 'base')
tstArr =
adgbehcfk
```

# PutCharArray

---

Server function names, like `PutCharArray`, are case sensitive when using the dot notation syntax shown in the Syntax section.

There is no difference in the operation of the three syntaxes shown above for the MATLAB client.

## Examples

Store string `str` in the base workspace of the server using `PutCharArray`.

### MATLAB Client

```
h = actxserver('matlab.application');
h.PutCharArray('str', 'base', ...
    'He jests at scars that never felt a wound.')

S = h.GetCharArray('str', 'base')
S =
    He jests at scars that never felt a wound.
```

### Visual Basic .NET Client

This example uses the Visual Basic `MsgBox` command to control flow between MATLAB and the Visual Basic Client.

```
Dim Matlab As Object
Try
    Matlab = GetObject(, "matlab.application")
Catch e As Exception
    Matlab = CreateObject("matlab.application")
End Try
MsgBox("MATLAB window created; now open it...")
```

Open the MATLAB window, then click **Ok**.

```
Matlab.PutCharArray("str", "base", _
    "He jests at scars that never felt a wound.")
MsgBox("In MATLAB, type" & vbCrLf _
    & "str")
```

In the MATLAB window type `str`; MATLAB displays:

```
str =  
He jests at scars that never felt a wound.
```

Click **Ok**.

```
MsgBox("closing MATLAB window...")
```

Click **Ok** to close and terminate MATLAB.

```
Matlab.Quit()
```

# PutFullMatrix

---

**Purpose** Matrix in Automation server workspace

**Syntax** **MATLAB Client**  
`h.PutFullMatrix('varname', 'workspace', xreal, ximag)`  
`PutFullMatrix(h, 'varname', 'workspace', xreal, ximag)`

## IDL Method Signature

`PutFullMatrix([in] BSTR varname, [in] BSTR workspace,  
[in] SAFEARRAY(double) xreal, [in] SAFEARRAY(double) ximag)`

## Microsoft Visual Basic Client

`PutFullMatrix([in] varname As String, [in] workspace As String,  
[in] xreal As Double, [in] ximag As Double)`

**Description** `h.PutFullMatrix('varname', 'workspace', xreal, ximag)` stores a matrix in the specified workspace of the server attached to handle `h` and assigns it to variable `varname`. Use `xreal` and `ximag` for the real and imaginary parts of the matrix. The matrix cannot be a scalar, an empty array, or have more than two dimensions. The values for `workspace` are `base` or `global`.

`PutFullMatrix(h, 'varname', 'workspace', xreal, ximag)` is an alternate syntax.

For VBScript clients, use the `GetWorkspaceData` and `PutWorkspaceData` functions to pass numeric data to and from the MATLAB workspace. These functions use the variant data type instead of `safearray` which is not supported by VBScript.

**Examples** This example uses a MATLAB client to write a matrix to the base workspace of the server:

```
h = actxserver('matlab.application');  
h.PutFullMatrix('M', 'base', rand(5), zeros(5))  
%Use one output for real values only  
xreal = h.GetFullMatrix('M', 'base', zeros(5), zeros(5))
```

This example uses a Visual Basic .NET client to write a matrix to the base workspace of the server:

```
Dim MatLab As Object
Dim XReal(4, 4) As Double
Dim XImag(4, 4) As Double
Dim ZReal(4, 4) As Double
Dim ZImag(4, 4) As Double
Dim i, j As Integer

For i = 0 To 4
    For j = 0 To 4
        XReal(i, j) = Rnd() * 6
        XImag(i, j) = 0
    Next j
Next i

Matlab = CreateObject("matlab.application")
MatLab.PutFullMatrix("M", "base", XReal, XImag)
MatLab.GetFullMatrix("M", "base", ZReal, ZImag)
```

Use a MATLAB client to write a matrix to the global workspace of the server:

```
h = actxserver('matlab.application');
h.PutFullMatrix('X', 'global', [1 3 5; 2 4 6], ...
    [1 1 1; 1 1 1])
h.invoke('Execute', 'whos global')
```

Use a Visual Basic .NET client to write a matrix to the global workspace of the server:

```
Dim MatLab As Object
```

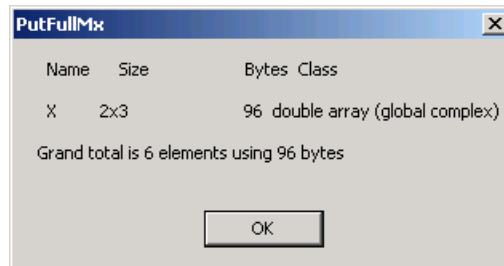

# PutFullMatrix

---

```
Dim XReal(1,2) As Double
Dim XImag(1,2) As Double
Dim result As String
Dim i,j As Integer

For i = 0 To 1
  For j = 0 To 2
    XReal(i,j) = (j * 2 + 1) + i
    XImag(i,j) = 1
  Next j
Next i

Matlab = CreateObject("matlab.application")
MatLab.PutFullMatrix("X","global",XReal,XImag)
result = Matlab.Execute("whos global")
MsgBox(result)
```

## How To

- “MATLAB COM Automation Server Interface”
- “Exchanging Data with the Server”

## Purpose

Data in Automation server workspace

## Syntax

### MATLAB Client

```
h.PutWorkspaceData('varname','workspace',data)
PutWorkspaceData(h,'varname','workspace',data)
```

### IDL Method Signature

```
PutWorkspaceData([in] BSTR varname, [in] BSTR workspace,
[in] VARIANT data)
```

### Microsoft Visual Basic Client

```
PutWorkspaceData(varname As String, workspace As String,
data As Object)
```

## Description

`h.PutWorkspaceData('varname','workspace',data)` stores data in the workspace of the server attached to handle `h` and assigns it to `varname`. The values for `workspace` are `base` or `global`.

`PutWorkspaceData(h,'varname','workspace',data)` is an alternate syntax.

Use `PutWorkspaceData` to pass numeric and character array data respectively to the server. Do *not* use `PutWorkspaceData` on sparse arrays, structures, or function handles. Use the `Execute` method for these data types.

The `GetWorkspaceData` and `PutWorkspaceData` functions pass numeric data as a variant data type. These functions are especially useful for VBScript clients as VBScript does not support the `safearray` data type used by `GetFullMatrix` and `PutFullMatrix`.

## Examples

Create an array in a MATLAB client and put it in the base workspace of the MATLAB Automation server:

```
h = actxserver('matlab.application');
for i = 0:6
    data(i+1) = i * 15;
end
```

# PutWorkspaceData

---

```
h.PutWorkspaceData('A','base',data)
```

---

Create an array in a Visual Basic .NET client and put it in the base workspace of the MATLAB Automation server:

- 1 Create the Visual Basic application. Use the `MsgBox` command to control flow between MATLAB and the application:

```
Dim Matlab As Object
Dim data(6) As Double
Dim i As Integer
MatLab = CreateObject("matlab.application")
For i = 0 To 6
    data(i) = i * 15
Next i
MatLab.PutWorkspaceData("A","base",data)
MsgBox("In MATLAB, type" & vbCrLf & "A")
```

- 2 Open the MATLAB window and type A. MATLAB displays:

```
A =
     0    15    30    45    60    75    90
```

- 3 Click **Ok** to close and terminate MATLAB.

| <b>Alternatives</b> | <ul style="list-style-type: none"><li>• Use the Current Folder toolbar.</li></ul>                                                                               |
| <b>See Also</b>     | <code>cd</code>   <code>dir</code>                                                                                                                              |

**Purpose** Quasi-minimal residual method

**Syntax**

```
x = qmr(A,b)
qmr(A,b,tol)
qmr(A,b,tol,maxit)
qmr(A,b,tol,maxit,M)
qmr(A,b,tol,maxit,M1,M2)
qmr(A,b,tol,maxit,M1,M2,x0)
[x,flag] = qmr(A,b,...)
[x,flag,relres] = qmr(A,b,...)
[x,flag,relres,iter] = qmr(A,b,...)
[x,flag,relres,iter,resvec] = qmr(A,b,...)
```

**Description** `x = qmr(A,b)` attempts to solve the system of linear equations  $A^*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and should be large and sparse. The column vector  $b$  must have length  $n$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x, 'notransp')` returns  $A^*x$  and `afun(x, 'transp')` returns  $A' * x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `qmr` converges, a message to that effect is displayed. If `qmr` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A^*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`qmr(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `qmr` uses the default,  $1e-6$ .

`qmr(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `qmr` uses the default,  $\min(n,20)$ .

`qmr(A,b,tol,maxit,M)` and `qmr(A,b,tol,maxit,M1,M2)` use preconditioners  $M$  or  $M = M1 * M2$  and effectively solve the system  $\text{inv}(M) * A^*x = \text{inv}(M) * b$  for  $x$ . If  $M$  is `[]` then `qmr` applies no

preconditioner.  $M$  can be a function handle `mfun` such that `mfun(x, 'notransp')` returns  $Mx$  and `mfun(x, 'transp')` returns  $M'x$ .

`qmr(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If  $x_0$  is `[]`, then `qmr` uses the default, an all zero vector.

`[x,flag] = qmr(A,b,...)` also returns a convergence flag.

| Flag | Convergence                                                                                                          |
|------|----------------------------------------------------------------------------------------------------------------------|
| 0    | qmr converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.                        |
| 1    | qmr iterated <code>maxit</code> times but did not converge.                                                          |
| 2    | Preconditioner $M$ was ill-conditioned.                                                                              |
| 3    | The method stagnated. (Two consecutive iterates were the same.)                                                      |
| 4    | One of the scalar quantities calculated during <code>qmr</code> became too small or too large to continue computing. |

Whenever `flag` is not 0, the solution  $x$  returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = qmr(A,b,...)` also returns the relative residual norm  $\|b-Ax\|/\|b\|$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = qmr(A,b,...)` also returns the iteration number at which  $x$  was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = qmr(A,b,...)` also returns a vector of the residual norms at each iteration, including  $\|b-Ax_0\|$ .

## Examples

### Using `qmr` with a Matrix Input

This example shows how to use `qmr` with a matrix input. The code:

```
n = 100;
on = ones(n,1);
```

```
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8; maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x = qmr(A,b,tol,maxit,M1,M2);
```

displays the message:

```
qmr converged at iteration 9 to a solution...
with relative residual
5.6e-009
```

### Using qmr with a Function Handle

This example replaces the matrix A in the previous example with a handle to a matrix-vector product function `afun`. The example is contained in a file `run_qmr` that

- Calls `qmr` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_qmr` are available to `afun`.

The following shows the code for `run_qmr`:

```
function x1 = run_qmr
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = qmr(@afun,b,tol,maxit,M1,M2);

function y = afun(x,transp_flag)
    if strcmp(transp_flag,'transp')
        y = 4 * x;
    else
        y = A * x;
    end
```

```

        y(1:n-1) = y(1:n-1) - 2 * x(2:n);
        y(2:n) = y(2:n) - x(1:n-1);
    elseif strcmp(transp_flag,'notransp') % y = A*x
        y = 4 * x;
        y(2:n) = y(2:n) - 2 * x(1:n-1);
        y(1:n-1) = y(1:n-1) - x(2:n);
    end
end
end
end

```

When you enter

```
x1=run_qmr;
```

MATLAB software displays the message

```
qmr converged at iteration 9 to a solution with relative residual
5.6e-009
```

### Using a Preconditioner

This example demonstrates the use of a preconditioner.

#### 1

Load A = west0479, a real 479-by-479 nonsymmetric sparse matrix:

```
load west0479;
A = west0479;
```

#### 2

Define b so that the true solution is a vector of all ones:

```
b = full(sum(A,2));
```

#### 3

Set the tolerance and maximum number of iterations:

```
tol = 1e-12; maxit = 20;
```

## 4

Use `qmr` to find a solution at the requested tolerance and number of iterations:

```
[x0,f10,rr0,it0,rv0] = qmr(A,b,tol,maxit);
```

`f10` is 1 because `qmr` does not converge to the requested tolerance  $1e-12$  within the requested 20 iterations. The seventeenth iterate is the best approximate solution and is the one returned as indicated by `it0 = 17`. MATLAB stores the residual history in `rv0`.

## 5

Plot the behavior of `qmr`:

```
semilogy(0:maxit,rv0/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

## 6

Create the preconditioner with `ilu`, since the matrix `A` is nonsymmetric:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

Error using `ilu`

There is a pivot equal to zero. Consider decreasing the drop tolerance or consider using the `'udiag'` option.

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

## 7

You can try again with a reduced drop tolerance, as indicated by the error message:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));  
[x1,f11,rr1,it1,rv1] = qmr(A,b,tol,maxit,L,U);
```

f11 is 0 because qmr drives the relative residual to  $4.1410e-014$  (the value of rr1). The relative residual is less than the prescribed tolerance of  $1e-12$  at the sixth iteration (the value of it1) when preconditioned by the incomplete LU factorization with a drop tolerance of  $1e-6$ . The output rv1(1) is norm(b), and the output rv1(7) is norm(b-A\*x2).

## 8

You can follow the progress of qmr by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0):

```
semilogy(0:it1,rv1/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

| `function_handle` | `mldivide`

**Purpose** Orthogonal-triangular decomposition

**Syntax**

```
[Q,R] = qr(A)
[Q,R] = qr(A,0)
[Q,R,E] = qr(A)
[Q,R,E] = qr(A,'matrix')
[Q,R,e] = qr(A,'vector')
[Q,R,e] = qr(A,0)
X = qr(A)
X = qr(A,0)
R = qr(A)
R = qr(A,0)
[C,R] = qr(A,B)
[C,R,E] = qr(A,B)
[C,R,E] = qr(A,B,'matrix')
[C,R,e] = qr(A,B,'vector')
[C,R] = qr(A,B,0)
[C,R,e] = qr(A,B,0)
```

**Description**  $[Q,R] = qr(A)$ , where  $A$  is  $m$ -by- $n$ , produces an  $m$ -by- $n$  upper triangular matrix  $R$  and an  $m$ -by- $m$  unitary matrix  $Q$  so that  $A = Q*R$ .

$[Q,R] = qr(A,0)$  produces the economy-size decomposition. If  $m > n$ , only the first  $n$  columns of  $Q$  and the first  $n$  rows of  $R$  are computed. If  $m \leq n$ , this is the same as  $[Q,R] = qr(A)$ .

If  $A$  is full:

$[Q,R,E] = qr(A)$  or  $[Q,R,E] = qr(A,'matrix')$  produces unitary  $Q$ , upper triangular  $R$  and a permutation matrix  $E$  so that  $A*E = Q*R$ . The column permutation  $E$  is chosen so that  $abs(diag(R))$  is decreasing.

$[Q,R,e] = qr(A,'vector')$  returns the permutation information as a vector instead of a matrix. That is,  $e$  is a row vector such that  $A(:,e) = Q*R$ .

$[Q,R,e] = qr(A,0)$  produces an economy-size decomposition in which  $e$  is a permutation vector, so that  $A(:,e) = Q*R$ .

$X = \text{qr}(A)$  and  $X = \text{qr}(A,0)$  return a matrix  $X$  such that  $\text{triu}(X)$  is the upper triangular factor  $R$ .

If  $A$  is sparse:

$R = \text{qr}(A)$  computes a Q-less QR decomposition and returns the upper triangular factor  $R$ . Note that  $R = \text{chol}(A' * A)$ . Since  $Q$  is often nearly full, this is preferred to  $[Q,R] = \text{QR}(A)$ .

$R = \text{qr}(A,0)$  produces economy-size  $R$ . If  $m > n$ ,  $R$  has only  $n$  rows. If  $m \leq n$ , this is the same as  $R = \text{qr}(A)$ .

$[Q,R,E] = \text{qr}(A)$  or  $[Q,R,E] = \text{qr}(A, 'matrix')$  produces unitary  $Q$ , upper triangular  $R$  and a permutation matrix  $E$  so that  $A * E = Q * R$ . The column permutation  $E$  is chosen to reduce fill-in in  $R$ .

$[Q,R,e] = \text{qr}(A, 'vector')$  returns the permutation information as a vector instead of a matrix. That is,  $e$  is a row vector such that  $A(:, e) = Q * R$ .

$[Q,R,e] = \text{qr}(A,0)$  produces an economy-size decomposition in which  $e$  is a permutation vector, so that  $A(:, e) = Q * R$ .

$[C,R] = \text{qr}(A,B)$ , where  $B$  has as many rows as  $A$ , returns  $C = Q' * B$ . The least-squares solution to  $A * X = B$  is  $X = R \setminus C$ .

$[C,R,E] = \text{qr}(A,B)$  or  $[C,R,E] = \text{qr}(A,B, 'matrix')$ , also returns a fill-reducing ordering. The least-squares solution to  $A * X = B$  is  $X = E * (R \setminus C)$ .

$[C,R,e] = \text{qr}(A,B, 'vector')$  returns the permutation information as a vector instead of a matrix. That is, the least-squares solution to  $A * X = B$  is  $X(e, :) = R \setminus C$ .

$[C,R] = \text{qr}(A,B,0)$  produces economy-size results. If  $m > n$ ,  $C$  and  $R$  have only  $n$  rows. If  $m \leq n$ , this is the same as  $[C,R] = \text{qr}(A,B)$ .

$[C,R,e] = \text{qr}(A,B,0)$  additionally produces a fill-reducing permutation vector  $e$ . In this case, the least-squares solution to  $A * X = B$  is  $X(e, :) = R \setminus C$ .

## Examples

Find the least squares approximate solution to  $A*x = b$  with the Q-less QR decomposition and one step of iterative refinement:

```
if issparse(A), R = qr(A);  
else R = triu(qr(A)); end  
x = R\(R\'\'(A'*b));  
r = b - A*x;  
err = R\'\'(A'*r);  
x = x + err;
```

**Purpose** Remove column or row from QR factorization

**Syntax**

```
[Q1,R1] = qrdelete(Q,R,j)
[Q1,R1] = qrdelete(Q,R,j,'col')
[Q1,R1] = qrdelete(Q,R,j,'row')
```

**Description**

`[Q1,R1] = qrdelete(Q,R,j)` returns the QR factorization of the matrix `A1`, where `A1` is `A` with the column `A(:,j)` removed and `[Q,R] = qr(A)` is the QR factorization of `A`.

`[Q1,R1] = qrdelete(Q,R,j,'col')` is the same as `qrdelete(Q,R,j)`.

`[Q1,R1] = qrdelete(Q,R,j,'row')` returns the QR factorization of the matrix `A1`, where `A1` is `A` with the row `A(j,:)` removed and `[Q,R] = qr(A)` is the QR factorization of `A`.

**Examples**

```
A = magic(5);
[Q,R] = qr(A);
j = 3;
[Q1,R1] = qrdelete(Q,R,j,'row');
```

```
Q1 =
    0.5274    -0.5197    -0.6697    -0.0578

## Algorithms

The `qrdelete` function uses a series of Givens rotations to zero out the appropriate elements of the factorization.

## See Also

`planerot` | `qr` | `qrinsert`

**Purpose** Insert column or row into QR factorization

**Syntax**

```
[Q1,R1] = qrinsert(Q,R,j,x)
[Q1,R1] = qrinsert(Q,R,j,x,'col')
[Q1,R1] = qrinsert(Q,R,j,x,'row')
```

**Description** [Q1,R1] = qrinsert(Q,R,j,x) returns the QR factorization of the matrix A1, where A1 is  $A = Q^*R$  with the column x inserted before  $A(:,j)$ . If A has n columns and  $j = n+1$ , then x is inserted after the last column of A.

[Q1,R1] = qrinsert(Q,R,j,x,'col') is the same as qrinsert(Q,R,j,x).

[Q1,R1] = qrinsert(Q,R,j,x,'row') returns the QR factorization of the matrix A1, where A1 is  $A = Q^*R$  with an extra row, x, inserted before  $A(j,:)$ .

## Examples

```
A = magic(5);
[Q,R] = qr(A);
j = 3;
x = 1:5;
[Q1,R1] = qrinsert(Q,R,j,x,'row')
```

## Algorithms

The `qrinsert` function inserts the values of `x` into the `j`th column (row) of `R`. It then uses a series of Givens rotations to zero out the nonzero elements of `R` on and below the diagonal in the `j`th column (row).

## See Also

`planerot` | `qr` | `qrdelete`

**Purpose** Rank 1 update to QR factorization

**Syntax** `[Q1,R1] = qrupdate(Q,R,u,v)`

**Description** `[Q1,R1] = qrupdate(Q,R,u,v)` when `[Q,R] = qr(A)` is the original QR factorization of A, returns the QR factorization of  $A + u \cdot v'$ , where u and v are column vectors of appropriate lengths.

**Tips** qrupdate works only for full matrices.

**Examples** The matrix

```
mu = sqrt(eps)
```

```
mu =
```

```
1.4901e-08
```

```
A = [ones(1,4); mu*eye(4)];
```

is a well-known example in least squares that indicates the dangers of forming  $A' \cdot A$ . Instead, we work with the QR factorization – orthonormal Q and upper triangular R.

```
[Q,R] = qr(A);
```

As we expect, R is upper triangular.

```
R =
```

```
-1.0000    -1.0000   -1.0000   -1.0000
         0     0.0000    0.0000    0.0000
         0         0     0.0000    0.0000
         0         0         0     0.0000
         0         0         0         0
```

# qrupdate

---

In this case, the upper triangular entries of R, excluding the first row, are on the order of  $\sqrt{\text{eps}}$ .

Consider the update vectors

$$u = [-1 \ 0 \ 0 \ 0 \ 0]'; \quad v = \text{ones}(4,1);$$

Instead of computing the rather trivial QR factorization of this rank one update to A from scratch with

$$[QT,RT] = \text{qr}(A + u*v')$$

QT =

$$\begin{bmatrix} 0 & 0 & 0 & 0 & 1 \\ -1 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 \end{bmatrix}$$

RT =

$$1.0\text{e-}007 * \begin{bmatrix} -0.1490 & 0 & 0 & 0 \\ 0 & -0.1490 & 0 & 0 \\ 0 & 0 & -0.1490 & 0 \\ 0 & 0 & 0 & -0.1490 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

we may use qrupdate.

$$[Q1,R1] = \text{qrupdate}(Q,R,u,v)$$

Q1 =

$$\begin{bmatrix} -0.0000 & -0.0000 & -0.0000 & -0.0000 & 1.0000 \\ 1.0000 & -0.0000 & -0.0000 & -0.0000 & 0.0000 \end{bmatrix}$$

```

0.0000    1.0000   -0.0000   -0.0000    0.0000
0.0000    0.0000    1.0000   -0.0000    0.0000
-0.0000   -0.0000   -0.0000    1.0000    0.0000

```

R1 =

```

1.0e-007 *
0.1490    0.0000    0.0000    0.0000
0         0.1490    0.0000    0.0000
0         0         0.1490    0.0000
0         0         0         0.1490
0         0         0         0

```

Note that both factorizations are correct, even though they are different.

## Algorithms

qrupdate uses the algorithm in section 12.5.1 of the third edition of *Matrix Computations* by Golub and van Loan. qrupdate is useful since, if we take  $N = \max(m, n)$ , then computing the new QR factorization from scratch is roughly an  $O(N^3)$  algorithm, while simply updating the existing factors in this way is an  $O(N^2)$  algorithm.

# quad

---

**Purpose** Numerically evaluate integral, adaptive Simpson quadrature

**Syntax**

```
q = quad(fun,a,b)
q = quad(fun,a,b,tol)
q = quad(fun,a,b,tol,trace)
[q,fcnt] = quad(...)
```

**Description** *Quadrature* is a numerical method used to find the area under the graph of a function, that is, to compute a definite integral.

$$q = \int_a^b f(x) dx$$

`q = quad(fun,a,b)` tries to approximate the integral of function `fun` from `a` to `b` to within an error of  $1e-6$  using recursive adaptive Simpson quadrature. `fun` is a function handle. Limits `a` and `b` must be finite. The function `y = fun(x)` should accept a vector argument `x` and return a vector result `y`, the integrand evaluated at each element of `x`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`q = quad(fun,a,b,tol)` uses an absolute error tolerance `tol` instead of the default which is  $1.0e-6$ . Larger values of `tol` result in fewer function evaluations and faster computation, but less accurate results. In MATLAB version 5.3 and earlier, the `quad` function used a less reliable algorithm and a default relative tolerance of  $1.0e-3$ .

`q = quad(fun,a,b,tol,trace)` with non-zero `trace` shows the values of `[fcnt a b-a Q]` during the recursion.

`[q,fcnt] = quad(...)` returns the number of function evaluations.

The function `quadl` may be more efficient with high accuracies and smooth integrands.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The `quad` function may be most efficient for low accuracies with nonsmooth integrands.
- The `quadl` function may be more efficient than `quad` at higher accuracies with smooth integrands.
- The `quadgk` function may be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite,  $[a, \text{Inf})$ , then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like  $\log|x-c|$  or  $|x-c|^p$  for  $p \geq -1/2$ . If the function is singular at points inside  $(a,b)$ , write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

## Examples

To compute the integral

$$\int_0^2 \frac{1}{x^3 - 2x - 5} dx,$$

write a function `myfun` that computes the integrand:

```
function y = myfun(x)
y = 1./(x.^3-2*x-5);
```

Then pass `@myfun`, a function handle to `myfun`, to `quad`, along with the limits of integration, 0 to 2:

# quad

---

```
Q = quad(@myfun,0,2)
```

```
Q =
```

```
-0.4605
```

Alternatively, you can pass the integrand to `quad` as an anonymous function handle `F`:

```
F = @(x)1./(x.^3-2*x-5);
```

```
Q = quad(F,0,2);
```

## Algorithms

`quad` implements a low order method using an adaptive recursive Simpson's rule.

## Diagnostics

`quad` may issue one of the following warnings:

'Minimum step size reached' indicates that the recursive interval subdivision has produced a subinterval whose length is on the order of roundoff error in the length of the original interval. A nonintegrable singularity is possible.

'Maximum function count exceeded' indicates that the integrand has been evaluated more than 10,000 times. A nonintegrable singularity is likely.

'Infinite or Not-a-Number function value encountered' indicates a floating point overflow or division by zero during the evaluation of the integrand in the interior of the interval.

## How To

- "Anonymous Functions"

**Purpose**

Numerically evaluate double integral over planar region

**Syntax**

```
q = quad2d(fun,a,b,c,d)
[q,errbnd] = quad2d(...)
q = quad2d(fun,a,b,c,d,param1,val1,param2,val2,...)
```

**Description**

`q = quad2d(fun,a,b,c,d)` approximates the integral of `fun(x,y)` over the planar region  $a \leq x \leq b$  and  $c(x) \leq y \leq d(x)$ . `fun` is a function handle, `c` and `d` may each be a scalar or a function handle.

All input functions must be vectorized. The function `Z=fun(X,Y)` must accept 2-D matrices `X` and `Y` of the same size and return a matrix `Z` of corresponding values. The functions `ymin=c(X)` and `ymax=d(X)` must accept matrices and return matrices of the same size with corresponding values.

`[q,errbnd] = quad2d(...)`. `errbnd` is an approximate upper bound on the absolute error,  $|Q - I|$ , where `I` denotes the exact value of the integral.

`q = quad2d(fun,a,b,c,d,param1,val1,param2,val2,...)` performs the integration as above with specified values of optional parameters:

|                     |                          |
|---------------------|--------------------------|
| <code>AbsTol</code> | absolute error tolerance |
| <code>RelTol</code> | relative error tolerance |

`quad2d` attempts to satisfy  $ERRBND \leq \max(AbsTol, RelTol * |Q|)$ . This is absolute error control when  $|Q|$  is sufficiently small and relative error control when  $|Q|$  is larger. A default tolerance value is used when a tolerance is not specified. The default value of `AbsTol` is  $1e-5$ . The default value of `RelTol` is  $100 * \text{eps}(\text{class}(Q))$ . This is also the minimum value of `RelTol`. Smaller `RelTol` values are automatically increased to the default value.

|                          |                                                                    |
|--------------------------|--------------------------------------------------------------------|
| <code>MaxFunEvals</code> | Maximum allowed number of evaluations of <code>fun</code> reached. |
|--------------------------|--------------------------------------------------------------------|

# quad2d

---

The `MaxFunEvals` parameter limits the number of vectorized calls to `fun`. The default is 2000.

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>FailurePlot</code> | Generate a plot if <code>MaxFunEvals</code> is reached. |
|--------------------------|---------------------------------------------------------|

Setting `FailurePlot` to `true` generates a graphical representation of the regions needing further refinement when `MaxFunEvals` is reached. No plot is generated if the integration succeeds before reaching `MaxFunEvals`. These (generally) 4-sided regions are mapped to rectangles internally. Clusters of small regions indicate the areas of difficulty. The default is `false`.

|                       |                                         |
|-----------------------|-----------------------------------------|
| <code>Singular</code> | Problem may have boundary singularities |
|-----------------------|-----------------------------------------|

With `Singular` set to `true`, `quad2d` will employ transformations to weaken boundary singularities for better performance. The default is `true`. Setting `Singular` to `false` will turn these transformations off, which may provide a performance benefit on some smooth problems.

## Examples

### Example 1

Integrate  $y \sin(x) + x \cos(y)$  over  $\pi \leq x \leq 2\pi$ ,  $0 \leq y \leq \pi$ . The true value of the integral is  $-\pi^2$ .

```
Q = quad2d(@(x,y) y.*sin(x)+x.*cos(y),pi,2*pi,0,pi)
```

### Example 2

Integrate  $[(x+y)^{1/2}(1+x+y)^2]^{-1}$  over the triangle  $0 \leq x \leq 1$  and  $0 \leq y \leq 1-x$ . The integrand is infinite at (0,0). The true value of the integral is  $\pi/4 - 1/2$ .

```
fun = @(x,y) 1./(sqrt(x + y) .* (1 + x + y).^2 )
```

In Cartesian coordinates:

```
ymax = @(x) 1 - x;
```

```
Q = quad2d(fun,0,1,0,ymax)
```

In polar coordinates:

```
polarfun = @(theta,r) fun(r.*cos(theta),r.*sin(theta)).*r;
rmax = @(theta) 1./(sin(theta) + cos(theta));
Q = quad2d(polarfun,0,pi/2,0,rmax)
```

## Limitations

quad2d begins by mapping the region of integration to a rectangle. Consequently, it may have trouble integrating over a region that does not have four sides or has a side that cannot be mapped smoothly to a straight line. If the integration is unsuccessful, some helpful tactics are leaving `Singular` set to its default value of `true`, changing between Cartesian and polar coordinates, or breaking the region of integration into pieces and adding the results of integration over the pieces.

For example:

```
fun = @(x,y)abs(x.^2 + y.^2 - 0.25);
c = @(x)-sqrt(1 - x.^2);
d = @(x)sqrt(1 - x.^2);
quad2d(fun,-1,1,c,d,'AbsTol',1e-8,...
    'FailurePlot',true,'Singular',false)
Warning: Reached the maximum number of function ...
    evaluations (2000). The result fails the ...
    global error test.
```

The failure plot shows two areas of difficulty, near the points  $(-1,0)$  and  $(1,0)$  and near the circle  $x^2 + y^2 = 0.25$ :

# quad2d

Changing the value of `Singular` to `true` will cope with the geometric singularities at  $(-1,0)$  and  $(1,0)$ . The larger shaded areas may need refinement but are probably not areas of difficulty.

```
Q = quad2d(fun,-1,1,c,d,'AbsTol',1e-8, ...  
          'FailurePlot',true,'Singular',true)  
Warning: Reached the maximum number of function ...  
         evaluations (2000). The result passes the ...  
         global error test.
```

From here you can take advantage of symmetry:

```
Q = 4*quad2d(fun,0,1,0,d,'Abstol',1e-8,...
             'Singular',true, 'FailurePlot',true)
```

However, the code is still working very hard near the singularity. It may not be able to provide higher accuracy:

```
Q = 4*quad2d(fun,0,1,0,d,'Abstol',1e-10,...
             'Singular',true,'FailurePlot',true)
```

```
Warning: Reached the maximum number of function ...
         evaluations (2000). The result passes the ...
         global error test.
```

# quad2d

At higher accuracy, a change in coordinates may work better.

```
polarfun = @(theta,r) fun(r.*cos(theta),r.*sin(theta)).*r;  
Q = 4*quad2d(polarfun,0,pi/2,0,1,'AbsTol',1e-10)
```

It is best to put the singularity on the boundary by splitting the region of integration into two parts:

```
Q1 = 4*quad2d(polarfun,0,pi/2,0,0.5,'AbsTol',5e-11);  
Q2 = 4*quad2d(polarfun,0,pi/2,0.5,1,'AbsTol',5e-11);  
Q = Q1 + Q2
```

**How To**

- “Anonymous Functions”

# quadgk

**Purpose** Numerically evaluate integral, adaptive Gauss-Kronrod quadrature

**Syntax**  
`q = quadgk(fun,a,b)`  
`[q,errbnd] = quadgk(fun,a,b)`  
`[q,errbnd] = quadgk(fun,a,b,param1,val1,param2,val2,...)`

**Description** `q = quadgk(fun,a,b)` attempts to approximate the integral of a scalar-valued function `fun` from `a` to `b` using high-order global adaptive quadrature and default error tolerances. The function `y = fun(x)` should accept a vector argument `x` and return a vector result `y`, where `y` is the integrand evaluated at each element of `x`. `fun` must be a function handle. Limits `a` and `b` can be `-Inf` or `Inf`. If both are finite, they can be complex. If at least one is complex, the integral is approximated over a straight line path from `a` to `b` in the complex plane.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[q,errbnd] = quadgk(fun,a,b)` returns an approximate upper bound on the absolute error,  $|Q - I|$ , where `I` denotes the exact value of the integral.

`[q,errbnd] = quadgk(fun,a,b,param1,val1,param2,val2,...)` performs the integration with specified values of optional parameters. The available parameters are

| Parameter | Description                                                                                        |                                                                                                                                                                  |

When a, b, and the waypoints are all real, only the waypoints between a and b are used, and they are used in sorted order. Note that waypoints are not intended for singularities in <math>\text{fun}(x)</math>. Singular points should be handled by making them endpoints of separate integrations and adding the results.</p> <p>If a, b, or any entry of the waypoints vector is complex, the integration is performed over a</p> |

# quadgk

| Parameter          | Description                                                       |                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|-------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    |                                                                   | sequence of straight line paths in the complex plane, from a to the first waypoint, from the first waypoint to the second, and so forth, and finally from the last waypoint to b.                                                                                                                                                                            |
| 'MaxIntervalCount' | Maximum number of intervals allowed.<br>The default value is 650. | The 'MaxIntervalCount' parameter limits the number of intervals that quadgk uses at any one time after the first iteration. A warning is issued if quadgk returns early because of this limit. Routinely increasing this value is not recommended, but it may be appropriate when errbnd is small enough that the desired accuracy has nearly been achieved. |

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The quad function may be most efficient for low accuracies with nonsmooth integrands.
- The quadl function may be more efficient than quad at higher accuracies with smooth integrands.

- The `quadgk` function may be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite,  $[a, \text{Inf})$ , then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like  $\log|x-c|$  or  $|x-c|^p$  for  $p \geq -1/2$ . If the function is singular at points inside  $(a,b)$ , write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

## Examples

### Integrand with a singularity at an integration end point

Write a function `myfun` that computes the integrand:

```
function y = myfun(x)
y = exp(x).*log(x);
```

Then pass `@myfun`, a function handle to `myfun`, to `quadgk`, along with the limits of integration, 0 to 1:

```
q = quadgk(@myfun,0,1)
```

```
q =
```

```
-1.3179
```

Alternatively, you can pass the integrand to `quadgk` as an anonymous function handle `F`:

# quadgk

---

```
f = @(x)exp(x).*log(x);  
q = quadgk(f,0,1);
```

## Oscillatory integrand on a semi-infinite interval

Integrate over a semi-infinite interval with specified tolerances, and return the approximate error bound:

```
f = @(x)x.^5.*exp(-x).*sin(x);  
[q,errbnd] = quadgk(f,0,inf,'RelTol',1e-8,'AbsTol',1e-12)
```

```
q =
```

```
-15.0000
```

```
errbnd =
```

```
9.4386e-009
```

## Contour integration around a pole

Use Waypoints to integrate around a pole using a piecewise linear contour:

```
f = @(z)1./(2*z - 1);  
q = quadgk(f,-1-i,-1-i,'Waypoints',[1-i,1+i,-1+i])
```

```
q =
```

```
0.0000 + 3.1416i
```

## Algorithms

quadgk implements adaptive quadrature based on a Gauss-Kronrod pair (15<sup>th</sup> and 7<sup>th</sup> order formulas).

## Diagnostics

quadgk may issue one of the following warnings:

'Minimum step size reached' indicates that interval subdivision has produced a subinterval whose length is on the order of roundoff

error in the length of the original interval. A nonintegrable singularity is possible.

'Reached the limit on the maximum number of intervals in use' indicates that the integration was terminated before meeting the tolerance requirements and that continuing the integration would require more than `MaxIntervalCount` subintervals. The integral may not exist, or it may be difficult to approximate numerically. Increasing `MaxIntervalCount` usually does not help unless the tolerance requirements were nearly met when the integration was previously terminated.

'Infinite or Not-a-Number function value encountered' indicates a floating point overflow or division by zero during the evaluation of the integrand in the interior of the interval.

## How To

- “Anonymous Functions”

# quadl

---

**Purpose** Numerically evaluate integral, adaptive Lobatto quadrature

**Syntax**

```
q = quadl(fun,a,b)
q = quadl(fun,a,b,tol)
quadl(fun,a,b,tol,trace)
[q,fcnt] = quadl(...)
```

**Description** `q = quadl(fun,a,b)` approximates the integral of function `fun` from `a` to `b`, to within an error of  $10^{-6}$  using recursive adaptive Lobatto quadrature. `fun` is a function handle. It accepts a vector `x` and returns a vector `y`, the function `fun` evaluated at each element of `x`. Limits `a` and `b` must be finite.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`q = quadl(fun,a,b,tol)` uses an absolute error tolerance of `tol` instead of the default, which is  $1.0e-6$ . Larger values of `tol` result in fewer function evaluations and faster computation, but less accurate results.

`quadl(fun,a,b,tol,trace)` with non-zero `trace` shows the values of `[fcnt a b-a q]` during the recursion.

`[q,fcnt] = quadl(...)` returns the number of function evaluations.

Use array operators `.*`, `./` and `.^` in the definition of `fun` so that it can be evaluated with a vector argument.

The function `quad` might be more efficient with low accuracies or nonsmooth integrands.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The `quad` function might be most efficient for low accuracies with nonsmooth integrands.
- The `quadl` function might be more efficient than `quad` at higher accuracies with smooth integrands.

- The `quadgk` function might be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite,  $[a, \text{Inf})$ , then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like  $\log|x-c|$  or  $|x-c|^p$  for  $p \geq -1/2$ . If the function is singular at points inside  $(a,b)$ , write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

## Examples

Pass the function handle, `@myfun`, to `quadl`:

```
Q = quadl(@myfun,0,2);
```

where the function `myfun.m` is:

```
function y = myfun(x)  
y = 1./(x.^3-2*x-5);
```

Pass anonymous function handle `F` to `quadl`:

```
F = @(x) 1./(x.^3-2*x-5);  
Q = quadl(F,0,2);
```

## Algorithms

`quadl` implements a high order method using an adaptive Gauss/Lobatto quadrature rule.

# quadl

---

## Diagnostics

quadl might issue one of the following warnings:

'Minimum step size reached' indicates that the recursive interval subdivision has produced a subinterval whose length is on the order of roundoff error in the length of the original interval. A nonintegrable singularity is possible.

'Maximum function count exceeded' indicates that the integrand has been evaluated more than 10,000 times. A nonintegrable singularity is likely.

'Infinite or Not-a-Number function value encountered' indicates a floating point overflow or division by zero during the evaluation of the integrand in the interior of the interval.

## How To

- "Anonymous Functions"

**Purpose**

Vectorized quadrature

**Syntax**

```
Q = quadv(fun,a,b)
Q = quadv(fun,a,b,tol)
Q = quadv(fun,a,b,tol,trace)
[Q,fcnt] = quadv(...)
```

**Description**

`Q = quadv(fun,a,b)` approximates the integral of the complex array-valued function `fun` from `a` to `b` to within an error of  $1.e-6$  using recursive adaptive Simpson quadrature. `fun` is a function handle. The function `Y = fun(x)` should accept a scalar argument `x` and return an array result `Y`, whose components are the integrands evaluated at `x`. Limits `a` and `b` must be finite.

“Parameterizing Functions” explains how to provide addition parameters to the function `fun`, if necessary.

`Q = quadv(fun,a,b,tol)` uses the absolute error tolerance `tol` for all the integrals instead of the default, which is  $1.e-6$ .

---

**Note** The same tolerance is used for all components, so the results obtained with `quadv` are usually not the same as those obtained with `quad` on the individual components.

---

`Q = quadv(fun,a,b,tol,trace)` with non-zero `trace` shows the values of `[fcnt a b-a Q(1)]` during the recursion.

`[Q,fcnt] = quadv(...)` returns the number of function evaluations.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The `quad` function might be most efficient for low accuracies with nonsmooth integrands.
- The `quadl` function might be more efficient than `quad` at higher accuracies with smooth integrands.

- The `quadgk` function might be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite,  $[a, \text{Inf})$ , then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like  $\log|x-c|$  or  $|x-c|^p$  for  $p \geq -1/2$ . If the function is singular at points inside  $(a,b)$ , write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

## Examples

For the parameterized array-valued function `myarrayfun`, defined by

```
function Y = myarrayfun(x,n)
Y = 1./((1:n)+x);
```

the following command integrates `myarrayfun`, for the parameter value `n = 10` between `a = 0` and `b = 1`:

```
Qv = quadv(@(x)myarrayfun(x,10),0,1);
```

The resulting array `Qv` has 10 elements estimating  $Q(k) = \log((k+1)/(k))$ , for  $k = 1:10$ .

The entries in `Qv` are slightly different than if you compute the integrals using `quad` in a loop:

```
for k = 1:10
    Qs(k) = quadv(@(x)myscalarfun(x,k),0,1);
end
```

where `myscalarfun` is:

```
function y = myscalarfun(x,k)
y = 1./(k+x);
```

# questdlg

---

**Purpose** Create and open question dialog box

**Syntax**

```
button = questdlg('qstring')
button = questdlg('qstring','title')
button = questdlg('qstring','title',default)
button = questdlg('qstring','title','str1','str2',default)
button = questdlg('qstring','title','str1','str2','str3',
    default)
button = questdlg('qstring','title', ..., options)
```

**Description** `button = questdlg('qstring')` displays a modal dialog box presenting the question 'qstring'. The dialog has three default buttons, **Yes**, **No**, and **Cancel**. If the user presses one of these three buttons, `button` is set to the name of the button pressed. If the user presses the close button on the dialog without making a choice, `button` is set to the empty string. If the user presses the **Return** key, `button` is set to 'Yes'. 'qstring' is a cell array or a string that automatically wraps to fit within the dialog box.

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

---

`button = questdlg('qstring','title')` displays a question dialog with 'title' displayed in the dialog's title bar.

`button = questdlg('qstring','title',default)` specifies which push button is the default in the event that the **Return** key is pressed. '*default*' must be 'Yes', 'No', or 'Cancel'.

`button = questdlg('qstring','title','str1','str2',default)` creates a question dialog box with two push buttons labeled 'str1' and 'str2'. '*default*' specifies the default button selection and must be 'str1' or 'str2'.

```
button =
questdlg('qstring','title','str1','str2','str3',default)
creates a question dialog box with three push buttons labeled 'str1',
'str2', and 'str3'. default specifies the default button selection and
must be 'str1', 'str2', or 'str3'.
```

When *default* is specified, but is not set to one of the button names, pressing the **Enter** key displays a warning and the dialog remains open.

```
button = questdlg('qstring','title', ..., options) replaces
the string default with a structure, options. The structure specifies
which button string is the default answer, and whether to use TeX to
interpret the question string, qstring. Button strings and dialog titles
cannot use TeX interpretation. The options structure must include the
fields Default and Interpreter, both strings. It can include other
fields, but questdlg does not use them. You can set Interpreter to
'none' or 'tex'. If the Default field does not contain a valid button
name, a command window warning is issued and the dialog box does
not respond to pressing the Enter key.
```

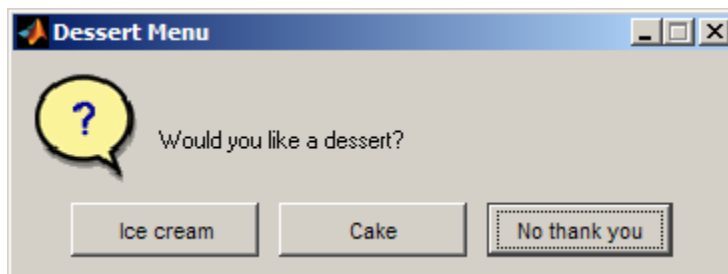

## Examples

### Example 1

Create a dialog that requests a dessert preference and encode the resulting choice as an integer.

```
% Construct a questdlg with three options
choice = questdlg('Would you like a dessert?', ...
'Dessert Menu', ...
'Ice cream','Cake','No thank you','No thank you');
% Handle response
switch choice
case 'Ice cream'
    disp([choice ' coming right up.'])
    dessert = 1;
case 'Cake'
    disp([choice ' coming right up.'])
    dessert = 2;
case 'No thank you'
    disp('I'll bring you your check.')
```

```
        dessert = 0;  
end
```

To access the return value assigned to `dessert`, save the example as a function, for example `choosedessert`, by inserting this line on top:

```
function dessert = choosedessert
```

You can generalize the function by providing the cases as string or cell array calling arguments.

As the example shows, case statements can contain white space (but are case-sensitive).

## Example 2

Specify an options structure to use the TeX interpreter to format a question.

```
options.Interpreter = 'tex';  
% Include the desired Default answer  
options.Default = 'Don''t know';  
% Create a TeX string for the question  
qstring = 'Is  $\Sigma(\alpha - \beta) < 0$ ?';  
choice = questdlg(qstring, 'Boundary Condition', ...  
    'Yes', 'No', 'Don''t know', options)
```

# quit

---

**Purpose** Terminate MATLAB program

**Alternatives** As an alternative to the quit function, use the Close box in the MATLAB desktop.

**Syntax**

```
quit  
quit cancel  
quit force
```

**Description** quit displays a confirmation dialog box if the confirm upon quitting preference is selected, and if confirmed or if the confirmation preference is not selected, terminates MATLAB after running `finish.m`, if `finish.m` exists. The workspace is not automatically saved by quit. To save the workspace or perform other actions when quitting, create a `finish.m` file to perform those actions. For example, you can display a custom dialog box to confirm quitting using a `finish.m` file—see the following examples for details. If an error occurs while `finish.m` is running, quit is canceled so that you can correct your `finish.m` file without losing your workspace.

quit **cancel** is for use in `finish.m` and cancels quitting. It has no effect anywhere else.

quit **force** bypasses `finish.m` and terminates MATLAB. Use this to override `finish.m`, for example, if an errant `finish.m` will not let you quit.

**Tips** When using Handle Graphics objects in `finish.m`, use `uiwait`, `waitfor`, or `drawnow` so that figures are visible. See the reference pages for these functions for more information.

If you want MATLAB to display the following confirmation dialog box after running quit, select **Preferences** in the **Environment** section on the **Home** tab. Then select the check box for Confirm before exiting MATLAB, and click **OK**.

## Examples

Two sample `finish.m` files are included with MATLAB. Use them to help you create your own `finish.m`, or rename one of the files to `finish.m` to use it.

- `finishesav.m`—Saves the workspace to a MAT-file when MATLAB quits.
- `finishdlg.m`—Displays a dialog allowing you to cancel quitting; it uses `quit cancel` and contains the following code:

```
button = questdlg('Ready to quit?', ...
    'Exit Dialog', 'Yes', 'No', 'No');
switch button
    case 'Yes',
        disp('Exiting MATLAB');
        %Save variables to matlab.mat
        save
    case 'No',
        quit cancel;
end
```

## See Also

`exit` | `save` | `finish` | `startup`

# Quit (COM)

---

**Purpose** Terminate MATLAB Automation server

**Syntax** **MATLAB Client**  
h.Quit  
Quit(h)  
invoke(h, 'Quit')

**IDL Method Signature**  
void Quit(void)

**Microsoft Visual Basic Client**  
Quit

**Description** Quit terminates the MATLAB server session attached to handle h.

**Tips** Server function names, like Quit, are case sensitive when using the first syntax shown.

There is no difference in the operation of the three syntaxes shown above for the MATLAB client.

**Purpose**

Quiver or velocity plot

**Syntax**

```
quiver(x,y,u,v)
quiver(u,v)
quiver(...,scale)
quiver(...,LineStyle)
quiver(...,LineStyle,'filled')
quiver(...,'PropertyName',PropertyValue,...)
quiver(axes_handle,...)
h = quiver(...)
```

**Description**

A quiver plot displays velocity vectors as arrows with components  $(u, v)$  at the points  $(x, y)$ .

For example, the first vector is defined by components  $u(1), v(1)$  and is displayed at the point  $x(1), y(1)$ .

`quiver(x,y,u,v)` plots vectors as arrows at the coordinates specified in each corresponding pair of elements in  $x$  and  $y$ . The matrices  $x$ ,  $y$ ,  $u$ , and  $v$  must all be the same size and contain corresponding position and velocity components. However,  $x$  and  $y$  can also be vectors, as explained in the next section. By default, the arrows are scaled to just not overlap, but you can scale them to be longer or shorter if you want.

`quiver(u,v)` draws vectors specified by  $u$  and  $v$  at equally spaced points in the  $x$ - $y$  plane.

`quiver(...,scale)` automatically scales the arrows to fit within the grid and then stretches them by the factor `scale`. `scale = 2` doubles their relative length, and `scale = 0.5` halves the length. Use `scale = 0` to plot the velocity vectors without automatic scaling. You can also tune the length of arrows after they have been drawn by choosing the **Plot**

**Edit**  tool, selecting the `quivergroup` object, opening the Property Editor, and adjusting the **Length** slider.

`quiver(...,LineStyle)` specifies line style, marker symbol, and color using any valid `LineStyle`. `quiver` draws the markers at the origin of the vectors.

`quiver(...,LineStyle,'filled')` fills markers specified by `LineStyle`.

`quiver(...,'PropertyName',PropertyValue,...)` specifies property name and property value pairs for the `quivergroup` objects the function creates.

`quiver(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = quiver(...)` returns the handle to the `quivergroup` object.

## Expanding x- and y-Coordinates

MATLAB expands `x` and `y` if they are not matrices. This expansion is equivalent to calling `meshgrid` to generate matrices from vectors:

```
[x,y] = meshgrid(x,y);  
quiver(x,y,u,v)
```

In this case, the following must be true:

`length(x) = n` and `length(y) = m`, where `[m,n] = size(u) = size(v)`.

The vector `x` corresponds to the columns of `u` and `v`, and vector `y` corresponds to the rows of `u` and `v`.

## Examples

### Showing the Gradient with Quiver Plots

Plot the gradient field of the function  $z = xe^{(-x^2 - y^2)}$ :

```
figure  
[X,Y] = meshgrid(-2:.2:2);  
Z = X.*exp(-X.^2 - Y.^2);  
[DX,DY] = gradient(Z,.2,.2);  
contour(X,Y,Z)  
hold on  
quiver(X,Y,DX,DY)  
colormap hsv
```

hold off

**See Also**

[contour](#) | [LineStyle](#) | [plot](#) | [quiver3](#)

**How To**

- [Two-Dimensional Quiver Plots](#)

# quiver3

---

## Purpose

3-D quiver or velocity plot

## Syntax

```
quiver3(x,y,z,u,v,w)
quiver3(z,u,v,w)
quiver3(...,scale)
quiver3(...,LineStyle)
quiver3(...,LineStyle,'filled')
quiver3(...,'PropertyName',PropertyValue,...)
quiver3(axes_handle,...)
h = quiver3(...)
```

## Description

A three-dimensional quiver plot displays vectors with components  $(u,v,w)$  at the points  $(x,y,z)$ , where  $u,v,w,x,y$ , and  $z$  all have real (non-complex) values.

`quiver3(x,y,z,u,v,w)` plots vectors with components  $(u,v,w)$  at the points  $(x,y,z)$ . The matrices  $x,y,z,u,v,w$  must all be the same size and contain the corresponding position and vector components.

`quiver3(z,u,v,w)` plots the vectors at the equally spaced surface points specified by matrix  $z$ . `quiver3` automatically scales the vectors based on the distance between them to prevent them from overlapping.

`quiver3(...,scale)` automatically scales the vectors to prevent them from overlapping, and then multiplies them by `scale`. `scale = 2` doubles their relative length, and `scale = 0.5` halves them. Use `scale = 0` to plot the vectors without the automatic scaling.

`quiver3(...,LineStyle)` specifies line type and color using any valid `LineStyle`.

`quiver3(...,LineStyle,'filled')` fills markers specified by `LineStyle`.

`quiver3(...,'PropertyName',PropertyValue,...)` specifies property name and property value pairs for the quivergroup objects the function creates.

`quiver3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = quiver3(...)` returns a vector of line handles.

## Examples

Plot the surface normals of the function  $z = xe^{(-x^2 - y^2)}$ .

```
figure
[X,Y] = meshgrid(-2:0.25:2,-1:0.2:1);
Z = X.* exp(-X.^2 - Y.^2);
[U,V,W] = surfnorm(X,Y,Z);
quiver3(X,Y,Z,U,V,W,0.5);
hold on
surf(X,Y,Z);
colormap hsv
view(-35,45)
axis([-2 2 -1 1 -.6 .6])
hold off
```

## How To

- [Three-Dimensional Quiver Plots](#)

## Purpose

Define quivergroup properties

## Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or the Property Editor (`propertyeditor`).

Note that you cannot define default properties for quivergroup objects.

See Plot Objects for more information on quivergroup objects.

## Quivergroup Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

### Annotation

`hg.Annotation` object (read-only)

*Control the display of quivergroup objects in legends.* Specifies whether this quivergroup object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the quivergroup object is displayed in a figure legend.

| <b>IconDisplayStyle Value</b> | <b>Purpose</b>                                                                        |
|-------------------------------|---------------------------------------------------------------------------------------|
| on                            | Include the quivergroup object in a legend as one entry, but not its children objects |
| off                           | Do not include the quivergroup or its children in a legend (default)                  |
| children                      | Include only the children of the quivergroup as separate entries in the legend        |

# Quivergroup Properties

---

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Controlling Legends” for more information and examples.

`AutoScale`  
{on} | off

*Autoscale arrow length.* Based on average spacing in the  $x$  and  $y$  directions, `AutoScale` scales the arrow length to fit within the grid-defined coordinate data and keeps the arrows from overlapping. After autoscaling, `quiver` applies the `AutoScaleFactor` to the arrow length.

`AutoScaleFactor`  
scalar (default = 0.9)

*User-specified scale factor.* When `AutoScale` is on, the `quiver` function applies this user-specified autoscale factor to the arrow length. A value of 2 doubles the length of the arrows; 0.5 halves the length.

`BeingDeleted`  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to on when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to on while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

## `BusyAction`

`cancel` | `{queue}`

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

# Quivergroup Properties

---

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

## Children

array of graphics object handles

*Children of the quivergroup object.* An array containing the handles of all line objects parented to this object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0, 'ShowHiddenHandles', 'on')
```

## Clipping

{on} | off

*Clipping mode.* MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

## Color

ColorSpec

*Color of the object.* A three-element RGB vector or one of the MATLAB predefined names, specifying the object's color. The default value is [0 0 0] (black).

See the `ColorSpec` reference page for more information on specifying color. See “Adding Arrows and Lines to Graphs”.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where @*CallbackFcn* is a function handle that references the callback function and *graphicfcn* is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See `Function Handle Callbacks` for information on how to use function handles to define the callback function.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

# Quivergroup Properties

---

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DisplayName`  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the quivergroup object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.

- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

## EraseMode

`{normal} | none | xor | background`

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object’s color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

# Quivergroup Properties

---

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## HandleVisibility

`{on} | callback | off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching

the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

`HitTest`  
{on} | off

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and

# Quivergroup Properties

---

the figure `CurrentObject` property) as a result of a mouse click on the line objects that compose the quiver plot. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`HitTestArea`  
`on` | `{off}`

*Select the object by clicking lines or area of extent.* Select plot objects by:

- Clicking quiver arrows (default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is `off`, you must click the quiver lines (excluding the baseline) to select the object. When `HitTestArea` is `on`, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses all the arrows).

`Interruptible`  
`off` | `{on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a *drawnow*, *figure*, *getframe*, *waitfor*, or *pause* command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

`LineStyle`

{-} | -- | : | -. | none

*Line style of quivergroup object.*

# Quivergroup Properties

---

### Line Style Specifiers Table

| Specifier | Line Style           |
|-----------|----------------------|
| '-'       | Solid line (default) |
| '--'      | Dashed line          |
| '.'       | Dotted line          |
| '-.'      | Dash-dot line        |
| 'none'    | No line              |

Use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

#### LineWidth

size in points

*Width of linear objects and edges of filled areas.* Specify in points. 1 point =  $1/72$  inch. The default is 0.5 points.

#### Marker

character (see table)

*Marker symbol.* Specifies marks that display at data points. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

### Marker Specifiers Table

| Specifier | Marker Type |
|-----------|-------------|
| '+'       | Plus sign   |
| 'o'       | Circle      |
| '*'       | Asterisk    |

| Specifier             | Marker Type                   |
|-----------------------|-------------------------------|
| '.'                   | Point                         |
| 'x'                   | Cross                         |
| 'square' or 's'       | Square                        |
| 'diamond' or 'd'      | Diamond                       |
| '^'                   | Upward-pointing triangle      |
| 'v'                   | Downward-pointing triangle    |
| '>'                   | Right-pointing triangle       |
| '<'                   | Left-pointing triangle        |
| 'pentagram' or 'p'    | Five-pointed star (pentagram) |
| 'hexagram' or 'h' ' ' | Six-pointed star (hexagram)   |
| 'none'                | No marker (default)           |

## MarkerEdgeColor

ColorSpec | none | {auto}

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Specifies no color, which makes nonfilled markers invisible.
- `auto` — Uses same color as the `Color` property.

## MarkerFaceColor

ColorSpec | {none} | auto

*Fill color for closed-shape markers.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

# Quivergroup Properties

---

- `ColorSpec` — User-defined color.
- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Sets the fill color to the axes `Color` property. If the axes `Color` property is `none` (the factory default for axes objects), sets the fill color to the figure `Color`.

`MarkerSize`  
scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

`MaxHeadSize`  
scalar (default = 0.2)

*Maximum size of arrowhead.* A value determining the maximum size of the arrowhead relative to the length of the arrow.

`Parent`  
handle of parent axes, `hgroup`, or `hgtransform`

*Parent of object.* Handle of the object's parent. The parent is normally the axes, `hgroup`, or `hgtransform` object that contains the object.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

`Selected`  
on | {off}

*Object selection state.* When you set this property to on, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also on (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to on, thereby indicating that this particular object is selected. This property is also set to on when an object is manually selected in plot edit mode.

`SelectionHighlight`  
{on} | off

*Object highlighted when selected.*

- on — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- off — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

`ShowArrowHead`  
{on} | off

*Display arrowheads on vectors.* When this property is on, MATLAB draws arrowheads on the vectors displayed by `quiver`. When you set this property to off, `quiver` draws the vectors as lines without arrowheads.

`Tag`  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an `areaseries` object and set the `Tag` property.

```
t = area(Y, 'Tag', 'area1')
```

# Quivergroup Properties

---

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag','area1'),'FaceColor','red')
```

## Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For stem objects, `Type` is `'hgroup'`. This statement finds all the `hgroup` objects in the current axes.

```
t = findobj(gca,'Type','hgroup');
```

## UIContextMenu

handle of `uicontextmenu` object

*Associate context menu with object.* Handle of a `uicontextmenu` object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

## UserData

array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## Visible

{on} | off

*Visibility of object and its children.*

- **on** — Object and all children of the object are visible unless the child object's **Visible** property is off.
- **off** — Object not displayed. However, the object still exists and you can set and query its properties.

## UData

matrix

*One dimension of 2-D or 3-D vector components.* UData, VData and WData (for 3-D) together specify the components of the vectors displayed as arrows in the quiver graph. For example, the first vector is defined by components `UData(1),VData(1),WData(1)`.

## UDataSource

string (MATLAB variable)

*Link UData to MATLAB variable.* Set this property to a MATLAB variable that, by default, is evaluated in the base workspace to generate the UData. The default value is an empty array.

```
set(h, 'UDataSource', 'Udatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `UDataSource` does not change the object's `UData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

# Quivergroup Properties

---

## VData

matrix

*One dimension of 2-D or 3-D vector components.* UData, VData and WData (for 3-D) together specify the components of the vectors displayed as arrows in the quiver graph. For example, the first vector is defined by components UData(1),VData(1),WData(1).

## VDataSource

MATLAB variable, as a string

*Link VData to MATLAB variable.* Set this property to a MATLAB variable that, by default, is evaluated in the base workspace to generate the VData. The default value is an empty array.

```
set(h, 'VDataSource', 'Vdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's VDataSource does not change the object's VData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## WData

matrix

*One dimension of 2-D or 3-D vector components.* UData, VData and WData (for 3-D) together specify the components of the vectors

displayed as arrows in the quiver graph. For example, the first vector is defined by components `UData(1),VData(1),WData(1)`.

## WDataSource

MATLAB variable, as a string

*Link WData to MATLAB variable.* Set this property to a MATLAB variable that, by default, is evaluated in the base workspace to generate the WData. The default value is an empty array.

```
set(h,'WDataSource','Wdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's WDataSource does not change the object's WData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## XData

vector | matrix

*X-axis coordinates of arrows.* The `quiver` function draws an individual arrow at each *x*-axis location in the XData array. XData can be either a matrix equal in size to all other data properties or for 2-D, a vector equal in length to the number of columns in UData or VData. That is, `length(XData) == size(UData,2)`.

# Quivergroup Properties

---

If you do not specify XData (which is the input argument X), the quiver function uses the indices of UData to create the quiver graph. See the XDataMode property for related information.

XDataMode  
{auto} | manual

*Use automatic or user-specified x-axis values.* If you specify XData (by setting the XData property or specifying the input argument X), the quiver function sets this property to manual.

If you set XDataMode to auto after having specified XData, the quiver function resets the x tick-mark labels to the indices of the U, V, and W data, overwriting any previous values.

XDataSource  
MATLAB variable, as a string

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the XData. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatavariablename')
```

MATLAB requires a call to refreshdata when you set this property. Changing workspace variables used as an object's XDataSource does not change the object's XData values, but you can use refreshdata to force an update of the object's data. refreshdata also lets you specify that the data source variable be evaluated in the workspace of a function from which you call refreshdata.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## YData

vector | matrix

*Y-axis coordinates of arrows.* The `quiver` function draws an individual arrow at each *y*-axis location in the `YData` array. `YData` can be either a matrix equal in size to all other data properties or for 2-D, a vector equal in length to the number of rows in `UData` or `VData`. That is, `length(YData) == size(UData,1)`.

If you do not specify `YData` (which is the input argument `Y`), the `quiver` function uses the indices of `VData` to create the quiver graph. See the `YDataMode` property for related information.

The input argument `Y` in the `quiver` function calling syntax assigns values to `YData`.

## YDataMode

{auto} | manual

*Use automatic or user-specified y-axis values.* If you specify `YData` (by setting the `YData` property or specifying the input argument `Y`), MATLAB sets this property to `manual`.

If you set `YDataMode` to `auto` after having specified `YData`, MATLAB resets the *y* tick-mark labels to the indices of the `U`, `V`, and `W` data, overwriting any previous values.

## YDataSource

MATLAB variable, as a string

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's

# Quivergroup Properties

---

`YDataSource` does not change the object's `YData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## ZData

vector | matrix

*Z-axis coordinates of arrows.* The `quiver` function draws an individual arrow at each *z*-axis location in the `ZData` array. `ZData` must be a matrix equal in size to `XData` and `YData`.

The input argument `Z` in the `quiver3` function calling syntax assigns values to `ZData`.

**Purpose**

QZ factorization for generalized eigenvalues

**Syntax**

```
[AA, BB, Q, Z] = qz(A, B)
[AA, BB, Q, Z, V, W] = qz(A, B)
qz(A, B, flag)
```

**Description**

The qz function gives access to intermediate results in the computation of generalized eigenvalues.

`[AA, BB, Q, Z] = qz(A, B)` for square matrices  $A$  and  $B$ , produces upper quasitriangular matrices  $AA$  and  $BB$ , and unitary matrices  $Q$  and  $Z$  such that  $Q^*A^*Z = AA$ , and  $Q^*B^*Z = BB$ . For complex matrices,  $AA$  and  $BB$  are triangular.

`[AA, BB, Q, Z, V, W] = qz(A, B)` also produces matrices  $V$  and  $W$  whose columns are generalized eigenvectors.

`qz(A, B, flag)` for real matrices  $A$  and  $B$ , produces one of two decompositions depending on the value of `flag`:

|           |                                                                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------|
| 'complex' | Produces a possibly complex decomposition with a triangular $AA$ . For compatibility with earlier versions, 'complex' is the default. |
| 'real'    | Produces a real decomposition with a quasitriangular $AA$ , containing 1-by-1 and 2-by-2 blocks on its diagonal.                      |

If  $AA$  is triangular, the diagonal elements of  $AA$  and  $BB$ ,  $\alpha = \text{diag}(AA)$  and  $\beta = \text{diag}(BB)$ , are the generalized eigenvalues that satisfy

$$A * V * \beta = B * V * \alpha$$

$$\beta' * W' * A = \alpha' * W' * B$$

The eigenvalues produced by

$$\lambda = \text{eig}(A, B)$$

are the ratios of the  $\alpha$ s and  $\beta$ s.

$$\lambda = \alpha / \beta$$

If  $AA$  is not triangular, it is necessary to further reduce the 2-by-2 blocks to obtain the eigenvalues of the full system.

**See Also**

eig

**Purpose**

Uniformly distributed pseudorandom numbers

**Syntax**

```
r = rand(n)
r = rand(m,n)
r = rand([m,n])
r = rand(m,n,p,...)
r = rand([m,n,p,...])
r = rand
r = rand(size(A))
r = rand(..., 'double')
r = rand(..., 'single')
```

**Description**

`r = rand(n)` returns an  $n$ -by- $n$  matrix containing pseudorandom values drawn from the standard uniform distribution on the open interval (0,1). `r = rand(m,n)` or `r = rand([m,n])` returns an  $m$ -by- $n$  matrix. `r = rand(m,n,p,...)` or `r = rand([m,n,p,...])` returns an  $m$ -by- $n$ -by- $p$ -by-... array. `r = rand` returns a scalar. `r = rand(size(A))` returns an array the same size as  $A$ .

`r = rand(..., 'double')` or `r = rand(..., 'single')` returns an array of uniform values of the specified class.

---

**Note** The size inputs  $m$ ,  $n$ ,  $p$ , ... should be nonnegative integers. Negative integers are treated as 0.

---

The sequence of numbers produced by `rand` is determined by the internal settings of the uniform random number generator that underlies `rand`, `randi`, and `randn`. You can control that shared random number generator using `rng`.

---

**Note** To use the `rng` function instead of `rand` or `randn` with the 'seed', 'state', or 'twister' inputs, see the documentation on “Updating Your Random Number Generator Syntax”

---

## Examples

### Example 1

Generate values from the uniform distribution on the interval [a, b]:

```
r = a + (b-a).*rand(100,1);
```

### Example 2

Use the `randi` function, instead of `rand`, to generate integer values from the uniform distribution on the set 1:100:

```
r = randi(100,1,5);
```

### Example 3

Reset the random number generator used by `rand`, `randi`, and `randn` to its default startup settings, so that `rand` produces the same random numbers as if you restarted MATLAB:

```
rng('default')
rand(1,5)
ans =
    0.8147    0.9058    0.1270    0.9134    0.6324
```

### Example 4

Save the settings for the random number generator used by `rand`, `randi`, and `randn`, generate 5 values from `rand`, restore the settings, and repeat those values:

```
s = rng;
u1 = rand(1,5)
u1 =
    0.0975    0.2785    0.5469    0.9575    0.9649

rng(s);
u2 = rand(1,5)
u2 =
    0.0975    0.2785    0.5469    0.9575    0.9649
```

`u2` contains exactly the same values as `u1`.

**Example 5**

Reinitialize the random number generator used by `rand`, `randi`, and `randn` with a seed based on the current time. `rand` returns different values each time you do this. Note that it is usually not necessary to do this more than once per MATLAB session as it may affect the statistical properties of the random numbers MATLAB produces:

```
rng('shuffle');  
rand(1,5);
```

**See Also**

`randi` | `randn` | `rng` | `@RandStream` | `rand (RandStream)` | `sprand` | `sprandn` | `randperm`

# rand (RandStream)

---

**Purpose** Uniformly distributed random numbers

**Class** RandStream

**Syntax**

```
r = rand(s,n)
rand(s,m,n)
rand(s,[m,n])
rand(s,m,n,p,...)
rand(s,[m,n,p,...])
rand(s)
rand(s,size(A))
r = rand(..., 'double')
r = rand(..., 'single')
```

**Description** `r = rand(s,n)` returns an  $n$ -by- $n$  matrix containing pseudorandom values drawn from the standard uniform distribution on the open interval  $(0,1)$ . The values are drawn from the random stream `s`. `rand(s,m,n)` or `rand(s,[m,n])` returns an  $m$ -by- $n$  matrix. `rand(s,m,n,p,...)` or `rand(s,[m,n,p,...])` returns an  $m$ -by- $n$ -by- $p$ -by-... array. `rand(s)` returns a scalar. `rand(s,size(A))` returns an array the same size as `A`.

`r = rand(..., 'double')` or `r = rand(..., 'single')` returns an array of uniform values of the specified class.

---

**Note** The size inputs `m`, `n`, `p`, ... should be nonnegative integers. Negative integers are treated as 0.

---

The sequence of numbers produced by `rand` is determined by the internal state of the random number stream `s`. Resetting that stream to the same fixed state allows computations to be repeated. Setting the stream to different states leads to unique computations, however, it does not improve any statistical properties.

### See Also

randperm (RandStream)

# randi

---

**Purpose** Uniformly distributed pseudorandom integers

**Syntax**

```
r = randi(imax,n)
r = randi(imax,m,n)
r = randi(imax,[m,n])
r = randi(imax,p1,...,pn)
r = randi(imax,[p1,...,pn])
r = randi(imax)
r = randi(imax,size(A))
r = randi([imin,imax],...)
r = randi(..., classname)
```

**Description** `r = randi(imax,n)` returns an n-by-n matrix containing pseudorandom integer values drawn from the discrete uniform distribution on the interval [1,imax]. Use `r = randi(imax,m,n)` or `r = randi(imax,[m,n])` to obtain an m-by-n matrix of numbers. Use `r = randi(imax,p1,...,pn)` or `r = randi(imax,[p1,...,pn])` to obtain a n-dimensional array. Use `r = randi(imax)` to obtain a scalar value between 1 and imax. This is the same as `r = randi(imax,1)`. Use `r = randi(imax,size(A))` to obtain an array the same size as A.

`r = randi([imin,imax],...)` returns an array containing integer values drawn from the discrete uniform distribution on the interval [imin,imax].

`r = randi(..., classname)` returns an array of integer values of class `classname`. `classname` does not support 64-bit integers.

Specify the size arguments, `m`, `n` or `p1,..., pn`, as nonnegative integers. If you pass a negative size value, it will be treated as 0.

If you specify a distribution range using two numbers, `[imin,imax]`, both numbers must be integers that satisfy  $imin \leq imax$ . If you specify the range using only the upper bound, `imax`, it must be a positive integer (greater than zero).

The sequence of numbers produced by `randi` is determined by the settings of the uniform random number generator that underlies `rand`, `randn`, and `randi`. `randi` uses one uniform random value to create each

integer random value. You can control that shared random number generator using `rng`.

## Examples

### Example 1

Generate a 100-by-1 array of integer values from the uniform distribution on the set 1:10:

```
r = randi(10,100,1);
```

### Example 2

Generate a 100-by-1 array of integers drawn uniformly from 1:10:

```
r = randi(10,100,1,'uint32');
```

### Example 3

Generate a 100-by-1 array of integer values drawn uniformly from -10:10:

```
r = randi([-10 10],100,1);
```

### Example 4

Reset the random number generator used by `rand`, `randi`, and `randn` to its default startup settings, so that `randi` produces the same random numbers as if you restarted MATLAB:

```
rng('default');  
randi(10,1,5)
```

```
ans =  
     9     10     2     10     7
```

### Example 5

Save the settings for the random number generator used by `rand`, `randi`, and `randn`, generate 5 values from `randi`, restore the settings, and repeat those values:

```
s = rng;  
i1 = randi(10,1,5)
```

# randi

---

```
i1 =  
    1     3     6    10    10  
rng(s);  
i2 = randi(10,1,5)  
i2 =  
    1     3     6    10    10
```

`i2` contains exactly the same values as `i1`.

## Example 6

Reinitialize the random number generator used by `rand`, `randi`, and `randn` with a seed based on the current time. `randi` returns different values each time you do this. Note that it is usually not necessary to do this more than once per MATLAB session:

```
rng('shuffle');  
randi(10,1,5);
```

randi(s,imax,[m,n])
randi(s,imax,m,n,p,...)
randi(s,imax,[m,n,p,...])
randi(s,imax)
randi(s,imax,size(A))
r = randi(s,[imin,imax],...)
r = randi(..., classname)
```

**Description**

`r = randi(s,imax,n)` returns an n-by-n matrix containing pseudorandom integer values drawn from the discrete uniform distribution on `1:imax`. `randi` draws those values from the random stream `s`. `randi(s,imax,m,n)` or `randi(s,imax,[m,n])` returns an m-by-n matrix. `randi(s,imax,m,n,p,...)` or `randi(s,imax,[m,n,p,...])` returns an m-by-n-by-p-by-... array. `randi(s,imax)` returns a scalar. `randi(s,imax,size(A))` returns an array the same size as `A`.

`r = randi(s,[imin,imax],...)` returns an array containing integer values drawn from the discrete uniform distribution on `imin:imax`.

`r = randi(..., classname)` returns an array of integer values of class `classname`. `classname` does not support 64-bit integers.

---

**Note** The size inputs `m`, `n`, `p`, ... should be nonnegative integers. Negative integers are treated as 0.

---

The sequence of numbers produced by `randi` is determined by the internal state of the random stream `s`. `randi` uses one uniform value from `s` to generate each integer value. Resetting `s` to the same fixed

## randi (RandStream)

---

state allows computations to be repeated. Setting the stream to different states leads to unique computations, however, it does not improve any statistical properties.

randi | RandStream | rand (RandStream) | randn (RandStream)

**Purpose** Normally distributed pseudorandom numbers

**Syntax**

```
r = randn(n)
r = randn(m,n)
r = randn([m,n])
r = randn(m,n,p,...)
r = randn([m,n,p,...])
r = randn
r = randn(size(A))
r = randn(..., 'double')
r = randn(..., 'single')
```

**Description** `r = randn(n)` returns an  $n$ -by- $n$  matrix containing pseudorandom values drawn from the standard normal distribution. `r = randn(m,n)` or `r = randn([m,n])` returns an  $m$ -by- $n$  matrix. `r = randn(m,n,p,...)` or `r = randn([m,n,p,...])` returns an  $m$ -by- $n$ -by- $p$ -by-... array. `r = randn` returns a scalar. `r = randn(size(A))` returns an array the same size as `A`.

`r = randn(..., 'double')` or `r = randn(..., 'single')` returns an array of normal values of the specified class.

---

**Note** The size inputs `m`, `n`, `p`, ... should be nonnegative integers. Negative integers are treated as 0.

---

The sequence of numbers produced by `randn` is determined by the settings of the uniform random number generator that underlies `rand`, `randn`, and `randi`. `randn` uses one or more uniform random values to create each normal random value. You can control that shared random number generator using `rng`.

---

**Note** To use the `rng` function instead of `rand` or `randn` with the 'seed', 'state', or 'twister' inputs, see the documentation on “Updating Your Random Number Generator Syntax”

---

## Examples

### Example 1

Generate values from a normal distribution with mean 1 and standard deviation 2:

```
r = 1 + 2.*randn(100,1);
```

### Example 2

Generate values from a bivariate normal distribution with specified mean vector and covariance matrix:

```
mu = [1 2];  
Sigma = [1 .5; .5 2]; R = chol(Sigma);  
z = repmat(mu,100,1) + randn(100,2)*R;
```

### Example 3

Reset the random number generator used by `rand`, `randi`, and `randn` to its default startup settings, so that `randn` produces the same random numbers as if you restarted MATLAB:

```
rng('default');  
randn(1,5)  
ans =  
    0.5377    1.8339   -2.2588    0.8622    0.3188
```

### Example 4

Save the settings for the random number generator used by `rand`, `randi`, and `randn`, generate 5 values from `randn`, restore the settings, and repeat those values:

```
s = rng;
```

```
z1 = randn(1,5)
z1 =
    -1.3077    -0.4336     0.3426     3.5784     2.7694
rng(s);
z2 = randn(1,5)
z2 =
    -1.3077    -0.4336     0.3426     3.5784     2.7694
```

z2 contains exactly the same values as z1.

### Example 5

Reinitialize the random number generator used by `rand`, `randi`, and `randn` with a seed based on the current time. `randn` returns different values each time you do this. Note that it is usually not necessary to do this more than once per MATLAB session:

```
rng('shuffle');
randn(1,5)
```

### See Also

`rand` | `randi` | `rng` | `@RandStream` | `randn` (`RandStream`)

# randn (RandStream)

---

**Purpose** Normally distributed pseudorandom numbers

**Class** RandStream

**Syntax**

```
randn(s,m,n)
randn(s,[m,n])
randn(s,m,n,p,...)
randn(s,[m,n,p,...])
randn(s)
randn(s,size(A))
r = randn(..., 'double')
r = randn(..., 'single')
```

**Description**

`r = randn(s,n)` returns an  $n$ -by- $n$  matrix containing pseudorandom values drawn from the standard normal distribution. `randn` draws those values from the random stream `s`. `randn(s,m,n)` or `randn(s,[m,n])` returns an  $m$ -by- $n$  matrix. `randn(s,m,n,p,...)` or `randn(s,[m,n,p,...])` returns an  $m$ -by- $n$ -by- $p$ -by-... array. `randn(s)` returns a scalar. `randn(s,size(A))` returns an array the same size as `A`.

`r = randn(..., 'double')` or `r = randn(..., 'single')` returns an array of uniform values of the specified class.

---

**Note** The size inputs `m`, `n`, `p`, ... should be nonnegative integers. Negative integers are treated as 0.

---

The sequence of numbers produced by `randn` is determined by the internal state of the random stream `s`. `randn` uses one or more uniform values from `s` to generate each normal value. Resetting that stream to the same fixed state allows computations to be repeated. Setting the stream to different states leads to unique computations, however, it does not improve any statistical properties.

**See Also** `randn` | `RandStream` | `rand` (`RandStream`) | `randi` (`RandStream`)

**Purpose** Random permutation

**Syntax** `p = randperm(n)`  
`p = randperm(n,k)`

**Description** `p = randperm(n)` returns a row vector containing a random permutation of the integers from 1 to `n` inclusive.  
`p = randperm(n,k)` returns a row vector containing `k` unique integers selected randomly from 1 to `n` inclusive.

**Tips** For `p = randperm(n,k)`, `p` contains `k` *unique* values. `randperm` performs `k`-permutations (sampling without replacement). To allow repeated values in the output (sampling with replacement), use `randi(n,1,k)`.  
`randperm` uses the same random number generator as `rand`, `randi`, and `randn`. You control this generator with `rng`.

**Examples** `randperm(6)`  
might be the vector  
`[3 2 6 4 1 5]`

or it might be some other permutation of the integers from 1 to 6, depending on the state of the random number generator. Two successive calls to `randperm` would in most cases return two different vectors:

```
randperm(6)
ans =
     5     2     6     4     1     3
```

```
randperm(6)
ans =
     4     1     6     2     3     5
```

---

# randperm

---

`randperm(6,3)`

might be the vector

`[4 2 5]`

or it might be some other permutation of any three integers from 1 to 6 inclusive, depending on the state of the random number generator.

## **See Also**

`permute` | `nchoosek` | `randi` | `randperm(RandStream)` | `perms` | `rng`

**Purpose** Random permutation

**Class** RandStream

**Syntax**  
`p = randperm(s,n)`  
`p = randperm(s,n,k)`

**Description** `p = randperm(s,n)` returns a row vector containing a random permutation of integers from 1 to *n* inclusive. `randperm(s,n)` uses random values drawn from the random stream *s*.

`p = randperm(s,n,k)` returns a row vector containing *k* unique integers selected randomly from 1 to *n* inclusive.

**Tips** For `p = randperm(s,n,k)`, *p* contains *k* *unique* values. `randperm` performs *k*-permutations (sampling without replacement). To allow repeated values in the output (sampling with replacement), use `randi(s,n,1,k)`.

**Examples** Create a random stream *s* and generate a random permutation of the integers from 1 to 6 based on *s*:

```
s = RandStream('mt19937ar','Seed',0);  
randperm(s,6)
```

MATLAB returns the vector

```
[6    3    5    1    2    4]
```

Use the random stream *s* to generate three integers between 1 and 10:

```
randperm(s,10,3)  
ans =  
     1     8     9
```

**See Also** `permute` | `randperm` | `nchoosek` | `perms` | `rand` | `randi` (RandStream)

# RandStream

---

**Purpose** Random number stream

**Constructor** RandStream

**Description** Pseudorandom numbers in MATLAB come from one or more random number streams. The simplest way to generate arrays of random numbers is to use `rand`, `randn`, or `randi`. These functions all rely on the same stream of uniform random numbers, known as the *global stream*. You can create other streams that act separately from the global stream, and you can use their `rand`, `randi`, or `randn` methods to generate arrays of random numbers. You can also create a random number stream and make it the global stream.

To create a single random number stream, use the `RandStream` constructor. To create multiple independent random number streams, use `RandStream.create`. The `rng` function provides a simple interface to create a new global stream.

`stream = RandStream.getGlobalStream` returns the global random number stream, that is, the one currently used by the `rand`, `randi`, and `randn` functions.

`prevstream = RandStream.setGlobalStream(stream)` designates the random number stream `stream` as the new global stream to be used by the `rand`, `randi`, and `randn` functions, and returns the previous global stream.

A random number stream `s` has properties that control its behavior. Access or assign to a property using `p = s.Property` or `s.Property = p`. The following table lists defined properties:

## Properties

| Property    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Type        | (Read-only) Generator algorithm used by the stream. The list of possible generators is given by <code>RandStream.list</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Seed        | (Read-only) Seed value used to create the stream.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| NumStreams  | (Read-only) Number of streams in the group in which the current stream was created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| StreamIndex | (Read-only) Index of the current stream from among the group of streams with which it was created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| State       | <p>Internal state of the generator. You should not depend on the format of this property. The value you assign to <code>S.State</code> must be a value read from <code>S.State</code> previously. Use <code>reset</code> to return a stream to a predictable state without having previously read from the <code>State</code> property.</p> <p>The sequence of random numbers produced by a random number stream <code>s</code> is determined by the internal state of its random number generator. Saving and restoring the generator's internal state with the <code>State</code> property allows you to reproduce a sequence of random numbers.</p> |

# RandStream

---

| Property        | Description                                                                                                                                                                                                                                                                                                     |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Substream       | Index of the substream to which the stream is currently set. The default is 1. Multiple substreams are not supported by all generator types; the multiplicative lagged Fibonacci generator ( <code>m1fg6331_64</code> ) and combined multiple recursive generator ( <code>mrg32k3a</code> ) support substreams. |
| NormalTransform | Transformation algorithm used by <code>randn(s, ...)</code> to generate normal pseudorandom values. Possible values are 'Ziggurat', 'Polar', or 'Inversion'.                                                                                                                                                    |
| RandnAlg        | <p>RandnAlg will be removed in a future release. Use NormalTransform instead.</p> <p>Transformation algorithm that will be used by <code>randn(S, ...)</code> to generate normal pseudorandom values. Options are 'Ziggurat', 'Polar', or 'Inversion'.</p>                                                      |
| Antithetic      | Logical value indicating whether <code>S</code> generates antithetic pseudorandom values. For uniform values, these are the usual values subtracted from 1. The default is false.                                                                                                                               |
| FullPrecision   | Logical value indicating whether <code>S</code> generates values using its full precision. Some generators can create pseudorandom values faster, but with fewer random bits, if FullPrecision is false. The default is true.                                                                                   |

## Methods

| Method                                   | Description                                                                                                                                                                                                                                                                                                          |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>RandStream</code>                  | Create a random number stream.                                                                                                                                                                                                                                                                                       |
| <code>RandStream.create</code>           | Create multiple independent random number streams.                                                                                                                                                                                                                                                                   |
| <code>get</code>                         | Get the properties of a random stream object.                                                                                                                                                                                                                                                                        |
| <code>list</code>                        | List available random number generator algorithms.                                                                                                                                                                                                                                                                   |
| <code>set</code>                         | Set random stream property.                                                                                                                                                                                                                                                                                          |
| <code>RandStream.getGlobalStream</code>  | Get the global random number stream.                                                                                                                                                                                                                                                                                 |
| <code>RandStream.getDefaultStream</code> | <code>RandStream.getDefaultStream</code> will be removed in a future release. Use <code>RandStream.getGlobalStream</code> instead. The shared random number stream used by <code>rand</code> , <code>randi</code> , and <code>randn</code> is now referred to as the global stream.<br>Default random number stream. |
| <code>RandStream.setGlobalStream</code>  | Set global random number stream.                                                                                                                                                                                                                                                                                     |
| <code>RandStream.setDefaultStream</code> | <code>RandStream.setDefaultStream</code> will be removed in a future release. Use <code>RandStream.setGlobalStream</code> instead.<br>Set default random number stream property.                                                                                                                                     |
| <code>reset</code>                       | Reset a stream to its initial internal state                                                                                                                                                                                                                                                                         |
| <code>rand</code>                        | Pseudorandom numbers from a uniform distribution                                                                                                                                                                                                                                                                     |

# RandStream

---

| Method   | Description                                                |
|----------|------------------------------------------------------------|
| randn    | Pseudorandom numbers from a standard normal distribution   |
| randi    | Pseudorandom integers from a uniform discrete distribution |
| randperm | Random permutation of a set of values                      |

## Examples

### Example 1

Create a single stream and designate it as the current global stream:

```
s = RandStream('mt19937ar', 'Seed', 1);  
RandStream.setGlobalStream(s);
```

### Example 2

Create three independent streams:

```
[s1,s2,s3] = RandStream.create('mrg32k3a', 'NumStreams', 3);  
r1 = rand(s1, 100000, 1);  
r2 = rand(s2, 100000, 1);  
r3 = rand(s3, 100000, 1);  
corrcoef([r1,r2,r3])
```

### Example 3

Create only one stream from a set of three independent streams, and designate it as the current global stream:

```
s2 = RandStream.create('mrg32k3a', 'NumStreams', 3, ...  
    'StreamIndices', 2);  
RandStream.setGlobalStream(s2);
```

### Example 4

Reset the global random number stream that underlies rand, randi, and randn back to its beginning, to reproduce previous results:

```
stream = RandStream.getGlobalStream;
```

```
reset(stream);
```

## Example 5

Save and restore the current global stream's state to reproduce the output of rand:

```
stream = RandStream.getGlobalStream;
savedState = stream.State;
u1 = rand(1,5)
u1 =
    0.8147    0.9058    0.1270    0.9134    0.6324

stream.State = savedState;
u2 = rand(1,5)
u2 =
    0.8147    0.9058    0.1270    0.9134    0.6324
```

u2 contains exactly the same values as u1.

## Example 6

Reset the global random number stream to its initial settings. This causes rand, randi, and randn to start over, as if in a new MATLAB session:

```
s = RandStream('mt19937ar','Seed',0);
RandStream.setGlobalStream(s);
```

## Example 7

Reinitialize the global random number stream using a seed based on the current time. This causes rand, randi, and randn to return different values in different MATLAB sessions. It is usually not desirable to do this more than once per MATLAB session as it may affect the statistical properties of the random numbers MATLAB produces:

```
s = RandStream('mt19937ar','Seed','shuffle');
RandStream.setGlobalStream(s);
```

# RandStream

---

## Example 8

Change the transformation algorithm that `randn` uses to create normal pseudorandom values from uniform values. This does not replace or reset the global stream.

```
stream = RandStream.getGlobalStream;  
stream.NormalTransform = 'inversion'
```

## See Also

`rand` | `rng` | `randn` | `randi`

**Purpose** Random number stream

**Class** RandStream

**Syntax**  
`s = RandStream('gentype')`  
`s = RandStream('gentype',Name,Value)`

**Description** `s = RandStream('gentype')` creates a random number stream that uses the uniform pseudorandom number generator algorithm specified by `gentype`. `RandStream.list` returns all possible values for `gentype`, or see “Choosing a Random Number Generator” for details on generator algorithms.

`s = RandStream('gentype',Name,Value)` allows you to specify one or more optional `Name,Value` pairs to control creation of the stream.

Once you have created a random, you can use `RandStream.setGlobalStream` to make it the global stream, so that the functions `rand`, `randi`, and `randn` draw values from it.

Parameters for `RandStream` are:

| Parameter       | Description                                                                                                                                                                                 |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Seed            | Nonnegative scalar integer with which to initialize all streams. Seeds must be an integer between 0 and $2^{32} - 1$ or 'shuffle' to create a seed based on the current time. Default is 0. |
| NormalTransform | Transformation algorithm used by <code>randn(s, ...)</code> to generate normal pseudorandom values.                                                                                         |

# RandStream constructor

---

| Parameter | Description                                                                                                                                                                                                       |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | Possible values are 'Ziggurat', 'Polar', or 'Inversion'.                                                                                                                                                          |
| RandnAlg  | RandnAlg will be removed in a future release. Use NormalTransform instead.<br><br>Transformation algorithm used by randn to generate normal pseudorandom values. Options are 'Ziggurat', 'Polar', or 'Inversion'. |

## Examples

### Example 1

Create a random number stream, make it the global stream, and save and restore its state to reproduce the output of randn:

```
s = RandStream('mrg32k3a');
RandStream.setGlobalStream(s);
savedState = s.State;
z1 = randn(1,5)
z1 =
    -0.1894    -1.4426    -0.3592     0.8883    -0.4337
s.State = savedState;
z2 = randn(1,5)
z2 =
    -0.1894    -1.4426    -0.3592     0.8883    -0.4337
```

z2 contains exactly the same values as z1.

### Example 2

Return rand, randi, and randn to their default startup settings:

```
s = RandStream('mt19937ar','Seed',0)
RandStream.setGlobalStream(s);
```

## Example 3

Replace the current global random number stream with a stream whose seed is based on the current time, so `rand`, `randi`, and `randn` will return different values in different MATLAB sessions. It is usually not desirable to do this more than once per MATLAB session as it may affect the statistical properties of the random numbers MATLAB produces:

```
s = RandStream('mt19937ar','Seed','shuffle');  
RandStream.setGlobalStream(s);
```

# RandStream.getGlobalStream

---

**Purpose** Current global random number stream

**Class** @RandStream

**Syntax** stream = RandStream.getGlobalStream

**Description** stream = RandStream.getGlobalStream returns the global random number stream. The MATLAB functions rand, randi, and randn use the global stream to generate values.

rand, randi, and randn all rely on a stream of uniform pseudorandom numbers known as the *global stream*. randi uses one uniform value from the global stream to generate each integer value; randn uses one or more uniform values from the global stream to generate each normal value. Note that there are also rand, randi, and randn methods for which you specify a specific random stream from which to draw values.

The rng function is a shorter alternative for many common uses of RandStream.getGlobalStream.

**See Also** RandStream | rng | RandStream.setGlobalStream | rand | randi | randn

**Purpose**

Set global random number stream

**Syntax**

```
prevstream = RandStream.setGlobalStream(stream)
```

**Description**

`prevstream = RandStream.setGlobalStream(stream)` designates the random number stream `stream` as the stream to be used by the `rand`, `randi`, and `randn` functions, and returns the previous global random number stream.

`rand`, `randi`, and `randn` all rely on the same stream of uniform pseudorandom numbers, known as the *global stream*. `randi` uses one uniform value from the global stream to generate each integer value. `randn` uses one or more uniform values from the global stream to generate each normal value. Note that there are also `rand`, `randi`, and `randn` methods for which you specify a specific random stream from which to draw values.

The `rng` function is a shorter alternative for many common uses of `RandStream.setGlobalStream`.

# rank

---

**Purpose** Rank of matrix

**Syntax**  
`k = rank(A)`  
`k = rank(A,tol)`

**Description** The rank function provides an estimate of the number of linearly independent rows or columns of a full matrix.

`k = rank(A)` returns the number of singular values of A that are larger than the default tolerance, `max(size(A))*eps(norm(A))`.

`k = rank(A,tol)` returns the number of singular values of A that are larger than `tol`.

**Tips** Use `sprank` to determine the structural rank of a sparse matrix.

**Algorithms** There are a number of ways to compute the rank of a matrix. MATLAB software uses the method based on the singular value decomposition, or SVD. The SVD algorithm is the most time consuming, but also the most reliable.

The rank algorithm is

```
s = svd(A);  
tol = max(size(A))*eps(max(s));  
r = sum(s > tol);
```

**See Also** `sprank`

**Purpose** Rational fraction approximation

**Syntax** `[N,D] = rat(X)`  
`[N,D] = rat(X,tol)`  
`rat(X)`

**Description** Even though all floating-point numbers are rational numbers, it is sometimes desirable to approximate them by simple rational numbers, which are fractions whose numerator and denominator are small integers. The `rat` function attempts to do this. Rational approximations are generated by truncating continued fraction expansions. The `rats` function calls `rat`, and returns strings.

`[N,D] = rat(X)` returns arrays `N` and `D` so that `N./D` approximates `X` to within the default tolerance, `1.e-6*norm(X(:),1)`.

`[N,D] = rat(X,tol)` returns `N./D` approximating `X` to within `tol`.  
`rat(X)`, with no output arguments, simply displays the continued fraction.

**Examples** Ordinarily, the statement

```
s = 1 - 1/2 + 1/3 - 1/4 + 1/5 - 1/6 + 1/7
```

produces

```
s =  
    0.7595
```

However, with

```
format rat
```

or with

```
rats(s)
```

the printed result is

```
s =  
    319/420
```

This is a simple rational number. Its denominator is 420, the least common multiple of the denominators of the terms involved in the original expression. Even though the quantity `s` is stored internally as a binary floating-point number, the desired rational form can be reconstructed.

To see how the rational approximation is generated, the statement `rat(s)` produces

```
1 + 1/(-4 + 1/(-6 + 1/(-3 + 1/(-5))))
```

And the statement

```
[n,d] = rat(s)
```

produces

```
n = 319, d = 420
```

The mathematical quantity  $\pi$  is not a rational number, but the MATLAB quantity `pi` that approximates it is a rational number. `pi` is the ratio of a large integer and  $2^{52}$ :

```
14148475504056880/4503599627370496
```

However, this is not a simple rational number. The value printed for `pi` with `format rat`, or with `rats(pi)`, is

```
355/113
```

This approximation was known in Euclid's time. Its decimal representation is

```
3.14159292035398
```

and so it agrees with `pi` to seven significant figures. The statement

```
rat(pi)
```

produces

```
3 + 1/(7 + 1/(16))
```

This shows how the 355/113 was obtained. The less accurate, but more familiar approximation 22/7 is obtained from the first two terms of this continued fraction.

## Algorithms

The `rat(X)` function approximates each element of `X` by a continued fraction of the form

$$\frac{n}{d} = d_1 + \frac{1}{d_2 + \frac{1}{\left(d_3 + \dots + \frac{1}{d_k}\right)}}$$

The  $d$ s are obtained by repeatedly picking off the integer part and then taking the reciprocal of the fractional part. The accuracy of the approximation increases exponentially with the number of terms and is worst when  $X = \text{sqrt}(2)$ . For  $x = \text{sqrt}(2)$ , the error with  $k$  terms is about  $2.68 * (.173)^k$ , so each additional term increases the accuracy by less than one decimal digit. It takes 21 terms to get full floating-point accuracy.

`format` | `rats`

# rbbox

---

**Purpose** Create rubberband box for area selection

**Syntax**

```
rbbox
rbbox(initialRect)
rbbox(initialRect, fixedPoint)
rbbox(initialRect, fixedPoint, stepSize)
finalRect = rbbox(...)
```

**Description** `rbbox` initializes and tracks a rubberband box in the current figure. It sets the initial rectangular size of the box to 0, anchors the box at the figure's `CurrentPoint`, and begins tracking from this point.

`rbbox(initialRect)` specifies the initial location and size of the rubberband box as `[x y width height]`, where `x` and `y` define the lower left corner, and `width` and `height` define the size. `initialRect` is in the units specified by the current figure's `Units` property, and measured from the lower left corner of the figure window. The corner of the box closest to the pointer position follows the pointer until `rbbox` receives a button-up event.

`rbbox(initialRect, fixedPoint)` specifies the corner of the box that remains fixed. All arguments are in the units specified by the current figure's `Units` property, and measured from the lower left corner of the figure window. `fixedPoint` is a two-element vector, `[x y]`. The tracking point is the corner diametrically opposite the anchored corner defined by `fixedPoint`.

`rbbox(initialRect, fixedPoint, stepSize)` specifies how frequently the rubberband box is updated. When the tracking point exceeds `stepSize` figure units, `rbbox` redraws the rubberband box. The default stepsize is 1.

`finalRect = rbbox(...)` returns a four-element vector, `[x y width height]`, where `x` and `y` are the `x` and `y` components of the lower left corner of the box, and `width` and `height` are the dimensions of the box.

## Tips

rbbox is useful for defining and resizing a rectangular region:

- For box definition, `initialRect` is `[x y 0 0]`, where `(x,y)` is the figure's `CurrentPoint`.
- For box resizing, `initialRect` defines the rectangular region that you resize (e.g., a legend). `fixedPoint` is the corner diametrically opposite the tracking point.

rbbox returns immediately if a button is not currently pressed. Therefore, you use rbbox with `waitforbuttonpress` so that the mouse button is down when rbbox is called. rbbox returns when you release the mouse button.

## Examples

Assuming the current view is `view(2)`, use the current axes' `CurrentPoint` property to determine the extent of the rectangle in dataspace units:

```
k = waitforbuttonpress;
point1 = get(gca,'CurrentPoint');    % button down detected
finalRect = rbbox;                  % return figure units
point2 = get(gca,'CurrentPoint');    % button up detected
point1 = point1(1,1:2);              % extract x and y
point2 = point2(1,1:2);
p1 = min(point1,point2);              % calculate locations
offset = abs(point1-point2);          % and dimensions
x = [p1(1) p1(1)+offset(1) p1(1)+offset(1) p1(1) p1(1)];
y = [p1(2) p1(2) p1(2)+offset(2) p1(2)+offset(2) p1(2)];
hold on
axis manual
plot(x,y)                            % redraw in dataspace units
```

# rcond

---

**Purpose** Matrix reciprocal condition number estimate

**Syntax** `c = rcond(A)`

**Description** `c = rcond(A)` returns an estimate for the reciprocal of the condition of  $A$  in 1-norm. If  $A$  is well conditioned, `rcond(A)` is near 1.0. If  $A$  is badly conditioned, `rcond(A)` is near 0.0. Compared to `cond`, `rcond` is a more efficient, but less reliable, method of estimating the condition of a matrix.

**See Also** `cond` | `condest` | `norm` | `normest` | `rank` | `svd`

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>         | Right array division                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Syntax</b>          | $x = A./B$<br>$x = \text{rdivide}(A,B)$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

# rdivide

---

## Output Arguments

### x - Solution

numeric array | sparse numeric array

Solution, specified as a sparse or full numeric array. If either A or B are integer data types, then x is that same integer data type.

## Examples

### Divide Two Numeric Arrays

```
A = [2 4 6 8;3 5 7 9];
```

```
B = 10*ones(2,4);
```

```
x = A./B
```

```
x =
```

```
    0.2000    0.4000    0.6000    0.8000  
    0.3000    0.5000    0.7000    0.9000
```

### Integer Division

MATLAB rounds the results when dividing integer data types.

```
a = int16(10);
```

```
b = int16([3 4 6]);
```

```
x = a./b
```

```
x =
```

```
     3     3     2
```

### Divide a Scalar by a Numeric Array

```
C = 5;
```

```
D = magic(3);
```

```
x = C./D
```

```
x =
```

```
    0.6250    5.0000    0.8333  
    1.6667    1.0000    0.7143  
    1.2500    0.5556    2.5000
```

## Tips

- When dividing integers, use `idivide` for more rounding options.
- MATLAB does not support complex integer division.

# VideoReader.read

---

**Purpose** Read video frame data from file

**Syntax**  
`video = read(obj)`  
`video = read(obj,index)`

**Description** `video = read(obj)` reads in all video frames from the file associated with `obj`.

`video = read(obj,index)` reads only the specified frames. `index` can be a single number or a two-element array representing an index range of the video stream.

## Input Arguments

### **obj**

Name of multimedia object created with `VideoReader`.

### **index**

Frames to read, where the first frame number is 1. Use `Inf` to represent the last frame of the file.

For example:

```
video = read(obj, 1);           % first frame only
video = read(obj, [1 10]);      % first 10 frames
video = read(obj, Inf);         % last frame only
video = read(obj, [50 Inf]);    % frame 50 thru end
```

MATLAB cannot determine the number of frames in a variable frame rate file until you read the last frame. If the requested *index* extends beyond the end of the file, `read` returns either a warning or an error. For more information, see “Reading Variable Frame Rate Video”.

**Default:** `[1 Inf]`

## Output Arguments

### **video**

Array of data representing video frames. The dimensions are *H-by-W-by-B-by-F*, where:

|          |                                                        |
|----------|--------------------------------------------------------|
| <i>H</i> | Image frame height.                                    |
| <i>W</i> | Image frame width.                                     |
| <i>B</i> | Number of bands in the image (for example, 3 for RGB). |
| <i>F</i> | Number of frames read.                                 |

The class of *video* depends on the data in the file. For example, given a file that contains 8-bit unsigned values corresponding to three color bands (RGB24), *video* is an array of `uint8` values.

## Examples

Read and play back the movie file `xylophone.mpg`:

```
xyloObj = VideoReader('xylophone.mpg');

nFrames = xyloObj.NumberOfFrames;
vidHeight = xyloObj.Height;
vidWidth = xyloObj.Width;

% Preallocate movie structure.
mov(1:nFrames) = ...
    struct('cdata', zeros(vidHeight, vidWidth, 3, 'uint8'),...
          'colormap', []);

% Read one frame at a time.
for k = 1 : nFrames
    mov(k).cdata = read(xyloObj, k);
end

% Size a figure based on the video's width and height.
hf = figure;
set(hf, 'position', [150 150 vidWidth vidHeight])

% Play back the movie once at the video's frame rate.
movie(hf, mov, 1, xyloObj.FrameRate);
```

# VideoReader.read

---

**See Also**      [movie](#) | [VideoReader](#)

**How To**        • [“Read Video Files”](#)

**Purpose**

Read entire image

**Syntax**

```
imageData = tiffobj.read()  
[Y,Cb,Cr] = tiffobj.read()
```

**Description**

`imageData = tiffobj.read()` reads the image data from the current image file directory (IFD) in the TIFF file associated with the `Tiff` object, `tiffobj`.

`[Y,Cb,Cr] = tiffobj.read()` reads the YCbCr component data from the current directory in the TIFF file. Depending upon the values of the `YCbCrSubSampling` tag, the size of the Cb and Cr channels might differ from the Y channel.

**Examples**

Open a `Tiff` object and read data from the TIFF file:

```
t = Tiff('mytif.tif', 'r');  
imageData = t.read();
```

| <b>Purpose</b>     | Read data asynchronously from device                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Syntax</b>      | <code>readasync(obj)</code><br><code>readasync(obj, size)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | <p><code>readasync(obj)</code> initiates an asynchronous read operation on the serial port object, <code>obj</code>.</p> <p><code>readasync(obj, size)</code> asynchronously reads, at most, the number of bytes given by <code>size</code>. If <code>size</code> is greater than the difference between the <code>InputBufferSize</code> property value and the <code>BytesAvailable</code> property value, an error is returned.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Tips</b>        | <p>Before you can read data, you must connect <code>obj</code> to the device with the <code>fopen</code> function. A connected serial port object has a <code>Status</code> property value of <code>open</code>. An error is returned if you attempt to perform a read operation while <code>obj</code> is not connected to the device.</p> <p>You should use <code>readasync</code> only when you configure the <code>ReadAsyncMode</code> property to <code>manual</code>. <code>readasync</code> is ignored if used when <code>ReadAsyncMode</code> is <code>continuous</code>.</p> <p>The <code>TransferStatus</code> property indicates if an asynchronous read or write operation is in progress. You can write data while an asynchronous read is in progress because serial ports have separate read and write pins. You can stop asynchronous read and write operations with the <code>stopasync</code> function.</p> <p>You can monitor the amount of data stored in the input buffer with the <code>BytesAvailable</code> property. Additionally, you can use the <code>BytesAvailableFcn</code> property to execute a callback function when the terminator or the specified amount of data is read.</p> <p><b>Rules for Completing an Asynchronous Read Operation</b></p> <p>An asynchronous read operation with <code>readasync</code> completes when one of these conditions is met:</p> <ul style="list-style-type: none"><li>• The terminator specified by the <code>Terminator</code> property is read.</li></ul> |

- The time specified by the Timeout property passes.
- The specified number of bytes is read.
- The input buffer is filled (if size is not specified).

Because `readasync` checks for the terminator, this function can be slow. To increase speed, you might want to configure `ReadAsyncMode` to `continuous` and continuously return data to the input buffer as soon as it is available from the device.

## Examples

This example creates the serial port object `s` on a Windows platform. It connects `s` to a Tektronix TDS 210 oscilloscope, configures `s` to read data asynchronously only if `readasync` is issued, and configures the instrument to return the peak-to-peak value of the signal on channel 1.

```
s = serial('COM1');
fopen(s)
s.ReadAsyncMode = 'manual';
fprintf(s, 'Measurement:Meas1:Source CH1')
fprintf(s, 'Measurement:Meas1:Type Pk2Pk')
fprintf(s, 'Measurement:Meas1:Value?')
```

Begin reading data asynchronously from the instrument using `readasync`. When the read operation is complete, return the data to the MATLAB workspace using `fscanf`.

```
readasync(s)
s.BytesAvailable
ans =
    15
out = fscanf(s)
out =
2.03999999619E0
fclose(s)
```

# Tiff.readEncodedStrip

---

**Purpose** Read data from specified strip

**Syntax**  
`stripData = tiffobj.readEncodedStrip(stripNumber)`  
`[Y,Cb,Cr] = tiffobj.readEncodedStrip(stripNumber)`

**Description** `stripData = tiffobj.readEncodedStrip(stripNumber)` reads data from the strip specified by `stripNumber`. Strip numbers are one-based numbers.

`[Y,Cb,Cr] = tiffobj.readEncodedStrip(stripNumber)` reads YCbCr component data from the specified strip. The size of the chrominance components Cb and Cr might differ from the size of the luminance component Y depending on the value of the YCbCrSubSampling tag.

`readEncodeStrip` clips the last strip, if the strip extends past the `ImageLength` boundary.

**Examples** Open a Tiff object and read a strip of data. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path.

```
t = Tiff('myfile.tif', 'r');
%
% Check if image is tiled or stipped.
if ~t.isTiled()
    data = t.readEncodedStrip(1);
end
```

**References** This method corresponds to the `TIFFReadEncodedStrip` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**See Also** `Tiff.readEncodedTile` | `Tiff.isTiled`

**Tutorials**

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

**Purpose**

Read data from specified tile

**Syntax**

```
tileData = tiffobj.readEncodedTile(tileNumber)
[Y,Cb,Cr] = tiffobj.readEncodedTile(tileNumber)
```

**Description**

`tileData = tiffobj.readEncodedTile(tileNumber)` reads data from the tile specified by `tileNumber`. Tile numbers are one-based numbers.

`[Y,Cb,Cr] = tiffobj.readEncodedTile(tileNumber)` reads YCbCr component data from the specified tile. The size of the chrominance components Cb and Cr might differ from the size of the luminance component Y, depending on the value of the YCbCrSubSampling tag.

`readEncodedTile` clips tiles on the last row or right-most column of an image if the tile extends past the `ImageLength` and `ImageLength` boundaries.

**Examples**

Open a Tiff object and read a tile of data. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path.

```
t = Tiff('myfile.tif', 'r');
%
% Check if image is tiled or stipped.
if t.isTiled()
    data = t.readEncodedTile(1);
end
```

**References**

This method corresponds to the `TIFFReadEncodedTile` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**Purpose** Convenience function for static .NET System.Delegate Remove method

**Syntax** `result = Remove(combinedDelegate, removedDelegate)`

**Description** `result = Remove(combinedDelegate, removedDelegate)` removes last instance of the removedDelegate delegate from the combinedDelegate delegate.

**Input Arguments**

**combinedDelegate**  
.NET System.Delegate object. The combined delegate from which to remove the removedDelegate delegate.

**removedDelegate**  
.NET System.Delegate object. The delegate to remove from the combinedDelegate delegate.

**Output Arguments**

**result**  
.NET System.Delegate object. A new delegate which is the same as the combinedDelegate delegate except without the last instance of the removedDelegate delegate.

**Alternatives** Use the static Remove method of the System.Delegate class.

## Purpose

Create timeseries object

## Description

Time series are data vectors sampled over time, in order, often at regular intervals. They are distinguished from randomly sampled data that form the basis of many other data analyses. Time series represent the time-evolution of a dynamic population or process. The linear ordering of time series gives them a distinctive place in data analysis, with a specialized set of techniques. Time series analysis is concerned with:

- Identifying patterns
- Modeling patterns
- Forecasting values

## Construction

`ts = timeseries` creates an empty time-series object.

`ts = timeseries(data)` creates the time-series object using the specified data.

`ts = timeseries(tsname)` creates the time-series object using the name, `tsname`, for the time-series object. This name can differ from the time-series variable name.

`ts = timeseries(data,time)` creates the time-series object using the specified data and time.

`ts = timeseries(data,time,quality)` specifies quality in terms of codes defined by `QualityInfo.Code`.

`ts = timeseries(data,Name,Value)` uses one or more `Name`, `Value` pair arguments.

`ts = timeseries(data,time,Name,Value)` creates the time-series object using the specified (`data,time`), `time`, and `Name`, `Value` pair arguments.

`ts = timeseries(data,time,quality,Name,Value)` uses the specified quality.

## Input Arguments

### **data**

The time-series data, which can be an array of samples

### **tsname**

Time-series name specified as a string

**Default:** ''

### **time**

The time vector.

When time values are date strings, you must specify `Time` as a cell array of date strings. When the time vector contains duplicate values:

- Duplicated values must occupy contiguous elements.
- Time values must not be decreasing.

Interpolating time-series data using methods like `resample` and `synchronize` can produce different results depending on whether the input `timeseries` contains duplicate times.

**Default:** A time vector that ranges from 0 to N-1 with a 1-second interval, where N is the number of samples.

### **quality**

An integer vector with values -128 to 127 that specifies the quality in terms of codes defined by `QualityInfo.Code`

When `Quality` is a vector:

- `Quality` must have the same length as the time vector.
- Each `Quality` value applies to the corresponding data sample.

When `Quality` is an array:

- `Quality` must have the same size as the data array.
- Each `Quality` value applies to the corresponding data value of the `ts.data` array.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### **IsTimeFirst**

Specify `'IsTimeFirst'`, `true` when the time vector runs along the first dimension of the data array. Alternatively, if the time vector runs along the last dimension of the data array, specify `'IsTimeFirst'`, `false`.

You can set this property when a 2-D data array is square and, therefore, the dimension that is aligned with time is ambiguous. 3-D and higher dimension data requires `IsTimeFirst` to be `false`; for such data, time steps always lie along the last dimension.

---

**Note** In a future release, `IsTimeFirst` will default to `false` for 3-D and higher dimensional data. Setting `IsTimeFirst` to `true` for such data will generate an error.

---

**Default:** `true`

### **Name**

Specify `'Name'` followed by a string value if you want to name the `timeseries` object. For example, `'Name'`, `'myTSObject'` names the `timeseries` object `'myTSObject'`.

# timeseries

---

## Properties

### Data

Time-series data, where each data sample corresponds to a specific time

The data can be a scalar, a vector, or a multidimensional array. Either the first or last dimension of the data must align with `Time`.

By default, NaNs represent missing or unspecified data. Set the `TreatNaNasMissing` property to determine how missing data is treated in calculations.

### Attributes:

Dependent true

### DataInfo

Contains fields for storing contextual information about `Data`:

- `Unit` — String that specifies data units
- `Interpolation` — A `tsdata.interpolation` object that specifies the interpolation method for this `timeseries` object.

Fields of the `tsdata.interpolation` object include:

- `Fhandle` — Function handle to a user-defined interpolation function
- `Name` — String that specifies the name of the interpolation method. Predefined methods include `'linear'` and `'zoh'` (zero-order hold). `'linear'` is the default.
- `UserData` — Any user-defined information entered as a string

### Events

An array of `tsdata.event` objects that stores event information for this `timeseries` object.

You add events by using the `addevent` method. Fields of the `tsdata.event` object include the following:

- **EventData** — Any user-defined information about the event
- **Name** — String that specifies the name of the event
- **Time** — Time value when this event occurs, specified as a real number or a date string
- **Units** — Time units
- **StartDate** — A reference date specified in MATLAB date-string format. **StartDate** is empty when you have a numerical (non-date-string) time vector.

### **IsTimeFirst**

Logical value (**true** or **false**) specifies whether the first or last dimension of the **Data** array is aligned with the time vector.

You can set this property when the **Data** array is square and it is ambiguous which dimension is aligned with time. By default, the first **Data** dimension that matches the length of the time vector is aligned with the time vector.

When you set this property to:

- **true** — The first dimension of the data array is aligned with the time vector. For example:  

```
ts=timeseries(rand(3,3),1:3, 'IsTimeFirst',true);
```
- **false** — The last dimension of the data array is aligned with the time vector. For example:  

```
ts=timeseries(rand(3,3),1:3, 'IsTimeFirst',false);
```

### **Attributes:**

|           |      |
|-----------|------|
| Dependent | true |
|-----------|------|

### **Length**

Length of the time vector in the **timeseries** object

### **Attributes:**

|           |             |
|-----------|-------------|
| Dependent | true        |
| SetAccess | 'protected' |

## Name

The `timeseries` object name entered as a string.

This name can differ from the name of the `timeseries` variable in the MATLAB workspace.

## Quality

An integer vector or array containing values -128 to 127 that specify the quality in terms of codes defined by `QualityInfo.Code`.

When `Quality` is a vector, it must have the same length as the time vector. In this case, each `Quality` value applies to a corresponding data sample.

When `Quality` is an array, it must have the same size as the data array. In this case, each `Quality` value applies to the corresponding value of the data array.

## Attributes:

|           |      |
|-----------|------|
| Dependent | true |
|-----------|------|

## QualityInfo

Provides a lookup table that converts numerical `Quality` codes to readable descriptions.

`QualityInfo` fields include the following:

- `Code` — Integer vector containing values -128 to 127 that define the “dictionary” of quality codes. You can assign one of these integer values to each `Data` value by using the `Quality` property.
- `Description` — Cell vector of strings, where each element provides a readable description of the associated quality `Code`.

- **UserData** — Stores any additional user-defined information.

Lengths of Code and Description must match.

### **Time**

Array of time values.

When `TimeInfo.StartDate` is empty, the numerical `Time` values are measured relative to 0 in specified units. When `TimeInfo.StartDate` is defined, the time values are date strings measured relative to the `StartDate` in specified units.

The length of `Time` must be the same as either the first or the last dimension of `Data`.

#### **Attributes:**

|           |      |
|-----------|------|
| Dependent | true |
|-----------|------|

### **TimeInfo**

Uses the following fields for storing contextual information about `Time`:

- **Units** — Time units having any of following values: 'weeks', 'days', 'hours', 'minutes', 'seconds', 'milliseconds', 'microseconds', or 'nanoseconds'
- **Start** — Start time
- **End** — End time (read only)
- **Increment** — Interval between two subsequent time values
- **Length** — Length of the time vector (read only)
- **Format** — String defining the date string display format. See the MATLAB `datestr` function reference page for more information.

- **StartDate** — Date string defining the reference date. See the MATLAB `setabstime` function reference page for more information.
- **UserData** — Stores any additional user-defined information

## **TreatNaNasMissing**

Logical value that specifies how to treat NaN values in `Data`:

- `true` — (Default) Treats all NaN values as missing data except during statistical calculations.
- `false` — Includes NaN values in statistical calculations, in which case NaN values are propagated to the result.

## **UserData**

Generic field for data of any class that you want to add to the object.

**Default:** []

## Methods to Query and Set Object Properties and Plot the Data

|                                |                                                                                                                                  |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>get</code>               | Query <code>timeseries</code> object property values.                                                                            |
| <code>getdatasamplesize</code> | Return the size of each data sample in a <code>timeseries</code> object.                                                         |
| <code>getqualitydesc</code>    | Return data quality descriptions based on the <code>Quality</code> property values assigned to a <code>timeseries</code> object. |
| <code>plot</code>              | Plot the <code>timeseries</code> object.                                                                                         |
| <code>set</code>               | Set <code>timeseries</code> property values.                                                                                     |

## Methods to Manipulate Data and Time

|                             |                                                                                                                                                             |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>addsample</code>      | Add a data sample to a <code>timeseries</code> object.                                                                                                      |
| <code>append</code>         | Concatenate <code>timeseries</code> objects in the time dimension.                                                                                          |
| <code>ctranspose</code>     | Transpose a <code>timeseries</code> object.                                                                                                                 |
| <code>delsample</code>      | Delete a sample from a <code>timeseries</code> object.                                                                                                      |
| <code>detrend</code>        | Subtract the mean or best-fit line and remove all NaNs from time-series data.                                                                               |
| <code>filter</code>         | Shape frequency content of time-series data using a 1-D digital filter.                                                                                     |
| <code>getabstime</code>     | Extract a date-string time vector from a <code>timeseries</code> object into a cell array.                                                                  |
| <code>getdatasamples</code> | Extract a subset of data samples from an existing <code>timeseries</code> object into an array using a subscripted indexed array.                           |
| <code>getsamples</code>     | Extract a subset of data samples from an existing <code>timeseries</code> object into a new <code>timeseries</code> object using a subscript indexed array. |

## (Continued)

|                                  |                                                                                                                                                              |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>getinterpmethod</code>     | Get the interpolation method for a <code>timeseries</code> object.                                                                                           |
| <code>getsamplingsingtime</code> | Extract data samples from an existing <code>timeseries</code> object into a new <code>timeseries</code> object based on specified start and end time values. |
| <code>idealfilter</code>         | Apply an ideal pass or notch (noncausal) filter to a <code>timeseries</code> object.                                                                         |
| <code>resample</code>            | Select or interpolate data in a <code>timeseries</code> object using a new time vector.                                                                      |
| <code>setabstime</code>          | Set the time values in the time vector as date strings.                                                                                                      |
| <code>setinterpmethod</code>     | Set interpolation method for a <code>timeseries</code> object.                                                                                               |
| <code>setuniformtime</code>      | Assign uniform time vector to <code>timeseries</code> object.                                                                                                |
| <code>synchronize</code>         | Synchronize and resample two <code>timeseries</code> objects using a common time vector.                                                                     |
| <code>transpose</code>           | Transpose a <code>timeseries</code> object.                                                                                                                  |

## Event Methods

To construct an event object, use the constructor `tsdata.event`. For an example of defining events for a time-series object, see “Defining Events”.

|                       |                                                                  |
|-----------------------|------------------------------------------------------------------|
| <code>addevent</code> | Add one or more events to a <code>timeseries</code> object.      |
| <code>delevent</code> | Delete one or more events from a <code>timeseries</code> object. |

## (Continued)

|                                 |                                                                                                                                                      |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>gettsafteratevent</code>  | Create a new <code>timeseries</code> object by extracting the samples from an existing time series that occur after or at a specified event.         |
| <code>gettsafterevent</code>    | Create a new <code>timeseries</code> object by extracting the samples that occur after a specified event from an existing time series.               |
| <code>gettsatevent</code>       | Create a new <code>timeseries</code> object by extracting the samples that occur at the same time as a specified event from an existing time series. |
| <code>gettsbeforeatevent</code> | Create a new <code>timeseries</code> object by extracting the samples that occur before or at a specified event from an existing time series.        |
| <code>gettsbeforeevent</code>   | Create a new <code>timeseries</code> object by extracting the samples that occur before a specified event from an existing time series.              |
| <code>gettsbetweenevents</code> | Create a new <code>timeseries</code> object by extracting the samples that occur between two specified events from an existing time series.          |

## Methods to Arithmetically Combine `timeseries` Objects

|                 |                                                                                  |
|-----------------|----------------------------------------------------------------------------------|
| <code>+</code>  | Addition of the corresponding data values of <code>timeseries</code> objects.    |
| <code>-</code>  | Subtraction of the corresponding data values of <code>timeseries</code> objects. |
| <code>.*</code> | Element-by-element multiplication of <code>timeseries</code> data.               |

## (Continued)

|    |                                                                       |
|----|-----------------------------------------------------------------------|
| *  | Matrix-multiply <code>timeseries</code> data.                         |
| ./ | Right element-by-element division of <code>timeseries</code> data.    |
| /  | Right matrix division of <code>timeseries</code> data.                |
| .\ | Element-by-element left-array divide of <code>timeseries</code> data. |
| \  | Left matrix division of <code>timeseries</code> data.                 |

## Methods to Calculate Descriptive Statistics for a `timeseries` Object

|                     |                                                                 |
|---------------------|-----------------------------------------------------------------|
| <code>iqr</code>    | Return the interquartile range of <code>timeseries</code> data. |
| <code>max</code>    | Return the maximum value of <code>timeseries</code> data.       |
| <code>mean</code>   | Return the mean of <code>timeseries</code> data.                |
| <code>median</code> | Return the median of <code>timeseries</code> data.              |
| <code>min</code>    | Return the minimum of <code>timeseries</code> data.             |
| <code>std</code>    | Return the standard deviation of <code>timeseries</code> data.  |
| <code>sum</code>    | Return the sum of <code>timeseries</code> data.                 |
| <code>var</code>    | Return the variance of <code>timeseries</code> data.            |

## Definitions

### **timeseries**

The time-series object, called `timeseries`, is a MATLAB variable that contains time-indexed data and properties in a single, coherent structure. For example, in addition to data and time values, you can also use the time-series object to store events, descriptive information about data and time, data quality, and the interpolation method.

## Data Sample

A time-series *data sample* consists of one or more values recorded at a specific time. The number of data samples in a time series is the same as the length of the time vector.

For example, suppose that `ts.data` has the size 3-by-4-by-5 and the time vector has the length 5. Then, the number of samples is 5 and the total number of data values is  $3 \times 4 \times 5 = 60$ .

## Time Vector

A time vector of a `timeseries` object can be either numerical (double) values or valid MATLAB date strings.

When the `timeseries` `TimeInfo.StartDate` property is empty, the numerical time values are measured relative to 0 (or another numerical value) in specified units. In this case, the time vector is described as *relative* (that is, it contains time values that are not associated with a specific start date).

When `TimeInfo.StartDate` is nonempty, the time values are date strings measured relative to `StartDate` in specified units. In this case, the time vector is described as *absolute* (that is, it contains time values that are associated with a specific calendar date).

MATLAB supports the following date-string formats for time-series applications.

| Date-String Format   | Usage Example        |
|----------------------|----------------------|
| dd-mmm-yyyy HH:MM:SS | 01-Mar-2000 15:45:17 |
| dd-mmm-yyyy          | 01-Mar-2000          |
| mm/dd/yy             | 03/01/00             |
| mm/dd                | 03/01                |
| HH:MM:SS             | 15:45:17             |
| HH:MM:SS PM          | 3:45:17 PM           |
| HH:MM                | 15:45                |

# timeseries

---

| Date-String Format   | Usage Example        |
|----------------------|----------------------|
| HH:MM PM             | 3:45 PM              |
| mmm.dd,yyyy HH:MM:SS | Mar.01,2000 15:45:17 |
| mmm.dd,yyyy          | Mar.01,2000          |
| mm/dd/yyyy           | 03/01/2000           |

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB Programming Fundamentals documentation](#).

## Examples

Create a `timeseries` object called 'LaunchData' that contains four data sets, each stored as a column of length 5 and using the default time vector:

```
b = timeseries(rand(5, 4), 'Name', 'LaunchData')
```

---

Create a `timeseries` object containing a single data set of length 5 and a time vector starting at 1 and ending at 5:

```
b = timeseries(rand(5,1), [1 2 3 4 5])
```

---

Create a `timeseries` object called 'FinancialData' containing five data points at a single time point:

```
b = timeseries(rand(1,5), 1, 'Name', 'FinancialData')
```

## Alternatives

Use the “Time Series Tools”.

**How To**

- “MATLAB Objects”

# timeseries.addsample

---

**Purpose** Add data sample to timeseries object

**Syntax**

```
ts1 = addsample(ts, s)
ts1 = addsample(ts, 'Data', data-value,
    'Time', time-value, ...,
    Name, Value)
```

**Description** `ts1 = addsample(ts, s)` adds one or more new data samples stored in a structure `s` to the timeseries object `ts`.

`ts1 = addsample(ts, 'Data', data-value, 'Time', time-value, ..., Name, Value)` adds one or more data samples to the timeseries object `ts` along with additional options specified by one or more `Name, Value` pair arguments.

**Tips**

- If `N` is the number of data samples, you can get the sample size of each time with `SampleSize = getsamplesize(ts)`.

When `ts.IsTimeFirst` is true, the size of the data is `N-by-SampleSize`. When `ts.IsTimeFirst` is false, the size of the data is `SampleSize-by-N`.

## Input Arguments

**s**

A structure that you must define before passing as an argument to `addsample`. It consists of the following optional fields:

- `s.data`
- `s.time`
- `s.quality`
- `s.overwriteflag`

### **data-value**

A numeric data value.

### **time-value**

A valid time vector.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## Quality

Array of data quality codes.

**Default:** []

## OverwriteFlag

Logical value that controls whether to overwrite a data sample at the same time with the new sample you are adding to your `timeseries` object. When set to `true`, the new sample overwrites the old sample at the same time.

**Default:** `false`

## Output Arguments

**ts1**

The `timeseries` object that results when you add the specified samples to the original `timeseries` object.

## Definitions

### data sample

One or more values recorded at a specific time. The number of data samples in a time series is the same as the length of the time vector.

## Examples

Add a data value of 420 at time 3:

```
ts = ts.addsample('Time',3,'Data',420);
```

---

# timeseries.addsample

---

Add a data value of 420 at time 3 and specify quality code 1 for this data value. Set the `OverwriteFlag` to overwrite an existing value at time 3.

```
ts = ts.addsample('Data',3.2,'Quality',1,'OverwriteFlag',...  
                 true,'Time',3);
```

|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Concatenate time series objects in time dimension                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Syntax</b>           | <code>ts = append(ts1,ts2, ... tsn)</code>                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b>      | <code>ts = append(ts1,ts2, ... tsn)</code> creates a new <code>timeseries</code> object by concatenating <code>timeseries</code> <code>ts1</code> , <code>ts2</code> , and so on, along the time dimension.                                                                                                                                                                                                            |
| <b>Tips</b>             | <ul style="list-style-type: none"><li>• A single overlapping time between each input time series is valid, as long as the overlapping samples are identical.</li><li>• The time vectors must not overlap by a nonzero amount. That is, the last time in <code>ts1</code> must be earlier than or equal to the first time in <code>ts2</code>.</li><li>• The sample size of the time series must be the same.</li></ul> |
| <b>Input Arguments</b>  | <p><b>ts1</b><br/>The first <code>timeseries</code> object that you want to append.</p> <p><b>ts2</b><br/>The second <code>timeseries</code> object that you want to append.</p> <p><b>tsn</b><br/>The <code>n</code>th <code>timeseries</code> object that you want to append.</p>                                                                                                                                    |
| <b>Output Arguments</b> | <p><b>ts</b><br/>The <code>timeseries</code> object that results from appending the input <code>timeseries</code> objects.</p>                                                                                                                                                                                                                                                                                         |
| <b>Examples</b>         | <p>After creating <code>timeseries</code> objects, <code>ts1</code> and <code>ts2</code>, append them:</p> <pre>ts1 = timeseries(rand(5,1),[1 2 3 4 5]);<br/>ts2 = timeseries(rand(5,1),[6 7 8 9 10]);<br/>ts3 = append(ts1, ts2)</pre>                                                                                                                                                                                |
| <b>See Also</b>         | <code>timeseries</code>                                                                                                                                                                                                                                                                                                                                                                                                |

# timeseries.ctranspose

---

**Purpose** Transpose timeseries object

**Syntax** `ts1 = ctranspose(ts)`

**Description** `ts1 = ctranspose(ts)` returns a new timeseries object `ts1` with the `IsTimeFirst` value set to opposite of what it is for `ts`. For example, if `ts` has the first data dimension aligned with the time vector, `ts1` has the last data dimension aligned with the time vector as a result of this operation.

- Tips**
- The overloaded `ctranspose` method for timeseries objects does not transpose the data. Instead, this method changes whether the first or the last dimension of the data aligns with the time vector. To transpose the data, you must transpose the `Data` property of the timeseries object. For example, you can use the syntax `ctranspose(ts.Data)` or `(ts.Data)'`. The `Data` property value must be a 2-D array.
  - Consider a timeseries object with 10 samples with the property `IsTimeFirst = True`. When you transpose this object, the data size changes from 10-by-1 to 1-by-1-by-10. Note that the first dimension of the `Data` property is shown explicitly.

The following table summarizes the size for `Data` property of the timeseries object (up to three dimensions) before and after transposing.

## Data Size Before and After Transposing

| Size of Original Data | Size of Transposed Data |
|-----------------------|-------------------------|
| N-by-1                | 1-by-1-by-N             |
| N-by-M                | M-by-1-by-N             |
| N-by-M-by-L           | M-by-L-by-N             |

## Input Arguments

**ts**

The timeseries object you want to transpose.

## Output Arguments

**ts1**

The transposed timeseries object.

## Examples

Suppose that a timeseries object `ts` has `ts.data` size 10-by-3-by-2 and its time vector has a length of 10. The `IsTimeFirst` property of `ts` is set to `true`, which means that the first dimension of the data is aligned with the time vector. `ctranspose(ts)` modifies `ts`, such that the last dimension of the data is now aligned with the time vector. This permutes the data, such that the size of `ts.Data` becomes 3-by-2-by-10.

## See Also

`timeseries` | `transpose`

# timeseries.delsample

---

**Purpose** Remove sample from timeseries object

**Syntax** `ts1 = delsample(ts,Name,Value)`

**Description** `ts1 = delsample(ts,Name,Value)` deletes samples from the timeseries object `ts` based on the specified `Name,Value` pair arguments.

**Input Arguments**

**ts**  
A timeseries object.

**Name-Value Pair Arguments** Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Index**

The indices of the time vector that correspond to the samples you want to delete.

**Value**

The time values that correspond to the samples you want to delete.

**Output Arguments**

**ts1**  
The timeseries object that results from removing the specified samples.

**Examples** Create a timeseries object, and then remove samples:

```
ts = timeseries(rand(5,1),[10 20 30 40 50]);  
  
% Remove data sample at time index 1  
  
ts1 = delsample(ts,'Index', 1)
```

```
% Remove data sample at time value 20:  
ts2 = delsample(ts, 'Value', [20])  
set | timeseries
```

# timeseries.detrend

---

**Purpose** Subtract mean or best-fit line and all NaNs from `timeseries` object

**Syntax**  
`ts1 = detrend(ts, method)`  
`ts1 = detrend(ts, method, index)`

**Description** `ts1 = detrend(ts, method)` subtracts either a mean or a best-fit line from time-series data, using the specified `method`. Usually for FFT processing.

`ts1 = detrend(ts, method, index)` uses the optional `index` to specify the columns or rows to detrend.

**Tips**

- You cannot apply `detrend` to `timeseries` data with more than two dimensions.

**Input Arguments**

**ts**  
The `timeseries` object from which you want to subtract the mean or best-fit line and all NaNs.

**method**  
A string that specifies one of the following detrend methods:

- 'constant' — Subtracts the mean.
- 'linear' — Subtracts the best-fit line.

**index**  
An integer array that specifies the columns or rows to detrend when `ts.IsTimeFirst` is true.

**Output Arguments**

**ts1**  
The `timeseries` object resulting from detrending the input `timeseries` object.

**See Also** `timeseries`

**Purpose**

Shape frequency content of time-series

**Syntax**

```
ts1 = filter(ts, numerator, denominator)
ts1=filter(ts, numerator, denominator, index)
```

**Description**

`ts1 = filter(ts, numerator, denominator)` applies the transfer function filter  $b(z^{-1})/a(z^{-1})$  to the data in the timeseries object `ts`. `b` and `a` are the coefficient arrays of the transfer function numerator and denominator, respectively.

`ts1=filter(ts, numerator, denominator, index)` uses the optional `index` integer array to specify either the columns or rows to filter, depending on the value of `ts.IsTimeFirst`.

**Tips**

- The time-series data must be uniformly sampled to use this filter.
- The following function

```
y = filter(b,a,x)
```

creates filtered data `y` by processing the data in vector `x` with the filter described by vectors `a` and `b`.

- The `filter` function is a general tapped delay-line filter, described by the difference equation:

$$a(1)y(n) = b(1)x(n) + b(2)x(n-1) + \dots + b(nb)x(n-nb+1) - a(2)y(n-1) - \dots - a(N_a)y(n-N_b+1).$$

Here,  $n$  is the index of the current sample,  $N_a$  is the order of the polynomial described by vector `a`, and  $N_b$  is the order of the polynomial described by vector `b`. The output  $y(n)$  is a linear combination of current and previous inputs,  $x(n) x(n-1)\dots$ , and previous outputs,  $y(n-1) y(n-2)\dots$ .

- You use the discrete filter to shape the data by applying a transfer function to the input signal.

# timeseries.filter

---

Depending on your objectives, the transfer function you choose might alter both the amplitude and the phase of the variations in the data at different frequencies to produce either a smoother or a rougher output.

- In digital signal processing (DSP), it is customary to write transfer functions as rational expressions in  $z^{-1}$  and to order the numerator and denominator terms in ascending powers of  $z^{-1}$ .

Taking the z-transform of the difference equation

$$a(1)y(n) = b(1)x(n) + b(2)x(n-1) + \dots + b(nb)x(n-nb+1) - a(2)y(n-1) - \dots - a(na)y(na+1),$$

results in the transfer function

$$Y(z) = H(z^{-1})X(z) = \frac{b(1) + b(2)z^{-1} + \dots + b(nb)z^{-nb+1}}{a(1) + a(2)z^{-1} + \dots + a(na)z^{-na+1}} X(z),$$

where  $Y(z)$  is the z-transform of the filtered output  $y(n)$ . The coefficients  $b$  and  $a$  are unchanged by the z-transform.

## Input Arguments

### **ts**

The first `timeseries` object for which you want to shape the frequency content.

### **numerator**

The coefficient array of the transfer function numerator.

### **denominator**

The coefficient array of the transfer function denominator.

### **index**

An integer array that specifies the columns or rows to filter when `ts.IsTimeFirst` is true.

**Output Arguments****ts1**

The timeseries object that results from filtering the input timeseries object.

**Examples**

This example applies the following transfer function to the data in count.dat:

$$H(z^{-1}) = \frac{b(z^{-1})}{a(z^{-1})} = \frac{2 + 3z^{-1}}{1 + 0.2z^{-1}}$$

```
% Load the matrix count into the workspace:
```

```
load count.dat;
```

```
% Create a time-series object based on this matrix:
```

```
count1=timeseries(count(:,1),[1:24]);
```

```
% Enter the coefficients of the denominator ordered in
% ascending powers of z-1 to
% represent 1 + 0.2x-1:
```

```
a = [1 0.2];
```

```
% Enter the coefficients of the numerator to represent 2 - 3z-1:
```

```
b = [2 3];
```

```
% Call the filter method:
```

```
filter_count = filter(count1, b, a)
```

```
% Compare the original data and the shaped data with an
% overlaid plot of the two curves:
```

```
plot(count1,'-.'), grid on, hold on
```

# timeseries.filter

---

```
plot(filter_count, '- -')  
legend('Original Data', 'Shaped Data', 2)
```

# timeseries.getabstime

---

**Purpose** Extract date-string time vector into cell array

**Syntax** `getabstime(ts)`

**Description** `getabstime(ts)` extracts the time vector from the `timeseries` object `ts` as a cell array of date strings.

**Tips**

- To define the time vector relative to a calendar date, set the `TimeInfo.StartDate` property of the `timeseries` object. When the `TimeInfo.StartDate` format is a valid `datestr` format, the output strings from `getabstime` have the same format.

**Input Arguments**

**ts**

The `timeseries` object from which you want to extract the time vector.

**Examples**

The following example extracts a time vector as a cell array of date strings from a `timeseries` object.

First, create a `timeseries` object.

```
ts = timeseries([3 6 8 0 10]);
```

The default time vector for `ts` is `[0 1 2 3 4]`, which starts at 0 and increases in 1-second increments. The length of the time vector is equal to the length of the data.

Next, set the `StartDate` property.

```
ts.TimeInfo.StartDate = '10/27/2005 07:05:36';
```

Extract the time vector.

```
getabstime(ts)
```

MATLAB returns:

```
'27-Oct-2005 07:05:36'
```

```
'27-Oct-2005 07:05:37'  
'27-Oct-2005 07:05:38'  
'27-Oct-2005 07:05:39'  
'27-Oct-2005 07:05:40'
```

Change the date-string format of the time vector, and then extract the time vector with the new date-string format:

```
ts.TimeInfo.Format = 'mm/dd/yy';  
getabstime(ts)
```

MATLAB returns:

```
'10/27/05'  
'10/27/05'  
'10/27/05'  
'10/27/05'  
'10/27/05'
```

# timeseries.getdatasamples

---

**Purpose** Returns subset of time series samples using subscripted index array

**Syntax** `datasamples = getdatasamples(ts, i)`

**Description** `datasamples = getdatasamples(ts, i)` returns an array corresponding to the samples indicated by the array, `i`.

**Input Arguments**

**ts**  
The timeseries object from which you want to exact samples.

**i**  
An array of linear indices or logical values that specifies the time value or values for which you want to extract the corresponding samples.

**Output Arguments**

**datasamples**  
The array that results from extracting the samples corresponding to the time value or values, `ts.time(i)`.

**Examples**

After creating a timeseries object, `ts`, extract the second and third data samples into an array:

```
ts = timeseries(rand(5,1),[1 2 3 4 5]);  
samples = getdatasamples(ts, [2 3])
```

# timeseries.getinterpmethod

---

**Purpose** Interpolation method for `timeseries` object

**Syntax** `getinterpmethod(ts)`

**Description** `getinterpmethod(ts)` returns the interpolation method that the `timeseries` object `ts`, uses as a string.

**Input Arguments** **ts**  
The `timeseries` object from which you want to extract the interpolation method.

**Definitions** **interpolation method**  
Predefined interpolation methods are zero-order hold, `zoh`, and linear interpolation, `linear`. Linear interpolation is the default.

**Examples** Create a `timeseries` object, and then get its interpolation method:

```
ts = timeseries(rand(5));  
getinterpmethod(ts)
```

MATLAB returns:

```
linear
```

# timeseries.getsampleusingtime

---

**Purpose** Extract data samples into new timeseries object

**Syntax**  
`ts1 = getsampleusingtime(ts, time)`  
`ts1 = getsampleusingtime(ts, starttime, endtime)`

**Description**  
`ts1 = getsampleusingtime(ts, time)` returns a new timeseries object, `ts1`, with a single sample corresponding to specified `time` in `ts`.  
`ts1 = getsampleusingtime(ts, starttime, endtime)` returns a new timeseries object, `ts1`, with samples between the times `starttime` and `endtime` in `ts`.

**Tips**

- If the time vector in `ts` is not relative to a calendar date, then `starttime` and `endtime` must be numeric.
- If the time vector in `ts` is relative to a calendar date, then `starttime` and `endtime` values must be dates—either strings or `datetime` values.

## Input Arguments

**ts**  
The timeseries object from which you want to extract data samples.

**time**  
The time corresponding to data sample you want to extract.

**starttime**  
The time corresponding to the first data sample you want to extract.

**endtime**  
The time corresponding to the last data sample you want to extract.

## Output Arguments

**ts1**  
A timeseries object that contains the subset of data samples from the original timeseries object.

**See Also** [timeseries](#)

# timeseries.idealfilter

---

**Purpose** Apply ideal (noncausal) filter to timeseries object

**Syntax**  
`ts1 = idealfilter(ts, interval, filtertype)`  
`ts1 = idealfilter(ts, interval, filtertype, index)`

**Description** `ts1 = idealfilter(ts, interval, filtertype)` applies an ideal filter of `filtertype` to one or more frequency intervals that `interval` specifies for the timeseries object, `ts`.

`ts1 = idealfilter(ts, interval, filtertype, index)` applies an ideal filter and uses the optional `index` integer array to specify the columns or rows to filter.

- Tips**
- Ideal filters require data to have a mean of zero and prepare the data by subtracting its mean. You can restore the filtered signal amplitude by adding the mean of the input data to the filter output values.
  - Use the ideal *notch* filter when you want to remove variations in a specific frequency range. Alternatively, use the ideal *pass* filter to allow only the variations in a specific frequency range.
  - If the time-series data is sampled nonuniformly, filtering resamples this data on a uniform time vector.
  - All NaNs in the time series are interpolated before filtering, using the interpolation method you assigned to the timeseries object.

## Input Arguments

**ts**  
The timeseries object to which you want to apply an ideal filter.

**interval**  
The frequency interval (specified in cycles per time unit) at which you want the ideal filter applied. To specify several frequency intervals, use an n-by-2 array of start and end frequencies, where n represents the number of intervals.

**filtertype**

A string specifying the type of filter you want to apply, either pass or notch.

## **index**

An integer array that specifies the columns or rows to filter when `ts.IsTimeFirst` is true.

## **Output Arguments**

### **ts1**

The `timeseries` object that results when you apply an ideal filter to the original `timeseries` object.

## **Definitions**

### **ideal filter**

Filters are *ideal* in the sense that they are *not realizable*. An ideal filter is noncausal and the ends of the filter amplitude are perfectly flat in the frequency domain.

## **Examples**

These examples first apply an ideal notch filter to the data in `count.dat`. Then, they apply a pass filter to the data:

```
% Load the count matrix into the workspace:
```

```
load count.dat;
```

```
% Create a timeseries object from column one of this matrix.
```

```
% Specify a time vector that ranges from 1 to 24 s in 1-s intervals.
```

```
count1=timeseries(count(:,1),1:24);
```

```
% Obtain the mean of the data:
```

```
countmean = mean(count1);
```

```
% Enter the frequency interval, in hertz, for filtering the data:
```

```
interval=[0.08 0.2];
```

## timeseries.idealfilter

---

```
% Invoke an ideal notch filter:
idealfilter_countn = idealfilter(count1,interval,'notch')

% Compare the original data and the shaped data on a line plot:

plot(count1,'-.'), grid on, hold on
plot(idealfilter_countn,'-')

% Restore the mean to the filtered data and show it on the line plot,
% adding a legend and a title:

countn_restored = idealfilter_countn + countmean;
plot(countn_restored,':m');
title('Notch Filter')
legend('Original Data','Shaped Data','Mean Restored',...
      'Location','NorthWest')
```

```

% Close the Figure window:
close
% Then, repeat the process using a pass rather than a notch filter:
figure
plot(count1,'-.'), grid on, hold on
idealfilter_countp = idealfilter(count1, interval, 'pass');
plot(idealfilter_countp, '-')
countp_restored = idealfilter_countp + countmean;
plot(countp_restored, ':m');
title('Pass Filter')
legend('Original Data', 'Shaped Data', 'Mean Restored', ...

```

# timeseries.idealfilter

'Location', 'NorthWest')

# timeseries.iqr

---

- When `ts.Data` is a vector, `ts_iqr` is the difference between the 75th and the 25th percentiles of the `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_iqr` is a row vector containing the interquartile range of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `iqr` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

Create a time series with a missing value, represented by `NaN`, and then calculate the interquartile range of `ts.Data` after removing the missing value from the calculation:

```
ts = timeseries([3.0 NaN 5 6.1 8], 1:5);  
iqr(ts, 'MissingData', 'remove')
```

MATLAB returns:

```
3.0500
```

## See Also

`max` | `mean` | `median` | `min` | `std` | `sum` | `timeseries` | `var`

## Purpose

Maximum value of timeseries data

## Syntax

```
ts_max = max(ts)
ts_max = max(ts,Name,Value)
```

## Description

`ts_max = max(ts)` returns the maximum value in the timeseries data.

`ts_max = max(ts,Name,Value)` returns the maximum value in the timeseries data with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **ts**

The timeseries object for which you want to determine the maximum data value.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **MissingData**

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** `remove`

### **Quality**

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

# timeseries.max

---

## Output Arguments

### **ts\_max**

The maximum data value in the specified timeseries object, as follows:

- When `ts.Data` is a vector, `ts_max` is the maximum value of `ts.Data` values.
- When `ts.Data` is a matrix, `IsTimeFirst` is true, and the first dimension of `ts` is aligned with time, then `ts_max` is a row vector containing the maximum value of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `max` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example illustrates how to find the maximum values in multivariate time-series data:

```
% Load a 24-by-3 data array:
load count.dat

% Create a timeseries object with 24 time values:
count_ts = timeseries(count,[1:24],'Name','CountPerSecond')

% Find the maximum in each data column for this timeseries object:

max(count_ts)
```

MATLAB returns:

```
114    145    257
```

## See Also

`iqr` | `mean` | `median` | `min` | `std` | `sum` | `timeseries` | `var`

**Purpose** Mean value of `timeseries` data

**Syntax**  
`ts_mn = mean(ts)`  
`ts_mn = mean(ts,Name,Value)`

**Description**  
`ts_mn = mean(ts)` returns the mean value of `ts.Data`.  
`ts_mn = mean(ts,Name,Value)` returns the mean value of `ts.Data` with additional options specified by one or more `Name,Value` pair arguments.

**Input Arguments**  
**ts**  
The `timeseries` object for which you want the mean value of data.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **MissingData**

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** `remove`

### **Quality**

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

### **Weighting**

# timeseries.mean

---

A string specifying one of two possible values, `none` or `time`.  
When you specify `time`, larger time values correspond to larger weights.

## Output Arguments

**ts\_mn**

The mean value of `ts.Data`, as follows:

- When `ts.Data` is a vector, `ts_mn` is the mean value of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is true and the first dimension of `ts` is aligned with time, then `ts_mn` is a row vector containing the mean value of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `mean` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

Find the mean values in multivariate time-series data:

```
% Load a 24-by-3 data array:
```

```
load count.dat
```

```
% Create a timeseries object with 24 time values:
```

```
count_ts = timeseries(count,[1:24],'Name','CountPerSecond')
```

```
% Find the mean of each data column for this timeseries object:
```

```
mean(count_ts)
```

MATLAB returns:

```
32.0000    46.5417    65.5833
```

## Algorithms

MATLAB determines weighting by:

- 1 Attaching a weighting to each time value, depending on its order, as follows:
  - First time point — The duration of the first time interval ( $t(2) - t(1)$ ).
  - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval ( $(t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2$ ).
  - Last time point — The duration of the last time interval ( $(t(\text{end}) - t(\text{end} - 1))$ ).
- 2 Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

---

**Note** If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

---

- 3 Multiplying the data for each time by its normalized weighting.

# timeseries.median

---

**Purpose** Median value of timeseries data

**Syntax**  
`ts_med = median(ts)`  
`ts_med = method(ts,Name,Value)`

**Description** `ts_med = median(ts)` returns the median value of `ts.Data`.  
`ts_med = method(ts,Name,Value)` returns the median value of `ts.Data` with additional options specified by one or more `Name,Value` pair arguments.

**Input Arguments** **ts**  
The timeseries object for which you want the median data value.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## **MissingData**

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** `remove`

## **Quality**

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

## **Weighting**

A string specifying one of two possible values, `none` or `time`.  
When you specify `time`, larger time values correspond to larger weights.

## Output Arguments

### `ts_med`

The median value of `ts.Data`, as follows:

- When `ts.Data` is a vector, `ts_med` is the mean value of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_med` is a row vector containing the median value of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `median` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example finds the median values in multivariate time-series data. MATLAB finds the median independently for each data column in the `timeseries` object:

```
% Load a 24-by-3 data array:

load count.dat

% Create a timeseries object with 24 time values:

count_ts = timeseries(count,[1:24],'Name','CountPerSecond');

% Find the median of each data column for this timeseries object:

median(count_ts)

MATLAB returns:

23.5000    36.0000    39.0000
```

## Algorithms

MATLAB determines weighting by:

- 1 Attaching a weighting to each time value, depending on its order, as follows:
  - First time point — The duration of the first time interval ( $t(2) - t(1)$ ).
  - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval ( $(t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2$ ).
  - Last time point — The duration of the last time interval ( $(t(\text{end}) - t(\text{end} - 1))$ ).
- 2 Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

---

**Note** If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

---

# timeseries.min

---

## Output Arguments

### `ts_min`

The minimum value of `ts.Data`, as follows:

- When `ts.Data` is a vector, `ts_min` is the minimum value of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_min` is a row vector containing the minimum value of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `min` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example finds the minimum values in multivariate time-series data. MATLAB finds the minimum independently for each data column in the `timeseries` object.

```
% Load a 24-by-3 data array:
```

```
load count.dat
```

```
% Create a timeseries object with 24 time values:
```

```
count_ts = timeseries(count,[1:24],'Name','CountPerSecond');
```

```
% Find the minimum in each data column for this timeseries object:
```

```
min(count_ts)
```

```
MATLAB returns:
```

```
7     9     7
```

## See Also

`iqr` | `max` | `mean` | `median` | `std` | `sum` | `timeseries` | `var`

**Purpose**

Plot time series

**Syntax**

```
plot(ts)
plot(tsc.tsname)
plot(ts,linespec)
plot(tsc.tsname,linespec)
plot(ts,Name, Value)
plot(tsc.tsname,Name, Value)
```

**Description**

`plot(ts)` plots the timeseries data `ts` against time and interpolates values between samples by using either zero-order-hold ('zoh') or linear interpolation (the default). The plot displays in the current axes. MATLAB creates a title and axes, if none exists.

`plot(tsc.tsname)` plots the timeseries object, `tsname` that is part of the `tscollection`, `tsc`.

`plot(ts,linespec)` plots the timeseries data using a line graph and applies the specified `linespec` to lines, markers, or both.

`plot(tsc.tsname,linespec)` plots the timeseries object that is part of a timeseries collection as a line graph and applies the specified `linespec` to lines, markers, or both.

`plot(ts,Name, Value)` plots a line graph of the time series data using the values specified for `lineseries` properties.

`plot(tsc.tsname,Name, Value)` plots a line graph of the timeseries object that is part of the specified timeseries collection using the values specified for `lineseries` properties.

**Tips**

- The `timeseries/plot` method generates titles and axis labels automatically. These labels are:
  - Plot Title — 'Time Series Plot: <name>'  
where <name> is the string assigned to `ts.Name`, or by default, 'unnamed'
  - X-Axis Label — 'Time (<units>)'

# timeseries.plot

---

where `<units>` is the value of the `ts.TimeInfo.Units` field, which defaults to `'seconds'`

▪ Y-Axis Label — `'<name>'`

where `<name>` is the string assigned to `ts.Name`, or by default, `'unnamed'`

- You can place new time series data on a time series plot (by setting `hold on`, for example, and issuing another `timeseries/plot` command). When you add data to a plot, the title and axis labels become blank strings to avoid labeling confusion. You can add your own labels after plotting using the `title`, `xlabel`, and `ylabel` commands.
- Time series events, when defined, are marked in the plot with a circular marker with red fill. You can also specify markers for all data points using a `linespec` or `name/value` syntax in addition to any event markers your data defines. The event markers plot on top of the markers you define.
- The value assigned to `ts.DataInfo.Interpolation.Name` controls the type of interpolation the plot method uses when plotting and resampling time series data. Invoke the `timeseries` method `setinterpmethod` to change default linear interpolation to zero-order hold interpolation (staircase). This method creates a new `timeseries` object, with which you can overwrite the original one if you want. For example, to cause time series `ts` to use zero-order hold interpolation, type the following:

```
ts = ts.setinterpmethod('zoh');
```

## Input Arguments

**ts**  
A `timeseries` object.

**tsc**  
A `tscollection`.

**tsname**

The name of a timeseries object within the tscollection .

## Examples

### Plot Time Series Object with Specified Start Date

Create a time series object, set the start date, and then plot the time vector relative to the start date.

```
x = [2 5 8 2 11 3 6];  
ts1 = timeseries(x,1:7);  
ts1.Name = 'Daily Count';  
ts1.TimeInfo.Units = 'days';  
ts1.TimeInfo.StartDate='01-Jan-2011' % Set start date.  
ts1.TimeInfo.Format = 'mmm dd, yy' % Set format for display on x-axis.  
ts1.Time=ts1.Time-ts1.Time(1); % Express time relative to the start date.  
plot(ts1)
```

## Plot Two Time Series Objects on the Same Axes

Create two time series objects from traffic count data, and then plot them in sequence on the same axes. Add an event to one series, which is automatically displayed with a red marker.

```
load count.dat;  
count1=timeseries(count(:,1),1:24);  
count1.Name = 'Oak St. Traffic Count';  
count1.TimeInfo.Units = 'hours';  
plot(count1,':b'), grid on
```

```
% Obtain time of maximum value and add it as an event:  
[~,index] = max(count1.Data);  
max_event = tsdata.event('peak',count1.Time(index));  
max_event.Units = 'hours';  
% Add the event to the time series:  
count1 = addevent(count1,max_event);
```

```
% Replace plot with new one showing the event:
plot(count1,'.-b'), grid on
```

```
% Make a new ts object from column 2 of the same data source:
count2=timeseries(count(:,2),1:24);
count2.Name = 'Maple St. Traffic Count';
count2.TimeInfo.Units = 'Hours';
% Turn hold on to add the new data to the plot:
hold on
% The plot method does not add labels to a held plot.
% Use property/value pair to customize markers:
plot(count2,'s-m','MarkerSize',6),
```

# timeseries.plot

```
% Labels are erased, so generate them manually:  
title('Time Series: Oak Street and Maple Street')  
xlabel('Hour of day')  
ylabel('Vehicle count')  
% Add a legend in the upper left:  
legend('Oak St.', 'Maple St.', 'Location', 'northwest')
```

**See Also**

`timeseries` | `setinterpmethod` | `tscollection` | `tsdata.event`  
| `plot`

# timeseries.resample

---

**Purpose** Select or interpolate timeseries data using new time vector

**Syntax**

```
ts1 = resample(ts, time)
ts1 = resample(ts, time, interp_method)
ts1 = resample(ts, time, interp_method, code)
```

**Description**

`ts1 = resample(ts, time)` resamples the timeseries object, `ts`, using the new `time` vector. The `resample` method uses the default interpolation method, which you can view by using the `getinterpmethod(ts)` syntax.

`ts1 = resample(ts, time, interp_method)` resamples the timeseries object `ts` using the specified interpolation method, `interp_method`.

`ts1 = resample(ts, time, interp_method, code)` resamples the timeseries object `ts` using the interpolation method given by the string `interp_method`. MATLAB applies the `code` to all samples.

## Input Arguments

**ts**  
The timeseries object that you want to resample.

**time**  
The time vector you want to use to resample the timeseries object.  
When `ts` uses date strings and `time` is numeric, then `time` is treated as specified relative to the `ts.TimeInfo.StartDate` property and in the same units that `ts` uses.

**interp\_method**  
A string specifying the interpolation method. Valid interpolation methods are `linear` and `zero-order hold, zoh`.

**Default:** `linear`

**code**

An integer value that specifies the user-defined Quality code for resampling. MATLAB applies this Quality code to all samples.

## Output Arguments

**ts1**

The `timeseries` object that results when you interpolate the original `timeseries` object with a new time vector.

## Examples

This example shows how to resample a `timeseries` object.

Create a `timeseries` object.

```
ts1 = timeseries([1.1; 2.9; 3.7; 4.0; 3.0],1:5,'Name','speed');
```

View the time, data, and interpolation method.

```
ts1.time  
ts1.data  
ts1.getinterpmethod
```

Resample `ts1` using its default interpolation method.

```
res_ts=resample(ts1,[1 1.5 3.5 4.5 4.9]);
```

View the time, data, and interpolation method for the resampled object.

```
res_ts.time  
res_ts.data  
res_ts.getinterpmethod
```

## See Also

`timeseries` | `getinterpmethod` | `setinterpmethod` | `synchronize`

# timeseries.set

---

**Purpose** Set properties of `timeseries` object

**Syntax** `set(ts, PropertyName, Value)`  
`set(ts, PropertyName)`  
`set(ts)`

**Description** `set(ts, PropertyName, Value)` sets the named property, `Name`, of the `timeseries` object, `ts`, to the value, `Value`. The following syntax is equivalent:

```
ts.Property = Value
```

`set(ts, PropertyName)` displays the value of the named property for the `timeseries` object, `ts`.

`set(ts)` displays all properties and values of the `timeseries` object `ts`.

## Input Arguments

**ts**  
A `timeseries` object.

### PropertyName

A string specifying the name of a `timeseries` property. For a list of `timeseries` properties, see `timeseries`.

### Value

The value to which you want to set the named property.

## Examples

Create a `timeseries`, set its name to `mytimeseries`, and then view the `timeseries` properties:

```
ts1 = timeseries(rand(5,1),[1 2 3 4 5]);  
set(ts1, 'Name', 'mytimeseries')  
set(ts1)
```

# timeseries.setinterpmethod

---

**Purpose** Set default interpolation method for timeseries object

**Syntax**

```
ts = setinterpmethod(ts, method)
ts = setinterpmethod(ts, fhandle)
ts = setinterpmethod(ts, interpobj)
```

**Description**

`ts = setinterpmethod(ts, method)` sets the default interpolation method, `method`, for timeseries object, `ts`, and outputs it to `ts1`.

`ts = setinterpmethod(ts, fhandle)` sets the default interpolation method for timeseries object `ts`, where `fhandle` is a function handle to the interpolation method.

`ts = setinterpmethod(ts, interpobj)` sets the default interpolation method for timeseries object `ts`, where `interpobj` is a `tsdata.interpolation` object that directly replaces the interpolation object stored in `ts`.

**Tips**

- This method is case sensitive.

## Input Arguments

**ts**

The timeseries object for which you want to set the default interpolation method.

**method**

A string specifying the interpolation method. Valid values are `linear` and `zero-order hold, zoh`.

**Default:** `linear`

**fhandle**

A function handle to the interpolation method. The order of input arguments defining the function handle must be `new_time`, `time`, and `data`. The single output argument must be the interpolated data only.

**interpobj**

A `tsdata.interpolation` object a `tsdata.interpolation` object that directly replaces the interpolation object stored in `ts`.

## Output Arguments

**ts1**

The `timeseries` object that results when you set the interpolation method for the original `timeseries` object.

## Examples

Set the default interpolation method for `timeseries` object `ts` to zero order hold:

```
ts = timeseries(rand(100,1),1:100);  
ts = setinterpmethod(ts,'zoh');  
plot(ts);
```

Set the default interpolation method for `timeseries` object `ts`, where `fhandle` is a function handle to the interpolation method defined by function handle `myFuncHandle`:

```
ts = timeseries(rand(100,1),1:100);  
myFuncHandle = @(new_time, time, data)...  
               interp1(time, data, new_time,...  
                       'linear','extrap');  
ts = setinterpmethod(ts, myFuncHandle);  
ts = resample(ts, [-5:0.1:10]);  
plot(ts);
```

Set the default interpolation method for `timeseries` object `ts` to a `tsdata.interpolation` object:

```
ts = timeseries(rand(100,1),1:100);  
myFuncHandle = @(new_time, time, data)...  
               interp1(time, data, new_time,...  
                       'linear','extrap');  
myInterpObj = tsdata.interpolation(myFuncHandle);  
ts = setinterpmethod(ts,myInterpObj);  
plot(ts);
```

# timeseries.setinterpmethod

---

## See Also

`timeseries | getinterpmethod`

## Purpose

Modify uniform time vector of timeseries object

## Syntax

```
ts2 = setuniformtime(ts1,'StartTime',StartTime)
ts2 = setuniformtime(ts1,'Interval',Interval)
ts2 = setuniformtime(ts1,'EndTime',EndTime)
ts2 = setuniformtime(ts1,'StartTime',StartTime,'Interval',
    Interval)
ts2 = setuniformtime(ts1,'StartTime',StartTime,'EndTime',
    EndTime)
ts2 = setuniformtime(ts1,'Interval',Interval,'EndTime',
    EndTime)
```

## Description

`ts2 = setuniformtime(ts1,'StartTime',StartTime)` returns the time series with a modified uniform time vector, determined from the `StartTime` and `Interval`. `EndTime = StartTime + (length(ts1) - 1)`. The unit of time is unchanged.

`ts2 = setuniformtime(ts1,'Interval',Interval)` sets the `StartTime` to 0, and uses `EndTime = (length(ts1) - 1)*Interval`.

`ts2 = setuniformtime(ts1,'EndTime',EndTime)` sets the `StartTime` to 0, and uses `Interval = EndTime/(length(ts1) - 1)`.

`ts2 = setuniformtime(ts1,'StartTime',StartTime,'Interval',Interval)` uses `EndTime = StartTime + (length(ts1) - 1) * Interval`.

`ts2 = setuniformtime(ts1,'StartTime',StartTime,'EndTime',EndTime)` uses `Interval = (EndTime - StartTime)/(length(ts1) - 1)`.

`ts2 = setuniformtime(ts1,'Interval',Interval,'EndTime',EndTime)` uses `StartTime = EndTime - (length(ts1) - 1) * Interval`.

## Input Arguments

### ts1

timeseries object to which you want to assign a uniform time vector.

# timeseries.setuniformtime

---

## StartTime

Start time of uniform time vector, specified as a numeric value.

## Interval

Time interval of uniform time vector, specified as a numeric scalar value.

## EndTime

End time of uniform time vector specified as a numeric scalar value.

## Output Arguments

### ts2

Time series with uniform time vector, returned as a `timeseries` object.

## Examples

### Specify New Start Time

Modify the uniform time vector of time series data by specifying a new start time.

- 1 Load the sample data.

```
load count.dat;
```

- 2 Create a `timeseries` object.

```
count_ts = timeseries(count,1:length(count),'Name','CountPerSecond');
```

- 3 Modify uniform time vector of `count_ts`.

```
count_ts = setuniformtime(count_ts,'StartTime',10);
```

The start time of the time vector is 10 seconds. `setuniformtime` uses a default time interval of 1 and computes the end time using:  $EndTime = StartTime + (length(count\_ts) - 1) * Interval$ .

## Specify New Start and End Times

Modify the uniform time vector of time series data by specifying a new start time and end time.

- 1 Load sample data.

```
load count.dat;
```

- 2 Create timeseries object.

```
count_ts = timeseries(count,1:length(count),'Name','CountPerSecond'
```

- 3 Assign a uniform time vector to count\_ts.

```
count_ts2 = setuniformtime(count_ts,'StartTime',10,'EndTime',20);
```

The start time of the time vector is now 10 seconds, and the end time is now 20 seconds. MATLAB computes the time interval using:  
 $Interval = (EndTime - StartTime) / (length(count\_ts) - 1)$

`timeseries`

# timeseries.synchronize

---

**Purpose** Synchronize and resample two `timeseries` objects using common time vector

**Syntax** `[ts1 ts2] = synchronize(ts1,ts2, synchronizemethod)`  
`[ts1 ts2] = synchronize(ts1,ts2, Name,Value)`

**Description** `[ts1 ts2] = synchronize(ts1,ts2, synchronizemethod)` creates two new `timeseries` objects by synchronizing `ts1` and `ts2` using a common time vector and the specified method.

`[ts1 ts2] = synchronize(ts1,ts2, Name,Value)` creates the two new `timeseries` objects with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

**ts1** One of the `timeseries` objects that you want to synchronize and resample.

**ts2** The other `timeseries` object that you want to synchronize and resample.

### **synchronizemethod**

A string that defines the method for synchronizing the `timeseries` object. It can be any one of the following:

- **Union** — Resample `timeseries` objects using a time vector that is a union of the time vectors of `ts1` and `ts2` on the time range where the two time vectors overlap.
- **Intersection** — Resample `timeseries` objects on a time vector that is the intersection of the time vectors of `ts1` and `ts2`.
- **Uniform** — Requires an additional argument as follows:

`[ts1 ts2] = synchronize(ts1,ts2,'Uniform','Interval',value)`

This method resamples time series on a uniform time vector, where `value` specifies the time interval between two consecutive samples. The uniform time vector is the overlap of the time vectors of `ts1` and `ts2`. The interval units are the smaller units of `ts1` and `ts2`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## **InterpMethod**

Forces the specified interpolation method (over the default method) for this synchronize operation. Can be either a string, `linear` or `zoh`, or a `tsdata.interpolation` object that contains a user-defined interpolation method.

**Default:** `linear`

## **QualityCode**

Integer (between -128 and 127) used as the quality code for both time series after the synchronization.

## **KeepOriginalTimes**

Logical value (`true` or `false`) indicating whether the new time series should keep the original time values.

## **tolerance**

Real number used as the tolerance for differentiating two time values when comparing the `ts1` and `ts2` time vectors. The default tolerance is  $1e-10$ . For example, when the sixth time value in `ts1` is  $5+(1e-12)$  and the sixth time value in `ts2` is  $5-(1e-13)$ , both values are treated as 5 by default. To differentiate those

# timeseries.synchronize

---

two times, you can set 'tolerance' to a smaller value such as 1e-15, for example.

## Output Arguments

**ts1**

One of the `timeseries` objects that you synchronized and resampled.

**ts2**

The other `timeseries` object that you synchronized and resampled.

## Examples

This example illustrates how the `KeepOriginalTime` property affects synchronization.

```
% Create two timeseries, such that ts1.timeinfo.StartDate  
% is one day after ts2.timeinfo.StartDate:
```

```
ts1 = timeseries([1 2],[datestr(now); datestr(now+1)]);  
ts2 = timeseries([1 2],[datestr(now-1); datestr(now)]);
```

```
% If you use this code, then ts1.timeinfo.StartDate  
% is changed to match ts2.TimeInfo.StartDate  
% and ts1.Time changes to 1:
```

```
[ts1 ts2] = synchronize(ts1,ts2,'union');
```

```
% But if you use this code, then ts1.timeinfo.StartDate  
% is unchanged and ts1.Time is still 0:
```

```
[ts1 ts2] = synchronize(ts1,ts2,'union','KeepOriginalTimes',true);
```

`set` | `timeseries`

**Purpose** Transpose timeseries object

**Syntax** `ts1 = transpose(ts)`

**Description** `ts1 = transpose(ts)` returns a new `timeseries` object, `ts1`, with `IsTimeFirst` value set to the opposite of what it is for `ts`. For example, if `ts` has the first data dimension aligned with the time vector, `ts1` has the last data dimension aligned with the time vector.

- Tips**
- The `transpose` function that is overloaded for `timeseries` objects does not transpose the data. Instead, this function changes whether the first or the last dimension of the data aligns with the time vector. To transpose the data, transpose the `Data` property of the time series. For example, you can use the syntax `transpose(ts.Data)` or `(ts.Data) . '`. The value of the `Data` property must be a 2-D array.
  - Consider a time series with 10 samples with the property `IsTimeFirst = True`. When you transpose this time series, the data size changes from 10-by-1 to 1-by-1-by-10. Note that the first dimension of the `Data` property is shown explicitly.

The following table summarizes how the size for timeseries data (up to three dimensions) display before and after transposing.

### Data Size Before and After Transposing

| Size of Original Data | Size of Transposed Data |
|-----------------------|-------------------------|
| N-by-1                | 1-by-1-by-N             |
| N-by-M                | M-by-1-by-N             |
| N-by-M-by-L           | M-by-L-by-N             |

### Input Arguments

**ts**  
The `timeseries` object that you want to transpose.

# timeseries.transpose

---

## Output Arguments

**ts1**

The `timeseries` object that is the result of transposing the original `timeseries` object.

## Examples

Suppose that a `timeseries` object, `ts`, has `ts.Data` size 10-by-3-by-2 and its time vector has a length of 10. The `IsTimeFirst` property of `ts` is `true`, which means that the first dimension of the data aligns with the time vector. `transpose(ts)` modifies the `timeseries` object, such that the last dimension of the data now aligns with the time vector. This permutes the data, such that the size of `ts.Data` becomes 3-by-2-by-10.

# timeseries.std

---

A string specifying one of two possible values, `none` or `time`.  
When you specify `time`, larger time values correspond to larger weights.

## Output Arguments

### `ts_std`

The standard deviation of `ts.Data` values as follows:

- When `ts.Data` is a vector, `ts_std` is the standard deviation of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_std` is the standard deviation of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `std` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example finds the standard deviation for a `timeseries` object. MATLAB calculates the standard deviation for each data column in the `timeseries` object.

```
% Load a 24-by-3 data array:
```

```
load count.dat
```

```
% Create a timeseries object with 24 time values:
```

```
count_ts = timeseries(count,1:24,'Name','CountPerSecond');
```

```
% Calculate the standard deviation of each data column for this  
% timeseries object:
```

```
std(count_ts)
```

```
MATLAB returns:
```

```
25.3703    41.4057    68.0281
```

## Algorithms

MATLAB determines weighting by:

- 1 Attaching a weighting to each time value, depending on its order, as follows:
  - First time point — The duration of the first time interval ( $t(2) - t(1)$ ).
  - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval ( $(t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2$ ).
  - Last time point — The duration of the last time interval ( $(t(\text{end}) - t(\text{end} - 1))$ ).
- 2 Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

---

**Note** If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

---

- 3 Multiplying the data for each time by its normalized weighting.

# timeseries.sum

---

**Purpose** Sum of timeseries data

**Syntax**  
`ts_sm = sum(ts)`  
`ts_sm = sum(ts,Name,Value)`

**Description** `ts_sm = sum(ts)` returns the sum of the timeseries data.  
`ts_sm = sum(ts,Name,Value)` specifies additional options with one or more `Name,Value` pair arguments.

**Input Arguments** **ts**  
The timeseries object for which you want the sum of the data.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## **MissingData**

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** `remove`

## **Quality**

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

## **Weighting**

A string specifying one of two possible values, `none` or `time`.  
When you specify `time`, larger time values correspond to larger weights.

## Output Arguments

### `ts_sm`

The sum of the `timeseries` data, as follows:

- When `ts.Data` is a vector, `ts_sm` is the sum of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_sm` is a row vector containing the sum of each column of `ts.Data`.

When `ts.Data` is a N-dimensional array, `sum` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

Calculate the sum of each data column for a `timeseries` object:

```
% Load a 24-by-3 data array:
```

```
load count.dat
```

```
% Create a timeseries object with 24 time values:
```

```
count_ts = timeseries(count,1:24,'Name','CountPerSecond');
```

```
% Calculate the sum of each data column for this timeseries object:
```

```
sum(count_ts)
```

```
MATLAB returns:
```

```
768          1117          1574
```

| <b>Purpose</b>         | Variance of timeseries data                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Syntax</b>          | <pre>ts_var = var(ts) ts_var = var(ts,Name,Value)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b>     | <p><code>ts_var = var(ts)</code> returns the variance of <code>ts.data</code>.</p> <p><code>ts_var = var(ts,Name,Value)</code> uses additional options specified by one or more <code>Name,Value</code> pair arguments.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Input Arguments</b> | <p><b>ts</b></p> <p>The timeseries object for which you want the variance of the data.</p> <p><b>Name-Value Pair Arguments</b></p> <p>Specify optional comma-separated pairs of <code>Name,Value</code> arguments, where <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as <code>Name1,Value1,...,NameN,ValueN</code>.</p> <p><b>MissingData</b></p> <p>A string specifying one of two possible values, <code>remove</code> or <code>interpolate</code>, indicating how to treat missing data during the calculation.</p> <p><b>Default:</b> <code>remove</code></p> <p><b>Quality</b></p> <p>A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).</p> <p><b>Weighting</b></p> |

# timeseries.var

---

A string specifying one of two possible values, `none` or `time`.  
When you specify `time`, larger time values correspond to larger weights.

## Output Arguments

### `ts_var`

The variance of `ts.data`, as follows:

- When `ts.Data` is a vector, then `ts_var` is the variance of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_var` is a row vector containing the variance of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `var` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example calculates the variance values of a multivariate `timeseries` object. MATLAB calculates the variance independently for each data column in the `timeseries` object.

Load a 24-by-3 data array. Then create a `timeseries` object with 24 time values.

```
load count.dat  
count_ts = timeseries(count,[1:24], 'Name', 'CountPerSecond');
```

Calculate the variance of each data column.

```
var(count_ts)
```

MATLAB returns:

```
1.0e+03 *  
    0.6437    1.7144    4.6278
```

## Algorithms

MATLAB determines weighting by:

- 1** Attaching a weighting to each time value, depending on its order, as follows:
  - First time point — The duration of the first time interval ( $t(2) - t(1)$ ).
  - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval ( $(t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2$ ).
  - Last time point — The duration of the last time interval ( $(t(\text{end}) - t(\text{end} - 1))$ ).
- 2** Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

---

**Note** If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

---

- 3** Multiplying the data for each time by its normalized weighting.

# real

---

**Purpose** Real part of complex number

**Syntax** `X = real(Z)`

**Description** `X = real(Z)` returns the real part of the elements of the complex array `Z`.

**Examples** `real(2+3*i)` is 2.

**See Also** `abs` | `angle` | `conj` | `i` | `j` | `imag`

**Purpose** Natural logarithm for nonnegative real arrays

**Syntax** `Y = reallog(X)`

**Description** `Y = reallog(X)` returns the natural logarithm of each element in array `X`. Array `X` must contain only nonnegative real numbers. The size of `Y` is the same as the size of `X`.

**Examples** `M = magic(4)`

```
M =  
    16     2     3    13  
     5    11    10     8  
     9     7     6    12  
     4    14    15     1
```

```
reallog(M)
```

```
ans =  
    2.7726    0.6931    1.0986    2.5649  
    1.6094    2.3979    2.3026    2.0794  
    2.1972    1.9459    1.7918    2.4849  
    1.3863    2.6391    2.7081         0
```

**See Also** `log` | `realpow` | `realsqrt`

# realmax

---

**Purpose** Largest positive floating-point number

**Syntax** `n = realmax`

**Description** `n = realmax` returns the largest finite floating-point number in IEEE double precision.

`realmax('double')` is the same as `realmax` with no arguments.

`realmax('single')` returns the largest finite floating-point number in IEEE single precision.

**Examples** Find the value of the constant `realmax`:

```
ndouble = realmax
nsingle = realmax('single')
```

```
ndouble =
    1.7977e+308
```

```
nsingle =
    3.4028e+38
```

**See Also** `eps` | `realmin` | `intmax`

**Tutorials** • “Floating-Point Numbers”

**Purpose**            Smallest positive normalized floating-point number

**Syntax**            `n = realmin`  
                      `realmin('double')`  
                      `realmin('single')`

**Description**        `n = realmin` returns the smallest positive normalized floating-point number in IEEE double precision.  
  
                      `realmin('double')` is the same as `realmin` with no arguments.  
  
                      `realmin('single')` returns the smallest positive normalized floating-point number in IEEE single precision.

**Examples**            Find the value of the constant `realmin`:

```
ndouble = realmin
nsingle = realmin('single')
```

```
ndouble =  
  
      2.2251e-308
```

```
nsingle =  
  
      1.1755e-38
```

# realpow

---

**Purpose**            Array power for real-only output

**Syntax**            `Z = realpow(X,Y)`

**Description**        `Z = realpow(X,Y)` raises each element of array `X` to the power of its corresponding element in array `Y`. Arrays `X` and `Y` must be the same size. The range of `realpow` is the set of all real numbers, i.e., all elements of the output array `Z` must be real.

**Examples**            `X = -2*ones(3,3)`

```
X =  
   -2   -2   -2  
   -2   -2   -2  
   -2   -2   -2
```

```
Y = pascal(3)
```

```
ans =  
     1     1     1  
     1     2     3  
     1     3     6
```

```
realpow(X,Y)
```

```
ans =  
   -2   -2   -2  
   -2    4   -8  
   -2   -8   64
```

**See Also**            `reallog` | `realsqrt` | Arithmetic Operator `.`<sup>^</sup>

**Purpose** Square root for nonnegative real arrays

**Syntax** `Y = realsqrt(X)`

**Description** `Y = realsqrt(X)` returns the square root of each element of array `X`. Array `X` must contain only nonnegative real numbers. The size of `Y` is the same as the size of `X`.

**Examples**

```
M = magic(4)

M =
    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1
```

```
realsqrt(M)
```

```
ans =
    4.0000    1.4142    1.7321    3.6056
    2.2361    3.3166    3.1623    2.8284
    3.0000    2.6458    2.4495    3.4641
    2.0000    3.7417    3.8730    1.0000
```

|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Record data and event information to file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Syntax</b>      | <code>record(obj)</code><br><code>record(obj, 'switch')</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | <code>record(obj)</code> toggles the recording state for the serial port object, <code>obj</code> .<br><code>record(obj, 'switch')</code> initiates or terminates recording for <code>obj</code> . <code>switch</code> can be <code>on</code> or <code>off</code> . If <code>switch</code> is <code>on</code> , recording is initiated. If <code>switch</code> is <code>off</code> , recording is terminated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Tips</b>        | <p>Before you can record information to disk, <code>obj</code> must be connected to the device with the <code>fopen</code> function. A connected serial port object has a <code>Status</code> property value of <code>open</code>. An error is returned if you attempt to record information while <code>obj</code> is not connected to the device. Each serial port object must record information to a separate file. Recording is automatically terminated when <code>obj</code> is disconnected from the device with <code>fclose</code>.</p> <p>The <code>RecordName</code> and <code>RecordMode</code> properties are read-only while <code>obj</code> is recording, and must be configured before using <code>record</code>.</p> <p>For a detailed description of the record file format and the properties associated with recording data and event information to a file, refer to <a href="#">Debugging: Recording Information to Disk</a>.</p> |
| <b>Examples</b>    | <p>This example creates the serial port object <code>s</code> on a Windows platform. It connects <code>s</code> to the device, configures <code>s</code> to record information to a file, writes and reads text data, and then disconnects <code>s</code> from the device.</p> <pre>s = serial('COM1'); fopen(s) s.RecordDetail = 'verbose'; s.RecordName = 'MySerialFile.txt'; record(s, 'on') fprintf(s, '*IDN?') out = fscanf(s); record(s, 'off')</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

`fclose(s)`

# audiorecorder.record

---

**Purpose** Record audio to audiorecorder object

**Syntax** `record(recorderObj)`  
`record(recorderObj, length)`

**Description** `record(recorderObj)` records audio from an input device, such as a microphone connected to your system. `recorderObj` is an audiorecorder object that defines the sample rate, bit depth, and other properties of the recording.

`record(recorderObj, length)` records for the number of seconds specified by `length`.

**Examples** Record 5 seconds of your speech with a microphone:

```
myVoice = audiorecorder;  
  
% Define callbacks to show when  
% recording starts and completes.  
myVoice.StartFcn = 'disp(''Start speaking.'')';  
myVoice.StopFcn = 'disp(''End of recording.'')';  
  
record(myVoice, 5);
```

To listen to the recording, call the `play` method:

```
play(myVoice);
```

**See Also** `audiorecorder` | `getaudiodata` | `recordblocking`

**How To**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Record audio to audiorecorder object, holding control until recording completes                                                                                                                                                                                                                                                                                                                                    |
| <b>Syntax</b>      | <code>recordblocking(recorderObj, length)</code>                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <code>recordblocking(recorderObj, length)</code> records audio from an input device, such as a microphone connected to your system, for the number of seconds specified by <i>length</i> . The <code>recordblocking</code> method does not return control until recording completes. <i>recorderObj</i> is an audiorecorder object that defines the sample rate, bit depth, and other properties of the recording. |
| <b>Examples</b>    | Record 5 seconds of your speech with a microphone, and play it back:<br><br><pre>myVoice = audiorecorder;<br/><br/>disp('Start speaking.');</pre> <code>recordblocking(myVoice, 5);</code> <pre>disp('End of recording. Playing back ...');</pre><br><pre>play(myVoice);</pre>                                                                                                                                     |
| <b>See Also</b>    | <code>audiorecorder</code>   <code>getaudiodata</code>   <code>record</code>                                                                                                                                                                                                                                                                                                                                       |
| <b>How To</b>      | <ul style="list-style-type: none"><li>• “Record Audio”</li></ul>                                                                                                                                                                                                                                                                                                                                                   |

# rectangle

---

**Purpose** Create 2-D rectangle object

**Syntax**

```
rectangle  
rectangle('Position',[x,y,w,h])  
rectangle('Curvature',[x,y])  
rectangle('PropertyName',propertyvalue,...)  
h = rectangle(...)
```

**Properties** For a list of properties, see Rectangle Properties.

**Description** `rectangle` draws a rectangle with Position `[0,0,1,1]` and Curvature `[0,0]` (i.e., no curvature).

`rectangle('Position',[x,y,w,h])` draws the rectangle from the point `x,y` and having a width of `w` and a height of `h`. Specify values in axes data units.

Note that, to display a rectangle in the specified proportions, you need to set the axes data aspect ratio so that one unit is of equal length along both the `x` and `y` axes. You can do this with the command `axis equal` or `daspect([1,1,1])`.

`rectangle('Curvature',[x,y])` specifies the curvature of the rectangle sides, enabling it to vary from a rectangle to an ellipse. The horizontal curvature `x` is the fraction of width of the rectangle that is curved along the top and bottom edges. The vertical curvature `y` is the fraction of the height of the rectangle that is curved along the left and right edges.

The values of `x` and `y` can range from 0 (no curvature) to 1 (maximum curvature). A value of `[0,0]` creates a rectangle with square sides. A value of `[1,1]` creates an ellipse. If you specify only one value for Curvature, then the same length (in axes data units) is curved along both horizontal and vertical sides. The amount of curvature is determined by the shorter dimension.

`rectangle('PropertyName',propertyvalue,...)` draws the rectangle using the values for the property name/property value pairs specified and default values for all other properties. For a description of the properties, see Rectangle Properties.

`h = rectangle(...)` returns the handle of the rectangle object created.

## Tips

Rectangle objects are 2-D and can be drawn in an axes only if the view is `[0 90]` (i.e., `view(2)`). Rectangles are children of axes and are defined in coordinates of the axes data.

## Examples

This example sets the data aspect ratio to `[1,1,1]` so that the rectangle is displayed in the specified proportions (`daspect`). Note that the horizontal and vertical curvature can be different. Also, note the effects of using a single value for `Curvature`.

```
rectangle('Position',[0.59,0.35,3.75,1.37],...
         'Curvature',[0.8,0.4],...
         'LineWidth',2,'LineStyle','--')
daspect([1,1,1])
```

Specifying a single value of `[0.4]` for `Curvature` produces

# rectangle

---

A Curvature of [1] produces a rectangle with the shortest side completely round:

This example creates an ellipse and colors the face red.

```
rectangle('Position',[1,2,5,10],'Curvature',[1,1],...  
         'FaceColor','r')  
daspect([1,1,1])  
xlim([0,7])
```

```
ylim([1,13])
```

## Setting Default Properties

You can set default rectangle properties on the axes, figure, and root object levels:

```
set(0, 'DefaultRectangleProperty', PropertyValue...)  
set(gcf, 'DefaultRectangleProperty', PropertyValue...)  
set(gca, 'DefaultRectangleProperty', PropertyValue...)
```

where *Property* is the name of the rectangle property whose default value you want to set and *PropertyValue* is the value you are specifying. Use `set` and `get` to access the surface properties.

# rectangle

---

## **See Also**

[line](#) | [patch](#) | [annotation](#) | [Rectangle Properties](#)

## Purpose

Define rectangle properties

## Creating Rectangle Objects

Use `rectangle` to create rectangle objects.

## Modifying Properties

You can set and query graphics object properties in two ways:

- “The Property Editor” is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see “Setting Default Property Values”.

See “Core Graphics Objects” for general information about this type of object.

## Rectangle Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

### Annotation

`hg.Annotation` object (read-only)

*Handle of Annotation object.* The `Annotation` property enables you to specify whether this rectangle object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the rectangle object is displayed in a figure legend:

# Rectangle Properties

---

| <b>IconDisplayStyle Value</b> | <b>Purpose</b>                                            |
|-------------------------------|-----------------------------------------------------------|
| on                            | Represent this rectangle object in a legend (default)     |
| off                           | Do not include this rectangle object in a legend          |
| children                      | Same as on because rectangle objects do not have children |

## Setting the IconDisplayStyle property

Set the IconDisplayStyle of a graphics object with handle `hobj` to off:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'off')
```

## Using the IconDisplayStyle property

See “Controlling Legends” for more information and examples.

**BeingDeleted**  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the **BeingDeleted** property to on when the object’s delete function callback is called (see the **DeleteFcn** property). It remains set to on while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s **BeingDeleted** property before acting.

**BusyAction**  
cancel | {queue}

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The **BusyAction** property of the *interrupting* callback determines how MATLAB handles its execution. When the **BusyAction** property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the **Interruptible** property of the callback controls whether other callbacks can interrupt the *running* callback, see the **Interruptible** property description.

**ButtonDownFcn**  
function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over the rectangle object.

See the figure's **SelectionType** property to determine if modifier keys were also pressed.

Set this property to a function handle that references the callback. The function must define at least two input arguments (handle of object associated with the button down event and an event structure, which is empty for this property).

# Rectangle Properties

---

The following example shows how to access the callback object's handle as well as the handle of the figure that contains the object from the callback function.

```
function button_down(src, evnt)
% src - the object that is the source of the event
% evnt - empty for this property
    sel_typ = get(gcf, 'SelectionType')
    switch sel_typ
        case 'normal'
            disp('User clicked left-mouse button')
            set(src, 'Selected', 'on')
        case 'extend'
            disp('User did a shift-click')
            set(src, 'Selected', 'on')
        case 'alt'
            disp('User did a control-click')
            set(src, 'Selected', 'on')
            set(src, 'SelectionHighlight', 'off')
    end
end
```

Suppose `h` is the handle of a rectangle object and the `button_down` function is on your MATLAB path. The following statement assigns the `button_down` function to the `ButtonDownFcn` property:

```
set(h, 'ButtonDownFcn', @button_down)
```

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

**Children**  
vector of handles

The empty matrix; rectangle objects have no children.

**Clipping**  
{on} | off

*Clipping mode.* MATLAB clips rectangles to the axes plot box by default. If you set `Clipping` to `off`, rectangles are displayed outside the axes plot box. This can occur if you create a rectangle, set `hold` to `on`, freeze axis scaling (`axis` set to `manual`), and then create a larger rectangle.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Executes when MATLAB creates a rectangle object. You must define this property as a default value for rectangles or in a call to the `rectangle` function to create a new rectangle object. For example, the statement:

```
set(0, 'DefaultRectangleCreateFcn', @rect_create)
```

defines a default value for the rectangle `CreateFcn` property on the root level that sets the axes `DataAspectRatio` whenever you create a rectangle object. The callback function must be on your MATLAB path when you execute the above statement.

```
function rect_create(src, evnt)
% src - the object that is the source of the event
% evnt - empty for this property
    axh = get(src, 'Parent');
    set(axh, 'DataAspectRatio', [1,1,1])
end
```

MATLAB executes this function after setting all rectangle properties. Setting this property on an existing rectangle object has no effect. The function must define at least two input arguments (handle of object created and an event structure, which is empty for this property).

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function

# Rectangle Properties

---

and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See `Function Handle Callbacks` for information on how to use function handles to define the callback function.

## Curvature

one- or two-element vector [x,y]

*Amount of horizontal and vertical curvature.* Specifies the curvature of the rectangle sides, which enables the shape of the rectangle to vary from rectangular to ellipsoidal. The horizontal curvature `x` is the fraction of width of the rectangle that is curved along the top and bottom edges. The vertical curvature `y` is the fraction of the height of the rectangle that is curved along the left and right edges.

The values of `x` and `y` can range from 0 (no curvature) to 1 (maximum curvature). A value of [0,0] creates a rectangle with square sides. A value of [1,1] creates an ellipse. If you specify only one value for `Curvature`, then the same length (in axes data units) is curved along both horizontal and vertical sides. The amount of curvature is determined by the shorter dimension.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Delete rectangle callback function.* Executes when you delete the rectangle object (for example, when you issue a `delete` command or clear the axes `cla` or figure `clf`).

For example, the following function displays object property data before the object is deleted.

```
function delete_fcn(src,evnt)
% src - the object that is the source of the event
% evnt - empty for this property
```

```
obj_tp = get(src,'Type');  
disp([obj_tp, ' object deleted'])  
disp('Its user data is:')  
disp(get(src,'UserData'))  
end
```

MATLAB executes the function before deleting the object's properties so these values are available to the callback function. The function must define at least two input arguments (handle of object being deleted and an event structure, which is empty for this property).

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

**DisplayName**  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the rectangle object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where  $n$  is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.

# Rectangle Properties

---

- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

## EdgeColor

`{ColorSpec} | none`

*Color of the rectangle edges.* Specifies the color of the rectangle edges as a color or specifies that no edges be drawn.

## EraseMode

`{normal} | none | xor | background`

*Erase mode.* Controls the technique MATLAB uses to draw and erase rectangle objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the rectangle when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the rectangle by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath the rectangle.

However, the rectangle's color depends on the color of whatever is beneath it on the display.

- **background** — Erase the rectangle by drawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` is none. This damages objects that are behind the erased rectangle, but rectangles are always properly colored.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`FaceColor`  
`ColorSpec` | `{none}`

*Color of rectangle face.* Specifies the color of the rectangle face, which is not colored by default.

`HandleVisibility`  
`{on}` | `callback` | `off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.

# Rectangle Properties

---

- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

You can set the `Root ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

`HitTest`  
{on} | off

*Selectable by mouse click.* Determines if the rectangle can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the

rectangle. If `HitTest` is off, clicking the rectangle selects the object below it (which might be the axes containing it).

## Interruptible

off | {on}

### *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

# Rectangle Properties

---

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

## LineStyle

{-} | -- | : | -. | none

*Line style of rectangle edge.*

## Line Style Specifiers Table

| Specifier | Line Style           |
|-----------|----------------------|
| '-'       | Solid line (default) |
| '--'      | Dashed line          |
| ':'       | Dotted line          |
| '-.'      | Dash-dot line        |
| 'none'    | No line              |

## LineWidth

size in points

*Width of the rectangle edge line.* Specify this value in points. 1 point =  $\frac{1}{72}$  inch. The default value is 0.5 points.

## Parent

handle of axes, hgroup, or hgtransform

*Parent of rectangle object.* Contains the handle of the rectangle object's parent. The parent of a rectangle object is the axes, hgroup, or hgtransform object that contains it.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## Position

four-element vector [x,y,width,height]

*Location and size of rectangle.* Specifies the location and size of the rectangle in the data units of the axes. The point defined by x, y specifies one corner of the rectangle, and width and height define the size in units along the x- and y-axes respectively.

## Selected

on | off

*Is object selected?* When this property is on MATLAB displays selection handles if the SelectionHighlight property is also on. You can, for example, define the ButtonDownFcn to set this property, allowing users to select the object with the mouse.

## SelectionHighlight

{on} | off

*Objects are highlighted when selected.* When the Selected property is on, MATLAB indicates the selected state by drawing handles at each vertex. When SelectionHighlight is off, MATLAB does not draw the handles.

## Tag

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

# Rectangle Properties

---

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

## Type

string (read-only)

*Class of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For rectangle objects, `Type` is always `'rectangle'`.

## UIContextMenu

handle of `uicontextmenu` object

*Associate a context menu with the rectangle.* Assign this property the handle of a `uicontextmenu` object created in the same figure as the rectangle. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the rectangle.

## UserData

matrix

*User-specified data.* Data you want to associate with the rectangle object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## Visible

{on} | off

*Rectangle visibility.* By default, all rectangles are visible. When set to `off`, the rectangle is not visible, but still exists, and you can `get` and `set` its properties.

## See Also

`rectangle`

**Purpose** Rectangle intersection area

**Syntax** `area = rectint(A,B)`

**Description** `area = rectint(A,B)` returns the area of intersection of the rectangles specified by position vectors `A` and `B`.

If `A` and `B` each specify one rectangle, the output `area` is a scalar.

`A` and `B` can also be matrices, where each row is a position vector. `area` is then a matrix giving the intersection of all rectangles specified by `A` with all the rectangles specified by `B`. That is, if `A` is `n`-by-4 and `B` is `m`-by-4, then `area` is an `n`-by-`m` matrix where `area(i,j)` is the intersection area of the rectangles specified by the `i`th row of `A` and the `j`th row of `B`.

---

**Note** A position vector is a four-element vector `[x,y,width,height]`, where the point defined by `x` and `y` specifies one corner of the rectangle, and `width` and `height` define the size in units along the `x` and `y` axes respectively.

---

**See Also** `polyarea`

# recycle

---

**Purpose** Set option to move deleted files to recycle folder

**Syntax**

```
recycle
stat = recycle
previousStat = recycle state
previousStat = recycle('state')
```

**Description** `recycle` displays the current state, on or off, for recycling files you remove using the `delete` function. When the value is on, deleted files move to a different location. The location varies by platform—see “Deleting Files and Folders Using Functions”. When the value is off, the `delete` function permanently removes the files. For details, see the Tips section.

`stat = recycle` returns the current state for recycling files to the character array `stat`.

`previousStat = recycle state` sets the recycle option for MATLAB to the specified state, either on or off. The `previousStat` value is the recycle state before running the statement.

`previousStat = recycle('state')` is the function form of the syntax.

**Tips** The preference for **Deleting files** sets the state of the `recycle` function at startup. When you change the preference, it changes the state of `recycle`. When you change the state of `recycle`, it does not change the preference. Use `recycle` to override the behavior of the preference. For example, regardless of the setting for the **Deleting files** preference, to remove `thisfile.m` permanently, run:

```
recycle('off')
delete('thisfile.m')
```

After setting the recycle state to off, all files you delete using the `delete` function are deleted permanently until you do one of the following:

- Run `recycle('on')`

- Restart MATLAB. Upon startup, MATLAB sets the state for `recycle` to match the **Deleting files** preference.

## Examples

Start from a state where file recycling is off. Verify the current `recycle` state:

```
recycle
ans =
    off
```

Turn file recycling on. Delete a file and move it to the recycle bin or temporary folder:

```
recycle on;
delete myfile.txt
```

## See Also

`delete` | `dir` | `ls` | `rmdir`

## How To

- “General Preferences”

# reducepatch

---

**Purpose** Reduce number of patch faces

**Syntax**

```
nfv = reducepatch(p,r)
nfv = reducepatch(fv,r)
nfv = reducepatch(p) or nfv = reducepatch(fv)
reducepatch(...,'fast')
reducepatch(...,'verbose')
nfv = reducepatch(f,v,r)
[nf,nv] = reducepatch(...)
```

**Description** `reducepatch(p,r)` reduces the number of faces of the patch identified by handle `p`, while attempting to preserve the overall shape of the original object. The MATLAB software interprets the reduction factor `r` in one of two ways depending on its value:

- If `r` is less than 1, `r` is interpreted as a fraction of the original number of faces. For example, if you specify `r` as 0.2, then the number of faces is reduced to 20% of the number in the original patch.
- If `r` is greater than or equal to 1, then `r` is the target number of faces. For example, if you specify `r` as 400, then the number of faces is reduced until there are 400 faces remaining.

`nfv = reducepatch(p,r)` returns the reduced set of faces and vertices but does not set the `Faces` and `Vertices` properties of patch `p`. The struct `nfv` contains the faces and vertices after reduction.

`nfv = reducepatch(fv,r)` performs the reduction on the faces and vertices in the struct `fv`.

`nfv = reducepatch(p)` or `nfv = reducepatch(fv)` uses a reduction value of 0.5.

`reducepatch(...,'fast')` assumes the vertices are unique and does not compute shared vertices.

`reducepatch(...,'verbose')` prints progress messages to the command window as the computation progresses.

`nfv = reducepatch(f,v,r)` performs the reduction on the faces in `f` and the vertices in `v`.

`[nf,nv] = reducepatch(...)` returns the faces and vertices in the arrays `nf` and `nv`.

## Tips

If the patch contains nonshared vertices, MATLAB computes shared vertices before reducing the number of faces. If the faces of the patch are not triangles, MATLAB triangulates the faces before reduction. The faces returned are always defined as triangles.

The number of output triangles may not be exactly the number specified with the reduction factor argument (`r`), particularly if the faces of the original patch are not triangles.

## Examples

This example illustrates the effect of reducing the number of faces to only 15% of the original value.

```
[x,y,z,v] = flow;
p = patch(isosurface(x,y,z,v,-3));
set(p,'facecolor','w','EdgeColor','b');
daspect([1,1,1])
view(3)
figure;
h = axes;
p2 = copyobj(p,h);
reducepatch(p2,0.15)
daspect([1,1,1])
view(3)
```

# reducepatch

---

Before Reduction

After Reduction to 15% of Original Number of Faces

## See Also

[isosurface](#) | [isocaps](#) | [isonormals](#) | [smooth3](#) | [subvolume](#) | [reducevolume](#)

## How To

- [Vector Field Displayed with Cone Plots](#)

# reducevolume

---

**Purpose** Reduce number of elements in volume data set

**Syntax**  
`[nx,ny,nz,nv] = reducevolume(X,Y,Z,V,[Rx,Ry,Rz])`  
`[nx,ny,nz,nv] = reducevolume(V,[Rx,Ry,Rz])`  
`nv = reducevolume(...)`

**Description** `[nx,ny,nz,nv] = reducevolume(X,Y,Z,V,[Rx,Ry,Rz])` reduces the number of elements in the volume by retaining every  $R_x^{\text{th}}$  element in the  $x$  direction, every  $R_y^{\text{th}}$  element in the  $y$  direction, and every  $R_z^{\text{th}}$  element in the  $z$  direction. If a scalar  $R$  is used to indicate the amount or reduction instead of a three-element vector, the MATLAB software assumes the reduction to be `[R R R]`.

The arrays  $X$ ,  $Y$ , and  $Z$  define the coordinates for the volume  $V$ . The reduced volume is returned in  $nv$ , and the coordinates of the reduced volume are returned in  $nx$ ,  $ny$ , and  $nz$ .

`[nx,ny,nz,nv] = reducevolume(V,[Rx,Ry,Rz])` assumes the arrays  $X$ ,  $Y$ , and  $Z$  are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)`, where `[m,n,p] = size(V)`.

`nv = reducevolume(...)` returns only the reduced volume.

## Examples

This example uses a data set that is a collection of MRI slices of a human skull. This data is processed in a variety of ways:

- The 4-D array is squeezed (`squeeze`) into three dimensions and then reduced (`reducevolume`) so that what remains is every fourth element in the  $x$  and  $y$  directions and every element in the  $z$  direction.
- The reduced data is smoothed (`smooth3`).
- The outline of the skull is an isosurface generated as a patch (`p1`) whose vertex normals are recalculated to improve the appearance when lighting is applied (`patch`, `isosurface`, `isonormals`).
- A second patch (`p2`) with an interpolated face color draws the end caps (`FaceColor`) `isocaps`).
- The view of the object is set (`view`, `axis`, `daspect`).

- A 100-element grayscale colormap provides coloring for the end caps (colormap).
- Adding a light to the right of the camera illuminates the object (camlight, lighting).

```
load mri
D = squeeze(D);
[x,y,z,D] = reducevolume(D,[4,4,1]);
D = smooth3(D);
p1 = patch(isosurface(x,y,z,D, 5,'verbose'),...
    'FaceColor','red','EdgeColor','none');
isonormals(x,y,z,D,p1);
p2 = patch(isocaps(x,y,z,D, 5),...
    'FaceColor','interp','EdgeColor','none');
view(3); axis tight; daspect([1,1,.4])
colormap(gray(100))
camlight; lighting gouraud
```

# refresh

---

|                    |                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Redraw current figure                                                                                                                    |
| <b>Syntax</b>      | <code>refresh</code><br><code>refresh(h)</code>                                                                                          |
| <b>Description</b> | <code>refresh</code> erases and redraws the current figure.<br><code>refresh(h)</code> redraws the figure identified by <code>h</code> . |

**Purpose** Refresh data in graph when data source is specified

**Syntax**

```
refreshdata
refreshdata(figure_handle)
refreshdata(object_handles)
refreshdata(object_handles, 'workspace')
```

**Description** `refreshdata` evaluates any data source properties (XDataSource, YDataSource, or ZDataSource) on all objects in graphs in the current figure. If the specified data source has changed, the MATLAB software updates the graph to reflect this change.

---

**Note** The variable assigned to the data source property must be in the base workspace or you must specify the *workspace* option as 'caller'.

---

`refreshdata(figure_handle)` refreshes the data of the objects in the specified figure.

`refreshdata(object_handles)` refreshes the data of the objects specified in *object\_handles* or the children of those objects. Therefore, *object\_handles* can contain figure, axes, or plot object handles.

`refreshdata(object_handles, 'workspace')` enables you to specify whether the data source properties are evaluated in the base workspace or the workspace of the function in which `refreshdata` was called. *workspace* is a string that can be

- `base` — Evaluate the data source properties in the base workspace.
- `caller` — Evaluate the data source properties in the workspace of the function that called `refreshdata`.

**Tips** The Linked Plots feature (see documentation for `linkdata`) sets up data sources for graphs and synchronizes them with the workspace variables they display. When you use this feature, you do not also need to call

# refreshdata

---

`refreshdata`, as it is essentially automatically triggered every time a data source changes.

If you are not using the Linked Plots feature, you need to set the `XDataSource`, `YDataSource`, and/or `ZDataSource` properties of a graph in order to use `refreshdata`. You can do that programmatically, as shown in the examples below, or use the Property Editor, one of the plotting tools. In the Property Editor, select the graph (e.g., a `lineseries` object) and type in (or select from the drop-down choices) the name(s) of the workspace variable(s) from which you want the plot to refresh, in the fields labelled **X Data Source**, **Y Data Source**, and/or **Z Data Source**. The call to `refreshdata` causes the graph to update.

## Examples

Plot a sine wave, identify data sources, and then modify its `YDataSource`:

```
x = 0:.1:8;
y = sin(x);
h = plot(x,y)
set(h, 'YDataSource', 'y')
set(h, 'XDataSource', 'x')
y = sin(x.^3);
refreshdata
```

Create a surface plot, identify a `ZDataSource` for it, and change the data to a different size.

```
Z = peaks(5);
h = surf(Z)
set(h, 'ZDataSource', 'Z')
pause(3)
Z = peaks(25);
refreshdata
```

## How To

- plot objects
- “Updating Plot Object Axis and Color Data”

**Purpose**

Match regular expression (case sensitive)

**Syntax**

```

regexp(string,expr)
[matchstart,matchend,tokenindices,matchstring,tokenstring,
 tokenname,splitstring] = regexp(string,expr)
[selected_outputs] = regexp(string,expr,outselect)
regexp(string,expr,options)

```

**Description**

regexp(string,expr) parses the input string locating those parts of string that match the character pattern(s) specified by regular expression, expr. This syntax returns the starting index of each match. If no matches are found, regexp returns an empty array.

[matchstart,matchend,tokenindices,matchstring,tokenstring,tokenname,splitstring] = regexp(string,expr) returns from one to seven output values, depending on the number of output variables you specify.

[selected\_outputs] = regexp(string,expr,outselect) returns from one to seven output values, depending on which flags you specify in outselect. The presence and ordering of the outselect inputs determine the presence and ordering of the corresponding outputs.

regexp(string,expr,options) calls regexp with one or more of the nondefault options listed in the Command Options on page 2-3866 table, below. These options must follow the string and expr inputs in the argument list.

**Tips**

- For more information on this and other regular expression functions, see “Regular Expressions” in the MATLAB Programming Fundamentals documentation.
- The string and expr inputs are required. Enter these as the first and second arguments, respectively. Any other input arguments are optional. Enter optional inputs, in any order, following the two required inputs.

## Input Arguments

### **string**

A string or cell array of strings containing the string you want to parse. This string can be of any length and can contain any characters. This argument can also be a cell array of strings.

### **expr**

A string or cell array of strings containing a MATLAB regular expression. This input consists of text and operators with which you specify character patterns to look for in `string`.

This table shows the main categories of metacharacters and operators that you can use in `expr`.

| Category                   | Metacharacters and Operators                                                                                                                                                                                              |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| “Character Type Operators” | One of a certain group of characters (for example, a character in a predefined set or range, a whitespace character, an alphabetic, numeric, or underscore character, or a character that is not in one of these groups). |
| “Character Representation” | Metacharacters that represent a special character (for example, backslash, new line, tab, hexadecimal values, any untranslated literal character, etc).                                                                   |
| “Grouping Operators”       | A grouping of letters or metacharacters to apply a regular expression operator to.                                                                                                                                        |
| “Nonmatching Operators”    | Text included in an expression for the purpose of adding a comment statement, but not to be used as a pattern to find a match for.                                                                                        |
| “Positional Operators”     | Location in the string where the characters or pattern must be positioned for there to be a match (for example, start or end of the string, start or end of a word, an entire word).                                      |

| Category                      | Metacharacters and Operators                                                                                                                                                                          |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| “Lookaround Operators”        | Characters or patterns that immediately precede or follow the intended match, but are not considered to be part of the match itself.                                                                  |
| “Quantifiers”                 | Various ways of expressing the number of times a character or pattern is to occur for there to be a match (for example, exact number, minimum, maximum, zero or one, zero or more, one or more, etc.) |
| “Tokens”                      | Characters or patterns selected from the string being parsed that you can use to match other characters in the string.                                                                                |
| “Named Capture”               | Operators used in assigning names to matched tokens, thus making your code more maintainable and the output easier to interpret.                                                                      |
| “Conditional Expressions”     | Operators that express conditions under which a certain match is considered to be acceptable.                                                                                                         |
| “Dynamic Regular Expressions” | Operators that include a subexpression or command that MATLAB parses or executes. MATLAB uses the result of that operation in parsing the overall expression.                                         |
| “String Replacement”          | Operators used with the <code>regexprep</code> function to specify the content of the replacement text.                                                                                               |

Any text in the expression must be an exact match for at least part of the text in the parse string. Operators, on the other hand, are symbolic. Each operator symbol stands for a *type* of character (for example, an uppercase letter ([A-Z]), a space character (\s), four characters of any type (.{4})).

**outselect**

An optional comma-separated list of one to seven keywords. The presence of any of these keywords in the input argument list tells `regexp` to return the corresponding output.

| <b>outselect Keyword</b> | <b>Selected Return Value</b> |
|--------------------------|------------------------------|
| 'start'                  | matchstart                   |
| 'end'                    | matchend                     |
| 'tokenExtents'           | tokenindices                 |
| 'match'                  | matchstring                  |
| 'tokens'                 | tokenstring                  |
| 'names'                  | tokenname                    |
| 'split'                  | splitstring                  |

You must supply one output variable for each `outselect` keyword you include as an input argument. The order of the keyword in the input argument list determines the order of the corresponding output in the output argument list.

For a description of all return values, see “Output Arguments” on page 2-3869 .

## **options**

`regexp` accepts one or more of the following options.

## **Command Options**

| <b>Option</b> | <b>Description</b>                                                                                                                    |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------|
| 'once'        | Return only the first match found.                                                                                                    |
| 'warnings'    | Display warnings regarding potential issues parsing the expression. This option only enables warnings for the command being executed. |
| mode          | Modify the parameters of a search. See the section on mode that follows this table.                                                   |

**The mode Option.** You can fine-tune your regular expression parsing using the optional mode inputs: Case Sensitivity, Empty Match, Dot Matching, Anchor Type, and Spacing. There are two ways to use the regexp modes:

- Use a mode keyword (for example, 'lineanchors') to apply the mode to the entire input string.
- Use a mode flag (for example, (?m)) to apply the mode to selected parts of the input string. (Not available for Empty Match mode.)

The mode option is available for the regexp, regexpi, and regexprep functions. For more information about regexp modes, see “Modifying Parameters of the Search (Modes)” in the MATLAB “Programming Fundamentals” documentation.

### Case Sensitivity Mode

Use the Case Sensitivity mode to control whether or not MATLAB considers letter case when matching an expression to a string.

| Mode Keyword | Flag  | Description                                                                                |
|--------------|-------|--------------------------------------------------------------------------------------------|
| 'matchcase'  | (?-i) | Letter case must match when matching patterns to a string. (The default for regexp).       |
| 'ignorecase' | (?i)  | Do not consider letter case when matching patterns to a string. (The default for regexpi). |

### Empty Match Mode

Use Empty Match mode to allow successful matches of length zero. Using this mode, you can match a location in a string in which nothing but the assertion is true.

| Mode Keyword   | Description                                        |
|----------------|----------------------------------------------------|
| 'noemptymatch' | Ignore zero length matches. (This is the default). |
| 'emptymatch'   | Allow matches of length zero.                      |

## Dot Matching Mode

Use the Dot Matching mode to control whether or not MATLAB includes the newline (`\n`) character when matching the dot (`.`) metacharacter in a regular expression.

| Mode Keyword       | Flag                 | Description                                                                                   |
|--------------------|----------------------|-----------------------------------------------------------------------------------------------|
| 'dotall'           | ( <code>?s</code> )  | Match dot ( <code>.</code> ) in the pattern string with any character. (This is the default). |
| 'dotexceptnewline' | ( <code>?-s</code> ) | Match dot in the pattern with any character that is not a newline.                            |

## Anchor Type Mode

Use the Anchor Type mode to control whether MATLAB considers the `^` and `$` metacharacters to represent the beginning and end of a string or the beginning and end of a line.

| Mode Keyword    | Flag                 | Description                                                                                                              |
|-----------------|----------------------|--------------------------------------------------------------------------------------------------------------------------|
| 'stringanchors' | ( <code>?-m</code> ) | Match the <code>^</code> and <code>\$</code> metacharacters at the beginning and end of a string. (This is the default). |
| 'lineanchors'   | ( <code>?m</code> )  | Match the <code>^</code> and <code>\$</code> metacharacters at the beginning and end of a line.                          |

### Spacing Mode

Use the Spacing mode to control how MATLAB interprets space characters and comments within the parsing string. Note that spacing mode applies to the parsing string (the second input argument that contains the metacharacters (for example, `\w`) and not the string being parsed.

| Mode Keyword              | Flag  | Description                                                                                                                                                         |
|---------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ' <b>literalspacing</b> ' | (?-x) | Parse space characters and comments (the # character and any text to the right of it) in the same way as any other characters in the string. (This is the default). |
| ' <b>freespacing</b> '    | (?x)  | Ignore spaces and comments when parsing the string. (You must use '\ ' and '\#' to match space and # characters.)                                                   |

### Output Arguments

Each of the first seven outputs listed below is returned as a 1-by-*m* array, where *m* is the number of matches found by `regexp`.

When parsing multiple strings (i.e., a 1-by-*n* or *n*-by-1 cell array of strings), `regexp` returns a 1-by-*n* cell array for each output specified. When parsing an *m*-by-*n* cell array of strings, `regexp` returns an *m*-by-*n* cell array for each output specified.

#### **matchstart**

The starting index of each substring of `string` that matches `expression`, `expr`. The output is an array of class `double`.

#### **matchend**

The ending index of each substring of `string` that matches `expression`, `expr`. The output is an array of class `double`.

To obtain this return value, you must call `regexp` with at least two output variables, or specify the `'end'` keyword as one of the `outselect` input arguments.

## **tokenindices**

The starting and ending indices of each substring of `string` that matches a token in `expr`. The output is a cell array, each cell of which contains an array of class `double`. The size of this inner array is `m-by-2`, where `m` is the number of tokens captured by the match. Any cells that do not represent matched tokens are returned empty. (The output is a `double` when you call `regexp` with the `'once'` option.)

To obtain this return value, you must call `regexp` with at least three output variables, or specify the `'tokenExtents'` keyword as one of the `outselect` input arguments.

## **matchstring**

The text of each substring of `string` that is a match. The output is a cell array of strings, (or a single string when you call `regexp` with the `'once'` option).

To obtain this return value, you must call `regexp` with at least four output variables, or specify the `'match'` keyword as one of the `outselect` input arguments.

## **tokenstring**

The text of each token captured by `regexp`. The output is a cell array of 1-by-`n` cell arrays, where `n` is the number of token expressions specified in the `expr` input. (The output is a cell array of strings when you call `regexp` with the `'once'` option).

To obtain this return value, you must call `regexp` with at least five output variables, or specify the `'tokens'` keyword as one of the `outselect` input arguments.

## **tokenname**

The name and text of each *named* token captured by `regexp`. The output is an array of structures, each containing `n` fields, where `n` is the number of token expressions specified in the `expr` input. Field names of the returned structure are set to the token names, and field values are the text of those tokens. Named tokens are generated by the expression (`?<tokenname>`). If there are no named tokens in `expr`, `regexp` returns a structure array with no fields.

To obtain this return value, you must call `regexp` with at least six output variables, or specify the `'names'` keyword as one of the `outselect` input arguments.

### **splitstring**

Those parts of the input string that are delimited by substrings matched by the expression. The output is a cell array of strings. Any cells that represent strings of zero length are returned empty. When using the `'split'` keyword, `regexp` returns one more string than the number of matches in the string.

To obtain this return value, you must call `regexp` with all seven output variables, or specify the `'split'` keyword as one of `outselect` the input arguments.

### **selected\_outputs**

From one to seven of the output values listed above. Select which outputs to include using the `outselect` input arguments. Specify which outputs you want returned and in what order you want them returned using the keywords shown in the table.

For example, to have `regexp` return the starting index and matching text, specify the keywords `'start'` and `'match'`

```
[index, matstr] = regexp('Jan 24', '\d', ...
    'start', 'match')
```

| Selected Outputs | Keyword Required |
|------------------|------------------|
| matchstart       | 'start'          |
| matchend         | 'end'            |
| tokenindices     | 'tokenExtents'   |
| matchstring      | 'match'          |
| tokenstring      | 'tokens'         |
| tokenname        | 'names'          |
| splitstring      | 'split'          |

## Examples

Return a row vector of indices that match words that start with `c`, end with `t`, and contain one or more vowels between them. Make the matches sensitive to letter case (by using the case-sensitive `regexp`):

```
str = 'bat cat can car COAT court cut ct CAT-scan';
regexp(str, 'c[aeiou]+t')
ans =
     5     28
```

---

Return a cell array of row vectors of indices that match capital letters and white spaces in the cell array of strings `str`:

```
str = {'Madrid, Spain' 'Romeo and Juliet' 'MATLAB is great'};
s1 = regexp(str, '[A-Z]');
s2 = regexp(str, '\s');
```

Capital letters, '`[A-Z]`', were found at these `str` indices:

```
s1{:}
ans =
     1     9
ans =
```

```

    1    11
ans =
    1     2     3     4     5     6

```

Space characters, '\s', were found at these str indices:

```

s2{:}
ans =
    8
ans =
    6    10
ans =
    7    10

```

Return the text and the starting and ending indices of words containing the letter x:

```

str = 'REGEXP helps you relax';
[m s e] = regexp(str, '\w*x\w*', 'match', 'start', 'end')
m =
    'relax'
s =
    18
e =
    22

```

Find the substrings delimited by the ^ character:

```

s1 = ['Use REGEXP to split ^this string into ' ...
      'several ^individual pieces'];

s2 = regexp(s1, '\^', 'split');

s2{:}
ans =

```

```
'Use REGEXP to split '  
'this string into several '  
'individual pieces'
```

---

Use the **'split'** keyword to return those parts of the input string that are not returned when using **'match'**. Note that when you match the beginning or ending characters in a string (as is done in this example), the first (or last) return value is always an empty string:

```
str = 'She sells sea shells by the seashore.';  
  
[matchstr splitstr] = regexp(str, '[Ss]h.', 'match', ...  
                             'split')  
matchstr =  
    'She'    'she'    'sho'  
splitstr =  
    ''    ' sells sea '    'lls by the sea'    're.'
```

For any string that has been split, you can reassemble the pieces into the initial string using the command

```
j = [splitstr; [matchstr {''}]]; [j{:}]  
  
ans =  
    She sells sea shells by the seashore.
```

---

Search a string for opening and closing HTML tags. Use the expression `<(\w+)` to find the opening tag (for example, `<tagname'`) and to create a token for it. Use the expression `</\1>` to find another occurrence of the same token, but formatted as a closing tag (for example, `</tagname>'`):

```
str = ['if <code>A</code> == x<sup>2</sup>, ' ...  
      '<em>disp(x)</em>']  
str =  
if <code>A</code> == x<sup>2</sup>, <em>disp(x)</em>
```

```

expr = '<(\w+).*?>.*?</\1>';

[tok mat] = regexp(str, expr, 'tokens', 'match');

tok{:}
ans =
    'code'
ans =
    'sup'
ans =
    'em'

mat{:}
ans =
    <code>A</code>
ans =
    <sup>2</sup>
ans =
    <em>disp(x)</em>

```

For information on using tokens, see “Tokens” in the MATLAB Programming Fundamentals documentation.

---

- 1 Enter a string containing two names, the first and last names being in a different order:

```

str = sprintf('John Davis\nRogers, James')
str =
    John Davis
    Rogers, James

```

- 2 Create an expression that generates first and last name tokens, assigning the names `first` and `last` to the tokens. Call `regexp` to get the text and names of each token found:

```

expr = ...

```

```
'(?<first>\w+)\s+(?<last>\w+)|(?<last>\w+)\s+(?<first>\w+)';
```

```
[tokens names] = regexp(str, expr, 'tokens', 'names');
```

- 3** Examine the `tokens` cell array that was returned. The first and last name tokens appear in the order in which they were generated: first name–last name, then last name–first name:

```
tokens{:}
ans =
    'John'    'Davis'
ans =
    'Rogers'  'James'
```

- 4** Now examine the `names` structure that was returned. First and last names appear in a more usable order:

```
names(:,1)
ans =
    first: 'John'
    last:  'Davis'

names(:,2)
ans =
    first: 'James'
    last:  'Rogers'
```

---

Use Case Sensitivity mode with `regexp`.

- 1** Given a string that has both uppercase and lowercase letters, use the `regexp` default mode (case-sensitive) to locate only the lowercase instance of the word `case`:

```
str = 'A string with UPPERCASE and lowercase text.';

regexp(str, 'case', 'match')
ans =
```

```
'case'
```

**2** Now disable case-sensitive matching to find both instances of case:

```
regexp(str, 'case', 'ignorecase', 'match')
ans =
    'CASE'    'case'
```

**3** Match 5 letters that are followed by 'CASE'. Use the (?-i) flag to turn off case insensitivity for the first match and (?i) to turn insensitivity on for the second:

```
M = regexp(str, {'(?-i)\w{5}(?=CASE)', ...
                '(?i)\w{5}(?=CASE)'} , 'match');

M{:}
ans =
    'UPPER'
ans =
    'UPPER'    'lower'
```

Use Empty Match mode with `regexp` to add the characters '=>' to the beginning of each line in the following text:

```
text = {'Use the REGEXPREP function in '; ...
        'Empty Match mode to insert a right '; ...
        'arrow at the start of each line.'};

newtext = regexprep(text, '^', '=>', 'emptymatch')

newtext =
'=> Use the REGEXPREP function in '
'=> Empty Match mode to insert a right '
'=> arrow at the start of each line.'
```

The `^` operator matches the beginning of each string. Because there are no other characters to match, and the `emptymatch` mode is enabled by

the fifth input argument of the command, there is an empty match at the beginning of each string.

---

- 1 Search the string 'MATLAB' for zero or more of the characters M, A, and T. Do not include matches of zero-length. (The mode defaults to `noemptymatch`):

```
regexp('MATLAB', '[MAT]*', 'match')
ans =
    'MAT'    'A'
```

- 2 Repeat this search, but this time specify `emptymatch` mode to include matches of zero-length.

---

**Note** Note that there is also a match for the position that follows the final character.

---

```
regexp('MATLAB', '[MAT]*', 'emptymatch', 'match')
ans =
    'MAT'    ''    'A'    ''    ''
```

- 3 Now, use the + (one or more) operator instead of the \* (zero or more) operator. Continue to use `emptymatch` mode:

```
regexp('MATLAB', '[MAT]+', 'emptymatch', 'match')
ans =
    'MAT'    'A'
```

No match is found for the L and B characters this time because `regexp` needs to find a least one occurrence of these characters for a match to be found.

---

Use Dot Matching mode with `regexp` to parse the following string, which contains a newline (`\n`) character:

```
str = sprintf('abc\ndef')
str =
    abc
    def
```

When you use the default mode, `dotall`, MATLAB includes the newline in the characters matched:

```
regexp(str, '.', 'match')
ans =
    'a'    'b'    'c'    [1x1 char]    'd'    'e'    'f'
```

When you use the `dotexceptnewline` mode, MATLAB skips the newline character:

```
regexp(str, '.', 'match', 'dotexceptnewline')
ans =
    'a'    'b'    'c'    'd'    'e'    'f'
```

Use Anchor Type mode with `regexp` to control whether you parse a multiline string line by line, or once for the entire string. Use the following two-line string:

```
str = sprintf('%s\n%s', 'Here is the first line', ...
              'followed by the second line')
str =
    Here is the first line
    followed by the second line
```

In `stringanchors` mode, MATLAB interprets the `$` metacharacter as an end-of-string specifier, and thus finds the last two words of the entire *string*:

```
regexp(str, '\w+\W\w+$', 'match', 'stringanchors')
```

```
ans =  
    'second line'
```

While in `lineanchors` mode, MATLAB interprets `$` as an end-of-line specifier, and finds the last two words of each *line*:

```
regexp(str, '\w+\W\w+$', 'match', 'lineanchors')  
ans =  
    'first line'    'second line'
```

---

Use Spacing mode with `regexp` to read a regular expression from a file, retrieving all operators and metacharacters from the file, but skipping any comment text:

- 1 Create a file called `regexp_str.txt` containing the following text.

```
(?x) # turn on freespacing.  
  
# This pattern matches a string with a repeated letter.  
  
\w* # First, match any number of preceding word characters.  
  
( # Mark a token.  
. # Match a character of any type.  
) # Finish capturing said token.  
\1 # Backreference to match what token #1 matched.  
  
\w* # Finally, match the remainder of the word.
```

- 2 Use the pattern expression read from the file to find those words that have consecutive matching letters. Because the first line enables freespacing mode, MATLAB ignores all spaces and comments that appear in the file:

```
str = ['Looking for words with letters that ' ...  
      'appear twice in succession.'];  
patt = fileread('regexp_str.txt');
```

```
regexp(str, patt, 'match')
ans =
    'Looking'    'letters'    'appear'    'succession'
```

---

Debug problems in parsing a string with `regexp`, `regexpi`, or `regexprep`, using the **'warnings'** option to view all warning messages:

```
regexp('$.', '[a-]', 'warnings')
Warning: Unbound range.
[a-]
|
```

## See Also

`regexpi` | `regexprep` | `regexprtranslate` | `strfind` | `strcmp` | `strcmpi` | `strncmp` | `strncmpi` | `strrep`

## How To

- “Regular Expressions”

# regexpi

---

**Purpose** Match regular expression (case insensitive)

**Syntax**

```
regexpi(string,expr)
[matchstart,matchend,tokenindices,matchstring,tokenstring,
 tokenname,splitstring] = regexpi(string,expr)
[selected_outputs] = regexpi(string,expr,outselect)
regexpi(string,expr,options)
```

**Description** `regexpi(string,expr)` parses the input `string` without regard to letter case. The function locates those parts of `string` that match the character pattern(s) specified by regular expression, `expr`. This syntax returns the starting index of each match. If no matches are found, `regexpi` returns an empty array.

`[matchstart,matchend,tokenindices,matchstring,tokenstring,tokenname,splitstring] = regexpi(string,expr)` returns from one to seven output values, depending on the number of output variables you specify.

`[selected_outputs] = regexpi(string,expr,outselect)` returns from one to seven output values, depending on which flags you specify in `outselect`. The presence and ordering of the `outselect` inputs determine the presence and ordering of the corresponding outputs.

`regexpi(string,expr,options)` calls `regexpi` with one or more of the nondefault options listed in the Command Options on page 2-3885 table, below. These options must follow the `string` and `expr` inputs in the argument list.

## Tips

- For more information on this and other regular expression functions, see “Regular Expressions” in the MATLAB Programming Fundamentals documentation.
- The `string` and `expr` inputs are required. Enter these as the first and second arguments, respectively. Any other input arguments are optional. Enter optional inputs, in any order, following the two required inputs.

**Input Arguments**

**string**

A string or cell array of strings containing the string you want to parse. This string can be of any length and can contain any characters. This argument can also be a cell array of strings.

**expr**

A string or cell array of strings containing a MATLAB regular expression. This input consists of text and operators with which you specify character patterns to look for in `string`.

This table shows the main categories of metacharacters and operators that you can use in `expr`.

| Category                   | Metacharacters and Operators                                                                                                                                                                                              |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| "Character Type Operators" | One of a certain group of characters (for example, a character in a predefined set or range, a whitespace character, an alphabetic, numeric, or underscore character, or a character that is not in one of these groups). |
| "Character Representation" | Metacharacters that represent a special character (for example, backslash, new line, tab, hexadecimal values, any untranslated literal character, etc).                                                                   |
| "Grouping Operators"       | A grouping of letters or metacharacters to apply a regular expression operator to.                                                                                                                                        |
| "Nonmatching Operators"    | Text included in an expression for the purpose of adding a comment statement, but not to be used as a pattern to find a match for.                                                                                        |
| "Positional Operators"     | Location in the string where the characters or pattern must be positioned for there to be a match (for example, start or end of the string, start or end of a word, an entire word).                                      |

# regexpi

| Category                      | Metacharacters and Operators                                                                                                                                                                          |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| “Lookaround Operators”        | Characters or patterns that immediately precede or follow the intended match, but are not considered to be part of the match itself.                                                                  |
| “Quantifiers”                 | Various ways of expressing the number of times a character or pattern is to occur for there to be a match (for example, exact number, minimum, maximum, zero or one, zero or more, one or more, etc.) |
| “Tokens”                      | Characters or patterns selected from the string being parsed that you can use to match other characters in the string.                                                                                |
| “Named Capture”               | Operators used in assigning names to matched tokens, thus making your code more maintainable and the output easier to interpret.                                                                      |
| “Conditional Expressions”     | Operators that express conditions under which a certain match is considered to be acceptable.                                                                                                         |
| “Dynamic Regular Expressions” | Operators that include a subexpression or command that MATLAB parses or executes. MATLAB uses the result of that operation in parsing the overall expression.                                         |
| “String Replacement”          | Operators used with the <code>regexprep</code> function to specify the content of the replacement text.                                                                                               |

Any text in the expression must be a case-insensitive match with part of the text in the parse string. Operators, on the other hand, are symbolic. Each operator symbol stands for a *type* of character (for example, an uppercase letter ([A-Z]), a space character (\s), four characters of any type (.{4})).

## **outselect**

An optional comma-separated list of one to seven keywords. The presence of any of these keywords in the input argument list tells `regexpi` to return the corresponding output.

| outselect Keyword | Selected Return Value |
|-------------------|-----------------------|
| 'start'           | matchstart            |
| 'end'             | matchend              |
| 'tokenExtents'    | tokenindices          |
| 'match'           | matchstring           |
| 'tokens'          | tokenstring           |
| 'names'           | tokenname             |
| 'split'           | splitstring           |

You must supply one output variable for each outselect keyword you include as an input argument. The order of the keyword in the input argument list determines the order of the corresponding output in the output argument list.

For a description of all return values, see “Output Arguments” on page 2-3869 .

### options

regexp accepts one or more of the following options.

### Command Options

| Option     | Description                                                                                                                           |
|------------|---------------------------------------------------------------------------------------------------------------------------------------|
| 'once'     | Return only the first match found.                                                                                                    |
| 'warnings' | Display warnings regarding potential issues parsing the expression. This option only enables warnings for the command being executed. |
| mode       | Modify the parameters of a search. See the section on mode that follows this table.                                                   |

**The mode Option.** You can fine-tune your regular expression parsing using the optional mode inputs: Case Sensitivity, Empty Match, Dot Matching, Anchor Type, and Spacing. There are two ways to use the `regex` modes:

- Use a mode keyword (for example, `'lineanchors'`) to apply the mode to the entire input string.
- Use a mode flag (for example, `(?m)`) to apply the mode to selected parts of the input string. (Not available for Empty Match mode.)

The mode option is available for the `regex`, `regexpi`, and `regexprep` functions. For more information about `regex` modes, see “Modifying Parameters of the Search (Modes)” in the MATLAB “Programming Fundamentals” documentation.

## Case Sensitivity Mode

Use the Case Sensitivity mode to control whether or not MATLAB considers letter case when matching an expression to a string.

| Mode Keyword              | Flag               | Description                                                                                              |
|---------------------------|--------------------|----------------------------------------------------------------------------------------------------------|
| <code>'matchcase'</code>  | <code>(?-i)</code> | Letter case must match when matching patterns to a string. (The default for <code>regex</code> ).        |
| <code>'ignorecase'</code> | <code>(?i)</code>  | Do not consider letter case when matching patterns to a string. (The default for <code>regexpi</code> ). |

## Empty Match Mode

Use Empty Match mode to allow successful matches of length zero. Using this mode, you can match a location in a string in which nothing but the assertion is true.

| Mode Keyword   | Description                                        |
|----------------|----------------------------------------------------|
| 'noemptymatch' | Ignore zero length matches. (This is the default). |
| 'emptymatch'   | Allow matches of length zero.                      |

### Dot Matching Mode

Use the Dot Matching mode to control whether or not MATLAB includes the newline (\n) character when matching the dot (.) metacharacter in a regular expression.

| Mode Keyword       | Flag  | Description                                                                      |
|--------------------|-------|----------------------------------------------------------------------------------|
| 'dotall'           | (?s)  | Match dot ('.') in the pattern string with any character. (This is the default). |
| 'dotexceptnewline' | (?-s) | Match dot in the pattern with any character that is not a newline.               |

### Anchor Type Mode

Use the Anchor Type mode to control whether MATLAB considers the ^ and \$ metacharacters to represent the beginning and end of a string or the beginning and end of a line.

| Mode Keyword    | Flag  | Description                                                                                    |
|-----------------|-------|------------------------------------------------------------------------------------------------|
| 'stringanchors' | (?-m) | Match the ^ and \$ metacharacters at the beginning and end of a string. (This is the default). |
| 'lineanchors'   | (?m)  | Match the ^ and \$ metacharacters at the beginning and end of a line.                          |

## Spacing Mode

Use the Spacing mode to control how MATLAB interprets space characters and comments within the parsing string. Note that spacing mode applies to the parsing string (the second input argument that contains the metacharacters (for example, `\w`) and not the string being parsed.

| Mode Keyword              | Flag  | Description                                                                                                                                                         |
|---------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ' <b>literalspacing</b> ' | (?-x) | Parse space characters and comments (the # character and any text to the right of it) in the same way as any other characters in the string. (This is the default). |
| ' <b>freespacing</b> '    | (?x)  | Ignore spaces and comments when parsing the string. (You must use '\ ' and '\#' to match space and # characters.)                                                   |

## Output Arguments

Each of the first seven outputs listed below is returned as a 1-by- $m$  array, where  $m$  is the number of matches found by `regexpi`.

When parsing multiple strings (i.e., a 1-by- $n$  or  $n$ -by-1 cell array of strings), `regexpi` returns a 1-by- $n$  cell array for each output specified. When parsing an  $m$ -by- $n$  cell array of strings, `regexpi` returns an  $m$ -by- $n$  cell array for each output specified.

### **matchstart**

The starting index of each substring of `string` that matches `expression`, `expr`. The output is an array of class `double`.

### **matchend**

The ending index of each substring of `string` that matches `expression`, `expr`. The output is an array of class `double`.

To obtain this return value, you must call `regexpi` with at least two output variables, or specify the `'end'` keyword as one of the `outselect` input arguments.

### **tokenindices**

The starting and ending indices of each substring of `string` that matches a token in `expr`. The output is a cell array, each cell of which contains an array of class `double`. The size of this inner array is `m-by-2`, where `m` is the number of tokens captured by the match. Any cells that do not represent matched tokens are returned empty. (The output is a `double` when you call `regex` with the `'once'` option.)

To obtain this return value, you must call `regex` with at least three output variables, or specify the `'tokenExtents'` keyword as one of the `outselect` input arguments.

### **matchstring**

The text of each substring of `string` that is a match. The output is a cell array of strings, (or a single string when you call `regexpi` with the `'once'` option).

To obtain this return value, you must call `regexpi` with at least four output variables, or specify the `'match'` keyword as one of the `outselect` input arguments.

### **tokenstring**

The text of each token captured by `regexpi`. The output is a cell array of 1-by-`n` cell arrays, where `n` is the number of token expressions specified in the `expr` input. (The output is a cell array of strings when you call `regexpi` with the `'once'` option).

To obtain this return value, you must call `regexpi` with at least five output variables, or specify the `'tokens'` keyword as one of the `outselect` input arguments.

### **tokenname**

The name and text of each *named* token captured by `regexpi`. The output is an array of structures, each containing *n* fields, where *n* is the number of token expressions specified in the `expr` input. Field names of the returned structure are set to the token names, and field values are the text of those tokens. Named tokens are generated by the expression (`?<tokenname>`). If there are no named tokens in `expr`, `regexpi` returns a structure array with no fields.

To obtain this return value, you must call `regexpi` with at least six output variables, or specify the `'names'` keyword as one of the `outselect` input arguments.

## **splitstring**

Those parts of the input string that are delimited by substrings matched by the expression. The output is a cell array of strings. Any cells that represent strings of zero length are returned empty. When using the `'split'` keyword, `regexp` returns one more string than the number of matches in the string.

To obtain this return value, you must call `regexp` with all seven output variables, or specify the `'split'` keyword as one of `outselect` the input arguments.

## **selected\_outputs**

From one to seven of the output values listed above. Select which outputs to include using the `outselect` input arguments. Specify which outputs you want returned and in what order you want them returned using the keywords shown in the table.

For example, to have `regexpi` return the starting index and matching text, specify the keywords `'start'` and `'match'`.

```
[index, matstr] = regexpi('Jan 24', '\d', ...  
'start', 'match')
```

| Selected Outputs | Keyword Required |
|------------------|------------------|
| matchstart       | 'start'          |
| matchend         | 'end'            |
| tokenindices     | 'tokenExtents'   |
| matchstring      | 'match'          |
| tokenstring      | 'tokens'         |
| tokenname        | 'names'          |
| splitstring      | 'split'          |

## Examples

Return a row vector of indices that match words that start with c, end with t, and contain one or more vowels between them. Make the matches insensitive to letter case (by using `regexpi` instead of `regex`):

```
str = 'bat cat can car COAT court cut ct CAT-scan';
regexpi(str, 'c[aeiou]+t')
ans =
     5     17     28     35
```

Use Case Sensitivity mode with `regexpi` to match 5 letters that are followed by 'CASE'. The first match defaults to case insensitivity. Use the `(?-i)` flag to turn on case sensitivity for the second match:

```
str = 'A string with UPPERCASE and lowercase text.';
M = regexpi(str, {'\w{5}(?=CASE)', ...
    '(?-i)\w{5}(?=CASE)'}, 'match');

M{:}
ans =
    'UPPER'    'lower'
ans =
    'UPPER'
```

# regexpi

---

---

Debug problems in parsing a string with `regexpi`, `regextpi`, or `regexprep`, use the '**warnings**' option to view all warning messages:

```
regexpi('$.', '[a-]', 'warnings')
Warning: Unbound range.
[a-]
|
```

| `strncmpi` | `strncmp`

## How To

- “Regular Expressions”

**Purpose** Replace string using regular expression

**Syntax** `s = regexprep('str', 'expr', 'repstr')`  
`s = regexprep('str', 'expr', 'repstr', options)`

**Description** `s = regexprep('str', 'expr', 'repstr')` replaces all occurrences of the regular expression `expr` in string `str` with the string `repstr`. The new string is returned in `s`. If no matches are found, return string `s` is the same as input string `str`. You can use character representations (e.g., `'\t'` for tab, or `'\n'` for newline) in replacement string `repstr`. See “Regular Expressions” in the MATLAB Programming Fundamentals documentation for more information.

If `str` is a cell array of strings, then the `regexprep` return value `s` is always a cell array of strings having the same dimensions as `str`.

To specify more than one expression to match or more than one replacement string, see the guidelines listed below under “Multiple Expressions or Replacement Strings” on page 2-3894.

You can capture parts of the input string as tokens and then reuse them in the replacement string. Specify the parts of the string to capture using the `(...)` operator. Specify the tokens to use in the replacement string using the operators `$1`, `$2`, `$N` to reference the first, second, and `N`th tokens captured. (See “Tokens” and the example “Using Tokens in a Replacement String” in the MATLAB Programming Fundamentals documentation for information on using tokens.)

`s = regexprep('str', 'expr', 'repstr', options)` By default, `regexprep` replaces all matches and is case sensitive. You can use one or more of the following options with `regexprep`.

| Option              | Description                                                                              |
|---------------------|------------------------------------------------------------------------------------------|
| <code>mode</code>   | See <code>mode</code> descriptions on the <code>regexp</code> reference page.            |
| <code>N</code>      | Replace only the <code>N</code> th occurrence of <code>expr</code> in <code>str</code> . |
| <code>'once'</code> | Replace only the first occurrence of <code>expr</code> in <code>str</code> .             |

| Option         | Description                                                                                                                                                     |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'ignorecase'   | Ignore case when matching and when replacing.                                                                                                                   |
| 'preserveCase' | Ignore case when matching (as with 'ignorecase'), but override the case of replace characters with the case of corresponding characters in str when replacing.  |
| 'warnings'     | Display any hidden warning messages issued by MATLAB during the execution of the command. This option only enables warnings for the one command being executed. |

## Tips

See “Regular Expressions” in the MATLAB Programming Fundamentals documentation for a listing of all regular expression metacharacters supported by MATLAB.

### Multiple Expressions or Replacement Strings

In the case of multiple expressions and/or replacement strings, `regexprep` attempts to make all matches and replacements. The first match is against the initial input string. Successive matches are against the string resulting from the previous replacement.

The `expr` and `repstr` inputs follow these rules:

- If `expr` is a cell array of strings and `repstr` is a single string, `regexprep` uses the same replacement string on each expression in `expr`.
- If `expr` is a single string and `repstr` is a cell array of N strings, `regexprep` attempts to make N matches and replacements.
- If both `expr` and `repstr` are cell arrays of strings, then `expr` and `repstr` must contain the same number of elements, and `regexprep` pairs each `repstr` element with its matching element in `expr`.

## Examples

### Example 1 – Making a Case-Sensitive Replacement

Perform a case-sensitive replacement on words starting with `m` and ending with `y`:

```
str = 'My flowers may bloom in May';
pat = 'm(\w*)y';
regexprep(str, pat, 'April')
```

```
ans =
    My flowers April bloom in May
```

Replace all words starting with `m` and ending with `y`, regardless of case, but maintain the original case in the replacement strings:

```
regexprep(str, pat, 'April', 'preserveCase')
```

```
ans =
    April flowers april bloom in April
```

### Example 2 – Using Tokens In the Replacement String

Replace all variations of the words 'walk up' using the letters following walk as a token. In the replacement string

```
str = 'I walk up, they walked up, we are walking up.';
pat = 'walk(\w*) up';
regexprep(str, pat, 'ascend$1')
```

```
ans =
    I ascend, they ascended, we are ascending.
```

### Example 3 – Operating on Multiple Strings

This example operates on a cell array of strings. It searches for consecutive matching letters (e.g., 'oo') and uses a common replacement value ('--') for all matches. The function returns a cell array of strings having the same dimensions as the input cell array:

```
str = {
    'Whose woods these are I think I know.' ; ...
```

```
'His house is in the village though;' ; ...
'He will not see me stopping here' ; ...
'To watch his woods fill up with snow.}';

a = regexprep(str, '(.)\1', '--', 'ignorecase')
```

```
a =
    'Whose w--ds these are I think I know.'
    'His house is in the vi--age though;'
    'He wi-- not s-- me sto--ing here'
    'To watch his w--ds fi-- up with snow.'
```

## Example 4 – Replacing Zero Length Matches

Request that `regexprep` replace text when the match is of zero length using the `emptymatch` flag.

```
regexprep('my_string', '^', 'BEGIN ', 'emptymatch')
```

```
ans =
    BEGIN my_string
```

MATLAB finds a zero length match for the `^` (beginning of string) operator just before the `my_string` input, and inserts the replacement characters `'BEGIN '` at that location.

## How To

- “Regular Expressions”

**Purpose** Translate string into regular expression

**Syntax** `s2 = regexptranslate(type, s1)`

**Description** `s2 = regexptranslate(type, s1)` translates string `s1` into a regular expression string `s2` that you can then use as input into one of the MATLAB regular expression functions such as `regexp`. The `type` input can be either one of the following strings that define the type of translation to be performed. See “Regular Expressions” in the MATLAB Programming Fundamentals documentation for more information.

| Type       | Description                                                                                                                                                                                                                                                                                                                                                                    |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'escape'   | Translate all special characters (e.g., '\$', '.', '?', '[') in string <code>s1</code> so that they are treated as literal characters when used in the <code>regexp</code> and <code>regexprep</code> functions. The translation inserts an escape character ('\') before each special character in <code>s1</code> . Return the new string in <code>s2</code> .               |
| 'wildcard' | Translate all wildcard and '.' characters in string <code>s1</code> so that they are treated as literal wildcards and periods when used in the <code>regexp</code> and <code>regexprep</code> functions. The translation replaces all instances of '*' with '.', all instances of '?' with '.', and all instances of '.' with '\.'. Return the new string in <code>s2</code> . |

## Examples

### Example 1 – Using the 'escape' Option

Because `regexp` interprets the sequence '\n' as a newline character, it cannot locate the two consecutive characters '\n' and '\n' in this string:

```
str = 'The sequence \n generates a new line';
pat = '\n';

regexp(str, pat)
ans =
     []
```

# regexptranslate

---

To have `regex` interpret the expression `expr` as the characters ``\`` and ``n``, first translate the expression using `regexptranslate`:

```
pat2 = regexptranslate('escape', pat)
pat2 =
    \\n

regex(str, pat2)
ans =
    14
```

## Example 2 – Using 'escape' In a Replacement String

Replace the word 'walk' with 'ascend' in this string, treating the characters '\$1' as a token designator:

```
str = 'I walk up, they walked up, we are walking up.';
pat = 'walk(\w*) up';

regexprep(str, pat, 'ascend$1')
ans =
    I ascend, they ascended, we are ascending.
```

Make another replacement on the same string, this time treating the '\$1' as literal characters:

```
regexprep(str, pat, regexptranslate('escape', 'ascend$1'))
ans =
    I ascend$1, they ascend$1, we are ascend$1.
```

## Example 3 – Using the 'wildcard' Option

Given the following string of filenames, pick out just the MAT-files. Use `regexptranslate` to interpret the '\*' wildcard as '\w+' instead of as a regular expression quantifier:

```
files = ['test1.mat, myfile.mat, newfile.txt, ' ...
        'jan30.mat, table3.xls'];
regex(str, regexptranslate('wildcard', '*.mat'), 'match')
ans =
```

```
'test1.mat' 'myfile.mat' 'jan30.mat'
```

To see the translation, you can type

```
regexptranslate('wildcard', '*.mat')
ans =
    \w+\.mat
```

## How To

- “Regular Expressions”

# registerevent

---

**Purpose** Associate event handler for COM object event at run time

**Syntax** `h.registerevent(eventhandler)`  
`registerevent(h, eventhandler)`

**Description** `h.registerevent(eventhandler)` registers event handler routines with their corresponding events. The `eventhandler` argument can be either a string that specifies the name of the event handler function, or a function handle that maps to that function. Strings used in the `eventhandler` argument are not case sensitive.

`registerevent(h, eventhandler)` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

**Examples** Show events in the MATLAB sample control:

```
f = figure ('position', [100 200 200 200]);  
h = actxcontrol ('mwsamp.mwsampctrl.2', [0 0 200 200], f);  
h.events
```

MATLAB displays all events associated with the instance of the control (output is formatted):

```
Click = void Click()  
DblClick = void DblClick()  
MouseDown = void MouseDown(int16 Button, int16 Shift,  
    Variant x, Variant y)  
Event_Args = void Event_Args(int16 typeshort,  
    int32 typelong, double typedouble, string typestring,  
    bool typebool)
```

---

Register all events with the same event handler routine, `sampev`:

```
h.registerevent('sampev');  
h.eventlisteners
```

MATLAB displays:

```
ans =  
    'Click'          'sampev'  
    'DblClick'      'sampev'  
    'MouseDown'     'sampev'  
    'Event_Args'    'sampev'
```

---

Register individual events:

```
%Unregister existing events  
h.unregisterallevents;  
%Register specific events  
h.registerevent({'click' 'myclick'; ...  
    'dblclick' 'my2click'});  
h.eventlisteners
```

MATLAB displays:

```
ans =  
    'click'          'myclick'  
    'dblclick'      'my2click'
```

---

Register events using a function handle (@sampev) instead of the function name:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200]);  
registerevent(h, @sampev);
```

## See Also

## How To

- “Writing Event Handlers”

# rehash

---

**Purpose** Refresh function and file system path caches

**Syntax**

```
rehash  
rehash path  
rehash toolbox  
rehash pathreset  
rehash toolboxreset  
rehash toolboxcache
```

**Description** `rehash` with no arguments updates the MATLAB list of known files and classes for directories on the search path that are not in `matlabroot/toolbox`. It compares the timestamps for loaded functions against their timestamps on disk. It clears loaded functions if the files on disk are newer. All of this normally happens each time MATLAB displays the Command Window prompt. Use `rehash` with no arguments only when you run a program file that updates another program file, and the calling file needs to reuse the updated version of the second file before the calling file has finished running.

`rehash path` performs the same updates as `rehash`, but uses a different technique for detecting the files and directories that require updates. Run `rehash path` only if you receive a warning during MATLAB startup notifying you that MATLAB could not tell if a directory has changed, and you encounter problems with MATLAB not using the most current versions of your program files.

`rehash toolbox` performs the same updates as `rehash path`, except it updates the list of known files and classes for *all* directories on the search path, including those in `matlabroot/toolbox`. Run `rehash toolbox` when you change, add, or remove files in `matlabroot/toolbox` during a session. Typically, you should not make changes to files and directories in `matlabroot/toolbox`.

`rehash pathreset` performs the same updates as `rehash path`, and also ensures the known files and classes list follows precedence rules for shadowed functions.

rehash **toolboxreset** performs the same updates as rehash **toolbox**, and also ensures the known files and classes list follows precedence rules for shadowed functions.

rehash **toolboxcache** performs the same updates as rehash **toolbox**, and also updates the cache file. This is the equivalent of clicking the **Update Toolbox Path Cache** button in the General Preferences dialog box.

## How To

- “Toolbox Path Caching in the MATLAB Program”
- “Using the MATLAB Search Path”

# release

---

**Purpose** Release COM interface

**Syntax** `h.release`  
`release(h)`

**Description** `h.release` releases the interface and all resources used by the interface. You must release the handle when you are done with the interface. A released interface is no longer valid. MATLAB generates an error if you try to use an object that represents that interface.

`release(h)` is an alternate syntax.

Releasing the interface does not delete the control itself (see the `delete` function), since other interfaces on that object might still be active.

COM functions are available on Microsoft Windows systems only.

**Examples** **1** Create an instance of a Microsoft Calendar control. Get a `TitleFont` interface and use it to change the appearance of the calendar title font:

```
f = figure('position',[300 300 500 500]);  
cal = actxcontrol('mscal.calendar', [0 0 500 500], f);
```

```
TFont = cal.TitleFont;  
TFont.Name = 'Viva BoldExtraExtended';  
TFont.Bold = 0;
```

**2** After working with the title font, release the `TitleFont` interface:

```
TFont.release;
```

**3** Delete the `cal` object and the figure window:

```
cal.delete;  
delete(f);  
clear f;
```

**See Also** `delete (COM)` | `actxcontrol` | `actxserver`

**How To**

- Releasing Interfaces

# relationaloperators (handle)

---

**Purpose** Equality and sorting of handle objects

**Syntax**

```
TF = eq(H1,H2)
TF = ne(H1,H2)
TF = lt(H1,H2)
TF = le(H1,H2)
TF = gt(H1,H2)
TF = ge(H1,H2)
```

**Description**

```
TF = eq(H1,H2)
TF = ne(H1,H2)
TF = lt(H1,H2)
TF = le(H1,H2)
TF = gt(H1,H2)
TF = ge(H1,H2)
```

For each pair of input arrays (H1 and H2), a logical array of the same size is returned in which each element is an element-wise equality or comparison test result. These methods perform scalar expansion in the same way as the MATLAB built-in functions. See [relationaloperators](#) for more information.

You can make the following assumptions about the result of a handle comparison:

- The same two handles always compare as equal and the repeated comparison of any two handles always yields the same result in the same MATLAB session.
- Different handles are always not-equal.
- The order of handle values is purely arbitrary and has no connection to the state of the handle objects being compared.
- If the input arrays belong to different classes (including the case where one input array belongs to a non-handle class such as `double`) then the comparison is always false.

- If a comparison is made between a handle object and an object of a dominant class, the method of the dominant class is invoked. You should generally test only like objects because a dominant class might not define one of these methods.
- An error occurs if the input arrays are not the same size and neither is scalar.

Use `isequal` when you want to determine if handle objects with different handles have the same data in all object properties.

### See Also

`handle` | `meta.class`

# rem

---

**Purpose**            Remainder after division

**Syntax**             $R = \text{rem}(X, Y)$

**Description**         $R = \text{rem}(X, Y)$  if  $Y \neq 0$ , returns  $X - n \cdot Y$  where  $n = \text{fix}(X./Y)$ . If  $Y$  is not an integer and the quotient  $X./Y$  is within roundoff error of an integer, then  $n$  is that integer. The inputs  $X$  and  $Y$  must be real arrays of the same size, or real scalars.

The following are true by convention:

- $\text{rem}(X, 0)$  is NaN
- $\text{rem}(X, X)$  for  $X \neq 0$  is 0
- $\text{rem}(X, Y)$  for  $X \neq Y$  and  $Y \neq 0$  has the same sign as  $X$ .

**Tips**                 $\text{mod}(X, Y)$  for  $X \neq Y$  and  $Y \neq 0$  has the same sign as  $Y$ .

$\text{rem}(X, Y)$  and  $\text{mod}(X, Y)$  are equal if  $X$  and  $Y$  have the same sign, but differ by  $Y$  if  $X$  and  $Y$  have different signs.

The `rem` function returns a result that is between 0 and  $\text{sign}(X) \cdot \text{abs}(Y)$ . If  $Y$  is zero, `rem` returns NaN.

**See Also**            `mod`

|                        |                                                                                                                                                                                                       |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>         | Remove key-value pairs from containers.Map object                                                                                                                                                     |
| <b>Syntax</b>          | <code>remove(mapObj, keySet)</code>                                                                                                                                                                   |
| <b>Description</b>     | <code>remove(mapObj, keySet)</code> erases all specified keys, and the values associated with them, from <code>mapObj</code> . Input <code>keySet</code> can be a scalar key or a cell array of keys. |
| <b>Input Arguments</b> | <p><b>mapObj</b><br/>Object of class <code>containers.Map</code>.</p> <p><b>keySet</b><br/>Scalar value, string, or cell array that specifies keys in <code>mapObj</code> to delete.</p>              |

## Examples

### Remove Key-Value Pairs from a Map

Create a map and view the keys and the Count property:

```
myKeys = {'a','b','c','d'};  
myValues = [1,2,3,4];  
mapObj = containers.Map(myKeys,myValues);
```

```
mapKeys = keys(mapObj)  
mapCount = mapObj.Count
```

The initial map contains four key-value pairs:

```
mapKeys =  
    'a'    'b'    'c'    'd'  
  
mapCount =  
         4
```

Remove the pairs corresponding to keys b and d:

```
keySet = {'b','d'};
```

## containers.Map.remove

---

```
remove(mapObj, keySet)

mapKeys = keys(mapObj)
mapCount = mapObj.Count
```

The modified map contains two key-value pairs:

```
mapKeys =
    'a'    'c'
```

```
mapCount =
                2
```

### See Also

[containers.Map](#) | [keys](#) | [values](#) | [isKey](#)

**Purpose** Remove timeseries objects from tscollection object

**Syntax** `tsc = removets(tsc,Name)`

**Description** `tsc = removets(tsc,Name)` removes one or more timeseries objects with the name specified in `Name` from the `tscollection` object `tsc`. `Name` can either be a string or a cell array of strings.

**Examples** The following example shows how to remove a time series from a `tscollection`.

**1** Create two timeseries objects, `ts1` and `ts2`.

```
ts1=timeseries([1.1 2.9 3.7 4.0 3.0],1:5,'name','acceleration');  
ts2=timeseries([3.2 4.2 6.2 8.5 1.1],1:5,'name','speed');
```

**2** Create a `tscollection` object `tsc`, which includes `ts1` and `ts2`.

```
tsc=tscollection({ts1 ts2});
```

**3** To view the members of `tsc`, type the following at the MATLAB prompt:

```
tsc
```

The response is

```
Time Series Collection Object: unnamed
```

```
Time vector characteristics
```

```
Start time          1 seconds  
End time            5 seconds
```

```
Member Time Series Objects:
```

# removets

---

```
acceleration
speed
```

The members of `tsc` are listed by name at the bottom: `acceleration` and `speed`. These are the `Name` properties of `ts1` and `ts2`, respectively.

- 4 Remove `ts2` from `tsc`.

```
tsc=removets(tsc,'speed');
```

- 5 To view the current members of `tsc`, type the following at the MATLAB prompt:

```
tsc
```

The response is

```
Time Series Collection Object: unnamed
```

```
Time vector characteristics
```

```
Start time      1 seconds
End time        5 seconds
```

```
Member Time Series Objects:
acceleration
```

The remaining member of `tsc` is `acceleration`. The timeseries `speed` has been removed.

## See Also

[addts](#) | [tscollection](#)

**Purpose** Rename file on FTP server

**Syntax** `rename(ftpobj,oldname,newname)`

**Description** `rename(ftpobj,oldname,newname)` changes the name of the file `oldname` to `newname` in the current folder on an FTP server.

**Input Arguments** **ftpobj**  
FTP object created by `ftp`.

**oldname**  
String enclosed in single quotation marks that specifies the original name of the file.

**newname**  
String enclosed in single quotation marks that specifies a new name for the file.

**Examples** Suppose that hypothetical FTP server `ftp.testsite.com` contains a file named `testfile.m`. Rename the file to `final.m`:

```
test = ftp('ftp.testsite.com');
rename(test, 'testfile.m', 'final.m');
close(test);
```

**See Also** `delete` | `dir` | `ftp` | `mget` | `mput`

# repmat

---

**Purpose** Replicate and tile array

**Syntax**  
B = repmat(A,m,n)  
B = repmat(A,[m n])  
B = repmat(A,[m n p...])

**Description** B = repmat(A,m,n) creates a large matrix B consisting of an m-by-n tiling of copies of A. The size of B is [size(A,1)\*m, (size(A,2)\*n)]. The statement repmat(A,n) creates an n-by-n tiling.

B = repmat(A,[m n]) accomplishes the same result as repmat(A,m,n).

B = repmat(A,[m n p...]) produces a multidimensional array B composed of copies of A. The size of B is [size(A,1)\*m, size(A,2)\*n, size(A,3)\*p, ...].

**Tips** repmat(A,m,n), when A is a scalar, produces an m-by-n matrix filled with A's value and having A's class. For certain values, you can achieve the same results using other functions, as shown by the following examples:

- repmat(NaN,m,n) returns the same result as NaN(m,n).
- repmat(single(inf),m,n) is the same as inf(m,n,'single').
- repmat(int8(0),m,n) is the same as zeros(m,n,'int8').
- repmat(uint32(1),m,n) is the same as ones(m,n,'uint32').
- repmat(eps,m,n) is the same as eps(ones(m,n)).

## Examples

### Example 1

In this example, repmat replicates 12 copies of the second-order identity matrix, resulting in a “checkerboard” pattern.

```
B = repmat(eye(2),3,4)
```

```
B =  
    1     0     1     0     1     0     1     0  
    0     1     0     1     0     1     0     1  
    1     0     1     0     1     0     1     0
```

```
0    1    0    1    0    1    0    1
1    0    1    0    1    0    1    0
0    1    0    1    0    1    0    1
```

The statement `N = repmat(NaN,[2 3])` creates a 2-by-3 matrix of NaNs.

### Example 2

If you have code that uses `repmat` and also a binary operator or function, you can transform the code to use the `bsxfun` function instead. In certain cases, this can provide a simpler and faster solution.

This example replaces the sum of two `repmat` operations with a single call to `bsxfun`:

```
x = 1:5; y = (1:10)';

% Replace this code
repmat(x,10,1) + repmat(y,1,5)

% with the following:
bsxfun(@plus, x, y)
```

### See Also

[reshape](#) | [bsxfun](#) | [NaN](#) | [Inf](#) | [ones](#) | [zeros](#)

# resample (tscollection)

---

**Purpose** Select or interpolate data in `tscollection` using new time vector

**Syntax**

```
tsc = resample(tsc,Time)
tsc = resample(tsc,Time,interp_method)
tsc = resample(tsc,Time,interp_method,code)
```

**Description** `tsc = resample(tsc,Time)` resamples the `tscollection` object `tsc` on the new `Time` vector. When `tsc` uses date strings and `Time` is numeric, `Time` is treated as numerical specified relative to the `tsc.TimeInfo.StartDate` property and in the same units that `tsc` uses. The `resample` method uses the default interpolation method for each time series member.

`tsc = resample(tsc,Time,interp_method)` resamples the `tscollection` object `tsc` using the interpolation method given by the string `interp_method`. Valid interpolation methods include 'linear' and 'zoh' (zero-order hold).

`tsc = resample(tsc,Time,interp_method,code)` resamples the `tscollection` object `tsc` using the interpolation method given by the string `interp_method`. The integer `code` is a user-defined quality code for resampling, applied to all samples.

**Examples** The following example shows how to resample a `tscollection` that consists of two `timeseries` members.

**1** Create two `timeseries` objects.

```
ts1=timeseries([1.1 2.9 3.7 4.0 3.0],1:5,'name','acceleration');
ts2=timeseries([3.2 4.2 6.2 8.5 1.1],1:5,'name','speed');
```

**2** Create a `tscollection` `tsc`.

```
tsc=tscollection({ts1 ts2});
```

The time vector of the collection `tsc` is `[1:5]`, which is the same as for `ts1` and `ts2` (individually).

- 3** Get the interpolation method for acceleration by typing

```
tsc.acceleration
```

MATLAB responds with

```
Time Series Object: acceleration
```

```
Time vector characteristics
```

```
Length           5
Start time       1 seconds
End time         5 seconds
```

```
Data characteristics
```

res_tsc=resample(tsc,[1 1.5 3.5 4.5 4.9])
```

## See Also

`getinterpmethod` | `setinterpmethod` | `tscollection`

**Purpose** Reset graphics object properties to their defaults

**Syntax** `reset(h)`

**Description** `reset(h)` resets all properties having factory defaults on the object identified by `h`. To see the list of factory defaults, use the statement

```
get(0, 'factory')
```

If `h` is a figure, the MATLAB software does not reset `Position`, `Units`, `WindowStyle`, or `PaperUnits`. If `h` is an axes, MATLAB does not reset `Position` and `Units`.

**Examples** `reset(gca)` resets the properties of the current axes.  
`reset(gcf)` resets the properties of the current figure.

**See Also** `cla` | `clf` | `gca` | `gcf` | `hold`

# reset (RandStream)

---

**Purpose** Reset random number stream

**Class** RandStream

**Syntax**  
`reset(s)`  
`reset(s,seed)`

**Description** `reset(s)` resets the generator for the random stream, `s`, to the internal state corresponding to its seed. This is similar to clearing `s` and recreating it using `RandStream(Type,...)`, except that `reset` does not set the stream's `NormalTransform`, `Antithetic`, and `FullPrecision` properties to their original values.

`reset(s,seed)` resets the generator for the random stream, `s`, to the internal state corresponding to `seed` (the seed value), and it updates the `seed` property of `s`. The value of `seed` must be an integer between 0 and  $2^{32} - 1$ . Resetting a stream's seed can invalidate independence with other streams.

---

**Note** Resetting a stream should be used primarily for reproducing results.

---

## Examples

### Example 1

Reset a random number stream to its initial state. This does not create a random number stream, it simply resets the stream:

```
stream = RandStream('twister','Seed',0)
```

```
stream =
```

```
mt19937ar random stream  
      Seed: 0  
NormalTransform: Ziggurat
```

```
reset(stream);  
stream.Seed
```

```
ans =
```

```
0
```

### Example 2

Reset a random number stream using a specific seed:

```
stream = RandStream('twister','Seed',0)
```

```
stream =
```

```
mt19937ar random stream  
Seed: 0  
NormalTransform: Ziggurat
```

```
reset(stream,1);  
stream.Seed
```

```
ans =
```

```
1
```

# reshape

---

## Purpose

Reshape array

## Syntax

```
B = reshape(A,m,n)
B = reshape(A,m,n,p,...)
B = reshape(A,[m n p ...])
B = reshape(A,...,[ ],...)
B = reshape(A,siz)
```

## Description

`B = reshape(A,m,n)` returns the  $m$ -by- $n$  matrix `B` whose elements are taken column-wise from `A`. An error results if `A` does not have  $m*n$  elements.

`B = reshape(A,m,n,p,...)` or `B = reshape(A,[m n p ...])` returns an  $n$ -dimensional array with the same elements as `A` but reshaped to have the size  $m$ -by- $n$ -by- $p$ -by-... The product of the specified dimensions,  $m*n*p*...$ , must be the same as `prod(size(A))`.

`B = reshape(A,...,[ ],...)` calculates the length of the dimension represented by the placeholder `[ ]`, such that the product of the dimensions equals `prod(size(A))`. The value of `prod(size(A))` must be evenly divisible by the product of the specified dimensions. You can use only one occurrence of `[ ]`.

`B = reshape(A,siz)` returns an  $n$ -dimensional array with the same elements as `A`, but reshaped to `siz`, a vector representing the dimensions of the reshaped array. The quantity `prod(siz)` must be the same as `prod(size(A))`.

## Examples

Reshape a 3-by-4 matrix into a 2-by-6 matrix.

```
A =
    1     4     7    10
    2     5     8    11
    3     6     9    12
```

```
B = reshape(A,2,6)
```

```
B =
```

```
    1    3    5    7    9   11
    2    4    6    8   10   12
B = reshape(A,2,[])
```

```
B =
    1    3    5    7    9   11
    2    4    6    8   10   12
```

# residue

---

**Purpose** Convert between partial fraction expansion and polynomial coefficients

**Syntax**  $[r,p,k] = \text{residue}(b,a)$   
 $[b,a] = \text{residue}(r,p,k)$

**Description** The residue function converts a quotient of polynomials to pole-residue representation, and back again.

$[r,p,k] = \text{residue}(b,a)$  finds the residues, poles, and direct term of a partial fraction expansion of the ratio of two polynomials,  $b(s)$  and  $a(s)$ , of the form

$$\frac{b(s)}{a(s)} = \frac{b_1s^m + b_2s^{m-1} + b_3s^{m-2} + \dots + b_{m+1}}{a_1s^n + a_2s^{n-1} + a_3s^{n-2} + \dots + a_{n+1}}$$

where  $b_j$  and  $a_j$  are the  $j$ th elements of the input vectors  $b$  and  $a$ .

$[b,a] = \text{residue}(r,p,k)$  converts the partial fraction expansion back to the polynomials with coefficients in  $b$  and  $a$ .

**Definitions** If there are no multiple roots, then

$$\frac{b(s)}{a(s)} = \frac{r_1}{s-p_1} + \frac{r_2}{s-p_2} + \dots + \frac{r_n}{s-p_n} + k(s)$$

The number of poles  $n$  is

$$n = \text{length}(a) - 1 = \text{length}(r) = \text{length}(p)$$

The direct term coefficient vector is empty if  $\text{length}(b) < \text{length}(a)$ ; otherwise

$$\text{length}(k) = \text{length}(b) - \text{length}(a) + 1$$

If  $p(j) = \dots = p(j+m-1)$  is a pole of multiplicity  $m$ , then the expansion includes terms of the form

$$\frac{r_j}{s-p_j} + \frac{r_j+1}{(s-p_j)^2} + \dots + \frac{r_j+m-1}{(s-p_j)^m}$$

## Arguments

|      |                                                                                      |
|------|--------------------------------------------------------------------------------------|
| b, a | Vectors that specify the coefficients of the polynomials in descending powers of $s$ |
| r    | Column vector of residues                                                            |
| p    | Column vector of poles                                                               |
| k    | Row vector of direct terms                                                           |

## Algorithms

It first obtains the poles with `roots`. Next, if the fraction is nonproper, the direct term `k` is found using `deconv`, which performs polynomial long division. Finally, the residues are determined by evaluating the polynomial with individual roots removed. For repeated roots, `resi2` computes the residues at the repeated root locations.

## Limitations

Numerically, the partial fraction expansion of a ratio of polynomials represents an ill-posed problem. If the denominator polynomial,  $a(s)$ , is near a polynomial with multiple roots, then small changes in the data, including roundoff errors, can make arbitrarily large changes in the resulting poles and residues. Problem formulations making use of state-space or zero-pole representations are preferable.

## Examples

If the ratio of two polynomials is expressed as

$$\frac{b(s)}{a(s)} = \frac{5s^3 + 3s^2 - 2s + 7}{-4s^3 + 8s + 3}$$

then

$$\begin{aligned} \mathbf{b} &= [ 5 \ 3 \ -2 \ 7 ] \\ \mathbf{a} &= [ -4 \ 0 \ 8 \ 3 ] \end{aligned}$$

and you can calculate the partial fraction expansion as

# residue

---

```
[r, p, k] = residue(b,a)
```

```
r =  
  -1.4167  
  -0.6653  
   1.3320
```

```
p =  
   1.5737  
  -1.1644  
  -0.4093
```

```
k =  
  -1.2500
```

Now, convert the partial fraction expansion back to polynomial coefficients.

```
[b,a] = residue(r,p,k)
```

```
b =  
  -1.2500   -0.7500   0.5000  -1.7500
```

```
a =  
   1.0000  -0.0000  -2.0000  -0.7500
```

The result can be expressed as

$$\frac{b(s)}{a(s)} = \frac{1.25s^3 - 0.75s^2 + 0.50s - 1.75}{s^3 - 2.00s - 0.75}.$$

Note that the result is normalized for the leading coefficient in the denominator.

# restoredefaultpath

---

**Purpose** Restore default search path

**Alternatives** As an alternative to the `restoredefaultpath` function, use the Set Path dialog box.

**Syntax**  
`restoredefaultpath`  
`restoredefaultpath; matlabrc`

**Description** `restoredefaultpath` sets the search path to include only folders for MathWorks installed products. Use `restoredefaultpath` when you are having problems with the search path.

`restoredefaultpath; matlabrc` sets the search path to include only folders for MathWorks installed products and corrects search path problems encountered during startup.

MATLAB does not support issuing `restoredefaultpath` from a UNC path name. Doing so might result in MATLAB being unable to find files on the search path. If you do issue `restoredefaultpath` from a UNC path name, restore the expected behavior by changing the current folder to an absolute path, and then reissuing `restoredefaultpath`.

**See Also** `addpath` | `genpath` | `matlabrc` | `rmpath` | `savepath`

**How To**

- “Recovering from Problems with the Search Path”
- “Using the MATLAB Search Path”

**Purpose** Reissue error

---

**Note** As of version 7.5, MATLAB supports error handling that is based on the `MException` class. Calling `rethrow` with a structure argument, as described on this page, is now replaced by calling `rethrow` with an `MException` object, as described on the reference page for `rethrow(MException)`. `rethrow` called with a structure input will be removed in a future version.

---

**Syntax** `rethrow(errorStruct)`

**Description** `rethrow(errorStruct)` reissues the error specified by `errorStruct`. The currently running function terminates and control returns to the keyboard (or to any enclosing catch block). The `errorStruct` argument must be a MATLAB structure containing at least the message and identifier fields:

| Fieldname               | Description                                        |
|-------------------------|----------------------------------------------------|
| <code>message</code>    | Text of the error message                          |
| <code>identifier</code> | Message identifier of the error message            |
| <code>stack</code>      | Information about the error from the program stack |

See "Message Identifiers" in the MATLAB documentation for more information on the syntax and usage of message identifiers.

**Tips** The `errorStruct` input can contain the field `stack`, identical in format to the output of the `dbstack` command. If the `stack` field is present, the stack of the rethrown error will be set to that value. Otherwise, the stack will be set to the line at which the `rethrow` occurs.

# rethrow

---

## Examples

rethrow is usually used in conjunction with try-catch statements to reissue an error from a catch block after performing catch-related operations. For example,

```
try
  do_something
catch
  do_cleanup
  rethrow(previous_error)
end
```

## See Also

rethrow(MException) | throw(MException) |  
throwAsCaller(MException) | try | catch | error | assert | dbstop

**Purpose** Reissue existing exception

**Syntax** `rethrow(exception)`

**Description** `rethrow(exception)` forces an exception (i.e., error report) to be reissued by MATLAB after the error reporting process has been temporarily suspended to diagnose or remedy the problem. MATLAB typically responds to errors by terminating the currently running program. Errors occurring within a try block, however, bypass this mechanism and transfer control of the program to error handling code in the catch block instead. This enables you to write your own error handling procedures for parts of your program that require them.

The *exception* input is a scalar object of the MException class that contains information about the cause and location of the error.

The code segment below shows the format of a typical try/catch statement.

|                     |             |
|---------------------|-------------|
| try                 | try block   |
| program-code        |             |
| program-code        |             |
| :                   | V           |
| catch exception     | catch block |
| error-handling code |             |
| :                   |             |
| rethrow(exception)  | V           |
| end                 |             |

An error detected within the try block causes MATLAB to enter the corresponding catch block. The error record constructed by MATLAB in the process of reporting this error passes to the catch command in the statement

```
catch exception
```

Error handling code within the catch block uses the information in the error record to address the problem in some predefined manner. The

## rethrow (MException)

---

catch block shown here ends with a `rethrow` statement which throws the exception returned in the catch statement, and then terminates the function:

```
rethrow(exception)
```

The most significant difference between `rethrow` and other MATLAB functions that throw exceptions is in how `rethrow` handles a piece of the exception record called the *stack*. The stack keeps a record of where the error occurred and what functions were called in the process. It is a struct array composed of the following fields, where each element of the array represents an exception:

| Fields of the Exception Stack | Description                                      |
|-------------------------------|--------------------------------------------------|
| <code>line</code>             | Line number from which the exception was thrown. |
| <code>name</code>             | Name of the function being executed at the time. |
| <code>file</code>             | Name of the file containing that function.       |

Functions such as `error`, `assert`, or `throw`, create the stack with the location from which they were executed. Calling `rethrow`, however, preserves information from the original exception. In doing so, `rethrow` enables you to retrace the path taken to the source of the error.

### Tips

There are four ways to throw an exception in MATLAB (see the list below). Use the first of these when testing the outcome of some action for failure and reporting the failure to MATLAB. Use one of the remaining techniques to throw an existing exception.

- Test the result of some action taken by your program. If the result is found to be incorrect or unexpected, compose an appropriate message and message identifier, and pass these to MATLAB using the `error` function.

- Reissue the original exception by throwing the initial error record unmodified. Use the `MException rethrow` method to do this.
- Collect additional information on the cause of the error, store it in a new or modified error record, and issue a new exception based on that record. Use the `MException addCause` and `throw` methods to do this.
- Make it appear that the error originated in the caller of the currently running function. Use the `MException throwAsCaller` method to do this.

`rethrow` can only issue a previously caught exception. Calling `rethrow` on an exception that was not previously thrown is an error.

### Examples

This example shows the difference between using `throw` and `rethrow` at the end of a catch block. The `combineArrays` function vertically concatenates arrays A and B. When the two arrays have rows of unequal length, the function throws an error.

The first time you run the function, comment out the `rethrow` command at the end of the catch block so that the function calls `throw` instead:

```
function C = combineArrays(A, B)
try
    catAlongDim1(A, B);           % Line 3
catch exception
    throw(exception)            % Line 5
    % rethrow(exception)        % Line 6
end

function catAlongDim1(V1, V2)
    C = cat(1, V1, V2);          % Line 10
```

When MATLAB throws the exception, it reports an error on line 5 which is the line that calls `throw`. In some cases, that might be what you want but, in this case, it does not show the true source of the error.

```
A = 4:3:19;    B = 3:4:19;
combineArrays(A, B)
```

## rethrow (MException)

---

```
Error using combineArrays (line 5)
CAT arguments dimensions are not consistent.
```

Make the following changes to `combineArrays.m` so that you use `rethrow` instead:

```
% throw(exception)           % Line 5
rethrow(exception)          % Line 6
```

Run the function again. This time, line 10 is the first line reported which is where the MATLAB concatenation function `cat` was called and the exception originated. The next error reported is on line 3 which is where the call to `catAlongDim1` was called:

```
combineArrays(A, B)
```

```
Error using cat
CAT arguments dimensions are not consistent.
```

```
Error in combineArrays>catAlongDim1 (line 10)
    C = cat(1, V1, V2);           % Line 10
Error in combineArrays (line 3)
    catAlongDim1(A, B);          % Line 3
```

```

**Purpose** Return to invoking function

**Syntax** return

**Description** return causes a normal return to the invoking function or to the keyboard. It also terminates keyboard mode.

**Examples** This determinant function uses return to handle the special case of an empty matrix:

```
function d = det(A)
%DET det(A) is the determinant of A.
if isempty(A)
    d = 1;
    return
else
    ...
end
```

**See Also** break | continue | disp | end | error | for | if | keyboard | switch | while

# Tiff.rewriteDirectory

---

**Purpose** Write modified metadata to existing IFD

**Syntax** `tiffobj.rewriteDirectory()`

**Description** `tiffobj.rewriteDirectory()` writes modified metadata (tag) data to an existing directory. Use this tag when you want to change the value of a tag in an existing image file directory.

**Examples** Open a Tiff object for modification and modify the value of a tag. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path.

```
t = Tiff('myfile.tif', 'r');
% Modify the value of a tag.
t.setTag('Software', 'MATLAB');
t.rewriteDirectory();
```

## References

This method corresponds to the `TIFFRewriteDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**See Also** `Tiff.writeDirectory`

**Tutorials**

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

**Purpose** Convert RGB colormap to HSV colormap

**Syntax**

```
cmap = rgb2hsv(M)  
hsv_image = rgb2hsv(rgb_image)
```

**Description** `cmap = rgb2hsv(M)` converts an RGB colormap `M` to an HSV colormap `cmap`. Both colormaps are  $m$ -by-3 matrices. The elements of both colormaps are in the range 0 to 1.

The columns of the input matrix `M` represent intensities of red, green, and blue, respectively. The columns of the output matrix `cmap` represent hue, saturation, and value, respectively.

`hsv_image = rgb2hsv(rgb_image)` converts the RGB image to the equivalent HSV image. RGB is an  $m$ -by- $n$ -by-3 image array whose three planes contain the red, green, and blue components for the image. HSV is returned as an  $m$ -by- $n$ -by-3 image array whose three planes contain the hue, saturation, and value components for the image.

**See Also** `brighten` | `colormap` | `hsv2rgb` | `rgbplot`

# rgb2ind

---

**Purpose** Convert RGB image to indexed image

**Syntax**

```
[X,map] = rgb2ind(RGB, n)
X = rgb2ind(RGB, map)
[X,map] = rgb2ind(RGB, tol)
[...] = rgb2ind(..., dither_option)
```

**Description** `rgb2ind` converts RGB images to indexed images using one of these methods:

- Uniform quantization
- Minimum variance quantization
- Colormap approximation

For all these methods, `rgb2ind` also dithers the image unless you specify 'nodither' for `dither_option`.

`[X,map] = rgb2ind(RGB, n)` converts the RGB image to an indexed image `X` using minimum variance quantization. `map` contains at most `n` colors. `n` must be less than or equal to 65,536.

`X = rgb2ind(RGB, map)` converts the RGB image to an indexed image `X` with colormap `map` by matching colors in `RGB` with the nearest color in the colormap `map`. `size(map,1)` must be less than or equal to 65,536.

`[X,map] = rgb2ind(RGB, tol)` converts the RGB image to an indexed image `X` using uniform quantization. `map` contains at most  $(\text{floor}(1/\text{tol})+1)^3$  colors. `tol` must be between 0.0 and 1.0.

`[...] = rgb2ind(..., dither_option)` enables or disables dithering. `dither_option` is a string that can have one of these values.

|                    |                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------|
| 'dither' (default) | dithers, if necessary, to achieve better color resolution at the expense of spatial resolution.       |
| 'nodither'         | maps each color in the original image to the closest color in the new map. No dithering is performed. |

**Note** The values in the resultant image  $X$  are indexes into the colormap map and cannot be used in mathematical processing, such as filtering operations.

## Class Support

The input image can be of class `uint8`, `uint16`, `single`, or `double`. If the length of `map` is less than or equal to 256, the output image is of class `uint8`. Otherwise, the output image is of class `uint16`.

## Tips

If you specify `tol`, `rgb2ind` uses uniform quantization to convert the image. This method involves cutting the RGB color cube into smaller cubes of length `tol`. For example, if you specify a `tol` of 0.1, the edges of the cubes are one-tenth the length of the RGB cube. The total number of small cubes is:

$$n = (\text{floor}(1/\text{tol})+1)^3$$

Each cube represents a single color in the output image. Therefore, the maximum length of the colormap is `n`. `rgb2ind` removes any colors that don't appear in the input image, so the actual colormap can be much smaller than `n`.

If you specify `n`, `rgb2ind` uses minimum variance quantization. This method involves cutting the RGB color cube into smaller boxes (not necessarily cubes) of different sizes, depending on how the colors are distributed in the image. If the input image actually uses fewer colors than the number you specify, the output colormap is also smaller.

# rgb2ind

---

If you specify `map`, `rgb2ind` uses colormap mapping, which involves finding the colors in `map` that best match the colors in the RGB image.

## Examples

Read and display a truecolor uint8 PNG image of the MathWorks logo. Zoom in to see color variation better.

```
imfile = fullfile(matlabroot,...  
                  'toolbox','matlab','demos','html','logodemo_01.png');  
RGB = imread(imfile,'PNG');  
figure('Name','RGB Truecolor Image')  
imagesc(RGB)  
axis image  
zoom(4)
```

```
% Convert RGB to an indexed image with 32 colors
[IND,map] = rgb2ind(RGB,32);
figure('Name','Indexed image with 32 Colors')
imagesc(IND)
colormap(map)
axis image
zoom(4)
```

# rgb2ind

`rgbplot(cmap)`

## Description

`rgbplot(cmap)` plots the three columns of `cmap`, where `cmap` is an  $m$ -by-3 colormap matrix. `rgbplot` draws the first column in red, the second in green, and the third in blue.

## Examples

Plot the RGB values of the copper colormap.

```
rgbplot(copper)
```

# rgbplot

---

## See Also

`colormap`

## Purpose

Ribbon plot

## Syntax

```
ribbon(Y)
ribbon(X,Y)
ribbon(X,Y,width)
ribbon(axes_handle,...)
h = ribbon(...)
```

## Description

`ribbon(Y)` plots the columns of `Y` as three-dimensional ribbons of uniform width using `X = 1:size(Y,1)`. Ribbons advance along the  $x$ -axis centered on tick marks at unit intervals, three-quarters of a unit in width. Ribbon maps values in `X` to colors in `colormap` linearly. To change ribbon colors in the graph, change the `colormap`.

`ribbon(X,Y)` plots three dimensional ribbons for data in `Y`, centered at locations specified in `X`. `X` and `Y` are vectors or matrices of the same size. Additionally, `X` can be a row or a column vector, and `Y` a matrix with `length(X)` rows. When `Y` is a matrix, `ribbon` plots each column in `Y` as a ribbon at the corresponding `X` location.

`ribbon(X,Y,width)` specifies the width of the ribbons. The default is 0.75. If `width = 1`, the ribbons touch, leaving no space between them when viewed down the  $z$ -axis. If `width > 1`, ribbons overlap and can intersect.

`ribbon(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ribbon(...)` returns a vector of handles to surface graphics objects. `ribbon` returns one handle per strip.

## Examples

Create a ribbon plot of the peaks function.

```
[x,y] = meshgrid(-3:.5:3,-3:.1:3);
z = peaks(x,y);
```

# ribbon

---

```
ribbon(y,z)
xlabel('X')
ylabel('Y')
zlabel('Z')
colormap hsv
```

**Purpose** Remove application-defined data

**Syntax** `rmappdata(h,name)`

**Description** `rmappdata(h,name)` removes the application-defined data name from the object specified by handle h.

**Tips** Application data is data that is meaningful to or defined by your application which you attach to a figure or any GUI component (other than ActiveX controls) through its `AppData` property. Only Handle Graphics MATLAB objects use this property.

**See Also** `getappdata` | `isappdata` | `setappdata`

# rmdir

---

## Purpose

Remove folder

## Syntax

```
rmdir(folderName)
rmdir(folderName,'s')
[status, message, messageid] = rmdir(folderName,'s')
```

## Description

`rmdir(folderName)` removes the folder `folderName` from the current folder if `folderName` is empty. If `folderName` is not in the current folder, then specify the relative path or the full path for `folderName`.

`rmdir(folderName,'s')` removes the folder `folderName` and its contents from the current folder. With the 's' option, `rmdir` attempts to remove all subfolders and files in `folderName` regardless of their write permissions.

`[status, message, messageid] = rmdir(folderName,'s')` removes the folder `folderName` and its contents from the current folder, returning the status, a message, and the MATLAB message ID.

## Tips

- If you specify the 's' flag or include a wildcard in the folder name, MATLAB produces an error if it is unable to remove all folders. The error message lists the folder and files that MATLAB could not remove.

## Input Arguments

### **folderName**

String specifying the absolute or relative path name of the folder you want to remove.

**Default:** None

### **'s'**

Literal string that directs `rmdir` to remove all subfolders and files in the specified folder, regardless of their write permissions. The result for read-only files follows the practices of the operating system.

**Default:** `rmdir` does not remove subfolders and files in the specified folder.

## Output Arguments

### **status**

Logical scalar indicating the outcome of the `rmdir` operation. The status value is 1 if the operation was successful and 0 if it returned an error.

### **message**

String containing the warning or error message text if the operation is unsuccessful. An empty string, if the operation is successful.

### **messageid**

String containing the warning or error message ID, if the operation is unsuccessful. MATLAB returns an empty string if the operation is successful.

## Examples

These examples remove an empty folder, `myfiles`, assuming it is in the current folder:

```
% Remove myfiles from the current folder:
```

```
rmdir('myfiles')
```

```
% Use the relative path to remove myfiles. Assuming  
% the current folder is matlab/work and myfiles is in  
% d:/matlab/work/project, type this:
```

```
rmdir('project/myfiles')
```

```
% Use the full path to remove myfiles, assuming  
% the current folder is matlab/work and myfiles is in  
% d:/matlab/work/project:
```

```
rmdir('d:/matlab/work/project/myfiles')
```

---

This example removes the `myfiles` folder and its contents, assuming `myfiles` is in the current folder:

```
rmdir('myfiles','s')
```

---

This example unsuccessfully attempts to remove the `myfiles` folder and its contents. It directs MATLAB to display the results.

```
[stat, mess, id]=rmdir('myfiles')
```

MATLAB returns:

```
stat =  
      0
```

```
mess =
```

```
No directories were removed.
```

```
id =
```

```
MATLAB:RMDIR:NoDirectoriesRemoved
```

---

This example successfully removes the `myfiles` folder and its contents. It directs MATLAB to display the results.

```
[stat, mess]=rmdir('myfiles','s')
```

MATLAB returns:

```
stat =  
      1
```

```
mess =
```

..

**Alternatives** Open the Current Folder browser by running `filebrowser`. Then, in the Current Folder browser, right-click the folder name and select **Delete** from the context menu.

# FTP.rmdir

---

**Purpose** Remove folder on FTP server

**Syntax** `rmdir(ftpobj, folder)`

**Description** `rmdir(ftpobj, folder)` removes the specified folder from the current folder on an FTP server.

**Input Arguments**

**ftpobj**

FTP object created by `ftp`.

**folder**

String enclosed in single quotation marks that specifies the name of the folder to delete.

**Examples**

Remove the folder `temp` from the hypothetical FTP server `ftp.testsite.com`:

```
test = ftp('ftp.testsite.com');  
rmdir(test, 'temp');
```

**See Also**

`cd` | `delete` | `dir` | `ftp` | `mkdir`

**Purpose** Remove fields from structure

**Syntax** `s = rmfield(s, 'fieldname')`  
`s = rmfield(s, fields)`

**Description** `s = rmfield(s, 'fieldname')` removes the specified field from the structure array `s`.

`s = rmfield(s, fields)` removes more than one field at a time. `fields` is a character array of field names or cell array of strings.

**See Also** `fieldnames` | `setfield` | `getfield` | `isfield` | `orderfields`

**How To**

- dynamic field names

# rmpath

---

|                     |                                                                                                                                                                                                                                                                                                           |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>      | Remove folders from search path                                                                                                                                                                                                                                                                           |

**Purpose**

Remove preference

**Syntax**

```
rmpref('group','pref')  
rmpref('group',{'pref1','pref2',... 'prefn'})  
rmpref('group')
```

**Description**

`rmpref('group','pref')` removes the preference specified by `group` and `pref`. It is an error to remove a preference that does not exist.

`rmpref('group',{'pref1','pref2',... 'prefn'})` removes each preference specified in the cell array of preference names. It is an error if any of the preferences do not exist.

`rmpref('group')` removes all the preferences for the specified group. It is an error to remove a group that does not exist.

**Examples**

```
addpref('mytoolbox','version','1.0')  
rmpref('mytoolbox')
```

**See Also**

`addpref` | `getpref` | `ispref` | `setpref` | `uigetpref` | `uisetpref`

**Purpose** Control random number generation

**Syntax**

```
rng(sd)
rng('shuffle')
rng(sd, generator)
rng('shuffle', generator)
rng('default')
scurr = rng
rng(s)
sprex = rng(...)
```

## Description

---

**Note** To use the `rng` function instead of `rand` or `randn` with the 'seed', 'state', or 'twister' inputs, see the documentation on “Updating Your Random Number Generator Syntax”

---

`rng(sd)` seeds the random number generator using the nonnegative integer `sd` so that `rand`, `randi`, and `randn` produce a predictable sequence of numbers.

`rng('shuffle')` seeds the random number generator based on the current time so that `rand`, `randi`, and `randn` produce a different sequence of numbers after each time you call `rng`.

`rng(sd, generator)` and `rng('shuffle', generator)` additionally specify the type of the random number generator used by `rand`, `randi`, and `randn`. The generator input is one of:

| Generator       | Description                         |
|-----------------|-------------------------------------|
| 'twister'       | Mersenne Twister                    |
| 'combRecursive' | Combined Multiple Recursive         |
| 'multFibonacci' | Multiplicative Lagged Fibonacci     |
| 'v5uniform'     | Legacy MATLAB 5.0 uniform generator |

| Generator  | Description                        |
|------------|------------------------------------|
| 'v5normal' | Legacy MATLAB 5.0 normal generator |
| 'v4'       | Legacy MATLAB 4.0 generator        |

`rng('default')` puts the settings of the random number generator used by `rand`, `randi`, and `randn` to their default values so that they produce the same random numbers as if you restarted MATLAB. In this release, the default settings are the Mersenne Twister with seed 0.

`scurr = rng` returns the current settings of the random number generator used by `rand`, `randi`, and `randn`. The settings are returned in a structure `scurr` with fields `'Type'`, `'Seed'`, and `'State'`.

`rng(s)` restores the settings of the random number generator used by `rand`, `randi`, and `randn` back to the values captured previously with a command such as `s = rng`.

`sprev = rng(...)` returns the previous settings of the random number generator used by `rand`, `randi`, and `randn` before changing the settings.

## Examples

### Example 1 – Retrieve and Restore Generator Settings

Save the current generator settings in `s`:

```
s = rng;
```

Call `rand` to generate a vector of random values:

```
x = rand(1,5)
```

```
x =
```

```
    0.8147    0.9058    0.1270    0.9134    0.6324
```

Restore the original generator settings by calling `rng`. Generate a new set of random values and verify that `x` and `y` are equal:

```
rng(s);
y = rand(1,5)
```

```
y =  
    0.8147    0.9058    0.1270    0.9134    0.6324
```

## **Example 2 – Restore Settings for Legacy Generator**

Use the legacy generator.

```
sprev = rng(0, 'v5uniform')
```

```
sprev =  
    Type: 'twister'  
    Seed: 0  
    State: [625x1 uint32]
```

```
x = rand
```

```
x =  
    0.9501
```

Restore the previous settings by calling `rng`:

```
rng(sprev)
```

### **See Also**

`rand` | `randi` | `randn` | `RandStream` | `now`

**Purpose** Root

**Description** The root is a graphics object that corresponds to the computer screen. There is only one root object and it has no parent. The children of the root object are figures.

The root object exists when you start MATLAB; you never have to create it and you cannot destroy it. Use `set` and `get` to access the root properties.

**Object Hierarchy**

**See Also** [diary](#) | [echo](#) | [figure](#) | [format](#) | [gcf](#) | [get](#) | [set](#) | [Root Properties](#)

# Root Properties

---

**Purpose** Root properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- Property Editor is an interactive tool that enables you to see and change object property values.
- The set and get commands enable you to set and query the values of properties.

To change the default values of properties, see “Setting Default Property Values”.

## Root Properties

This section provides a description of properties. Curly braces { } enclose default values.

BusyAction

cancel | {queue}

Not used by the root object.

ButtonDownFcn

string

Not used by the root object.

CallbackObject

handle (read-only)

*Handle of current callback's object.* Contains the handle of the object whose callback routine is currently executing. If no callback routines are executing, this property contains an empty double array [ ]. See also the `gco` command.

Children

vector of handles

*Handles of child objects.* A vector containing the handles of all nonhidden figure objects (see `HandleVisibility` for more

information). You can change the order of the handles and thereby change the sorting order of the figures on the display.

## Clipping

{on} | off

*Clipping mode.* This property has no effect on the root object.

## CommandWindowSize

[columns rows]

*Current size of command window.* Size of the MATLAB command window, in a two-element vector. The first element is the number of columns wide and the second element is the number of rows tall.

For example, a value of [50,25] means that 50 characters can display across the Command Window, and 25 lines can display without scrolling.

Enabling the Command Window Display preference **Set matrix display width to eighty columns** forces the returned value for number of columns wide to be 80 regardless of the window width.

## CreateFcn

The root object does not use this property.

## CurrentFigure

figure handle

*Handle of the current figure,* which is the one most recently created, clicked in, or made current with the statement:

```
figure(h) % h is a figure handle
```

which re-sorts the figure to the top of the figures displayed on the screen, or:

```
set(0, 'CurrentFigure', h)
```

# Root Properties

---

which does not re-sort the figures. In these statements, `h` is the handle of an existing figure. If there are no figure objects:

```
get(0, 'CurrentFigure')
```

returns an empty double array. Note, however, that `gcf` always returns a figure handle. Calling `gcf` creates a new figure if there are no existing figure objects that can become the current figure (for example, figures with hidden handles cannot become the current figure).

DeleteFcn  
string

This property is not used because you cannot delete the root object.

Diary  
on | {off}

*Diary file mode.* When this property is on, MATLAB maintains a file (whose name is specified by the `DiaryFile` property) that saves a copy of all keyboard input and most of the resulting output. See also the `diary` command.

DiaryFile  
string

*Diary file name.* The default name is `diary`. Set this property to the name of the file MATLAB uses write the command-line diary when the `Diary` property is set to on.

Echo  
on | {off}

*Script echoing mode.* When `Echo` is on, MATLAB displays each line of a script file as it executes. See also the `echo` command.

ErrorMessage  
string

*Text of last error message.* Contains the last error message issued by MATLAB.

**FixedWidthFontName**  
font name

*Fixed-width font to use for axes, text, and uicontrols whose FontName is set to FixedWidth.* MATLAB uses the font name specified for this property as the value for axes, text, and uicontrol FontName properties when their FontName property is FixedWidth.

Specifying the font name with this property eliminates the need to hardcode font names in MATLAB applications and thereby enables these applications to run without modification in locales where non-ASCII character sets are required. In these cases, MATLAB attempts to set the value of FixedWidthFontName to the correct value for a given locale.

MATLAB application developers should not change this property, but should create axes, text, and uicontrols with FontName properties set to FixedWidth when they want to use a fixed-width font for these objects.

MATLAB end users can set this property if they do not want to use the preselected value. Courier is the default in locales that use Latin-based characters.

**Format**  
short | {shortE} | long | longE | bank |  
hex | + | rat

*Output format mode.* Format used to display numbers. See also the format command.

- short — Fixed-point format with 5 digits
- shortE — Floating-point format with 5 digits

# Root Properties

---

- `shortG` — Fixed- or floating-point format displaying as many significant figures as possible with 5 digits
- `long` — Scaled fixed-point format with 15 digits
- `longE` — Floating-point format with 15 digits
- `longG` — Fixed- or floating-point format displaying as many significant figures as possible with 15 digits
- `bank` — Fixed-format of dollars and cents
- `hex` — Hexadecimal format
- `+` — Displays + and - symbols
- `rat` — Approximation by ratio of small integers

`FormatSpacing`  
`compact` | `{loose}`

*Output format spacing* (see also `format` command).

- `compact` — Suppress extra line feeds for more compact display.
- `loose` — Display extra line feeds for a more readable display.

`HandleVisibility`  
`{on}` | `callback` | `off`

This property is not useful on the root object because the handle is always 0.

`HitTest`  
`{on}` | `off`

This property is not useful on the root object.

`Interruptible`  
`{on}` | `off`

This property is not useful on the root object.

## Language

string

System environment setting.

## MonitorPositions

*Width and height of monitors, in pixels.* Contains information about the size and relative location of monitors connected to your computer. The information returned by the `MonitorPosition` property depends on which computer system you are using.

## Windows Systems

Windows systems define one monitor as device 1, which becomes the reference by which MATLAB determines other monitor positions. The position data is of the form:

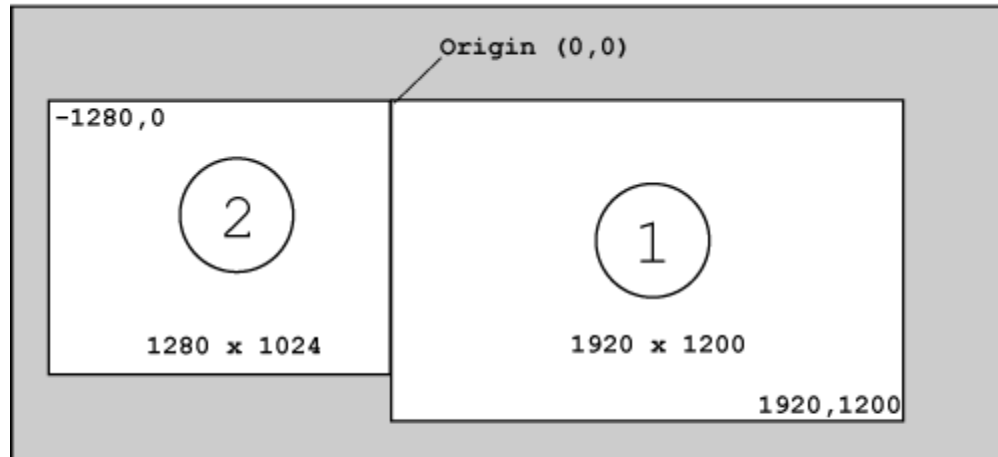

```
[xmin2,ymin2,xmax2,ymax2;  
 xmin1,ymin1,xmax1,ymax1]
```

The values for minimum and maximum are relative to the origin.

The following picture show the values returned when querying the `MonitorPositions` property on a Windows system having two monitors arranged as shown.

# Root Properties

Windows System with Two Monitors

```
get(0, 'MonitorPosition')
```

```
-1279  1    0   1024  
  1    1  1920  1200
```

The `MonitorPositions` property contains an `n`-by-4 array, with each row representing a monitor position. The first row is the  $n^{\text{th}}$  monitor and the last row corresponds to device 1.

The monitor labeled as device 1 in the Windows control panel remains the reference monitor that defines the position of the origin however you reposition the monitors.

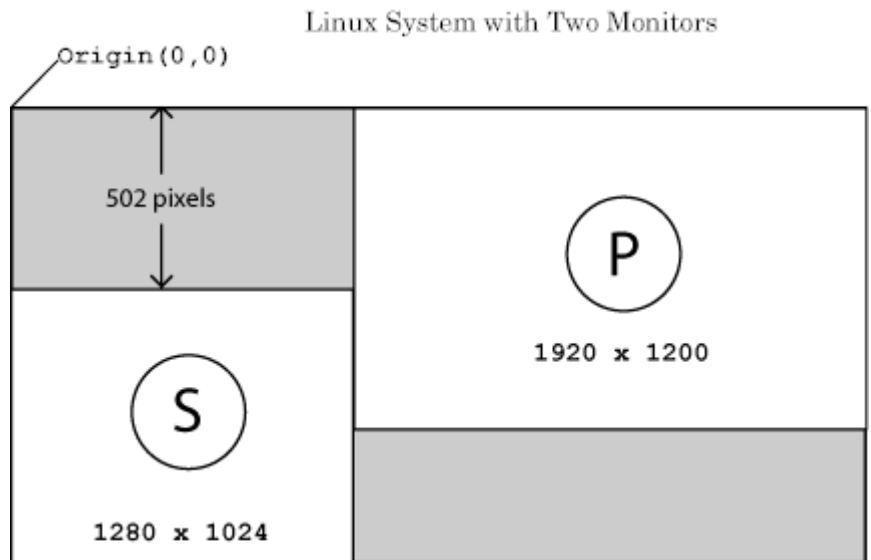

## Linux Systems

On Linux systems, the upper-left corner of a rectangle enclosing the system monitors forms the origin. The position data is of the form:

```
[xp yp widthp heightp;  
 xs ys widths heights]
```

Where the values represent the offset from the left (x), the offset from the top (y), and the width and height of the monitor. The `MonitorPositions` property contains an n-by-4 array, with each row representing a monitor position. The first row is the position of the primary monitor.

The following picture show the values returned when querying the `MonitorPositions` property on a Linux system that has two monitors arranged as shown.

```
get(0, 'MonitorPosition')
```

```
1281  0  1920  1200  
  1  503  1280  1024
```

# Root Properties

---

MATLAB on Linux reads control panel settings only at startup. MATLAB does not recognize changes made to the arrangement of monitors during a MATLAB session.

## Macintosh Systems

MATLAB on Macintosh systems recognize only the main monitor. The position data is of the form:

[x,y,width,height-menuHeight]

Where the values are  $x = 0$ ,  $y = 0$ , monitor width, and monitor height minus the height of the menubar.

The main monitor is determined by which display has the menu bar. The **System Preferences Displays** control panel provides a way to arrange representations of multiple displays, and set one as the main monitor. To make another display the main monitor, drag the representation of the menu bar in the panel from the default display to the other display.

Parent  
handle

*Handle of parent object.* This property always contains an empty double array, because the root object has no parent.

PointerLocation  
[x,y]

*Current location of pointer.* A vector containing the  $x$ - and  $y$ -coordinates of the pointer position, measured from the lower left corner of the screen. Move the pointer by changing the values of this property. The `Units` property determines the units of this measurement.

PointerLocation always contains the current pointer location, even if the pointer is not in a MATLAB window. A callback

routine querying the `PointerLocation` property can get a value that is different from the location of the pointer when the callback was triggered. This difference results from delays in callback execution caused by competition for system resources.

On Apple Macintosh platforms, you cannot change the pointer location using the `set` command.

## `PointerWindow`

handle (read-only)

*Handle of window containing the pointer.* MATLAB sets this property to the handle of the figure containing the pointer. If the pointer is not in a MATLAB window, the value of this property is 0. A callback routine querying the `PointerWindow` can get the wrong window handle if you move the pointer to another window before the callback executes. This error results from delays in callback execution caused by competition for system resources.

## `RecursionLimit`

integer

*Number of nested MATLAB file calls.* The limit of the number of nested calls to MATLAB files that MATLAB makes before stopping (or potentially running out of memory). By default the value is set to a large value. Setting this property to a smaller value (something like 150, for example) should prevent MATLAB from running out of memory and instead causes MATLAB to issue an error when it reaches the limit.

## `ScreenDepth`

bits per pixel

*Screen depth.* The depth of the display bitmap (the number of bits per pixel). The maximum number of simultaneously displayed colors on the current graphics device is 2 raised to this power.

# Root Properties

---

`ScreenDepth` supersedes the `BlackAndWhite` property. To override automatic hardware checking, set this property to 1. Then MATLAB assumes the display is monochrome. Setting `ScreenDepth` to 1 is useful if MATLAB is running on color hardware but is being displayed on a monochrome terminal. Such a situation can cause MATLAB to determine erroneously that the display is color.

`ScreenPixelsPerInch`  
Display resolution

*DPI setting for your display.* Contains the setting of your display resolution specified in your system preferences.

`ScreenSize`  
four-element rectangle vector (read-only)

*Screen size.* A four-element vector:

[left,bottom,width,height]

that defines the display size. `left` and `bottom` are 0 for all Units except pixels, in which case `left` and `bottom` are both 1. `width` and `height` are the screen dimensions in units specified by the `Units` property.

## Determining Screen Size

Note that the screen size in absolute units (for example, inches) is determined by dividing the number of pixels in width and height by the screen DPI (see the `ScreenPixelPerInch` property). This value is approximate and might not represent the actual size of the screen.

Note that the `ScreenSize` property is static. Its values are read-only at MATLAB startup and not updated if system display settings change. Also, the values returned might not represent

the usable screen size for application developers due to the presence of other GUIs, such as the Microsoft Windows task bar.

**Selected**  
on | off

This property has no effect on the root object.

**SelectionHighlight**  
{on} | off

This property has no effect on the root object.

**ShowHiddenHandles**  
on | {off}

*Show or hide handles marked as hidden.* When set to on, this property disables handle hiding and exposes all object handles regardless of the setting of an object's `HandleVisibility` property. When set to off, all objects so marked remain hidden within the graphics hierarchy.

**Tag**  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. While it is not necessary to identify the root object with a tag (since its handle is always 0), you can use this property to store any string value, which you can later retrieve using `get`.

**Type**  
string (read-only)

*Class of graphics object.* For the root object, `Type` is always the string `root`.

**UIContextMenu**  
handle

# Root Properties

---

This property is not used by the root object.

## Units

{pixels} | normalized | inches | centimeters | points  
| characters

*Unit of measurement.* Specifies the units MATLAB uses to interpret size and location data contained in the `PointerLocation` and `ScreenSize` properties. All units are measured from the lower left corner of the screen.

- `normalized` — Map the lower left corner of the screen to (0,0) and the upper right corner to (1.0,1.0).
- `inches`, `centimeters`, and `points` — Absolute units. 1 point =  $1/72$  inch.
- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter x, and the height of one `characters` unit is the distance between the baselines of two lines of text.

If you change the value of `Units`, it is good practice to return it to its default value after completing your operation, so as not to affect other functions that assume `Units` is set to the default value.

## UserData

matrix

*User-specified data.* Data you want to associate with the root object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## Visible

{on} | off

*Object visibility.* This property has no effect on the root object.

## See Also

root object

**Purpose**

Polynomial roots

**Syntax**

`r = roots(c)`

**Description**

`r = roots(c)` returns a column vector whose elements are the roots of the polynomial `c`.

Row vector `c` contains the coefficients of a polynomial, ordered in descending powers. If `c` has `n+1` components, the polynomial it represents is  $c_1s^n + \dots + c_n s + c_{n+1}$ .

**Tips**

Note the relationship of this function to `p = poly(r)`, which returns a row vector whose elements are the coefficients of the polynomial. For vectors, `roots` and `poly` are inverse functions of each other, up to ordering, scaling, and roundoff error.

**Examples**

The polynomial  $s^3 - 6s^2 - 72s - 27$  is represented in MATLAB software as

```
p = [1 -6 -72 -27]
```

The roots of this polynomial are returned in a column vector by

```
r = roots(p)
```

```
r =
    12.1229
    -5.7345
    -0.3884
```

**Algorithms**

The algorithm simply involves computing the eigenvalues of the companion matrix:

```
A = diag(ones(n-1,1),-1);
A(1,:) = -c(2:n+1)./c(1);
eig(A)
```

## roots

---

It is possible to prove that the results produced are the exact eigenvalues of a matrix within roundoff error of the companion matrix  $A$ , but this does not mean that they are the exact roots of a polynomial with coefficients within roundoff error of those in  $c$ .

### **See Also**

fzero | poly | residue

**Purpose**

Angle histogram plot

**Syntax**

```
rose(theta)
rose(theta,x)
rose(theta,nbins)
rose(axes_handle,...)
h = rose(...)
[tout,rout] = rose(...)
```

**Description**

`rose(theta)` creates an angle histogram, which is a polar plot showing the distribution of values grouped according to their numeric range, showing the distribution of `theta` in 20 angle bins or less. The vector `theta`, expressed in radians, determines the angle of each bin from the origin. The length of each bin reflects the number of elements in `theta` that fall within a group, which ranges from 0 to the greatest number of elements deposited in any one bin.

`rose(theta,x)` uses the vector `x` to specify the number and the locations of bins. `length(x)` is the number of bins and the values of `x` specify the center angle of each bin. For example, if `x` is a five-element vector, `rose` distributes the elements of `theta` in five bins centered at the specified `x` values.

`rose(theta,nbins)` plots `nbins` equally spaced bins in the range `[0, 2*pi]`. The default is 20.

`rose(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = rose(...)` returns the handles of the line objects used to create the graph.

`[tout,rout] = rose(...)` returns the vectors `tout` and `rout` so `polar(tout,rout)` generates the histogram for the data. This syntax does not generate a plot.

**Examples**

Load data on sunspot activity over 288 years. Generate a rose histogram of the number of sunspots observed using 12 bins.

```
figure  
load sunspot.dat % Contains a 2-column vector named sunspot  
rose(sunspot(:,2),12)
```

**How To**

- Histograms in Polar Coordinates

# rosser

---

**Purpose** Classic symmetric eigenvalue test problem

**Syntax** A = rosser

**Description** A = rosser returns the Rosser matrix. The matrix is 8-by-8 with integer elements. It has:

- A double eigenvalue
- Three nearly equal eigenvalues
- Dominant eigenvalues of opposite sign
- A zero eigenvalue
- A small, nonzero eigenvalue

## Examples

```
rosser
```

```
ans =
```

```
  611   196  -192   407    -8   -52   -49    29
  196   899   113  -192   -71   -43    -8   -44
 -192   113   899   196    61    49    8    52
  407  -192   196   611     8    44    59   -23
   -8   -71    61     8   411  -599   208   208
  -52   -43    49    44  -599   411   208   208
  -49    -8     8    59   208   208    99  -911
   29   -44    52   -23   208   208  -911    99
```

**Purpose** Rotate matrix 90 degrees

**Syntax**  $B = \text{rot90}(A)$   
 $B = \text{rot90}(A, k)$

**Description**  $B = \text{rot90}(A)$  rotates matrix  $A$  counterclockwise by 90 degrees.  
 $B = \text{rot90}(A, k)$  rotates matrix  $A$  counterclockwise by  $k \cdot 90$  degrees, where  $k$  is an integer.

**Examples** The matrix

```
X =  
    1    2    3  
    4    5    6  
    7    8    9
```

rotated by 90 degrees is

```
Y = rot90(X)  
Y =  
    3    6    9  
    2    5    8  
    1    4    7
```

**See Also** [flipdim](#) | [fliplr](#) | [flipud](#)

# rotate

---

**Purpose** Rotate object about specified origin and direction

**Syntax** `rotate(h,direction,alpha)`  
`rotate(...,origin)`

**Description** The rotate function rotates a graphics object in three-dimensional space.

`rotate(h,direction,alpha)` rotates the graphics object `h` by `alpha` degrees. `direction` is a two- or three-element vector that describes the axis of rotation in conjunction with the origin of the axis of rotation. The default origin of the axis of rotation is the center of the plot box. This point is not necessarily the origin of the axes.

Positive `alpha` is defined as the righthand-rule angle about the direction vector as it extends from the origin of rotation.

If `h` is an array of handles, all objects must be children of the same axes.

`rotate(...,origin)` specifies the origin of the axis of rotation as a three-element vector `[x0,y0,z0]`.

**Tips** The rotation transformation modifies the object's data. This technique is different from that used by `view` and `rotate3d`, which modify only the viewpoint.

The axis of rotation is defined by an origin of rotation and a point `P`. Specify `P` as the spherical coordinates `[theta phi]` or as the Cartesian coordinates `[xp,yp,zp]`.

In the two-element form for direction,  $\theta$  is the angle in the  $x$ - $y$  plane counterclockwise from the positive  $x$ -axis.  $\phi$  is the elevation of the direction vector from the  $x$ - $y$  plane.

The three-element form for direction specifies the axis direction using Cartesian coordinates. The direction vector is the vector from the origin of rotation to P.

# rotate

---

## Examples

Create a 2-by-2 set of surface plots and rotate them around their  $x$  and  $y$  axes.

```
figure
sp11 = subplot(2,2,1);
h11 = surf(sp11, peaks(20));
title('No Rotation')
sp12 = subplot(2,2,2);
h12 = surf(sp12, peaks(20));
title('Rotation Around X-Axis')
zdir = [1 0 0];
rotate(h12,zdir,25)
sp21 = subplot(2,2,3);
h21 = surf(sp21, peaks(20));
title('Rotation Around Y-Axis')
zdir = [0 1 0];
rotate(h21,zdir,25)
sp22 = subplot(2,2,4);
h22 = surf(sp22, peaks(20));
title('Rotation Around X- and Y-Axis')
zdir = [1 1 0];
rotate(h22,zdir,25)
```

**Tips**

`rotate` changes the values of the `Xdata`, `Ydata`, and `Zdata` properties to rotate graphics objects.

# rotate3d

---

**Purpose** Rotate 3-D view using mouse

**Syntax**

```
rotate3d on
rotate3d off
rotate3d
rotate3d(figure_handle,...)
rotate3d(axes_handle,...)
h = rotate3d(figure_handle)
```

**Description**

`rotate3d on` enables mouse-base rotation on all axes within the current figure.

`rotate3d off` disables interactive axes rotation in the current figure.

`rotate3d` toggles interactive axes rotation in the current figure.

`rotate3d(figure_handle,...)` enables rotation within the specified figure instead of the current figure.

`rotate3d(axes_handle,...)` enables rotation only in the specified axes.

`h = rotate3d(figure_handle)` returns a `rotate3d mode object` for figure `figure_handle` for you to customize the mode's behavior.

## Using Rotate Mode Objects

You access the following properties of rotate mode objects via `get` and modify some of them using `set`.

- `FigureHandle <handle>` — The associated figure handle, a read-only property that cannot be set
- `Enable 'on' | 'off'` — Specifies whether this figure mode is currently enabled on the figure
- `RotateStyle 'orbit' | 'box'` — Sets the method of rotation
  - 'orbit' rotates the entire axes; 'box' rotates a plot-box outline of the axes.

## Rotate3D Mode Callbacks

You can program the following callbacks for rotate3d mode operations.

- **ButtonDownFilter** <function\_handle> — Function to intercept ButtonDown events

The application can inhibit the rotate operation under circumstances the programmer defines, depending on what the callback returns. The input function handle should reference a function with two implicit arguments (similar to handle callbacks):

```
function [res] = myfunction(obj,event_obj)
% obj          handle to the object that has been clicked on
% event_obj    handle to event data object (empty in this release)
% res [output] logical flag to determine whether the rotate
                operation should take place or the 'ButtonDownFcn'
                property of the object should take precedence
```

- **ActionPreCallback** <function\_handle> — Function to execute before rotating

Set this callback to listen to when a rotate operation will start. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function myfunction(obj,event_obj)
% obj          handle to the figure that has been clicked on
% event_obj    object containing struct of event data
```

The event data has the following field:

|      |                                             |
|------|---------------------------------------------|
| Axes | The handle of the axes that is being panned |
|------|---------------------------------------------|

- **ActionPostCallback** <function\_handle> — Function to execute after rotating

# rotate3d

---

Set this callback to listen to when a rotate operation has finished. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function myfunction(obj,event_obj)
% obj          handle to the figure that has been clicked on
% event_obj    object containing struct of event data (same as the
%              event data of the 'ActionPreCallback' callback)
```

## Rotate3D Mode Utility Functions

The following functions in pan mode query and set certain of its properties.

- `flags = isAllowAxesRotate(h,axes)` — Function querying permission to rotate axes

Calling the function `isAllowAxesRotate` on the `rotate3d` object, `h`, with a vector of axes handles, `axes`, as input will return a logical array of the same dimension as the `axes` handle vector which indicate whether a rotate operation is permitted on the axes objects.

- `setAllowAxesRotate(h,axes,flag)` — Function to set permission to pan axes

Calling the function `setAllowAxesRotate` on the `rotate3d` object, `h`, with a vector of axes handles, `axes`, and a logical scalar, `flag`, will either allow or disallow a rotate operation on the axes objects.

## Examples

### Example 1

Simple 3-D rotation:

```
surf(peaks);
rotate3d on
% rotate the plot using the mouse pointer.
```

## Example 2

Rotate the plot using the "Plot Box" rotate style:

```
surf(peaks);
h = rotate3d;
set(h,'RotateStyle','box','Enable','on');
% Rotate the plot.
```

## Example 3

Create two axes as subplots and then prevent one from rotating:

```
ax1 = subplot(1,2,1);
surf(peaks);
h = rotate3d;
ax2 = subplot(1,2,2);
surf(membrane);
setAllowAxesRotate(h,ax2,false);
% rotate the plots.
```

## Example 4

Create a `ButtonDown` callback for rotate mode objects to trigger. Copy the following code to a new file, execute it, and observe rotation behavior:

```
function demo_mbd
% Allow a line to have its own 'ButtonDownFcn' callback.
hLine = plot(rand(1,10));
set(hLine,'ButtonDownFcn','disp(''This executes'')');
set(hLine,'Tag','DoNotIgnore');
h = rotate3d;
set(h,'ButtonDownFilter',@mycallback);
set(h,'Enable','on');
% mouse-click on the line
%
function [flag] = mycallback(obj,event_obj)
```

```
% If the tag of the object is 'DoNotIgnore', then return true.
objTag = get(obj,'Tag');
if strcmpi(objTag,'DoNotIgnore')
    flag = true;
else
    flag = false;
end
```

## Example 5

Create callbacks for pre- and post-buttonDown events for rotate3D mode objects to trigger. Copy the following code to a new file, execute it, and observe rotation behavior:

```
function demo_mbd2
% Listen to rotate events
surf(peaks);
h = rotate3d;
set(h,'ActionPreCallback',@myprecallback);
set(h,'ActionPostCallback',@mypostcallback);
set(h,'Enable','on');
%
function myprecallback(obj,evd)
disp('A rotation is about to occur.');
```

```
%
function mypostcallback(obj,evd)
newView = round(get(evd.Axes,'View'));
msgbox(sprintf('The new view is [%d %d].',newView));
```

## Tips

When enabled, rotate3d provides continuous rotation of axes and the objects it contains through mouse movement. A numeric readout appears in the lower left corner of the figure during rotation, showing the current azimuth and elevation of the axes. Releasing the mouse button removes the animated box and the readout. This differs from the camorbit function in that while the rotate3d tool modifies the View property of the axes, the camorbit function fixes the aspect ratio

and modifies the `CameraTarget`, `CameraPosition` and `CameraUpVector` properties of the axes. See [Axes Properties](#) for more information.

You can also enable 3-D rotation from the figure **Tools** menu or the figure toolbar.

You can create a `rotate3d` mode object once and use it to customize the behavior of different axes, as example 3 illustrates. You can also change its callback functions on the fly.

---

**Note Do not change figure callbacks within an interactive mode.** While a mode is active (when panning, zooming, etc.), you will receive a warning if you attempt to change any of the figure’s callbacks and the operation will not succeed. The one exception to this rule is the figure `WindowButtonMotionFcn` callback, which can be changed from within a mode. Therefore, if you are creating a GUI that updates a figure’s callbacks, the GUI should some keep track of which interactive mode is active, if any, before attempting to do this.

---

When you assign different 3-D rotation behaviors to different subplot axes via a mode object and then link them using the `linkaxes` function, the behavior of the axes you manipulate with the mouse will carry over to the linked axes, regardless of the behavior you previously set for the other axes.

## Alternatives

Use the Rotate3D tool  on the figure toolbar to enable and disable rotate3D mode on a plot, or select **Rotate 3D** from the figure’s **Tools** menu. For details, see “Rotate in 3-D”.

## See Also

# round

---

**Purpose** Round to nearest integer

**Syntax**  $Y = \text{round}(X)$

**Description**  $Y = \text{round}(X)$  rounds the elements of  $X$  to the nearest integers. Positive elements with a fractional part of 0.5 round up to the nearest positive integer. Negative elements with a fractional part of -0.5 round down to the nearest negative integer. For complex  $X$ , the imaginary and real parts are rounded independently.

## Examples

```
a = [-1.9, -0.2, 3.4, 5.6, 7.0, 2.4+3.6i]
```

```
a =  
Columns 1 through 4  
-1.9000      -0.2000      3.4000      5.6000  
Columns 5 through 6  
7.0000      2.4000 + 3.6000i
```

```
round(a)
```

```
ans =  
Columns 1 through 4  
-2.0000      0      3.0000      6.0000  
Columns 5 through 6  
7.0000      2.0000 + 4.0000i
```

## See Also

`ceil` | `fix` | `floor`

**Purpose**

Reduced row echelon form

**Syntax**

```
R = rref(A)
[R, jb] = rref(A)
[R, jb] = rref(A, tol)
```

**Description**

`R = rref(A)` produces the reduced row echelon form of `A` using Gauss Jordan elimination with partial pivoting. A default tolerance of  $(\max(\text{size}(A)) * \text{eps} * \text{norm}(A, \text{inf}))$  tests for negligible column elements.

`[R, jb] = rref(A)` also returns a vector `jb` such that:

- `r = length(jb)` is this algorithm's idea of the rank of `A`.
- `x(jb)` are the pivot variables in a linear system  $Ax = b$ .
- `A(:, jb)` is a basis for the range of `A`.
- `R(1:r, jb)` is the `r`-by-`r` identity matrix.

`[R, jb] = rref(A, tol)` uses the given tolerance in the rank tests.

Roundoff errors may cause this algorithm to compute a different value for the rank than `rank`, `orth` and `null`.

**Examples**

Use `rref` on a rank-deficient magic square:

```
A = magic(4), R = rref(A)
```

```
A =
    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1
```

```
R =
     1     0     0     1
     0     1     0     3
     0     0     1    -3
```

# rref

---

0 0 0 0

## See Also

[inv](#) | [lu](#) | [rank](#)

**Purpose** Convert real Schur form to complex Schur form

**Syntax** `[U,T] = rsf2csf(U,T)`

**Description** The *complex Schur form* of a matrix is upper triangular with the eigenvalues of the matrix on the diagonal. The *real Schur form* has the real eigenvalues on the diagonal and the complex eigenvalues in 2-by-2 blocks on the diagonal.

`[U,T] = rsf2csf(U,T)` converts the real Schur form to the complex form.

Arguments `U` and `T` represent the unitary and Schur forms of a matrix `A`, respectively, that satisfy the relationships:  $A = U^*T^*U'$  and  $U' * U = \text{eye}(\text{size}(A))$ . See `schur` for details.

## Examples

Given matrix `A`,

```

1     1     1     3
1     2     1     1
1     1     3     1
-2    1     1     4

```

with the eigenvalues

```

4.8121    1.9202 + 1.4742i    1.9202 + 1.4742i    1.3474

```

Generating the Schur form of `A` and converting to the complex Schur form

```

[u,t] = schur(A);
[U,T] = rsf2csf(u,t)

```

yields a triangular matrix `T` whose diagonal (underlined here for readability) consists of the eigenvalues of `A`.

`U =`

|         |                   |                   |         |

| 0      | 0                 | 0                 | 1.3474           |

## See Also

schur

**Purpose** Run MATLAB script

**Syntax** `run(scriptname)`

**Description** `run(scriptname)` runs the MATLAB script specified by `scriptname`.

**Input Arguments** **scriptname - Full or relative script path**  
*string*

Full or relative script path to a MATLAB script, specified as a string. `scriptname` can specify any file type that MATLAB can execute, such as MATLAB script files, Simulink models, or MEX-files.

### Tips

- `run` executes scripts not currently on the MATLAB path. However, you should use `cd` or `addpath` to navigate to or to add the appropriate folder, making a script executable by entering its name alone.
- `scriptname` can access any variables in the current workspace.
- `run` changes to the folder that contains the script, executes it, and resets back to the original folder. If the script itself changes folders, then `run` does not revert to the original folder, unless `scriptname` changes to the folder in which this script resides.
- If `scriptname` corresponds to both a `.m` file and a P-file residing in the same folder, then `run` executes the P-file. This occurs even if you specify `scriptname` with a `.m` extension.

### Examples

#### Run Script Not on Current Path

Create a temporary folder and copy an example MATLAB script to it.

```
tmp = tempname;  
mkdir(tmp);  
runtmp = fullfile(tmp,'buckyball.m');  
demodir = fullfile(matlabroot,'toolbox','matlab','demos','buckydem.m');  
copyfile(demodir,runtmp);
```

Run the new script.

```
run(runtmp)
```

## Concepts

- “Making Files and Folders Accessible to MATLAB”

## Purpose

Save workspace variables to file

## Syntax

```
save(filename)
save(filename, variables)
save(filename, '-struct', structName, fieldNames)
save(filename, ..., '-append')
save(filename, ..., format)
save(filename, ..., version)
save filename ...
```

## Description

`save(filename)` stores all variables from the current workspace in a MATLAB formatted binary file (MAT-file) called *filename*.

`save(filename, variables)` stores only the specified variables.

`save(filename, '-struct', structName, fieldNames)` stores the fields of the specified scalar structure as individual variables in the file. If you include the optional *fieldNames*, the `save` function stores only the specified fields of the structure. You cannot specify *variables* and the `'-struct'` keyword in the same call to `save`.

`save(filename, ..., '-append')` adds new variables to an existing file. You can specify the `'-append'` option with additional inputs such as *variables*, `'-struct'`, *format*, or *version*.

`save(filename, ..., format)` saves in the specified format: `'-mat'` or `'-ascii'`. You can specify the *format* option with additional inputs such as *variables*, `'-struct'`, `'-append'`, or *version*.

`save(filename, ..., version)` saves to MAT-files in the specified version: `'-v4'`, `'-v6'`, `'-v7'`, or `'-v7.3'`. You can specify the *version* option with additional inputs such as *variables*, `'-struct'`, `'-append'`, or *format*.

`save filename ...` is the command form of the syntax, for convenient saving from the command line. With command syntax, you do not need to enclose input strings in single quotation marks. Separate inputs with spaces instead of commas. Do not use command syntax if inputs such as *filename* are variables. For more information, see “Command

vs. Function Syntax” in the MATLAB Programming Fundamentals documentation.

## Input Arguments

### **filename**

Name of a file. If you do not specify *filename*, the `save` function saves to a file named `matlab.mat`.

If *filename* does not include an extension and the value of *format* is `-mat` (the default), MATLAB appends `.mat`. If *filename* does not include a full path, MATLAB saves in the current folder. You must have permission to write to the file.

**Default:** `'matlab.mat'`

### **variables**

Description of the variables to save. Use one of the following forms:

`var1, var2, ...`

Save the listed variables. Use the `'*'` wildcard to match patterns. For example, `save('A*')` saves all variables that start with `A`.

`'-regexp', expressions`

Save only the variables that match the specified regular expressions. MATLAB treats all inputs as regular expressions, except the optional *filename*. The *filename* must appear immediately after the `save` command.

**Default:** all variables

**'-struct'**

Keyword to request saving the fields of a scalar structure as individual variables in the file. The *structName* input must appear immediately after the `-struct` keyword.

**structName**

Name of a scalar structure. Required when you use the `'-struct'` keyword.

**fieldNames**

Description of the fields of a structure to save as individual variables in the file. Use the same forms listed for *variables*. If you use the `'-regexp'` keyword, MATLAB treats all inputs as regular expressions except *filename* and *structName*.

**'-append'**

Keyword to add data to an existing file. For MAT-files, `-append` adds new variables to the file or replaces the saved values of existing variables with values in the workspace. For ASCII files, `-append` adds data to the end of the file.

**format**

Specifies the format of the file, regardless of any specified extension. Use one of the following combinations (not case sensitive):

|                                           |                                      |
|-------------------------------------------|--------------------------------------|
| <code>'-mat'</code>                       | Binary MAT-file format (default).    |
| <code>'-ascii'</code>                     | 8-digit ASCII format.                |
| <code>'-ascii', '-tabs'</code>            | Tab-delimited 8-digit ASCII format.  |
| <code>'-ascii', '-double'</code>          | 16-digit ASCII format.               |
| <code>'-ascii', '-double', '-tabs'</code> | Tab-delimited 16-digit ASCII format. |

For MAT-files, data saved on one machine and loaded on another machine retains as much accuracy and range as the different machine floating-point formats allow.

For ASCII file formats, the `save` function has the following limitations:

- Each variable must be a two-dimensional `double` or character array.
- MATLAB translates characters to their corresponding internal ASCII codes. For example, 'abc' appears in an ASCII file as:

```
9.7000000e+001 9.8000000e+001 9.9000000e+001
```

- The output includes only the real component of complex numbers.
- MATLAB writes data from each variable sequentially to the file. If you plan to use the `load` function to read the file, all variables must have the same number of columns. The `load` function creates a single variable from the file.

For more flexibility in creating ASCII files, use `dlmwrite` or `fprintf`.

## version

Specifies the version of the file. Applies to MAT-files only.

The following table shows the available MAT-file version options and the corresponding supported features.

| Option  | Can Load in Versions  | Supported Features                                                                                                                                                                    |
|---------|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| '-v7.3' | 7.3 (R2006b) or later | Version 7.0 features plus support for data items greater than or equal to 2 GB on 64-bit systems.                                                                                     |
| '-v7'   | 7.0 (R14) or later    | Version 6 features plus data compression and Unicode character encoding. Unicode encoding enables file sharing between systems that use different default character encoding schemes. |

| Option | Can Load in Versions | Supported Features                                                                                                          |
|--------|----------------------|-----------------------------------------------------------------------------------------------------------------------------|
| '-v6'  | 5 (R8) or later      | Version 4 features plus $N$ -dimensional arrays, cell arrays and structures, and variable names greater than 19 characters. |
| '-v4'  | all                  | Two-dimensional <code>double</code> , <code>character</code> , and <code>sparse</code> arrays.                              |

If any data items require features that the specified version does not support, MATLAB does not save those items and issues a warning. You cannot specify a version later than your version of MATLAB software.

To view or set the default version for MAT-files, select a **MAT-file save format** option in the General Preferences.

## Examples

Save all variables from the workspace in binary MAT-file `test.mat`. Remove the variables from the workspace, and retrieve the data with the `load` function.

```
save test.mat
clear
load test.mat
```

Create a variable `savefile` that stores the name of a file, `pqfile.mat`. Save two variables to the file.

```
savefile = 'pqfile.mat';
p = rand(1, 10);
q = ones(10);
save(savefile, 'p', 'q')
```

Save data to an ASCII file, and view the contents of the file with the `type` function:

## save

---

```
p = rand(1, 10);
q = ones(10);
save('pqfile.txt', 'p', 'q', '-ASCII')
type pqfile.txt
```

Alternatively, use command syntax for the `save` operation:

```
save pqfile.txt p q -ASCII
```

---

Save the fields of structure `s1` as individual variables. Check the contents of the file with the `whos` function. Clear the workspace and load the contents of a single field.

```
s1.a = 12.7;
s1.b = {'abc', [4 5; 6 7]};
s1.c = 'Hello!';

save('newstruct.mat', '-struct', 's1');

disp('Contents of newstruct.mat:')
whos('-file', 'newstruct.mat')

clear('s1')
load('newstruct.mat', 'b')
```

---

Save any variables in the workspace with names that begin with `Mon`, `Tue`, or `Wed` to `mydata.mat`:

```
save('mydata', '-regexp', '^Mon|^Tue|^Wed');
```

### How To

- “Ways to Save Workspace Variables”

- “Write to Delimited Data Files”
- “Supported File Formats”

# save (COM)

---

**Purpose** Serialize control object to file

**Syntax** `h.save('filename')`  
`save(h, 'filename')`

**Description** `h.save('filename')` saves the COM control object, `h`, to the file specified in the string, `filename`.  
`save(h, 'filename')` is an alternate syntax for the same operation.

---

**Note** The COM save function is only supported for controls at this time.

---

**Tips** COM functions are available on Microsoft Windows systems only.

**Examples** Create an `mwsamp` control and save its original state to the file `mwsample`:

```
f = figure('position', [100 200 200 200]);  
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], f);  
h.save('mwsample')
```

Now, alter the figure by changing its label and the radius of the circle:

```
h.Label = 'Circle';  
h.Radius = 50;  
h.Redraw;
```

Using the `load` function, you can restore the control to its original state:

```
h.load('mwsample');  
h.get
```

MATLAB displays the original values:

```
ans =  
    Label: 'Label'  
    Radius: 20
```

**See Also**

load (COM) | actxcontrol | actxserver | release | delete (COM)

# save (serial)

---

**Purpose** Save serial port objects and variables to file

**Syntax** `save filename`  
`save filename obj1 obj2...`

**Description** `save filename` saves all MATLAB variables to the file `filename`. If an extension is not specified for `filename`, then the `.mat` extension is used.

`save filename obj1 obj2...` saves the serial port objects `obj1 obj2...` to the file `filename`.

**Tips** You can use `save` in the functional form as well as the command form shown above. When using the functional form, you must specify the filename and serial port objects as strings. For example, to save the serial port object `s` to the file `MySerial.mat` on a Windows platform

```
s = serial('COM1');  
save('MySerial','s')
```

Any data that is associated with the serial port object is not automatically stored in the file. For example, suppose there is data in the input buffer for `obj`. To save that data to a file, you must bring it into the MATLAB workspace using one of the synchronous read functions, and then save to the file using a separate variable name. You can also save data to a text file with the `record` function.

You return objects and variables to the MATLAB workspace with the `load` command. Values for read-only properties are restored to their default values upon loading. For example, the `Status` property is restored to `closed`. To determine if a property is read-only, examine its reference pages.

**Examples** This example illustrates how to use the command and functional form of `save` on a Windows platform.

```
s = serial('COM1');  
set(s,'BaudRate',2400,'StopBits',1)  
save MySerial1 s
```

```
set(s, 'BytesAvailableFcn', @mycallback)
save('MySerial2', 's')
```

### See Also

[load](#) | [record](#) | [Status](#)

**Purpose** Save figure or Simulink block diagram using specified format

**Alternatives** Use **File > Save As** on the figure window menu to access the Save As dialog, in which you can select a graphics format. For details, see “Exporting in a Specific Graphics Format” in the MATLAB Graphics documentation. Sizes of files written to image formats by this GUI and by `saveas` can differ due to disparate resolution settings.

**Syntax**

```
saveas(h, 'filename.ext')  
saveas(h, 'filename', 'format')
```

**Description** `saveas(h, 'filename.ext')` saves the figure or Simulink block diagram with the handle `h` to the file `filename.ext`. The format of the file is determined by the extension, `ext`. Allowable values for `ext` are listed in this table.

You can pass the handle of any Handle Graphics object to `saveas`, which then saves the parent figure to the object you specified should `h` not be a figure handle. This means that `saveas` cannot save a subplot without also saving all subplots in its parent figure.

| Text Value | Format                                              |
|------------|-----------------------------------------------------|
| ai         | Adobe Illustrator '88                               |
| bmp        | Windows bitmap                                      |
| emf        | Enhanced metafile                                   |
| eps        | EPS Level 1                                         |
| fig        | MATLAB figure (invalid for Simulink block diagrams) |
| jpg        | JPEG image (invalid for Simulink block diagrams)    |
| m          | MATLAB file (invalid for Simulink block diagrams)   |
| pbm        | Portable bitmap                                     |

| Text Value | Format                    |
|------------|---------------------------|
| pcx        | Paintbrush 24-bit         |
| pdf        | Portable Document Format  |
| pgm        | Portable Graymap          |
| png        | Portable Network Graphics |
| ppm        | Portable Pixmap           |
| tif        | TIFF image, compressed    |

`saveas(h, 'filename', 'format')` saves the figure or Simulink block diagram with the handle `h` to the file called `filename` using the specified `format`. The filename can have an extension, but the extension is not used to define the file format. If no extension is specified, the standard extension corresponding to the specified format is automatically appended to the filename.

Allowable values for `format` are the extensions in the table above and the device drivers and graphic formats supported by `print`. The drivers and graphic formats supported by `print` include additional file formats not listed in the table above. When using a `print` device type to specify format for `saveas`, do not prefix it with `-d`.

## Tips

You can use `open` to open files saved using `saveas` with an `m` or `fig` extension. Other `saveas` and `print` formats are not supported by `open`. Both the **Save As** and **Export Setup** dialog boxes that you access from a figure's **File** menu use `saveas` with the `format` argument, and support all device and file types listed above.

---

**Note** Whenever you specify a format for saving a figure with the **Save As** menu item, that file format is used again the next time you save that figure or a new one. If you do not want to save in the previously-used format, use **Save As** and be sure to set the **Save as type** drop-down menu to the kind of file you want to write. However, saving a figure with the `saveas` function and a format does not change the **Save as type** setting in the GUI.

---

If you want to control the size or resolution of figures saved in image (bit-mapped) formats, such as BMP or JPG, use the `print` command and specify dots-per-inch resolution with the `r` switch.

### Examples

#### Example 1: Specify File Extension

Save the current figure that you annotated using the Plot Editor to a file named `pred_pre` using the MATLAB `fig` format. This allows you to open the file `pred_pre.fig` at a later time and continue editing it with the Plot Editor.

```
saveas(gcf, 'pred_pre.fig')
```

#### Example 2: Specify File Format but No Extension

Save the current figure, using Adobe Illustrator format, to the file `logo`. Use the `ai` extension from the above table to specify the format. The file created is `logo.ai`.

```
saveas(gcf, 'logo', 'ai')
```

This is the same as using the Adobe Illustrator format from the `print devices` table, which is `-dill`; use `doc print` or `help print` to see the table for print device types. The file created is `logo.ai`. MATLAB automatically appends the `ai` extension for an Illustrator format file because no extension was specified.

```
saveas(gcf, 'logo', 'ill')
```

### Example 3: Specify File Format and Extension

Save the current figure to the file `star.eps` using the Level 2 Color PostScript format. If you use `doc print` or `help print`, you can see from the table for print device types that the device type for this format is `-dpsc2`. The file created is `star.eps`.

```
saveas(gcf,'star.eps','psc2')
```

In another example, save the current Simulink block diagram to the file `trans.tiff` using the TIFF format with no compression. From the table for print device types, you can see that the device type for this format is `-dtiffn`. The file created is `trans.tiff`.

```
saveas(gcf,'trans.tiff','tiffn')
```

### Example 4: Saving a Simulink Diagram

Save a Simulink diagram from command line. The file is saved as `counters.bmp`

```
sldemo_tank  
saveas(get_param('sldemo_tank','Handle'),'topmodel.bmp');
```

Using `get_param`, get the handle of the model and save using the `saveas` command. The file can be saved in any desired standard image formats.

### See Also

[hgsave](#) | [open](#) | [print](#) | [save\\_system](#)

# saveobj

---

**Purpose** Modify save process for object

**Syntax** `b = saveobj(a)`

**Description** `b = saveobj(a)` is called by the `save` function if the class of `a` defines a `saveobj` method. `save` writes the returned value, `b`, to the MAT-file.

Define a `loadobj` method to take the appropriate action when loading the object.

If `A` is an array of objects, MATLAB invokes `saveobj` separately for each object saved.

**Examples** Call the superclass `saveobj` method from the subclass implementation of `saveobj` with the following syntax:

```
classdef mySub < super
    methods
        function subj = saveobj(obj)
            % Call superclass saveobj method
            subj = saveobj@super(obj);
            % Perform subclass save operations
            ...
        end
        ...
    end
    ...
end
```

See “Saving and Loading Objects from Class Hierarchies”.

---

Update object when saved:

```
function b = saveobj(a)
    % If the object does not have an account number,
    % call method to add account number to AccountNumber property
    if isempty(a.AccountNumber)
        a.AccountNumber = getAccountNumber(a);
    end
end
```

```
    end  
    b = a;  
end
```

See “Maintaining Class Compatibility”.

| <b>Purpose</b>      | Save current search path                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Alternatives</b> | As an alternative to the <code>savepath</code> function, use the Set Path dialog box.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Syntax</b>       | <pre>savepath savepath folderName/pathdef.m status = savepath...</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b>  | <p><code>savepath</code> updates the MATLAB search path for all users on the system so that the path can be reused in a future session. <code>savepath</code> saves the search path to the <code>pathdef.m</code> file that MATLAB located at startup, or to the current folder if a <code>pathdef.m</code> file exists there. To save the search path programmatically each time you exit MATLAB, use <code>savepath</code> in a <code>finish.m</code> file. On a Windows system with User Account Control (UAC) enabled, UAC might prompt you to allow the update operation because it requires administrator-level permission.</p> <p><code>savepath folderName/pathdef.m</code> saves the current search path to <code>pathdef.m</code> located in <code>folderName</code>. Use this form of the syntax if you do not have write access to the current <code>pathdef.m</code>. If you do not specify <code>folderName</code>, MATLAB saves <code>pathdef.m</code> in the current folder. <code>folderName</code> can be a relative or absolute path. To use the saved search path automatically in a future session, make <code>folderName</code> be the startup folder for MATLAB.</p> <p><code>status = savepath...</code> returns 0 when <code>savepath</code> was successful and 1 when <code>savepath</code> failed.</p> |
| <b>Examples</b>     | <p>Save the current search path to <code>pathdef.m</code>, located in <code>I:/my_matlab_files</code>:</p> <pre>savepath I:/my_matlab_files/pathdef.m</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**How To**

- “Running a Script When Exiting the MATLAB Program”
- “Using the MATLAB Search Path”

# scatter

---

## Purpose

Scatter plot

## Syntax

```
scatter(X,Y,S,C)
scatter(X,Y)
scatter(X,Y,S)
scatter(...,markertype)
scatter(...,'filled')
scatter(...,'PropertyName',propertyvalue)
scatter(axes_handle,...)
h = scatter(...)
```

## Description

`scatter(X,Y,S,C)` displays colored circles at the locations specified by the vectors `X` and `Y` (which must be the same size).

`S` determines the area of each marker (specified in  $\text{points}^2$ ). `S` can be a vector the same length as `X` and `Y` or a scalar. If `S` is a scalar, MATLAB draws all the markers the same size. If `S` is empty, the default size is used.

`C` determines the color of each marker. When `C` is a vector the same length as `X` and `Y`, the values in `C` are linearly mapped to the colors in the current colormap. When `C` is a 1-by-3 matrix, it specifies the colors of the markers as RGB values. If you have 3 points in the scatter plot and wish to have the colors be indices into the colormap, `C` should be a 3-by-1 matrix. `C` can also be a color string (see `ColorSpec` for a list of color string specifiers).

`scatter(X,Y)` draws the markers in the default size and color.

`scatter(X,Y,S)` draws the markers at the specified sizes (`S`) with a single color. This type of graph is also known as a bubble plot.

`scatter(...,markertype)` uses the marker type specified instead of 'o' (see `LineStyleSpec` for a list of marker specifiers).

`scatter(...,'filled')` fills the markers.

`scatter(..., 'PropertyName', propertyvalue)` creates the scatter graph, applying the specified property settings. See `scattergroup` properties for a description of properties.

`scatter(axes_handle, ...)` plots into the axes object with handle `axes_handle` instead of the current axes object (`gca`).

`h = scatter(...)` returns the handle of the `scattergroup` object created.

**Examples**

```
load seamount
scatter(x,y,5,z)
```

# scatter

```
% Vary the size of circles by inverse depth and fill them with dark red
figure
scatter(x,y,sqrt(-z/2),[.5 0 0],'filled')
zoom(2)
```

**See Also**

[scatter3](#) | [plot3](#) | [scattergroup](#) | [ColorSpec](#) | [LineStyle](#)

# scatter3

---

## Purpose

3-D scatter plot

## Syntax

```
scatter3(X,Y,Z,S,C)
scatter3(X,Y,Z)
scatter3(X,Y,Z,S)
scatter3(...,markertype)
scatter3(...,'filled')
scatter3(...,'PropertyName',propertyvalue)
h = scatter3(...)
```

## Description

`scatter3(X,Y,Z,S,C)` displays colored circles at the locations specified by the vectors `X`, `Y`, and `Z` (which must all be the same size).

`S` determines the area of each marker (specified in points<sup>2</sup>). `S` can be a vector the same length as `X`, `Y`, and `Z` or a scalar. If `S` is a scalar, MATLAB draws all the markers the same size.

`C` determines the color of each marker. When `C` is a vector the same length as `X` and `Y`, the values in `C` are linearly mapped to the colors in the current colormap. When `C` is a 1-by-3 matrix, it specifies the colors of the markers as RGB values. If you have 3 points in the scatter plot and wish to have the colors be indices into the colormap, `C` should be a 3-by-1 matrix. `C` can also be a color string (see `ColorSpec` for a list of color string specifiers).

`scatter3(X,Y,Z)` draws the markers in the default size and color.

`scatter3(X,Y,Z,S)` draws markers at the specified sizes (`S`) in a single color.

`scatter3(...,markertype)` uses the marker type specified instead of 'o' (see `LineStyle` for a list of marker specifiers).

`scatter3(...,'filled')` fills the markers.

`scatter3(..., 'PropertyName', propertyvalue)` creates the scatter graph, applying the specified property settings. See `scattergroup` properties for a description of properties.

`h = scatter3(...)` returns handles to the `scattergroup` objects created by `scatter3`. See `Scattergroup Properties` for property descriptions.

Use `plot3` for single color, single marker size 3-D scatter plots.

## Examples

```
figure
[x,y,z] = sphere(16);
X = [x(:)*.5 x(:)*.75 x(:)];
Y = [y(:)*.5 y(:)*.75 y(:)];
Z = [z(:)*.5 z(:)*.75 z(:)];
S = repmat([1 .75 .5]*10,numel(x),1);
C = repmat([1 2 3],numel(x),1);
scatter3(X(:),Y(:),Z(:),S(:),C(:),'filled'), view(-60,60)
view(40,35)
```

## scatter3

**Purpose** Define scattergroup properties

**Modifying Properties** You can set and query graphics object properties using the `set` and `get` commands or the Property Editor (`propertyeditor`).

Note that you cannot define default property values for scattergroup objects.

See Plot Objects for information on scattergroup objects.

**Scattergroup Property Descriptions** This section provides a description of properties. Curly braces { } enclose default values.

Annotation

hg.Annotation object (read-only)

*Control the display of scattergroup objects in legends.* Specifies whether this scattergroup object is represented in a figure legend.

Querying the Annotation property returns the handle of an hg.Annotation object. The hg.Annotation object has a property called LegendInformation, which contains an hg.LegendEntry object.

Once you have obtained the hg.LegendEntry object, you can set its IconDisplayStyle property to control whether the scattergroup object is displayed in a figure legend.

| IconDisplayStyle Value | Purpose                                                                                |
|------------------------|----------------------------------------------------------------------------------------|
| on                     | Include the scattergroup object in a legend as one entry, but not its children objects |
| off                    | Do not include the scattergroup or its children in a legend (default)                  |
| children               | Include only the children of the scattergroup as separate entries in the legend        |

# Scattergroup Properties

---

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Controlling Legends” for more information and examples.

### BeingDeleted

`on` | `{off}` (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

### BusyAction

`cancel` | `{queue}`

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the

*running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

# Scattergroup Properties

---

## CData

vector | m-by-3 matrix | ColorSpec

*Color of markers.* When CData is a vector the same length as XData and YData, the values in CData are linearly mapped to the colors in the current colormap. When CData is a `length(XData)-by-3` matrix, it specifies the colors of the markers as RGB values.

## CDataSource

string (MATLAB variable)

*Link CData to MATLAB variable.* Set this property to a MATLAB variable that, by default, is evaluated in the base workspace to generate the CData.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change CData.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## Children

array of graphics object handles

*Children of the scattergroup object.* An array containing the handle of a patch object parented to the scattergroup object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0, 'ShowHiddenHandles', 'on')
```

## Clipping

{on} | off

*Clipping mode.* MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function and `graphicfcn` is the plotting function which creates this object.

# Scattergroup Properties

---

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## `DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

## `DisplayName`

string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the scattergroup object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

## EraseMode

`{normal} | none | xor | background`

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.

# Scattergroup Properties

---

- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is none. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`HandleVisibility`  
{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.

- **callback** — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- **off** — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

# Scattergroup Properties

---

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## HitTest

{on} | off

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the markers that compose the scatter plot. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

## HitTestArea

on | {off}

*Select the object by clicking markers or area of extent.* Select plot objects by:

- Clicking scatter markers (default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is `off`, you must click the scatter markers to select the object. When `HitTestArea` is `on`, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses all the scatter markers).

Interruptible  
off | {on}

## *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

# Scattergroup Properties

---

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

**LineWidth**  
size in points

*Width of linear objects and edges of filled areas.* Specify in points. 1 point =  $\frac{1}{72}$  inch. The default is 0.5 points.

**Marker**  
character (see table)

*Marker symbol.* Specifies marks that display at data points. You can set values for the **Marker** property independently from the **LineStyle** property. For a list of supported marker symbols, see the following table.

## Marker Specifiers Table

| Specifier       | Marker Type |
|-----------------|-------------|
| '+'             | Plus sign   |
| 'o'             | Circle      |
| '*'             | Asterisk    |
| '.'             | Point       |
| 'x'             | Cross       |
| 'square' or 's' | Square      |

| Specifier          | Marker Type                   |
|--------------------|-------------------------------|
| 'diamond' or 'd'   | Diamond                       |
| '^'                | Upward-pointing triangle      |
| 'v'                | Downward-pointing triangle    |
| '>'                | Right-pointing triangle       |
| '<'                | Left-pointing triangle        |
| 'pentagram' or 'p' | Five-pointed star (pentagram) |
| 'hexagram' or 'h'  | Six-pointed star (hexagram)   |
| 'none'             | No marker (default)           |

## MarkerEdgeColor

ColorSpec | none | {auto}

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — Defines color to use.
- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Uses same color as the CData property.

## MarkerFaceColor

ColorSpec | {none} | auto

*Fill color for closed-shape markers.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — User-defined color.
- none — Makes the interior of the marker transparent, allowing the background to show through.

# Scattergroup Properties

---

- `auto` — Sets the fill color to the axes `Color` property. If the axes `Color` property is `none` (the factory default for axes objects), sets the fill color to the figure `Color`.

## Parent

handle of parent axes, `hgggroup`, or `hgtransform`

*Parent of object.* Handle of the object's parent. The parent is normally the axes, `hgggroup`, or `hgtransform` object that contains the object.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## Selected

`on` | `{off}`

*Object selection state.* When you set this property to `on`, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

## SelectionHighlight

`{on}` | `off`

*Object highlighted when selected.*

- `on` — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- `off` — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

## SizeData

square points

*Size of markers in square points.* Area of the marker in the scatter graph in units of points. Since there are 72 points to one inch, to specify a marker that has an area of one square inch you would use a value of  $72^2$ .

**SizeDataSource**  
string (MATLAB variable)

*Link SizeData to MATLAB variable.* Set this property to a MATLAB variable that, by default, is evaluated in the base workspace to generate the `SizeData`.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change `SizeData`.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

**Tag**  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

# Scattergroup Properties

---

For example, create an areaseries object and set the Tag property.

```
t = area(Y, 'Tag', 'area1')
```

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag', 'area1'), 'FaceColor', 'red')
```

## Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For stemseries objects, `Type` is `'hggroupp'`. The following statement finds all the `hggroupp` objects in the current axes.

```
t = findobj(gca, 'Type', 'hggroupp');
```

## UIContextMenu

handle of uicontextmenu object

*Associate context menu with object.* Handle of a `uicontextmenu` object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

## UserData

array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## Visible

{on} | off

*Visibility of object and its children.*

- on — Object and all children of the object are visible unless the child object's Visible property is off.
- off — Object not displayed. However, the object still exists and you can set and query its properties.

## XData

array

*X-coordinates of scatter markers.* The `scatter` function draws individual markers at each *x*-axis location in the XData array. The input argument X in the `scatter` function calling syntax assigns values to XData.

## XDataSource

MATLAB variable, as a string

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the XData. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's XDataSource does not change the object's XData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

# Scattergroup Properties

---

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## YData

scalar | vector | matrix

*Y-coordinates of scatter markers.* The `scatter` function draws individual markers at each *y*-axis location in the YData array.

The input argument *Y* in the `scatter` function calling syntax assigns values to YData.

## YDataSource

MATLAB variable, as a string

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the YData. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's YDataSource does not change the object's YData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## ZData

vector

*Z-coordinates.* A vector defining the *z*-coordinates for the graph. XData and YData must be the same length and have the same number of rows.

## ZDataSource

MATLAB variable, as a string

*Link ZData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the ZData. The default value is an empty array.

```
set(h, 'ZDataSource', 'zdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's ZDataSource does not change the object's ZData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

# schur

---

**Purpose** Schur decomposition

**Syntax**  
`T = schur(A)`  
`T = schur(A, flag)`  
`[U, T] = schur(A, ...)`

**Description** The `schur` command computes the Schur form of a matrix.

`T = schur(A)` returns the Schur matrix `T`.

`T = schur(A, flag)` for real matrix `A`, returns a Schur matrix `T` in one of two forms depending on the value of `flag`:

|           |                                                                                                                                              |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------|
| 'complex' | <code>T</code> is triangular and is complex if <code>A</code> has complex eigenvalues.                                                       |
| 'real'    | <code>T</code> has the real eigenvalues on the diagonal and the complex eigenvalues in 2-by-2 blocks on the diagonal. 'real' is the default. |

If `A` is complex, `schur` returns the complex Schur form in matrix `T`. The complex Schur form is upper triangular with the eigenvalues of `A` on the diagonal.

The function `rsf2csf` converts the real Schur form to the complex Schur form.

`[U, T] = schur(A, ...)` also returns a unitary matrix `U` so that `A = U*T*U'` and `U'*U = eye(size(A))`.

**Examples** `H` is a 3-by-3 eigenvalue test matrix:

```
H = [ -149   -50  -154
       537   180   546
       -27    -9   -25 ]
```

Its Schur form is

```
schur(H)
```

```
ans =  
    1.0000   -7.1119  -815.8706  
         0    2.0000  -55.0236  
         0         0    3.0000
```

The eigenvalues, which in this case are 1, 2, and 3, are on the diagonal. The fact that the off-diagonal elements are so large indicates that this matrix has poorly conditioned eigenvalues; small changes in the matrix elements produce relatively large changes in its eigenvalues.

# script

---

**Purpose** Sequence of MATLAB statements in file

**Description** A script file is an external file that contains a sequence of MATLAB statements. By typing the filename, you can obtain subsequent MATLAB input from the file. Script files have a filename extension of `.m`.

Scripts are the simplest kind of MATLAB program. They are useful for automating blocks of MATLAB commands, such as computations you have to perform repeatedly from the command line. Scripts can operate on existing data in the workspace, or they can create new data on which to operate. Although scripts do not return output arguments, any variables that they create remain in the workspace, so you can use them in further computations. In addition, scripts can produce graphical output using commands like `plot`.

Scripts can contain any series of MATLAB statements. They require no declarations or begin/end delimiters.

Like any MATLAB program, scripts can contain comments. Any text following a percent sign (`%`) on a given line is comment text. Comments can appear on lines by themselves, or you can append them to the end of any executable line.

**See Also** `echo` | `function` | `type`

**Purpose** Secant of argument in radians

**Syntax**  $Y = \sec(X)$

**Description** The `sec` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.  $Y = \sec(X)$  returns an array the same size as  $X$  containing the secant of the elements of  $X$ .

**Examples** Graph the secant over the domains  $-\pi/2 < x < \pi/2$  and  $\pi/2 < x < 3\pi/2$ .

```
x1 = -pi/2+0.01:0.01:pi/2-0.01;
x2 = pi/2+0.01:0.01:(3*pi/2)-0.01;
plot(x1,sec(x1),x2,sec(x2)), grid on
```

The expression `sec(pi/2)` does not evaluate as infinite but as the reciprocal of the floating-point accuracy `eps`, because `pi` is a floating-point approximation to the exact value of  $\pi$ .

# selectmoveresize

---

**Purpose** Select, move, resize, or copy axes and uicontrol graphics objects

**Syntax** `A = selectmoveresize`  
`set(gca, 'ButtonDownFcn', 'selectmoveresize')`

**Description** `selectmoveresize` is useful as the callback routine for axes and uicontrol button down functions. When executed, it selects the object and allows you to move, resize, and copy it.

`A = selectmoveresize` returns a structure array containing

- `A.Type`: a string containing the action type, which can be `Select`, `Move`, `Resize`, or `Copy`
- `A.Handles`: a list of the selected handles, or, for a `Copy`, an m-by-2 matrix containing the original handles in the first column and the new handles in the second column

`set(gca, 'ButtonDownFcn', 'selectmoveresize')` sets the `ButtonDownFcn` property of the current axes to `selectmoveresize`:

**See Also** `axes` | `uicontrol`

**Purpose** Semilogarithmic plot

**Syntax**

```
semilogx(Y)
semilogx(X1,Y1,...)
semilogx(X1,Y1,LineStyle,...)
semilogx(...,'PropertyName',PropertyValue,...)
h = semilogx(...)
```

**Description** semilogx plot data as logarithmic scales for the *x*-axis.

`semilogx(Y)` creates a plot using a base 10 logarithmic scale for the *x*-axis and a linear scale for the *y*-axis. It plots the columns of *Y* versus their index if *Y* contains real numbers. `semilogx(Y)` is equivalent to `semilogx(real(Y), imag(Y))` if *Y* contains complex numbers. `semilogx` ignores the imaginary component in all other uses of this function.

`semilogx(X1,Y1,...)` plots all *X<sub>n</sub>* versus *Y<sub>n</sub>* pairs. If only *X<sub>n</sub>* or *Y<sub>n</sub>* is a matrix, `semilogx` plots the vector argument versus the rows or columns of the matrix, along the dimension of the matrix whose length matches the length of the vector. If the matrix is square, its columns plot against the vector if their lengths match.

`semilogx(X1,Y1,LineStyle,...)` plots all lines defined by the *X<sub>n</sub>*, *Y<sub>n</sub>*, *LineStyle* triples. *LineStyle* determines line style, marker symbol, and color of the plotted lines.

`semilogx(...,'PropertyName',PropertyValue,...)` sets property values for all `lineseries` graphics objects created by `semilogx`.

`h = semilogx(...)` return a vector of handles to `lineseries` graphics objects, one handle per line.

# semilogx

---

## Tips

If you do not specify a color when plotting more than one line, `semilogx` automatically cycle through the colors and line styles in the order specified by the current axes `ColorOrder` and `LineStyleOrder` properties.

You can mix  $X_n, Y_n$  pairs with  $X_n, Y_n, \textit{LineSpec}$  triples; for example,

```
semilogx(X1, Y1, X2, Y2, LineSpec, X3, Y3)
```

If you attempt to add a `loglog`, `semilogx`, or `semilogy` plot to a linear axis mode graph with `hold` on, the axis mode remains as it is and the new data plots as linear.

## Renderer Support

The OpenGL renderer does not support logarithmic-scale axes. MATLAB automatically selects a different renderer when using logarithmic scaling. If you set the figure `Renderer` property to `opengl`, axis scales become linear. See the figure `Renderer` property for more information on renderers.

## Examples

Create a simple `semilogx` plot.

```
x = 0:0.1:10;  
semilogx(10.^x, x)
```

**See Also**

`line` | `LineStyle` | `loglog` | `plot` | `semilogy`

# semilogy

---

## Purpose

Semilogarithmic plot

## Syntax

```
semilogy(Y)
semilogy(X1,Y1,...)
semilogy(X1,Y1,LineStyle,...)
semilogy(...,'PropertyName',PropertyValue,...)
h = semilogy(...)
```

## Description

semilogy plots data with logarithmic scale for the y-axis.

semilogy(Y) creates a plot using a base 10 logarithmic scale for the y-axis and a linear scale for the x-axis. It plots the columns of Y versus their index if Y contains real numbers. semilogy(Y) is equivalent to semilogy(real(Y), imag(Y)) if Y contains complex numbers. semilogy ignores the imaginary component in all other uses of this function.

semilogy(X1,Y1,...) plots all Xn versus Yn pairs. If only Xn or Yn is a matrix, semilogy plots the vector argument versus the rows or columns of the matrix, along the dimension of the matrix whose length matches the length of the vector. If the matrix is square, its columns plot against the vector if their lengths match.

semilogy(X1,Y1,LineStyle,...) plots all lines defined by the Xn,Yn,LineStyle triples. LineSpec determines line style, marker symbol, and color of the plotted lines.

semilogy(...,'PropertyName',PropertyValue,...) sets property values for all lineseries graphics objects created by semilogy.

h = semilogy(...) returns a vector of handles to lineseries graphics objects, one handle per line.

**Tips**

If you do not specify a color when plotting more than one line, `semilogy` automatically cycle through the colors and line styles in the order specified by the current axes `ColorOrder` and `LineStyleOrder` properties.

You can mix  $X_n, Y_n$  pairs with  $X_n, Y_n, LineSpec$  triples; for example,

```
semilogy(X1, Y1, X2, Y2, LineSpec, X3, Y3)
```

If you attempt to add a `loglog`, `semilogx`, or `semilogy` plot to a linear axis mode graph with `hold` on, the axis mode remains as it is and the new data plots as linear.

**Renderer Support**

The OpenGL renderer does not support logarithmic-scale axes. MATLAB automatically selects a different renderer when using logarithmic scaling. If you set the figure `Renderer` property to `opengl`, axis scales become linear. See the figure `Renderer` property for more information on renderers.

**Examples**

Create a simple `semilogy` plot.

```
x = 0:.1:10;  
semilogy(x, 10.^x)
```

# semilogy

---

**Purpose** Send email message to address list

**Syntax**

```
sendmail(recipients,subject)
sendmail(recipients,subject,message)
sendmail(recipients,subject,message,attachments)
```

**Description** `sendmail(recipients,subject)` sends email to recipients with the specified subject. The recipients input is a string for a single address, or a cell array of strings for multiple addresses.

`sendmail(recipients,subject,message)` includes the specified message. If message is a string, `sendmail` automatically wraps text at 75 characters. To force a line break in the message text, use 10, as shown in the Examples. If message is a cell array of strings, each cell represents a new line of text.

`sendmail(recipients,subject,message,attachments)` attaches the files listed in the string or cell array attachments.

## Tips

- The `sendmail` function does not support HTML-formatted messages. However, you can send HTML files as attachments.
- If `sendmail` cannot determine your email address or outgoing SMTP mail server from your system registry, specify those settings using the `setpref` function. For example:

```
setpref('Internet','SMTP_Server','my_server.example.com');
setpref('Internet','E_mail','my_email@example.com');
```

To identify the SMTP server for the call to `setpref`, check the preferences for your electronic mail application, or consult your email system administrator. If you cannot easily determine the server name, try 'mail', which is a common default, such as:

```
setpref('Internet','SMTP_Server','mail');
```

- By default, the `sendmail` function does not support email servers that require authentication. To support these servers, change your

# sendmail

---

system settings and set preferences for the SMTP user name and password, with commands in the following form:

```
props = java.lang.System.getProperties();
props.setProperty('mail.smtp.auth','true');

setpref('Internet','SMTP_Username','myaddress@example.com');
setpref('Internet','SMTP_Password','mypassword');
```

## Examples

Send a message with two attachments to a hypothetical email address:

```
sendmail('user@otherdomain.com',...
        'Test subject','Test message',...
        {'folder/attach1.html','attach2.doc'});
```

---

Send a message with forced line breaks (using 10) to a hypothetical email address:

```
sendmail('user@otherdomain.com','New subject', ...
        ['Line1 of message' 10 'Line2 of message' 10 ...
        'Line3 of message' 10 'Line4 of message']);
```

The resulting message is:

```
Line1 of message
Line2 of message
Line3 of message
Line4 of message
```

---

Gmail™ servers require authentication and an encrypted connection (SSL) on port 465. Change your system settings to use your Gmail server and send a test message to your Gmail account:

```
% Modify these two lines to reflect
% your account and password.
```

```
myaddress = 'myaddress@gmail.com';
mypassword = 'mypassword';

setpref('Internet', 'E_mail', myaddress);
setpref('Internet', 'SMTP_Server', 'smtp.gmail.com');
setpref('Internet', 'SMTP_Username', myaddress);
setpref('Internet', 'SMTP_Password', mypassword);

props = java.lang.System.getProperties();
props.setProperty('mail.smtp.auth', 'true');
props.setProperty('mail.smtp.socketFactory.class', ...
                  'javax.net.ssl.SSLSocketFactory');
props.setProperty('mail.smtp.socketFactory.port', '465');

sendmail(myaddress, 'Gmail Test', 'This is a test message.');
```

## Alternatives

On Windows systems with Microsoft Outlook®, you can send email directly through Outlook by accessing the COM server with `actxserver`. For an example, see Solution 1-RTY6J.

`getpref` | `setpref`

## How To

- “Specify Proxy Server Settings for Connecting to the Internet”

# serial

---

**Purpose** Create serial port object

**Syntax**  
`obj = serial('port')`  
`obj = serial('port', 'PropertyName', PropertyValue, ...)`

**Description** `obj = serial('port')` creates a serial port object associated with the serial port specified by *port*. If *port* does not exist, or if it is in use, you will not be able to connect the serial port object to the device.

*Port* object name will depend upon the platform that the serial port is on. `instrhwinfo('serial')` provides a list of available serial ports. This list is an example of serial constructors on different platforms:

| Platform                     | Serial Port Constructor                     |
|------------------------------|---------------------------------------------|
| Linux and Linux 64           | <code>serial('/dev/ttyS0');</code>          |
| Mac OS X 64                  | <code>serial('/dev/tty.KeySerial1');</code> |
| Windows 32 and<br>Windows 64 | <code>serial('com1');</code>                |

`obj = serial('port', 'PropertyName', PropertyValue, ...)` creates a serial port object with the specified property names and property values. If an invalid property name or property value is specified, an error is returned and the serial port object is not created.

**Tips** When you create a serial port object, these property values are automatically configured:

- The **Type** property is given by `serial`.
- The **Name** property is given by concatenating `Serial` with the port specified in the `serial` function.
- The **Port** property is given by the port specified in the `serial` function.

You can specify the property names and property values using any format supported by the `set` function. For example, you can use property name/property value cell array pairs. Additionally, you can

specify property names without regard to case, and you can make use of property name completion. For example, the following commands are all valid on a Windows platform.

```
s = serial('COM1','BaudRate',4800);
s = serial('COM1','baudrate',4800);
s = serial('COM1','BAUD',4800);
```

Refer to [Configuring Property Values](#) for a list of serial port object properties that you can use with `serial`.

Before you can communicate with the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt a read or write operation while the object is not connected to the device. You can connect only one serial port object to a given serial port.

## Examples

This example creates the serial port object `s1` associated with the serial port COM1 on a Windows platform.

```
s1 = serial('COM1');
```

The `Type`, `Name`, and `Port` properties are automatically configured.

```
get(s1,{'Type','Name','Port'})
ans =
    'serial'    'Serial-COM1'    'COM1'
```

To specify properties during object creation

```
s2 = serial('COM2','BaudRate',1200,'DataBits',7);
```

## See Also

[fclose](#) | [fopen](#) | [Name](#) | [Port](#) | [Status](#) | [Type](#)

# serialbreak

---

**Purpose** Send break to device connected to serial port

**Syntax** `serialbreak(obj)`  
`serialbreak(obj,time)`

**Description** `serialbreak(obj)` sends a break of 10 milliseconds to the device connected to the serial port object, `obj`.  
`serialbreak(obj,time)` sends a break to the device with a duration, in milliseconds, specified by `time`. Note that the duration of the break might be inaccurate under some operating systems.

**Tips** For some devices, the break signal provides a way to clear the hardware buffer.

Before you can send a break to the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to send a break while `obj` is not connected to the device.

`serialbreak` is a synchronous function, and blocks the command line until execution is complete.

If you issue `serialbreak` while data is being asynchronously written, an error is returned. In this case, you must call the `stopasync` function or wait for the write operation to complete.

**See Also** `fopen` | `stopasync` | `Status`

**Purpose**

Set Handle Graphics object properties

**Syntax**

```
set(H, 'PropertyName', PropertyValue, ...)  
set(H, a)  
set(H, pn, pv, ...)  
set(H, pn, MxN_pv)  
a = set(h)  
pv = set(h, 'PropertyName')
```

**Description**

---

**Note** Do not use the `set` function on Java objects as it will cause a memory leak. For more information, see “Accessing Private and Public Data”

---

`set(H, 'PropertyName', PropertyValue, ...)` sets the named properties to the specified values on the object(s) identified by H. H can be a vector of handles, in which case `set` sets the properties' values for all the objects.

`set(H, a)` sets the named properties to the specified values on the object(s) identified by H. `a` is a structure array whose field names are the object property names and whose field values are the values of the corresponding properties.

`set(H, pn, pv, ...)` sets the named properties specified in the cell array `pn` to the corresponding value in the cell array `pv` for all objects identified in H.

`set(H, pn, MxN_pv)` sets `n` property values on each of `m` graphics objects, where `m = length(H)` and `n` is equal to the number of property names contained in the cell array `pn`. This allows you to set a given group of properties to different values on each object.

`a = set(h)` returns the user-settable properties and possible values for the object identified by `h`. `a` is a structure array whose field names are the object's property names and whose field values are the possible values of the corresponding properties. If you do not specify an output

argument, the MATLAB software displays the information on the screen. `h` must be scalar.

`pv = set(h, 'PropertyName')` returns the possible values for the named property. If the possible values are strings, `set` returns each in a cell of the cell array `pv`. For other properties, `set` returns a statement indicating that `PropertyName` does not have a fixed set of property values. If you do not specify an output argument, MATLAB displays the information on the screen. `h` must be scalar.

## Tips

You can use any combination of property name/property value pairs, structure arrays, and cell arrays in one call to `set`.

### Setting Property Units

Note that if you are setting both the `FontSize` and the `FontUnits` properties in one function call, you must set the `FontUnits` property first so that the MATLAB software can correctly interpret the specified `FontSize`. The same applies to figure and axes units — always set the `Units` property before setting properties whose values you want to be interpreted in those units. For example,

```
f = figure('Units','characters',...
          'Position',[30 30 120 35]);
```

## Examples

Set the `Color` property of the current axes to blue.

```
axes;
set(gca, 'Color', 'b')
```

Change all the lines in a plot to black.

```
plot(peaks)
set(findobj('Type','line'),'Color','k')
```

You can define a group of properties in a structure to better organize your code. For example, these statements define a structure called `active`, which contains a set of property definitions used for the

uicontrol objects in a particular figure. When this figure becomes the current figure, MATLAB changes the colors and enables the controls.

```
active.BackgroundColor = [.7 .7 .7];
active.Enable = 'on';
active.ForegroundColor = [0 0 0];

if gcf == control_fig_handle
    set(findobj(control_fig_handle,'Type','uicontrol'),active)
end
```

You can use cell arrays to set properties to different values on each object. For example, these statements define a cell array to set three properties,

```
PropName(1) = {'BackgroundColor'};
PropName(2) = {'Enable'};
PropName(3) = {'ForegroundColor'};
```

These statements define a cell array containing three values for each of three objects (i.e., a 3-by-3 cell array).

```
PropVal(1,1) = {[.5 .5 .5]};
PropVal(1,2) = {'off'};
PropVal(1,3) = {[.9 .9 .9]};
PropVal(2,1) = {[1 0 0]};
PropVal(2,2) = {'on'};
PropVal(2,3) = {[1 1 1]};
PropVal(3,1) = {[.7 .7 .7]};
PropVal(3,2) = {'on'};
PropVal(3,3) = {[0 0 0]};
```

Now pass the arguments to `set`,

```
set(H,PropName,PropVal)
```

where `length(H) = 3` and each element is the handle to a uicontrol.

## Setting Different Values for the Same Property on Multiple Objects

Suppose you want to set the value of the `Tag` property on five line objects, each to a different value. Note how the value cell array needs to be transposed to have the proper shape.

```
h = plot(rand(5));  
set(h,{'Tag'},{'line1','line2','line3','line4','line5'})
```

`findobj` | `gca` | `gcf` | `gco` | `gcbo` | `get`

**Purpose** Set property values for audioplayer object

**Syntax**

```
set(obj,Name,Value)
set(obj,cellOfNames,cellOfValues)
set(obj,structOfProperties)
settableProperties = set(obj)
```

**Description** `set(obj,Name,Value)` sets the named property to the specified value for the object `obj`.

`set(obj,cellOfNames,cellOfValues)` sets the properties listed in the cell array `cellOfNames` to the corresponding values in the cell array `cellOfValues`. Each cell array must contain the same number of elements.

`set(obj,structOfProperties)` sets the properties identified by each field of the structure array `structOfProperties` to the values of the associated fields.

`settableProperties = set(obj)` returns the names of the properties that you can set in a structure array. The field names of `settableProperties` are the property names.

**Tips** The `set` function allows combinations of property name/value pairs, cell array pairs, and structure arrays in the same function call.

**Examples** View the list of properties that you can set for an audioplayer object:

```
load handel.mat;
handelObj = audioplayer(y, Fs);
set(handelObj)
```

---

Set the `Tag` and `UserData` properties of an audioplayer object using a structure array:

```
newValues.Tag = 'My Tag';
newValues.UserData = {'My User Data', pi, [1 2 3 4]};
```

# audioplayer.set

---

```
load handel.mat;
handelObj = audioplayer(y, Fs);
set(handelObj, newValues)

% View the values all properties.
get(handelObj)
```

## Alternatives

To set the value of a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, set the Tag property for an object called handelObj (as created in the Examples):

```
handelObj.Tag = 'This is my tag.';
```

This command is exactly equivalent to:

```
set(handelObj, 'Tag', 'This is my tag.');
```

| <b>Purpose</b>     | Set object or interface property to specified value                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Syntax</b>      | <pre>h.set('pname',value) h.set('pname1',value1,'pname2',value2,...) set(h,...)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p><code>h.set('pname',value)</code> sets the property specified in the string <code>pname</code> to the given value.</p> <p><code>h.set('pname1',value1,'pname2',value2,...)</code> sets each property specified in the <code>pname</code> strings to the given value.</p> <p><code>set(h,...)</code> is an alternate syntax for the same operation.</p> <p>For information on how MATLAB converts workspace matrices to COM data types, see “Handling COM Data in MATLAB Software”.</p>                           |
| <b>Tips</b>        | COM functions are available on Microsoft Windows systems only.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Examples</b>    | <p>Create an <code>mwsamp</code> control and use <code>set</code> to change the <code>Label</code> and <code>Radius</code> properties:</p> <pre>f = figure ('position', [100 200 200 200]); h = actxcontrol ('mwsamp.mwsampctrl.1', [0 0 200 200], f);  h.set('Label', 'Click to fire event', 'Radius', 40); h.invoke('Redraw');</pre> <p>Here is another way to do the same thing, only without <code>set</code> and <code>invoke</code>:</p> <pre>h.Label = 'Click to fire event'; h.Radius = 40; h.Redraw;</pre> |
| <b>See Also</b>    | <code>get (COM)</code>   <code>inspect</code>   <code>isprop</code>   <code>addproperty</code>   <code>deleteproperty</code>                                                                                                                                                                                                                                                                                                                                                                                        |

# set (hgsetget)

---

**Purpose** Assign property values to handle objects derived from hgsetget class

**Syntax**

```
set(H, 'PropertyName', value, ...)  
set(H, pn, pv)  
set(H, S)  
S = set(h)
```

**Description**

`set(H, 'PropertyName', value, ...)` sets the named property to the specified value for the objects in the handle array `H`.

`set(H, pn, pv)` sets the named properties specified in the cell array of strings `pn` to the corresponding values in the cell array `pv` for all objects specified in `H`. The cell array `pn` must be 1-by-`n` (where `n` is the number of property names), but the cell array `pv` can be `m`-by-`n` where `m` is equal to `length(H)`. `set` updates each object with the associated set of values for the list of property names contained in.

`set(H, S)` sets the properties identified by each field name of struct `S` with the values contained in `S`. `S` is a struct whose field names are object property names.

`S = set(h)` returns the user-settable properties of scalar `h`. `S` is a struct whose field names are the object's property names and whose values are empty cell arrays.

Override the hgsetget class `setdisp` method to change how MATLAB displays this information.

**See Also** `handle` | `hgsetget` | `set` | `get` (`hgsetget`)

**How To**

- “Implementing a Set/Get Interface for Properties”

**Purpose** Set property values for video reader object

**Syntax**

```
set(obj,Name,Value)
set(obj,cellOfNames,cellOfValues)
set(obj,structOfProperties)
settableProperties = set(obj)
```

**Description** `set(obj,Name,Value)` sets the named property to the specified value for the object `obj`.

`set(obj,cellOfNames,cellOfValues)` sets the properties listed in the cell array `cellOfNames` to the corresponding values in the cell array `cellOfValues`. Each cell array must contain the same number of elements.

`set(obj,structOfProperties)` sets the properties identified by each field of the structure array `structOfProperties` to the values of the associated fields.

`settableProperties = set(obj)` returns the names of the properties that you can set in a structure array. The field names of `settableProperties` are the property names.

**Tips** The `set` function allows combinations of property name/value pairs, cell array pairs, and structure arrays in the same function call.

**Examples** View the list of properties that you can set for a video reader object:

```
xyloObj = VideoReader('xylophone.mpg');
set(xyloObj)
```

---

Set the `Tag` and `UserData` properties of a video reader object using a structure array:

```
newValues.Tag = 'My Tag';
newValues.UserData = {'My User Data', pi, [1 2 3 4]};
```

# VideoReader.set

---

```
xyloObj = VideoReader('xylophone.mpg');  
set(xyloObj, newValues)  
  
% View the values all properties.  
get(xyloObj)
```

## Alternatives

To set the value of a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, set the Tag property for a reader object called xyloObj (as created in the Examples):

```
xyloObj.Tag = 'This is my tag.';
```

This command is exactly equivalent to:

```
set(xyloObj, 'Tag', 'This is my tag.');
```

## See Also

VideoReader | get

**Purpose** Set random number stream property

**Class** RandStream

**Syntax**

```
set(stream, 'PropertyName', Value)
set(stream, 'Property1', Value1, 'Property2', Value2, ...)
set(stream, A)
A = set(stream, 'Property')
set(stream, 'Property')
A = set(stream)
set(stream)
```

**Description**

`set(stream, 'PropertyName', Value)` sets the property 'PropertyName' of the random stream `stream` to the value `Value`.

`set(stream, 'Property1', Value1, 'Property2', Value2, ...)` sets multiple random stream property values with a single statement.

`set(stream, A)` where `A` is a structure whose field names are property names of the random stream `stream` sets the properties of `stream` named by each field with the values contained in those fields.

`A = set(stream, 'Property')` or `set(stream, 'Property')` displays possible values for the specified property of `stream`.

`A = set(stream)` or `set(stream)` displays or returns all writable properties of `stream` and their possible values.

**See Also** RandStream | get (RandStream) | rand | randn | randi

# set (serial)

---

**Purpose** Configure or display serial port object properties

**Syntax**

```
set(obj)
props = set(obj)
set(obj, 'PropertyName')
props = set(obj, 'PropertyName')
set(obj, 'PropertyName', PropertyValue, ...)
set(obj, PN, PV)
set(obj, S)
```

**Description** `set(obj)` displays all configurable properties values for the serial port object, `obj`. If a property has a finite list of possible string values, then these values are also displayed.

`props = set(obj)` returns all configurable properties and their possible values for `obj` to `props`. `props` is a structure whose field names are the property names of `obj`, and whose values are cell arrays of possible property values. If the property does not have a finite set of possible values, then the cell array is empty.

`set(obj, 'PropertyName')` displays the valid values for *PropertyName* if it possesses a finite list of string values.

`props = set(obj, 'PropertyName')` returns the valid values for *PropertyName* to `props`. `props` is a cell array of possible string values or an empty cell array if *PropertyName* does not have a finite list of possible values.

`set(obj, 'PropertyName', PropertyValue, ...)` configures multiple property values with a single command.

`set(obj, PN, PV)` configures the properties specified in the cell array of strings `PN` to the corresponding values in the cell array `PV`. `PN` must be a vector. `PV` can be m-by-n where `m` is equal to the number of serial port objects in `obj` and `n` is equal to the length of `PN`.

`set(obj, S)` configures the named properties to the specified values for `obj`. `S` is a structure whose field names are serial port object properties, and whose field values are the values of the corresponding properties.

## Tips

Refer to [Configuring Property Values](#) for a list of serial port object properties that you can configure with `set`.

You can use any combination of property name/property value pairs, structures, and cell arrays in one call to `set`. Additionally, you can specify a property name without regard to case, and you can make use of property name completion. For example, if `s` is a serial port object, then the following commands are all valid.

```
set(s, 'BaudRate')
set(s, 'baudrate')
set(s, 'BAUD')
```

If you use the `help` command to display help for `set`, then you need to supply the pathname shown below.

```
help serial/set
```

## Examples

This example illustrates some of the ways you can use `set` to configure or return property values for the serial port object `s`, on a Windows platform.

```
s = serial('COM1');
set(s, 'BaudRate', 9600, 'Parity', 'even')
set(s, {'StopBits', 'RecordName'}, {2, 'sydney.txt'})
set(s, 'Parity')
[ {none} | odd | even | mark | space ]
```

## See Also

`get`

# set (timer)

---

**Purpose** Configure or display timer object properties

**Syntax**

```
set(obj)
prop_struct = set(obj)
set(obj, 'PropertyName')
prop_cell=set(obj, 'PropertyName')
set(obj, 'PropertyName',PropertyValue,...)
set(obj,S)
set(obj,PN,PV)
```

**Description**

`set(obj)` displays property names and their possible values for all configurable properties of timer object `obj`. `obj` must be a single timer object.

`prop_struct = set(obj)` returns the property names and their possible values for all configurable properties of timer object `obj`. `obj` must be a single timer object. The return value, `prop_struct`, is a structure whose field names are the property names of `obj`, and whose values are cell arrays of possible property values or empty cell arrays if the property does not have a finite set of possible string values.

`set(obj, 'PropertyName')` displays the possible values for the specified property, *PropertyName*, of timer object `obj`. `obj` must be a single timer object.

`prop_cell=set(obj, 'PropertyName')` returns the possible values for the specified property, *PropertyName*, of timer object `obj`. `obj` must be a single timer object. The returned array, `prop_cell`, is a cell array of possible value strings or an empty cell array if the property does not have a finite set of possible string values.

`set(obj, 'PropertyName',PropertyValue,...)` configures the property, *PropertyName*, to the specified value, *PropertyValue*, for timer object `obj`. You can specify multiple property name/property value pairs in a single statement. `obj` can be a single timer object or a vector of timer objects, in which case `set` configures the property values for all the timer objects specified.

`set(obj,S)` configures the properties of `obj`, with the values specified in `S`, where `S` is a structure whose field names are object property names.

`set(obj,PN,PV)` configures the properties specified in the cell array of strings, `PN`, to the corresponding values in the cell array `PV`, for the timer object `obj`. `PN` must be a vector. If `obj` is an array of timer objects, `PV` can be an `M`-by-`N` cell array, where `M` is equal to the length of timer object array and `N` is equal to the length of `PN`. In this case, each timer object is updated with a different set of values for the list of property names contained in `PN`.

---

**Note** When specifying parameter/value pairs, you can use any mixture of strings, structures, and cell arrays in the same call to `set`.

---

## Examples

Create a timer object.

```
t = timer;
```

Display all configurable properties and their possible values.

```
set(t)
  BusyMode: [ {drop} | queue | error ]
  ErrorFcn: string -or- function handle -or- cell array
  ExecutionMode: [ {singleShot} | fixedSpacing | fixedDelay | fixedRate ]
  Name
  ObjectVisibility: [ {on} | off ]
  Period
  StartDelay
  StartFcn: string -or- function handle -or- cell array
  StopFcn: string -or- function handle -or- cell array
  Tag
  TasksToExecute
  TimerFcn: string -or- function handle -or- cell array
  UserData
```

View the possible values of the `ExecutionMode` property.

## set (timer)

---

```
set(t, 'ExecutionMode')  
[ {singleShot} | fixedSpacing | fixedDelay | fixedRate ]
```

Set the value of a specific timer object property.

```
set(t, 'ExecutionMode', 'FixedRate')
```

Set the values of several properties of the timer object.

```
set(t, 'TimerFcn', 'callbk', 'Period', 10)
```

Use a cell array to specify the names of the properties you want to set and another cell array to specify the values of these properties.

```
set(t, {'StartDelay', 'Period'}, {30, 30})
```

### See Also

timer | get(timer)

**Purpose**

Set properties of tscollection object

**Syntax**

```
set(tsc, 'Property', Value)
set(tsc, 'Property1', Value1, 'Property2', Value2, ...)
set(tsc, 'Property')
```

**Description**

set(tsc, 'Property', Value) sets the property 'Property' of the tscollection tsc to the value Value. The following syntax is equivalent:

```
tsc.Property = Value
```

set(tsc, 'Property1', Value1, 'Property2', Value2, ...) sets multiple property values for tsc with a single statement.

set(tsc, 'Property') displays values for the specified property in the time-series collection tsc.

set(tsc) displays all properties and values of the tscollection object tsc.

**See Also**

get (tscollection)

# setabstime (tscollection)

---

**Purpose** Set times of tscollection object as date strings

**Syntax**

```
tsc = setabstime(tsc,Times)
tsc = setabstime(tsc,Times,format)
```

**Description** `tsc = setabstime(tsc,Times)` sets the times in `tsc` using the date strings `Times`. `Times` must be either a cell array of strings, or a char array containing valid date or time values in the same date format.

`tsc = setabstime(tsc,Times,format)` specifies the date-string format used in `Times` explicitly.

**Examples** **1** Create a tscollection object.

```
tsc = tscollection(timeseries(rand(3,1)))
```

**2** Set the absolute time vector.

```
tsc = setabstime(tsc,{'12-DEC-2005 12:34:56',...
                    '12-DEC-2005 13:34:56','12-DEC-2005 14:34:56'})
```

**See Also** `datestr` | `tscollection` | `getabstime (tscollection)`

**Purpose** Specify application-defined data

**Syntax** `setappdata(h, 'name', value)`

**Description** `setappdata(h, 'name', value)` sets application-defined data for the object with handle `h`. The application-defined data, which is created if it does not already exist, is assigned the specified name and value. The value can be any type of data.

**Tips** Application data is data that is meaningful to or defined by your application which you attach to a figure or any GUI component (other than ActiveX controls) through its `AppData` property. Only Handle Graphics MATLAB objects use this property.

**See Also** `getappdata` | `isappdata` | `rmappdata`

# RandStream.setDefaultStream

---

**Purpose** Set default random number stream

---

**Note** `RandStream.setDefaultStream` will be removed in a future version. Use `RandStream.setGlobalStream` instead. The shared global stream used by `rand`, `randi`, and `randn`, referred to in former versions of MATLAB as the *default stream* is now referred to as the *global stream*.

---

**Syntax** `prevstream = RandStream.setDefaultStream(stream)`

**Description** `prevstream = RandStream.setDefaultStream(stream)` returns the current global random number stream, and designates the random number stream `stream` as the new random number stream to be used by the `rand`, `randi`, and `randn` functions.

**Purpose**

Find set difference of two arrays

**Compatibility**

In a future release, the behavior of `setdiff` will change. This change is introduced for adoption in R2012a. For a detailed demonstration that shows how you can preview the future behavior and preserve the current behavior of your existing code, see the example, “Assessing the Impact of the Forthcoming Changes to `setdiff`” on page 2-4090. For a detailed explanation of all the forthcoming changes, see “Set Functions Changing Behavior in a Future Release”.

**Syntax**

```
C = setdiff(A,B)
C = setdiff(A,B,'rows')
[C,ia] = setdiff(A,B)
[C,ia] = setdiff(A,B,'rows')

[C,ia] = setdiff(__,'R2012a')

[C,ia] = setdiff(__,'legacy')

[C,ia] = setdiff(A,B,setOrder)

[C,ia] = setdiff(A,B,'rows',setOrder)
```

**Description**

`C = setdiff(A,B)` returns the values in A that are not in B. The values of C are in sorted order.

`C = setdiff(A,B,'rows')` returns the rows from A that are not in B. The rows of matrix C are in sorted order. The rows of the matrix C are in sorted order.

`[C,ia] = setdiff(A,B)` also returns the index vector `ia`, such that `C = A(ia)`.

`[C,ia] = setdiff(A,B,'rows')` also returns index vectors `ia`, such that `C = A(ia,:)`.

# setdiff

---

`[C,ia] = setdiff(___, 'R2012a')` adopts the future behavior of the `setdiff` function. `[C,ia] = setdiff(___, 'legacy')` preserves the current behavior. You can specify either flag, 'R2012a' or 'legacy', as the final input argument in any previous syntax.

`[C,ia] = setdiff(A,B,setOrder)` and `[C,ia] = setdiff(A,B,'rows',setOrder)` returns `C` in a specific order. `setOrder='sorted'` returns the values (or rows) of `C` in sorted order. `setOrder='stable'` returns the values (or rows) of `C` in the same order as `A`.

## Input Arguments

### A,B - Input arrays

vectors | matrices | N-D arrays

Input arrays, specified as `logical`, `char`, a cell array of strings, or any numeric class. `A` and `B` also can be any object with the class methods: `sort` (or `sortrows` for the 'rows' option), `eq`, and `ne`. This includes heterogeneous arrays derived from the same root class.

`A` and `B` must be of the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with double arrays.
- Cell arrays of strings can combine with `char` arrays.

If you specify the 'rows' option, `A` and `B` must have the same number of columns.

### Data Types

`double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

**Complex Number Support:** Yes

### 'rows' - Rows flag

Rows flag, specified as 'rows', identifies the rows of `A` and `B` as individual elements. When you specify this flag, `setdiff` returns the rows from `A` that are not in `B`. The arrays, `A` and `B`, must have the same

number of columns when you use the rows flag. This option does not support cell arrays.

### setOrder - Order flag

'sorted' | 'stable'

Order flag, specified as 'sorted' or 'stable', indicates the order of the values (or rows) in C.

| Order Flag | Meaning                                                                                                                                        |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| 'sorted'   | The values (or rows) in C, are returned in sorted order. For example:<br>C = setdiff([4 1 3 2],[2 1],'sorted') returns<br>C = [3 4].           |
| 'stable'   | The values (or rows) in C, are returned in the same order as in A. For example:<br>C = setdiff([4 1 3 2],[2 1],'stable') returns<br>C = [4 3]. |

### 'legacy' - Legacy behavior flag

Legacy behavior flag, when specified, preserves the current behavior. If the new behavior adversely affects your existing code, you can preserve the current behavior by specifying 'legacy' as the final argument.

### 'R2012a' - Future behavior flag

Future behavior flag, when specified, adopts the future behavior change. Specify 'R2012a' as the final argument to see what impact the new behavior has on your existing code.

## Output Arguments

### C - Difference of A and B

Vector | Matrix

Difference of A and B, returned as a vector or matrix. C is a vector, unless you specify the 'rows' flag. If 'rows' is specified, C is a matrix containing the rows of A that are not in B.

# setdiff

---

## **ia - Index to A**

Vector

Index to A, returned as a vector, identifies the values (or rows) in A that are not in B. If there is a repeated value (or row) appearing exclusively in A, then `ia` contains the index to the last occurrence of the value (or row).

If you call `setdiff` with the `setOrder` or `'R2012a'` argument, `ia` contains the index to the first occurrence of any repeated value (or row) in A.

## **Examples**

### **Difference of Two Vectors**

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];  
C = setdiff(A,B)
```

```
C =
```

```
     1     3     5
```

### **Find the Difference of Two Vectors and the Indices to the Different Values**

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];  
[C,ia] = setdiff(A,B)
```

```
C =
```

```
     1     3     5
```

```
ia =
```

```
     7     1     5
```

### **Difference of the Rows in Two Matrices**

```
A = [7 9 7; 0 0 0; 7 9 7; 5 5 5; 1 4 5];  
B = [0 0 0; 5 5 5];  
[C,ia] = setdiff(A,B,'rows')
```

```
C =
     1     4     5
     7     9     7
```

```
ia =
     5
     3
```

### Difference of Two Vectors with Specified Output Order

Use the `setOrder` argument to specify the ordering of the values in `C`.

Specify `'stable'` or `'sorted'` when the order of the values in `C` are important.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];
[C,ia] = setdiff(A,B,'stable')
```

```
C =
     3     1     5
```

```
ia =
     1
     4
     5
```

Alternatively, you can specify `'sorted'` order.

```
[C,ia] = setdiff(A,B,'sorted')
```

```
C =
     1     3     5
```

# setdiff

---

```
ia =  
  
    4  
    1  
    5
```

`setdiff` adopts the forthcoming behavior when you specify the `setOrder` argument. If you omit the `setOrder` argument, the output is sorted, but the size and content of `C` and `ia` conforms to the current behavior.

## Assessing the Impact of the Forthcoming Changes to `setdiff`

Use the 'R2012a' flag to assess the impact of the forthcoming behavior changes. Use the 'legacy' flag to preserve the current behavior of your existing code.

Find the difference of `A` and `B` with the current default behavior.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];  
[C1,ia1] = setdiff(A,B)
```

```
C1 =  
  
    1    3    5
```

```
ia1 =  
  
    7    1    5
```

Find the difference of `A` and `B`, and adopt the forthcoming behavior. In the future, this behavior will be the default.

```
[C2,ia2] = setdiff(A,B, 'R2012a')
```

```
C2 =  
  
    1    3    5
```

```
ia2 =
     4
     1
     5
```

Notice that `ia1` and `ia2` have different shapes and content.

Find the difference of `A` and `B`, and preserve the current behavior.

```
[C3,ia3] = setdiff(A,B,'legacy')
```

```
C3 =
     1     3     5
ia3 =
     7     1     5
```

`C3` and `ia3` match `C1` and `ia1`.

### Find the Difference of Vectors Containing NaNs

```
A = [5 NaN NaN]; B = [5 NaN];
C = setdiff(A,B)
```

```
C =
     NaN     NaN
```

`setdiff` treats NaN values as distinct.

# Tiff.setDirectory

---

**Purpose** Make specified IFD current IFD

**Syntax** `tiffobj.setDirectory(dirNum)`

**Description** `tiffobj.setDirectory(dirNum)` sets the image file directory (IFD) specified by `dirNum` as the current IFD. Tiff object methods operate on the current IFD. The directory index number is one-based.

**Examples** Open a TIFF file and move to an IFD in the file by specifying its index number. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path. The TIFF file should contain multiple images.

```
t = Tiff('myfile.tif', 'r');  
t.setDirectory(2);
```

**References** This method corresponds to the `TIFFSetDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**See Also** `Tiff.currentDirectory` | `Tiff.nextDirectory`

**Tutorials**

# setenv

---

**Purpose** Set environment variable

**Syntax** `setenv(name,value)`  
`setenv(name)`

**Description** `setenv(name,value)` sets the value of an environment variable belonging to the underlying operating system. Inputs `name` and `value` are both strings. If `name` already exists as an environment variable, then `setenv` replaces its current value with the string given in `value`. If `name` does not exist, `setenv` creates a new environment variable called `name` and assigns `value` to it.

`setenv(name)` is equivalent to `setenv(name, '')` and assigns a null value to the variable `name`. On the Microsoft Windows platform, this is equivalent to undefining the variable. On most UNIX platforms, it is possible to have an environment variable defined as empty.

The maximum number of characters in `name` is  $2^{15} - 2$  (or 32766). If `name` contains the character `=`, `setenv` throws an error. The behavior of environment variables with `=` in the name is not well-defined.

On all platforms, `setenv` passes the `name` and `value` strings to the operating system unchanged. Special characters such as `;`, `/`, `:`, `$`, `%`, etc. are left unexpanded and intact in the variable value.

Values assigned to variables using `setenv` are picked up by any process that is spawned using the MATLAB `system`, `unix`, `dos` or `!` functions. You can retrieve any value set with `setenv` by using `getenv(name)`.

**Examples** `% Set and retrieve a new value for the environment variable TEMP:`

```
setenv('TEMP', 'C:\TEMP');  
getenv('TEMP')
```

`% Append the Perl\bin folder to your system PATH variable:`

```
setenv('PATH', [getenv('PATH') 'D:\Perl\bin']);
```

**See Also** `getenv` | `system` | `unix` | `dos` | `!`

**Purpose**

Assign values to structure array field

**Syntax**

```
s = setfield(s, 'field', value)
s = setfield(s, {sIndx1, ..., sIndxM}, 'field', {fIndx1, ...,
    fIndxN}, value)
```

**Description**

`s = setfield(s, 'field', value)`, where `s` is a 1-by-1 structure, sets the contents of the specified field, equivalent to `s.field = value`. If `s` does not contain the specified `field`, the `setfield` function creates the field and assigns the specified value. Pass field references as strings.

```
s =
setfield(s, {sIndx1, ..., sIndxM}, 'field', {fIndx1, ..., fIndxN}, value)
```

sets the contents of the specified field, equivalent to `s(sIndx1, ..., sIndxM).field(fIndx1, ..., fIndxN) = value`. The `setfield` function supports multiple sets of `field` and `fIndx` inputs. If structure `s` or any of the fields is a nonscalar structure, the `Indx` inputs associated with that input are required. Otherwise, the `Indx` inputs are optional. If you specify a single colon operator for an index input, enclose it in single quotation marks: `' : '`.

**Tips**

- For most cases, add data to a structure array by indexing rather than using the `setfield` function. For more information, see “Access Data in a Structure Array” and “Generate Field Names from Variables”.
- Call `setfield` to simplify references to structure arrays with nested fields, as shown in the Examples section.

**Examples**

Add values to a structure that contains nested fields:

```
grades = [];
level = 5;
semester = 'Fall';
subject = 'Math';
student = 'John_Doe';
fieldnames = {semester subject student};
newGrades_Doe = [85, 89, 76, 93, 85, 91, 68, 84, 95, 73];
```

# setfield

---

```
grades = setfield(grades, {level}, ...
                 fieldnames{:}, {10, 21:30}, ...
                 newGrades_Doe);

% View the new contents.
grades(level).(semester).(subject).(student)(10, 21:30)
```

---

Using the structure defined in the previous example, remove the tenth row of the specified field:

```
grades = setfield(grades, {level}, fieldnames{:}, {10,':'}, []);
```

## See Also

## How To

- “Generate Field Names from Variables”
- “Access Data in a Structure Array”

**Purpose** Set component position in pixels

**Syntax** `setpixelposition(handle,position)`  
`setpixelposition(handle,position,recursive)`

**Description** `setpixelposition(handle,position)` sets the position of the component specified by `handle`, to the specified position relative to its parent. `position` is a four-element vector that specifies the location and size of the component: [pixels from left, pixels from bottom, pixels across, pixels high].

`setpixelposition(handle,position,recursive)` sets the position as above. If Boolean `recursive` is true, the position is set relative to the parent figure of `handle`.

**Examples** This example first creates a push button within a panel.

```
f = figure('Position',[300 300 300 200]);  
p = uipanel('Position',[.2 .2 .6 .6]);  
h1 = uicontrol(p,'Style','PushButton','Units','normalized',...  
             'String','Push Button','Position',[.1 .1 .5 .2]);
```

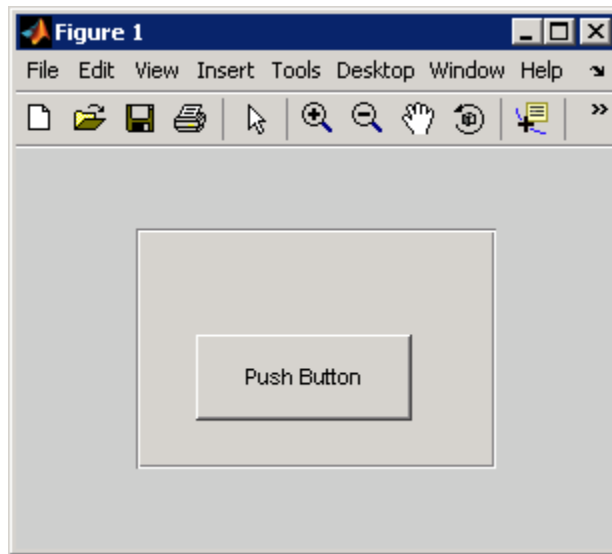

# setpixelposition

---

The example then retrieves the position of the push button and changes its position with respect to the panel.

```
pos1 = getpixelposition(h1);  
setpixelposition(h1,pos1 + [10 10 25 25]);
```

## See Also

[getpixelposition](#) | [uicontrol](#) | [uipanel](#)

# setpref

---

## Purpose

Set preference

## Syntax

```
setpref('group','pref',val)
setpref('group',{'pref1','pref2',...,'prefn'},{val1,val2,...,
    valn})
```

## Description

`setpref('group','pref',val)` sets the preference specified by `group` and `pref` to the value `val`. Individual preference values can be any MATLAB data type, including numeric types, strings, cell arrays, structures, and objects. Setting a preference that does not yet exist causes it to be created.

`group` labels a related collection of preferences. You can choose any name that is a legal variable name, and is descriptive enough to be unique, e.g., `'MathWorks_GUIDE_ApplicationPrefs'`. The input argument `pref` identifies an individual preference in that group, and must be a legal variable name.

`setpref('group',{'pref1','pref2',...,'prefn'},{val1,val2,...,valn})` sets each preference specified in the cell array of names to the corresponding value.

---

**Note** Preference values are persistent and maintain their values between MATLAB sessions. Where they are stored is system dependent.

---

## Examples

Use `addpref` to create a preference group called `mytoolbox` and a preference within it called `version`, and then modify the contents of `version` using `setpref`:

```
addpref('mytoolbox','version','1.0')
getpref('mytoolbox','version')
```

```
ans =
1.0
```

```
setpref('mytoolbox','version',{'1.0','beta'})
```

```
getpref('mytoolbox','version')
```

```
ans =  
    '1.0'    'beta'
```

## See Also

# setstr

---

**Purpose** Set string flag

---

**Note** setstr is not recommended. Use char instead.

---

**Description** This MATLAB 4 function has been renamed char in MATLAB 5.

**Purpose** Make subIFD specified by byte offset current IFD

**Syntax** `tiffobj.setSubDirectory(offset)`

**Description** `tiffobj.setSubDirectory(offset)` sets the subimage file directory (subIFD) specified by `offset` the current IFD. The `offset` value is given in bytes. Use this method when you want to access subIFDs linked through the SubIFD tag.

**Examples** Open a TIFF file and read the value of the SubIFD tag in the current IFD. The SubIFD tag contains byte offsets that specify the location of subIFDs in the IFD. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path. The TIFF file should contain subIFDs.

```
t = Tiff('myfile.tif', 'r');
%
% Read the value of the SubIFD tag to get subdirectory offsets.
offsets = t.getTag('SubIFD');
%
% Set one of the subdirectories (if more than one) as the current directory.
t.setSubDirectory(offsets(1));
```

**References** This method corresponds to the `TIFFSetSubDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**See Also** `Tiff.setDirectory`

**Tutorials**

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

# Tiff.setTag

---

**Purpose** Set value of tag

**Syntax** `tiffobj.setTag(tagId,tagValue)`  
`tiffobj.setTag(tagStruct)`

**Description** `tiffobj.setTag(tagId,tagValue)` sets the value of the TIFF tag specified by `tagId` to the value specified by `tagValue`. You can specify `tagId` as a character string ('ImageWidth') or using the numeric tag identifier defined by the TIFF specification (256). To see a list of all the tags with their numeric identifiers, view the value of the Tiff object `TagID` property. Use the `TagID` property to specify the value of a tag. For example, `Tiff.TagID.ImageWidth` is equivalent to the tag's numeric identifier.

`tiffobj.setTag(tagStruct)` sets the values of all of the tags with `name/value` fields in `tagStruct`. The names of fields in `tagstruct` must be the name of TIFF tags.

---

**Note** If you are modifying a tag rather than creating it, you must use the `Tiff.rewriteDirectory` method after using the `Tiff.setTag` method.

---

**Examples** Create a structure with fields named after TIFF tags and assign values to the fields. Pass this structure to the `setTag` method to set the values of these tags. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path.

```
t = Tiff('myfile.tif', 'r+');

tagStruct.ImageWidth = 1600;
tagStruct.ImageLength = 3200;
tagStruct.Photometric = Tiff.Photometric.RGB;
tagStruct.BitsPerSample = 8;
tagStruct.SamplesPerPixel = 3;
tagStruct.TileWidth = 160;
```

```
tagStruct.TileLength = 320;  
tagStruct.PlanarConfiguration = Tiff.PlanarConfiguration.Chunky;  
tagStruct.Software = 'MATLAB';  
t.setTag(tagStruct);
```

## References

This method corresponds to the `TIFFSetField` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

# settimeseriesnames

---

**Purpose** Change name of `timeseries` object in `tscollection`

**Syntax** `tsc = settimeseriesnames(tsc,old,new)`

**Description** `tsc = settimeseriesnames(tsc,old,new)` replaces the old name of `timeseries` object with the new name in `tsc`.

**See Also** `tscollection`

**Purpose**

Find set exclusive OR of two arrays

**Compatibility**

In a future release, the behavior of `setxor` will change. This change is introduced for adoption in R2012a. For a detailed demonstration that shows how you can preview the future behavior and preserve the current behavior of your existing code, see the example, “Assessing the Impact of the Forthcoming Changes to `setxor`” on page 2-4113. For a detailed explanation of all the forthcoming changes, see “Set Functions Changing Behavior in a Future Release”.

**Syntax**

```
C = setxor(A,B)
C = setxor(A,B,'rows')
[C,ia,ib] = setxor(A,B)
[C,ia,ib] = setxor(A,B,'rows')

[C,ia,ib] = setxor(__,'R2012a')

[C,ia,ib] = setxor(__,'legacy')

[C,ia,ib] = setxor(A,B,setOrder)

[C,ia,ib] = setxor(A,B,'rows',setOrder)
```

**Description**

`C = setxor(A,B)` returns the values of `A` and `B` that are not in their intersection (the symmetric difference). The values of `C` are in sorted order.

`C = setxor(A,B,'rows')` returns the rows of matrices `A` and `B` that are not in their intersection. The rows of the matrix `C` are in sorted order.

`[C,ia,ib] = setxor(A,B)` also returns index vectors `ia` and `ib`, such that `C` is a sorted combination of the elements `A(ia)` and `B(ib)`.

`[C,ia,ib] = setxor(A,B,'rows')` also returns index vectors `ia` and `ib`, such that `C` is a sorted combination of the elements `A(ia,:)` and `B(ib,:)`.

`[C,ia,ib] = setxor(___, 'R2012a')` adopts the future behavior of the `setxor` function. `[C,ia,ib] = setxor(___, 'legacy')` preserves the current behavior. You can specify either flag, `'R2012a'` or `'legacy'`, as the final input argument in any previous syntax.

`[C,ia,ib] = setxor(A,B,setOrder)` and `[C,ia,ib] = setxor(A,B,'rows',setOrder)` returns `C` in a specific order. `setOrder='sorted'` returns the values (or rows) of `C` in sorted order. `setOrder='stable'` returns the values (or rows) of `C` in the same order as `A` and `B`.

## Input Arguments

### **A,B - Input arrays**

vectors | matrices | N-D arrays

Input arrays of which to find the symmetric difference, specified as `logical`, `char`, a cell array of strings, or any numeric class. `A` and `B` also can be any object with the class methods: `sort` (or `sortrows` for the `'rows'` option), `eq`, and `ne`. This includes heterogeneous arrays derived from the same root class.

`A` and `B` must be of the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with double arrays.
- Cell arrays of strings can combine with `char` arrays.

If you specify the `'rows'` option, `A` and `B` must have the same number of columns.

### **Data Types**

`double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

**Complex Number Support:** Yes

**'rows' - Rows flag**

Rows flag, specified as 'rows', identifies the rows of A and B as individual elements. When you specify this flag, setxor returns the rows of A and B that are not in their intersection. A and B must have the same number of columns. This option does not support cell arrays.

**setOrder - Order flag**

'sorted' | 'stable'

Order flag, specified as 'sorted' or 'stable', indicates the order of the values (or rows) in C.

| Order Flag | Meaning                                                                                                                                                 |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'sorted'   | The values (or rows) in C, are returned in sorted order. For example:<br>C = setxor([5 1 3],[4 1 2],'sorted') returns<br>C = [2 3 4 5].                 |
| 'stable'   | The values (or rows) in C, are returned in the same order as in A and B. For example:<br>C = setxor([5 1 3],[4 1 2],'stable') returns<br>C = [5 3 4 2]. |

**'legacy' - Legacy behavior flag**

Legacy behavior flag, when specified, preserves the current behavior. If the new behavior adversely affects your existing code, you can preserve the current behavior by specifying 'legacy' as the final argument.

**'R2012a' - Future behavior flag**

Future behavior flag, when specified, adopts the future behavior change. Specify 'R2012a' as the final argument to see what impact the new behavior has on your existing code.

# setxor

---

## Output Arguments

### **C - Symmetric difference array**

vector | matrix

Symmetric difference array, returned as a vector or matrix. C is a vector, unless you specify the 'rows' flag. If 'rows' is specified, C is a matrix containing the rows of A and B that are not in their intersection.

### **ia - Index to A**

vector

Index to A, returned as a vector, identifies the values (or rows) in A that contribute to the symmetric difference. If there is a repeated value (or row) appearing exclusively in A, then ia contains the index to the last occurrence of the value (or row).

If you call `setxor` with the `setOrder` or 'R2012a' argument, ia contains the index to the first occurrence of any repeated value (or row) in A.

### **ib - Index to B**

vector

Index to B, returned as a vector, identifies the values (or rows) in B that contribute to the symmetric difference. If there is a repeated value (or row) appearing exclusively in B, then ib contains the index to the last occurrence of the value (or row).

If you call `setxor` with the `setOrder` or 'R2012a' argument, ib contains the index to the first occurrence of any repeated value (or row) in B.

## Examples

### **Symmetric Difference of Two Vectors**

```
A = [5 1 3 3 3]; B = [4 1 2];  
C = setxor(A,B)
```

```
C =
```

```
     2     3     4     5
```

### Find Symmetric Difference of Two Vectors and the Indices to the Different Values

```
A = [5 1 3 3 3]; B = [4 1 2];
[C,ia,ib] = setxor(A,B)
```

```
C =
     2     3     4     5
```

```
ia =
     5     1
```

```
ib =
     3     1
```

### Symmetric Difference of the Rows in Two Matrices

```
A = [7 8 9; 7 7 1; 7 7 1; 1 2 3; 4 5 6];
B = [1 2 3; 4 5 6; 7 7 2];
[C,ia,ib] = setxor(A,B,'rows')
```

```
C =
     7     7     1
     7     7     2
     7     8     9
```

```
ia =
     3
     1
```

```
ib =
     3
```

## Symmetric Difference of Two Vectors in a Specified Order

Use the `setOrder` argument to specify the ordering of the values in `C`.

Specify `'stable'` if you want the values in `C` to have the same order as `A` and `B`.

```
A = [5 1 3 3 3]; B = [4 1 2];  
[C,ia,ib] = setxor(A,B,'stable')
```

```
C =  
     5     3     4     2
```

```
ia =  
     1  
     3
```

```
ib =  
     1  
     3
```

Alternatively, you can specify `'sorted'` order.

```
[C,ia,ib] = setxor(A,B,'sorted')
```

```
C =  
     2     3     4     5
```

```
ia =  
     3  
     1
```

```
ib =
```

```
3
1
```

setxor adopts the forthcoming behavior when you specify the setOrder argument. If you omit the setOrder argument, the output is sorted, but the size and content of C, ia, and ib conforms to the current behavior.

### Assessing the Impact of the Forthcoming Changes to setxor

Use the 'R2012a' flag to assess the impact of the forthcoming behavior changes. Use the 'legacy' flag to preserve the current behavior of your existing code.

Find the symmetric difference of A and B with the current default behavior.

```
A = [5 1 3 3 3]; B = [4 1 2 2];
[C1,ia1,ib1] = setxor(A,B)
```

```
C1 =
```

```
     2     3     4     5
```

```
ia1 =
```

```
     5     1
```

```
ib1 =
```

```
     4     1
```

Find the symmetric difference and opt into the forthcoming behavior. In the future, this behavior will be the default.

```
[C2,ia2,ib2] = setxor(A,B,'R2012a')
```

```
C2 =
```

## setxor

---

```
          2     3     4     5
ia2 =
          3
          1

ib2 =
          3
          1
```

Notice that `ia1` and `ia2` have different shapes and content. This also true for `ib1` and `ib2`.

Find the symmetric difference and preserve the current behavior.

```
[C3,ia3,ib3] = setxor(A,B,'legacy')
```

```
C3 =
          2     3     4     5

ia3 =
          5     1

ib3 =
          4     1
```

Notice that `C3`, `ia3`, and `ic3` match `C1`, `ia1`, and `ic1` respectively.

### **Find Symmetric Difference of Vectors Containing NaNs**

```
A = [5 NaN NaN]; B = [5 NaN NaN];
C = setxor(A,B)
```

C =

NaN NaN NaN NaN

The `setxor` function treats NaN values as distinct.

| `sort`

# shading

---

**Purpose** Set color shading properties

**Syntax** shading flat  
shading faceted  
shading interp  
shading(*axes\_handle*,...)

**Description** The shading function controls the color shading of surface and patch graphics objects.

`shading flat` each mesh line segment and face has a constant color determined by the color value at the endpoint of the segment or the corner of the face that has the smallest index or indices.

`shading faceted` flat shading with superimposed black mesh lines. This is the default shading mode.

`shading interp` varies the color in each line segment and face by interpolating the colormap index or true color value across the line or face.

`shading(axes_handle,...)` applies the shading type to the objects in the axes specified by *axes\_handle*, instead of the current axes. Use quoted strings when using a function form. For example:

```
shading(gca, 'interp')
```

**Examples** Compare a flat, faceted, and interpolated-shaded sphere.

```
subplot(3,1,1)  
sphere(16)  
axis square  
shading flat  
title('Flat Shading')
```

```
subplot(3,1,2)  
sphere(16)  
axis square  
shading faceted
```

```
title('Faceted Shading')  
  
subplot(3,1,3)  
sphere(16)  
axis square  
shading interp  
title('Interpolated Shading')
```

# shading

---

Flat Shading

Faceted Shading

Interpolated Shading

## Algorithms

`shading` sets the `EdgeColor` and `FaceColor` properties of all surface and patch graphics objects in the current axes. `shading` sets the appropriate values, depending on whether the surface or patch objects represent meshes or solid surfaces.

## See Also

| `surf` | `patch` | `surface`

# shg

---

**Purpose** Show most recent graph window

**Syntax** shg

**Description** shg makes the current figure visible and raises it above all other figures on the screen. This is identical to using the command `figure(gcf)`.

**See Also** figure | gca |(gcf)

## Purpose

Shift dimensions

## Syntax

```
B = shiftdim(X,n)
[B,nshifts] = shiftdim(X)
```

## Description

`B = shiftdim(X,n)` shifts the dimensions of `X` by `n`. When `n` is positive, `shiftdim` shifts the dimensions to the left and wraps the `n` leading dimensions to the end. When `n` is negative, `shiftdim` shifts the dimensions to the right and pads with singletons.

`[B,nshifts] = shiftdim(X)` returns the array `B` with the same number of elements as `X` but with any leading singleton dimensions removed. A singleton dimension is any dimension for which `size(A,dim) = 1`. `nshifts` is the number of dimensions that are removed.

If `X` is a scalar, `shiftdim` has no effect.

## Examples

The `shiftdim` command is handy for creating functions that, like `sum` or `diff`, work along the first nonsingleton dimension.

```
a = rand(1,1,3,1,2);
[b,n] = shiftdim(a); % b is 3-by-1-by-2 and n is 2.
c = shiftdim(b,-n); % c == a.
d = shiftdim(a,3); % d is 1-by-2-by-1-by-1-by-3.
```

## See Also

`circshift` | `reshape` | `squeeze` | `permute` | `ipermute`

# showplottool

## Purpose

Show or hide figure plot tool

## Syntax

```
showplottool('tool')  
showplottool('on','tool')  
showplottool('off','tool')  
showplottool('toggle','tool')  
showplottool(figure_handle,...)
```

## Description

`showplottool('tool')` shows the specified plot tool on the current figure. `tool` can be one of the following strings:

- `figurepalette`
- `plotbrowser`
- `propertyeditor`

`showplottool('on','tool')` shows the specified plot tool on the current figure.

`showplottool('off','tool')` hides the specified plot tool on the current figure.

`showplottool('toggle','tool')` toggles the visibility of the specified plot tool on the current figure.

`showplottool(figure_handle,...)` operates on the specified figure instead of the current figure.

---

**Note** When you dock, undock, resize, or reposition a plotting tool and then close it, it will still be configured as you left it the next time you open it. There is no command to reset plotting tools to their original, default locations.

---

## Alternatives

Click the larger Plotting Tools icon  on the figure toolbar to collectively enable plotting tools, and the smaller icon  to collectively disable them. Individually select the **Figure Palette**, **Plot Browser**, and **Property Editor** tools from the figure's **View** menu. For details, see “Plotting Tools — Interactive Plotting”.

## See Also

[figurepalette](#) | [plotbrowser](#) | [plottools](#) | [propertyeditor](#)

# shrinkfaces

---

**Purpose** Reduce size of patch faces

**Syntax**

```
shrinkfaces(p,sf)
nfv = shrinkfaces(p,sf)
nfv = shrinkfaces(fv,sf)
shrinkfaces(p)
nfv = shrinkfaces(f,v,sf)
[nf,nv] = shrinkfaces(...)
```

**Description**

`shrinkfaces(p,sf)` shrinks the area of the faces in patch `p` to shrink factor `sf`. A shrink factor of 0.6 shrinks each face to 60% of its original area. If the patch contains shared vertices, the MATLAB software creates nonshared vertices before performing the face-area reduction.

`nfv = shrinkfaces(p,sf)` returns the face and vertex data in the struct `nfv`, but does not set the `Faces` and `Vertices` properties of patch `p`.

`nfv = shrinkfaces(fv,sf)` uses the face and vertex data from the struct `fv`.

`shrinkfaces(p)` and `shrinkfaces(fv)` (without specifying a shrink factor) assume a shrink factor of 0.3.

`nfv = shrinkfaces(f,v,sf)` uses the face and vertex data from the arrays `f` and `v`.

`[nf,nv] = shrinkfaces(...)` returns the face and vertex data in two separate arrays instead of a struct.

**Examples**

This example uses the flow data set, which represents the speed profile of a submerged jet within an infinite tank (type `help flow` for more information). Two isosurfaces provide a before and after view of the effects of shrinking the face size.

- First `reducevolume` samples the flow data at every other point and then `isosurface` generates the faces and vertices data.
- The `patch` command accepts the face/vertex struct and draws the first (`p1`) isosurface.

- Use the `daspect`, `view`, and `axis` commands to set up the view and then add a title.
- The `shrinkfaces` command modifies the face/vertex data and passes it directly to `patch`.

```
[x,y,z,v] = flow;
[x,y,z,v] = reducevolume(x,y,z,v,2);
fv = isosurface(x,y,z,v,-3);
p1 = patch(fv);
set(p1,'FaceColor','red','EdgeColor',[.5,.5,.5]);
daspect([1 1 1]); view(3); axis tight
title('Original')
```

```
figure
p2 = patch(shrinkfaces(fv,.3));
set(p2,'FaceColor','red','EdgeColor',[.5,.5,.5]);
daspect([1 1 1]); view(3); axis tight
title('After Shrinking')
```

# shrinkfaces

# sign

---

**Purpose** Signum function

**Syntax**  $Y = \text{sign}(X)$

**Description**  $Y = \text{sign}(X)$  returns an array  $Y$  the same size as  $X$ , where each element of  $Y$  is:

- 1 if the corresponding element of  $X$  is greater than zero
- 0 if the corresponding element of  $X$  equals zero
- -1 if the corresponding element of  $X$  is less than zero

For nonzero complex  $X$ ,  $\text{sign}(X) = X./\text{abs}(X)$ .

**See Also** `abs` | `conj` | `imag` | `real`

**Purpose** Sine of argument in radians

**Syntax**  $Y = \sin(X)$

**Description**  $Y = \sin(X)$  returns the circular sine of the elements of  $X$ . The `sin` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

**Examples** Graph the sine function over the domain  $-\pi \leq x \leq \pi$ .

```
x = -pi:0.01:pi;  
plot(x,sin(x)), grid on
```

[sin](#) | [asind](#) | [asin](#)

# single

---

**Purpose** Convert to single precision

**Syntax** `B = single(A)`

**Description** `B = single(A)` converts the matrix `A` to single precision, returning that value in `B`. `A` can be any numeric object (such as a `double`). If `A` is already single precision, `single` has no effect. Single-precision quantities require less storage than double-precision quantities, but have less precision and a smaller range.

The `single` class is primarily meant to be used to store single-precision values. Hence most operations that manipulate arrays without changing their elements are defined. Examples are `reshape`, `size`, the relational operators, subscripted assignment, and subscripted reference.

You can define your own methods for the `single` class by placing the appropriately named method in an `@single` folder within a folder on your path.

## Examples

```
a = magic(4);  
b = single(a);
```

```
whos
```

| Name | Size | Bytes | Class        |
|------|------|-------|--------------|
| a    | 4x4  | 128   | double array |
| b    | 4x4  | 64    | single array |

**See Also** `double`

**Purpose** Hyperbolic sine of argument in radians

**Syntax**  $Y = \sinh(X)$

**Description** The sinh function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

$Y = \sinh(X)$  returns the hyperbolic sine of the elements of  $X$ .

**Examples** Graph the hyperbolic sine function over the domain  $-5 \leq x \leq 5$ .

```
x = -5:0.01:5;  
plot(x,sinh(x)), grid on
```

**See Also** [sin](#) | [asinh](#) | [cosh](#)

# size

---

**Purpose** Array dimensions

**Syntax**

```
d = size(X)
[m,n] = size(X)
m = size(X,dim)
[d1,d2,d3,...,dn] = size(X),
```

**Description** `d = size(X)` returns the sizes of each dimension of array `X` in a vector `d` with `ndims(X)` elements. If `X` is a scalar, which MATLAB software regards as a 1-by-1 array, `size(X)` returns the vector `[1 1]`.

`[m,n] = size(X)` returns the size of matrix `X` in separate variables `m` and `n`.

`m = size(X,dim)` returns the size of the dimension of `X` specified by scalar `dim`.

`[d1,d2,d3,...,dn] = size(X)`, for  $n > 1$ , returns the sizes of the dimensions of the array `X` in the variables `d1,d2,d3,...,dn`, provided the number of output arguments `n` equals `ndims(X)`. If `n` does not equal `ndims(X)`, the following exceptions hold:

`n < ndims(X)`    `di` equals the size of the *i*th dimension of `X` for  $0 < i < n$ , but `dn` equals the product of the sizes of the remaining dimensions of `X`, that is, dimensions `n` through `ndims(X)`.

`n > ndims(X)`    `size` returns ones in the “extra” variables, that is, those corresponding to `ndims(X)+1` through `n`.

---

**Note** For a Java array, `size` returns the length of the Java array as the number of rows. The number of columns is always 1. For a Java array of arrays, the result describes only the top level array.

---

## Examples

### Example 1

The size of the second dimension of `rand(2,3,4)` is 3.

```
m = size(rand(2,3,4),2)
```

```
m =  
    3
```

Here the size is output as a single vector.

```
d = size(rand(2,3,4))
```

```
d =  
    2    3    4
```

Here the size of each dimension is assigned to a separate variable.

```
[m,n,p] = size(rand(2,3,4))
```

```
m =  
    2
```

```
n =  
    3
```

```
p =  
    4
```

## Example 2

If  $X = \text{ones}(3,4,5)$ , then

```
[d1,d2,d3] = size(X)
```

```
d1 =    d2 =    d3 =  
    3     4     5
```

But when the number of output variables is less than `ndims(X)`:

```
[d1,d2] = size(X)
```

```
d1 =    d2 =  
    3     20
```

# size

---

The “extra” dimensions are collapsed into a single product.

If  $n > \text{ndims}(X)$ , the “extra” variables all represent singleton dimensions:

```
[d1,d2,d3,d4,d5,d6] = size(X)
```

```
d1 =      d2 =      d3 =  
    3      4      5
```

```
d4 =      d5 =      d6 =  
    1      1      1
```

## Examples

### Determine the Size of a Map

Construct a map and find the number of key-value pairs:

```
myKeys = {'a','b','c'};
myValues = [1,2,3];
```

## containers.Map.size

---

```
mapObj = containers.Map(myKeys,myValues);  
dim = size(mapObj,1)
```

This code returns a scalar numeric value:

```
dim =  
    3
```

If you do not specify a second input argument,

```
dimVector = size(mapObj)
```

then the `size` method returns a vector:

```
dimVector =  
    3     1
```

Scalar numeric values, where `dimK` contains the size of the `K`th dimension of variable:

- If `N < ndims(variable)`, then `dimN`, equals the product of the sizes of dimensions `N` through `ndims(variable)`.
- If `N > ndims(variable)`, the `size` method returns ones in the output variables corresponding to dimensions `ndims(variable)+1` through `N`.

## **selectedDim**

Scalar numeric value that contains the size of the selected dimension for the specified variable.

## **Examples**

Find the size of the matrix `topo` in `topography.mat` without loading any data:

```
matObj = matfile('topography.mat');  
[nrows,ncols] = size(matObj,'topo');
```

---

Determine the dimensions of a variable, and process one part of the variable at a time. In this case, calculate and store the average of each column of variable `stocks` in the example file `stocks.mat`:

```
filename = 'stocks.mat';  
matObj = matfile(filename);  
[nrows,ncols] = size(matObj,'stocks');  
  
avgs = zeros(1,ncols);  
for idx = 1:ncols  
    avgs(idx) = mean(matObj.stocks(:,idx));  
end
```

---

Create a three-dimensional array, and call the `size` method with different numbers of output arguments:

```
matObj = matfile('temp.mat','Writable',true);
matObj.X = rand(2,3,4);

d = size(matObj,'X')
d2 = size(matObj,'X',2)
[m,n] = size(matObj,'X')
[m1,m2,m3,m4] = size(matObj,'X')
```

This code returns

```
d =
     2     3     4

d2 =
     3

m =
     2
n =
    12

m1 =
     2
m2 =
     3
m3 =
     4
m4 =
     1
```

## size (serial)

---

**Purpose** Size of serial port object array

**Syntax**

```
d = size(obj)
[m,n] = size(obj)
[m1,m2,m3,...,mn] = size(obj)
m = size(obj,dim)
```

**Description**

`d = size(obj)` returns the two-element row vector `d` containing the number of rows and columns in the serial port object, `obj`.

`[m,n] = size(obj)` returns the number of rows, `m` and columns, `n` in separate output variables.

`[m1,m2,m3,...,mn] = size(obj)` returns the length of the first `n` dimensions of `obj`.

`m = size(obj,dim)` returns the length of the dimension specified by the scalar `dim`. For example, `size(obj,1)` returns the number of rows.

**See Also** `length`

**Purpose** Size of triangulation matrix

**Syntax** `size(TR)`

**Description** `size(TR)` provides size information for a triangulation matrix. The matrix is of size `mtri-by-nv`, where `mtri` is the number of simplices and `nv` is the number of vertices per simplex (triangle/tetrahedron, etc).

**Input Arguments** `TR` Triangulation matrix

**Definitions** A simplex is a triangle/tetrahedron or higher-dimensional equivalent.

**See Also** `size`

## size (tscollection)

---

|                    |                                                                                                                                                                     |

| <b>Purpose</b>     | Size of tscollection object                                                                                                                                         |
| <b>Syntax</b>      | <code>size(tsc)</code>                                                                                                                                              |
| <b>Description</b> | <code>size(tsc)</code> returns <code>[n m]</code> , where <code>n</code> is the length of the time vector and <code>m</code> is the number of tscollection members. |
| <b>See Also</b>    | <code>length (tscollection)</code>   <code>isempty (tscollection)</code>   <code>tscollection</code>                                                                |

**Purpose**

Volumetric slice plot

**Syntax**

```
slice(V, sx, sy, sz)
slice(X, Y, Z, V, sx, sy, sz)
slice(V, XI, YI, ZI)
slice(X, Y, Z, V, XI, YI, ZI)
slice(..., 'method')
slice(axes_handle, ...)
h = slice(...)
```

**Description**

`slice` displays orthogonal slice planes through volumetric data.

`slice(V, sx, sy, sz)` draws slices along the  $x$ ,  $y$ ,  $z$  directions in the volume  $V$  at the points in the vectors  $sx$ ,  $sy$ , and  $sz$ .  $V$  is an  $m$ -by- $n$ -by- $p$  volume array containing data values at the default location  $X = 1:n$ ,  $Y = 1:m$ ,  $Z = 1:p$ . Each element in the vectors  $sx$ ,  $sy$ , and  $sz$  defines a slice plane in the  $x$ -,  $y$ -, or  $z$ -axis direction.

`slice(X, Y, Z, V, sx, sy, sz)` draws slices of the volume  $V$ .  $X$ ,  $Y$ , and  $Z$  are three-dimensional arrays specifying the coordinates for  $V$ .  $X$ ,  $Y$ , and  $Z$  must be monotonic and orthogonally spaced (as if produced by the function `meshgrid`). The color at each point is determined by 3-D interpolation into the volume  $V$ .

`slice(V, XI, YI, ZI)` draws data in the volume  $V$  for the slices defined by  $XI$ ,  $YI$ , and  $ZI$ .  $XI$ ,  $YI$ , and  $ZI$  are matrices that define a surface, and the volume is evaluated at the surface points.  $XI$ ,  $YI$ , and  $ZI$  must all be the same size.

`slice(X, Y, Z, V, XI, YI, ZI)` draws slices through the volume  $V$  along the surface defined by the arrays  $XI$ ,  $YI$ ,  $ZI$ .

`slice(..., 'method')` specifies the interpolation method. `'method'` is `'linear'`, `'cubic'`, or `'nearest'`.

- `linear` specifies trilinear interpolation (the default).

- `cubic` specifies tricubic interpolation.
- `nearest` specifies nearest-neighbor interpolation.

`slice(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes object (`gca`). The axes `clim` property is set to span the finite values of `V`.

`h = slice(...)` returns a vector of handles to surface graphics objects.

## Tips

The color drawn at each point is determined by interpolation into the volume `V`.

## Examples

Visualize the function

$$v = xe^{(-x^2-y^2-z^2)}$$

over the range  $-2 \leq x \leq 2$ ,  $-2 \leq y \leq 2$ ,  $-2 \leq z \leq 2$ :

```
[x,y,z] = meshgrid(-2:.2:2,-2:.25:2,-2:.16:2);  
v = x.*exp(-x.^2-y.^2-z.^2);  
xslice = [-1.2,.8,2]; yslice = 2; zslice = [-2,0];  
slice(x,y,z,v,xslice,yslice,zslice)  
colormap hsv
```

### Slicing At Arbitrary Angles

You can also create slices that are oriented in arbitrary planes. To do this,

- Create a slice surface in the domain of the volume (`surf`, `linspace`).
- Orient this surface with respect to the axes (`rotate`).
- Get the `XData`, `YData`, and `ZData` of the surface (`get`).
- Use this data to draw the slice plane within the volume.

For example, these statements slice the volume in the first example with a rotated plane. Placing these commands within a `for` loop “passes” the plane through the volume along the  $z$ -axis.

```
for i = -2:.5:2
    hsp = surf(linspace(-2,2,20),linspace(-2,2,20),zeros(20)+i);
    rotate(hsp,[1,-1,1],30)
```

# slice

---

```
xd = get(hsp, 'XData');
yd = get(hsp, 'YData');
zd = get(hsp, 'ZData');
delete(hsp)
slice(x,y,z,v,[-2,2],2,-2) % Draw some volume boundaries
hold on
slice(x,y,z,v,xd,yd,zd)
hold off
axis tight
view(-5,10)
drawnow
end
```

The following picture illustrates three positions of the same slice surface as it passes through the volume.

## Slicing with a Nonplanar Surface

You can slice the volume with any surface. This example probes the volume created in the previous example by passing a spherical slice surface through the volume.

```
[xsp,ysp,zsp] = sphere;
slice(x,y,z,v,[-2,2],2,-2) % Draw some volume boundaries

for i = -3:.2:3
    hsp = surface(xsp+i,ysp,zsp);
    rotate(hsp,[1 0 0],90)
    xd = get(hsp,'XData');
    yd = get(hsp,'YData');
    zd = get(hsp,'ZData');
    delete(hsp)
    hold on
    hslicer = slice(x,y,z,v,xd,yd,zd);
    axis tight
    xlim([-3,3])
    view(-10,35)
    drawnow
    delete(hslicer)
    hold off
end
```

The following picture illustrates three positions of the spherical slice surface as it passes through the volume.

# slice

## How To

- Exploring Volumes with Slice Planes

**Purpose** Smooth 3-D data

## Syntax

## Description

`W = smooth3(V)` smooths the input data `V` and returns the smoothed data in `W`.

`W = smooth3(V, 'filter')` *filter* determines the convolution kernel and can be the strings

- 'gaussian'
- 'box' (default)

`W = smooth3(V, 'filter', size)` sets the size of the convolution kernel (default is [3 3 3]). If `size` is scalar, then `size` is interpreted as [size, size, size].

`W = smooth3(V, 'filter', size, sd)` sets an attribute of the convolution kernel. When *filter* is gaussian, `sd` is the standard deviation (default is .65).

## Examples

This example smooths some random 3-D data and then creates an isosurface with end caps.

```
rng(9, 'twister')
data = rand(10,10,10);
data = smooth3(data, 'box', 5);
patch(isocaps(data, .5), 'FaceColor', 'interp', 'EdgeColor', 'none');
p1 = patch(isosurface(data, .5), 'FaceColor', 'blue', 'EdgeColor', 'none');
isonormals(data, p1)
view(3);
axis vis3d tight
camlight left;
lighting phong
```

| <b>Purpose</b>     | Force snapshot of image for inclusion in published document                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Syntax</b>      | snapnow                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | The snapnow command forces a snapshot of the image or plot that the code has most recently generated for presentation in a published document. The output appears in the published document at the end of the cell that contains the snapnow command. When used outside the context of publishing a file, snapnow has the same behavior as drawnow. That is, if you run a file that contains the snapnow command, the MATLAB software interprets it as though it were a drawnow command.                                                                                                                                                                                                                  |
| <b>Examples</b>    | <p>This example demonstrates the difference between publishing code that contains the snapnow command and running that code. The first image shows the results of publishing the code and the second image shows the results of running the code.</p> <p>Suppose you have a file that contains the following code:</p> <pre>%% Scale magic Data and %% Display as Image:  for i=1:3     imagesc(magic(i))     snapnow end</pre> <p>When you publish the code to HTML, the published document contains a title, a table of contents, the commented text, the code, and each of the three images produced by the for loop. (In the published document shown, the size of the images have been reduced.)</p> |

## Scale magic Data and

### Contents

- [Display as Image:](#)

### Display as Image:

```
for i=1:3
    imagesc(magic(i))
    snapnow
end
```

When you run the code, a single Figure window opens and MATLAB updates the image within this window as it evaluates each iteration of the for loop. Each successive image replaces the one that preceded it, so that the Figure window appears as follows when the code evaluation completes.

# sort

---

**Purpose** Sort array elements in ascending or descending order

**Syntax**

```
B = sort(A)
B = sort(A,dim)
B = sort(...,mode)
[B,IX] = sort(A,...)
```

**Description** `B = sort(A)` sorts the elements along different dimensions of an array, and arranges those elements in ascending order.

| If A is a ...          | sort(A) ...                                                                                                                                                                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Vector                 | Sorts the elements of A.                                                                                                                                                                                                                                                    |
| Matrix                 | Sorts each column of A.                                                                                                                                                                                                                                                     |
| Multidimensional array | Sorts A along the first non-singleton dimension, and returns an array of sorted vectors.                                                                                                                                                                                    |
| Cell array of strings  | Sorts the strings in ascending ASCII dictionary order, and returns a vector cell array of strings. The sort is case-sensitive; uppercase letters appear in the output before lowercase. You cannot use the <code>dim</code> or <code>mode</code> options with a cell array. |

Integer, floating-point, logical, and character arrays are permitted. Floating-point arrays can be complex. For elements of `A` with identical values, the order of these elements is preserved in the sorted list. When `A` is complex, the elements are sorted by magnitude, i.e., `abs(A)`, and where magnitudes are equal, further sorted by phase angle, i.e., `angle(A)`, on the interval  $[-\pi, \pi]$ . If `A` includes any NaN elements, `sort` places these at the high end.

`B = sort(A,dim)` sorts the elements along the dimension of `A` specified by a scalar `dim`.

`B = sort(...,mode)` sorts the elements in the specified direction, depending on the value of `mode`.

'ascend' Ascending order (default)

'descend' Descending order

`[B,IX] = sort(A,...)` also returns an array of indices `IX`, where `size(IX) == size(A)`. If `A` is a vector, `B = A(IX)`. If `A` is an `m`-by-`n` matrix, then each column of `IX` is a permutation vector of the corresponding column of `A`, such that

```
for j = 1:n
    B(:,j) = A(IX(:,j),j);
end
```

If `A` has repeated elements of equal value, the returned indices preserve the original ordering.

### Sorting Complex Entries

If `A` has complex entries `r` and `s`, `sort` orders them according to the following rule: `r` appears before `s` in `sort(A)` if either of the following hold:

- $\text{abs}(r) < \text{abs}(s)$
- $\text{abs}(r) = \text{abs}(s)$  and  $\text{angle}(r) < \text{angle}(s)$

where  $-\pi < \text{angle}(r) \leq \pi$

For example,

```
v = [1 -1 i -i];
angle(v)
```

```
ans =
```

```
0    3.1416    1.5708   -1.5708
```

```
sort(v)
```

```
ans =
```

```
0 - 1.0000i    1.0000
```

# sort

---

0 + 1.0000i -1.0000

---

**Note** sort uses a different rule for ordering complex numbers than do the relational operators. See the Relational Operators reference page for more information.

---

## Examples

### Example 1

Sort horizontal vector A:

```
A = [78 23 10 100 45 5 6];
```

```
sort(A)
```

```
ans =  
     5     6    10    23    45    78   100
```

### Example 2

Sort matrix A in each dimension:

```
A = [ 3 7 5  
     0 4 2 ];
```

```
sort(A,1)
```

```
ans =  
     0     4     2  
     3     7     5
```

```
sort(A,2)
```

```
ans =  
     3     5     7  
     0     2     4
```

Sort it again, this time returning an array of indices for the result:

```
[B, IX] = sort(A, 2)
```

```
B =  
    3    5    7  
    0    2    4
```

```
IX =  
    1    3    2  
    1    3    2
```

### Example 3

Sort each column of matrix A in descending order:

```
A = [ 3  7  5  
      6  8  3  
      0  4  2 ];
```

```
sort(A,1,'descend')
```

```
ans =  
    6    8    5  
    3    7    3  
    0    4    2
```

This is equivalent to

```
sort(A,'descend')
```

```
ans =  
    6    8    5  
    3    7    3  
    0    4    2
```

# sortrows

---

**Purpose** Sort rows in ascending order

**Syntax**  
B = sortrows(A)  
B = sortrows(A,column)  
[B,index] = sortrows(A,...)

**Description** B = sortrows(A) sorts the rows of A in ascending order. Argument A must be either a matrix or a column vector.

For strings, this is the familiar dictionary sort. When A is complex, the elements are sorted by magnitude, and, where magnitudes are equal, further sorted by phase angle on the interval  $[-\pi, \pi]$ .

B = sortrows(A,column) sorts the matrix based on the columns specified in the vector column. If an element of column is positive, the MATLAB software sorts the corresponding column of matrix A in ascending order; if an element of column is negative, MATLAB sorts the corresponding column in descending order. For example, sortrows(A,[2 -3]) sorts the rows of A first in ascending order for the second column, and then by descending order for the third column.

[B,index] = sortrows(A,...) also returns an index vector index.

If A is a column vector, then B = A(index). If A is an m-by-n matrix, then B = A(index,:).

**Examples** Start with an arbitrary matrix, A:

```
A=floor(gallery('uniformdata',[6 7],0)*100);  
A(1:4,1)=95; A(5:6,1)=76; A(2:4,2)=7; A(3,3)=73
```

```
A =  
    95    45    92    41    13     1    84  
    95     7    73    89    20    74    52  
    95     7    73     5    19    44    20  
    95     7    40    35    60    93    67  
    76    61    93    81    27    46    83  
    76    79    91     0    19    41     1
```

When called with only a single input argument, `sortrows` bases the sort on the first column of the matrix. For any rows that have equal elements in a particular column, (e.g., `A(1:4,1)` for this matrix), sorting is based on the column immediately to the right, (`A(1:4,2)` in this case):

```
B = sortrows(A)
B =
    76    61    93    81    27    46    83
    76    79    91     0    19    41     1
    95     7    40    35    60    93    67
    95     7    73     5    19    44    20
    95     7    73    89    20    74    52
    95    45    92    41    13     1    84
```

When called with two input arguments, `sortrows` bases the sort entirely on the column specified in the second argument. Rows that have equal elements in the specified column, (e.g., `A(2:4,:)`, if sorting matrix `A` by column 2) remain in their original order:

```
C = sortrows(A,2)
C =
    95     7    73    89    20    74    52
    95     7    73     5    19    44    20
    95     7    40    35    60    93    67
    95    45    92    41    13     1    84
    76    61    93    81    27    46    83
    76    79    91     0    19    41     1
```

This example specifies two columns to sort by: columns 1 and 7. This tells `sortrows` to sort by column 1 first, and then for any rows with equal values in column 1, to sort by column 7:

```
D = sortrows(A,[1 7])
D =
    76    79    91     0    19    41     1
    76    61    93    81    27    46    83
    95     7    73     5    19    44    20
    95     7    73    89    20    74    52
```

## sortrows

---

```
95    7    40    35    60    93    67
95   45    92    41    13     1    84
```

Sort the matrix using the values in column 4 this time and in reverse order:

```
E = sortrows(A, -4)
```

```
E =
```

```
95    7    73    89    20    74    52
76   61    93    81    27    46    83
95   45    92    41    13     1    84
95    7    40    35    60    93    67
95    7    73     5    19    44    20
76   79    91     0    19    41     1
```

Bit depth of the sample values, specified as an integer. Valid values depend on the audio hardware installed. Most platforms support bit depths of 8 bits or 16 bits.

## Examples

### Play Sample Data at Default Sample Rate

Load the example file `gong.mat`, which contains sample data `y` and rate `Fs`, and listen to the audio.

```
load gong.mat;  
sound(y);
```

### Play Sample Data at Specific Sample Rate

Play an excerpt from Handel's "Hallelujah Chorus" at twice the recorded sample rate.

```
load handel.mat;  
sound(y, 2*Fs);
```

### Play Sample Data with Specific Bit Depth

```
load handel.mat;  
nBits = 16;  
sound(y, Fs, nBits);
```

MATLAB plays the audio with a bit depth of 16 bits per sample, if this is supported on your system.

## Tips

- The `sound` function supports sound devices on all Windows and most UNIX platforms.
- Most sound cards support sample rates between 5 and 48 kilohertz. Specifying a sample rate outside this range might produce unexpected results.

# soundsc

---

**Purpose** Scale data and play as sound

**Syntax** `soundsc(y)`  
`soundsc(y,Fs)`  
`soundsc(y,Fs,nBits)`  
  
`soundsc( __ ,yRange)`

**Description** `soundsc(y)` scales the values of audio signal `y` to fit in the range from `-1.0` to `1.0`, and then sends the data to the speaker at the default sample rate of 8192 hertz. By first scaling the data, `soundsc` plays the audio as loudly as possible without clipping. The mean of the dynamic range of the data is set to zero.

`soundsc(y,Fs)` sends audio signal `y` to the speaker at sample rate `Fs`.

`soundsc(y,Fs,nBits)` uses `nBits` bits per sample for audio signal `y`.

`soundsc( __ ,yRange)`, where `yRange` is a vector of the form `[low,high]`, linearly scales the values in `y` between `low` and `high` to the full sound range `[-1.0,1.0]`. Values outside `[low,high]` are not clipped. You can use `yRange` with any of the input arguments in the above syntaxes.

## Input Arguments

**y - Audio data**  
column vector | `m`-by-2 matrix

Audio data, specified as an `m`-by-1 column vector for single-channel (mono) audio, or an `m`-by-2 matrix for stereo playback, where `m` is the number of audio samples. If `y` is an `m`-by-2 matrix, then the first column corresponds to the left channel, and the second column corresponds to the right channel. Stereo playback is available only if your system supports it.

**Data Types**  
double

**Fs - Sample rate**

8192 (default) | positive number

Sample rate, in hertz, of audio data  $y$ , specified as a positive number between 80 and 1000000.

**Data Types**

single | double

**nBits - Bit depth of sample values**

8 (default) | 16 | 24

Bit depth of the sample values, specified as an integer. Valid values depend on the audio hardware installed. Most platforms support bit depths of 8 bits or 16 bits.

**yRange - Range of audio data to scale** $[\min(y), \max(y)]$  (default) | two-element vector

Range of audio data to scale, specified as a two-element vector of the form  $[low, high]$ , where  $low$  and  $high$  are the lower and upper limits of the range.

**Example:**  $[-0.8, 0.8]$ **Data Types**

double

**Examples****Play Sample Data at Default Sample Rate**

Load the example file `gong.mat`, which contains sample data  $y$  and rate  $F_s$ , and listen to the audio.

```
load gong.mat;  
soundsc(y);
```

**Play Sample Data at Specific Sample Rate**

Play an excerpt from Handel's "Hallelujah Chorus" at twice the recorded sample rate.

```
load handel.mat;  
soundsc(y, 2*Fs);
```

## Play Sample Data with Specific Bit Depth

```
load handel.mat;  
nBits = 16;  
soundsc(y,Fs,nBits);
```

MATLAB plays the scaled audio with a bit depth of 16 bits per sample.

## Scale Selected Audio Data

```
load handel.mat;  
yRange = [-0.7,0.7];  
soundsc(y,yRange);
```

### Tips

- The sound function supports sound devices on all Windows and most UNIX platforms.
- Most sound cards support sample rates between 5 and 48 kilohertz. Specifying a sample rate outside this range might produce unexpected results.

**Purpose** Allocate space for sparse matrix

**Syntax** `S = spalloc(m,n,nzmax)`

**Description** `S = spalloc(m,n,nzmax)` creates an all zero sparse matrix `S` of size `m`-by-`n` with room to hold `nzmax` nonzeros. The matrix can then be generated column by column without requiring repeated storage allocation as the number of nonzeros grows.

`spalloc(m,n,nzmax)` is shorthand for

```
sparse([],[],[],m,n,nzmax)
```

**Examples** To generate efficiently a sparse matrix that has an average of at most three nonzero elements per column

```
S = spalloc(n,n,3*n);  
for j = 1:n  
    S(:,j) = [zeros(n-3,1)' round(rand(3,1))']';end
```

# sparse

---

## Purpose

Create sparse matrix

## Syntax

```
S = sparse(A)
S = sparse(i, j, s, m, n, nzmax)
S = sparse(i, j, s, m, n)
S = sparse(i, j, s)
S = sparse(m, n)
```

## Description

The `sparse` function generates matrices in the MATLAB sparse storage organization.

`S = sparse(A)` converts a full matrix to sparse form by squeezing out any zero elements. If `S` is already sparse, `sparse(S)` returns `S`.

`S = sparse(i, j, s, m, n, nzmax)` uses vectors `i`, `j`, and `s` to generate an `m`-by-`n` sparse matrix such that  $S(i(k), j(k)) = s(k)$ , with space allocated for `nzmax` nonzeros. Vectors `i`, `j`, and `s` are all the same length. Any elements of `s` that are zero are ignored, along with the corresponding values of `i` and `j`. Any elements of `s` that have duplicate values of `i` and `j` are added together.

---

**Note** If any value in `i` or `j` is larger than  $2^{31}-1$  for 32-bit platforms, or  $2^{48}-1$  on 64-bit platforms, then the sparse matrix cannot be constructed.

---

To simplify this six-argument call, you can pass scalars for the argument `s` and one of the arguments `i` or `j`—in which case they are expanded so that `i`, `j`, and `s` all have the same length.

`S = sparse(i, j, s, m, n)` uses `nzmax = length(s)`.

`S = sparse(i, j, s)` uses `m = max(i)` and `n = max(j)`. The maxima are computed before any zeros in `s` are removed, so one of the rows of `[i j s]` might be `[m n 0]`.

`S = sparse(m, n)` abbreviates `sparse([], [], [], m, n, 0)`. This generates the ultimate sparse matrix, an `m`-by-`n` all zero matrix.

## Tips

All of the MATLAB built-in arithmetic, logical, and indexing operations can be applied to sparse matrices, or to mixtures of sparse and full matrices. Operations on sparse matrices return sparse matrices and operations on full matrices return full matrices.

In most cases, operations on mixtures of sparse and full matrices return full matrices. The exceptions include situations where the result of a mixed operation is structurally sparse, for example,  $A.*S$  is at least as sparse as  $S$ .

## Examples

`S = sparse(1:n,1:n,1)` generates a sparse representation of the  $n$ -by- $n$  identity matrix. The same  $S$  results from `S = sparse(eye(n,n))`, but this would also temporarily generate a full  $n$ -by- $n$  matrix with most of its elements equal to zero.

`B = sparse(10000,10000,pi)` is probably not very useful, but is legal and works; it sets up a 10000-by-10000 matrix with only one nonzero element. Don't try `full(B)`; it requires 800 megabytes of storage.

This dissects and then reassembles a sparse matrix:

```
[i,j,s] = find(S);  
[m,n] = size(S);  
S = sparse(i,j,s,m,n);
```

So does this, if the last row and column have nonzero entries:

```
[i,j,s] = find(S);  
S = sparse(i,j,s);
```

# spaugment

---

**Purpose** Form least squares augmented system

**Syntax**  
 $S = \text{spaugment}(A, c)$   
 $S = \text{spaugment}(A)$

**Description**  $S = \text{spaugment}(A, c)$  creates the sparse, square, symmetric indefinite matrix  $S = [c \cdot I \ A; \ A' \ 0]$ . The matrix  $S$  is related to the least squares problem

$$\min \text{norm}(b - A \cdot x)$$

by

$$r = b - A \cdot x$$
$$S * [r/c; x] = [b; 0]$$

The optimum value of the residual scaling factor  $c$ , involves  $\min(\text{svd}(A))$  and  $\text{norm}(r)$ , which are usually too expensive to compute.

$S = \text{spaugment}(A)$  without a specified value of  $c$ , uses  $\max(\max(\text{abs}(A))) / 1000$ .

---

**Note** In previous versions of MATLAB product, the augmented matrix was used by sparse linear equation solvers,  $\backslash$  and  $/$ , for nonsquare problems. Now, MATLAB software performs a least squares solve using the  $qr$  factorization of  $A$  instead.

---

**See Also** `spparms`

**Purpose** Import matrix from sparse matrix external format

**Syntax** `S = spconvert(D)`

**Description** `spconvert` is used to create sparse matrices from a simple sparse format easily produced by non-MATLAB sparse programs. `spconvert` is the second step in the process:

- 1** Load an ASCII data file containing `[i,j,v]` or `[i,j,real,imag]` as rows into a MATLAB variable.
- 2** Convert that variable into a MATLAB sparse matrix.

`S = spconvert(D)` converts a matrix `D` with rows containing `[i,j,s]` or `[i,j,r,s]` to the corresponding sparse matrix. `D` must have an `nnz` or `nnz+1` row and three or four columns. Three elements per row generate a real matrix and four elements per row generate a complex matrix. A row of the form `[m n 0]` or `[m n 0 0]` anywhere in `D` can be used to specify `size(S)`. If `D` is already sparse, no conversion is done, so `spconvert` can be used after `D` is loaded from either a MAT-file or an ASCII file.

**Examples** Suppose the ASCII file `uphill.dat` contains

```

1   1   1.0000000000000000
1   2   0.5000000000000000
2   2   0.3333333333333333
1   3   0.3333333333333333
2   3   0.2500000000000000
3   3   0.2000000000000000
1   4   0.2500000000000000
2   4   0.2000000000000000
3   4   0.1666666666666667
4   4   0.142857142857143
4   4   0.0000000000000000

```

Then the statements

# spconvert

---

```
load uphill.dat
H = spconvert(uphill)
```

```
H =
    (1,1)    1.0000
    (1,2)    0.5000
    (2,2)    0.3333
    (1,3)    0.3333
    (2,3)    0.2500
    (3,3)    0.2000
    (1,4)    0.2500
    (2,4)    0.2000
    (3,4)    0.1667
    (4,4)    0.1429
```

recreate `sparse(triu(hilb(4)))`, possibly with roundoff errors. In this case, the last line of the input file is not necessary because the earlier lines already specify that the matrix is at least 4-by-4.

**Purpose**

Extract and create sparse band and diagonal matrices

**Syntax**

```
B = spdiags(A)
[B,d] = spdiags(A)
B = spdiags(A,d)
A = spdiags(B,d,A)
A = spdiags(B,d,m,n)
```

**Description**

The `spdiags` function generalizes the function `diag`. Four different operations, distinguished by the number of input arguments, are possible.

`B = spdiags(A)` extracts all nonzero diagonals from the  $m$ -by- $n$  matrix  $A$ .  $B$  is a  $\min(m,n)$ -by- $p$  matrix whose columns are the  $p$  nonzero diagonals of  $A$ .

`[B,d] = spdiags(A)` returns a vector  $d$  of length  $p$ , whose integer components specify the diagonals in  $A$ .

`B = spdiags(A,d)` extracts the diagonals specified by  $d$ .

`A = spdiags(B,d,A)` replaces the diagonals specified by  $d$  with the columns of  $B$ . The output is sparse.

`A = spdiags(B,d,m,n)` creates an  $m$ -by- $n$  sparse matrix by taking the columns of  $B$  and placing them along the diagonals specified by  $d$ .

---

**Note** In this syntax, if a column of  $B$  is longer than the diagonal it is replacing, and  $m \geq n$ , `spdiags` takes elements of super-diagonals from the lower part of the column of  $B$ , and elements of sub-diagonals from the upper part of the column of  $B$ . However, if  $m < n$ , then super-diagonals are from the upper part of the column of  $B$ , and sub-diagonals from the lower part. (See “Example 5A” on page 2-4181 and “Example 5B” on page 2-4183, below).

---

**Arguments**

The `spdiags` function deals with three matrices, in various combinations, as both input and output.

- A An  $m$ -by- $n$  matrix, usually (but not necessarily) sparse, with its nonzero or specified elements located on  $p$  diagonals.
- B A  $\min(m, n)$ -by- $p$  matrix, usually (but not necessarily) full, whose columns are the diagonals of A.
- d A vector of length  $p$  whose integer components specify the diagonals in A.

Roughly, A, B, and d are related by

```
for k = 1:p
    B(:,k) = diag(A,d(k))
end
```

Some elements of B, corresponding to positions outside of A, are not defined by these loops. They are not referenced when B is input and are set to zero when B is output.

## How the Diagonals of A are Listed in the Vector d

An  $m$ -by- $n$  matrix A has  $m+n-1$  diagonals. These are specified in the vector d using indices from  $-m+1$  to  $n-1$ . For example, if A is 5-by-6, it has 10 diagonals, which are specified in the vector d using the indices -4, -3, ... 4, 5. The following diagram illustrates this for a vector of all ones.

**Examples****Example 1**

For the following matrix,

```
A=[0 5 0 10 0 0;...
0 0 6 0 11 0;...
3 0 0 7 0 12;...
1 4 0 0 8 0;...
0 2 5 0 0 9]
```

A =

|   |   |   |    |    |    |
|---|---|---|----|----|----|
| 0 | 5 | 0 | 10 | 0  | 0  |
| 0 | 0 | 6 | 0  | 11 | 0  |
| 3 | 0 | 0 | 7  | 0  | 12 |
| 1 | 4 | 0 | 0  | 8  | 0  |
| 0 | 2 | 5 | 0  | 0  | 9  |

the command

```
[B, d] =spdiags(A)
```

returns

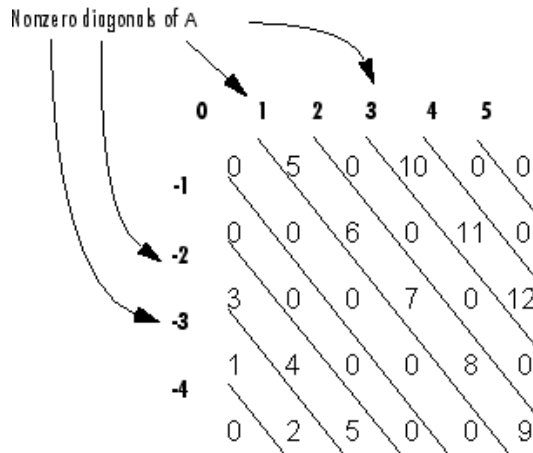

B =

|   |   |   |    |
|---|---|---|----|
| 0 | 0 | 5 | 10 |
| 0 | 0 | 6 | 11 |
| 0 | 3 | 7 | 12 |
| 1 | 4 | 8 | 0  |
| 2 | 5 | 9 | 0  |

d =

```
-3
-2
1
```

The columns of the first output **B** contain the nonzero diagonals of **A**. The second output **d** lists the indices of the nonzero diagonals of **A**, as shown in the following diagram. See “How the Diagonals of **A** are Listed in the Vector **d**” on page 2-4176.

Note that the longest nonzero diagonal in **A** is contained in column 3 of **B**. The other nonzero diagonals of **A** have extra zeros added to their corresponding columns in **B**, to give all columns of **B** the same length. For the nonzero diagonals below the main diagonal of **A**, extra zeros are added at the tops of columns. For the nonzero diagonals above the main diagonal of **A**, extra zeros are added at the bottoms of columns. This is illustrated by the following diagram.

### Example 2

This example generates a sparse tridiagonal representation of the classic second difference operator on  $n$  points.

```
e = ones(n,1);
A = spdiags([e -2*e e], -1:1, n, n)
```

Turn it into Wilkinson's test matrix (see gallery):

```
A = spdiags(abs(-(n-1)/2:(n-1)/2)', 0, A)
```

Finally, recover the three diagonals:

```
B = spdiags(A)
```

### Example 3

The second example is not square.

```
A = [11 0 13 0
      0 22 0 24]
```

# spdiags

---

```
0 0 33 0
41 0 0 44
0 52 0 0
0 0 63 0
0 0 0 74]
```

Here  $m = 7$ ,  $n = 4$ , and  $p = 3$ .

The statement `[B,d] = spdiags(A)` produces `d = [-3 0 2]'` and

```
B = [41 11 0
      52 22 0
      63 33 13
      74 44 24]
```

Conversely, with the above `B` and `d`, the expression `spdiags(B,d,7,4)` reproduces the original `A`.

## Example 4

This example shows how `spdiags` creates the diagonals when the columns of `B` are longer than the diagonals they are replacing.

```
B = repmat((1:6)', [1 7])
```

```
B =
```

```
1 1 1 1 1 1 1
2 2 2 2 2 2 2
3 3 3 3 3 3 3
4 4 4 4 4 4 4
5 5 5 5 5 5 5
6 6 6 6 6 6 6
```

```
d = [-4 -2 -1 0 3 4 5];
A = spdiags(B,d,6,6);
full(A)
```

```
ans =
```

```

1  0  0  4  5  6
1  2  0  0  5  6
1  2  3  0  0  6
0  2  3  4  0  0
1  0  3  4  5  0
0  2  0  4  5  6

```

### Example 5A

This example illustrates the use of the syntax `A = spdiags(B,d,m,n)`, under three conditions:

- `m` is equal to `n`
- `m` is greater than `n`
- `m` is less than `n`

The command used in this example is

```
A = full(spdiags(B, [-2 0 2], m, n))
```

where `B` is the 5-by-3 matrix shown below. The resulting matrix `A` has dimensions `m`-by-`n`, and has nonzero diagonals at `[-2 0 2]` (a sub-diagonal at -2, the main diagonal, and a super-diagonal at 2).

```

B =
   1   6  11
   2   7  12
   3   8  13
   4   9  14
   5  10  15

```

The first and third columns of matrix `B` are used to create the sub- and super-diagonals of `A` respectively. In all three cases though, these two outer columns of `B` are longer than the resulting diagonals of `A`. Because of this, only a part of the columns is used in `A`.

When `m == n` or `m > n`, `spdiags` takes elements of the super-diagonal in `A` from the lower part of the corresponding column of `B`, and elements

of the sub-diagonal in A from the upper part of the corresponding column of B.

When  $m < n$ , `spdiags` does the opposite, taking elements of the super-diagonal in A from the upper part of the corresponding column of B, and elements of the sub-diagonal in A from the lower part of the corresponding column of B.

## Part 1 – m is equal to n.

```
A = full(spdiags(B, [-2 0 2], 5, 5))
```

| Matrix B |    |    |                | Matrix A |   |    |    |    |
|----------|----|----|----------------|----------|---|----|----|----|
| 1        | 6  | 11 |                | 6        | 0 | 13 | 0  | 0  |
| 2        | 7  | 12 |                | 0        | 7 | 0  | 14 | 0  |
| 3        | 8  | 13 | == spdiags ==> | 1        | 0 | 8  | 0  | 15 |
| 4        | 9  | 14 |                | 0        | 2 | 0  | 9  | 0  |
| 5        | 10 | 15 |                | 0        | 0 | 3  | 0  | 10 |

A(3,1), A(4,2), and A(5,3) are taken from the upper part of B(:,1).

A(1,3), A(2,4), and A(3,5) are taken from the lower part of B(:,3).

## Part 2 – m is greater than n.

```
A = full(spdiags(B, [-2 0 2], 5, 4))
```

| Matrix B |    |    |                | Matrix A |   |    |    |
|----------|----|----|----------------|----------|---|----|----|
| 1        | 6  | 11 |                | 6        | 0 | 13 | 0  |
| 2        | 7  | 12 |                | 0        | 7 | 0  | 14 |
| 3        | 8  | 13 | == spdiags ==> | 1        | 0 | 8  | 0  |
| 4        | 9  | 14 |                | 0        | 2 | 0  | 9  |
| 5        | 10 | 15 |                | 0        | 0 | 3  | 0  |

Same as in Part A.

## Part 3 – m is less than n.

```
A = full(spdiags(B, [-2 0 2], 4, 5))
```

| Matrix B     |                | Matrix A               |
|--------------|----------------|------------------------|
| 1    6    11 |                | 6    0    11    0    0 |
| 2    7    12 |                | 0    7    0    12    0 |
| 3    8    13 | == spdiags ==> | 3    0    8    0    13 |
| 4    9    14 |                | 0    4    0    9    0  |
| 5    10   15 |                |                        |

A(3,1) and A(4,2) are taken from the lower part of B(:,1).

A(1,3), A(2,4), and A(3,5) are taken from the upper part of B(:,3).

### Example 5B

Extract the diagonals from the first part of this example back into a column format using the command

```
B = spdiags(A)
```

You can see that in each case the original columns are restored (minus those elements that had overflowed the super- and sub-diagonals of matrix A).

### Part 1.

| Matrix A               |                | Matrix B     |
|------------------------|----------------|--------------|
| 6    0    13    0    0 |                | 1    6    0  |
| 0    7    0    14    0 |                | 2    7    0  |
| 1    0    8    0    15 | == spdiags ==> | 3    8    13 |
| 0    2    0    9    0  |                | 0    9    14 |
| 0    0    3    0    10 |                | 0    10   15 |

### Part 2.

| Matrix A          |                | Matrix B     |
|-------------------|----------------|--------------|
| 6    0    13    0 |                | 1    6    0  |
| 0    7    0    14 |                | 2    7    0  |
| 1    0    8    0  | == spdiags ==> | 3    8    13 |

# spdiags

---

```
0  2  0  9          0  9 14
0  0  3  0
```

## Part 3.

```
          Matrix A          Matrix B
6  0  11  0  0          0  6 11
0  7  0  12  0          0  7 12
3  0  8  0  13 == spdiags => 3  8 13
0  4  0  9  0          4  9  0
```

## See Also

[diag](#) | [speye](#)

**Purpose** Calculate specular reflectance

**Syntax** `R = specular(Nx,Ny,Nz,S,V)`

**Description** `R = specular(Nx,Ny,Nz,S,V)` returns the reflectance of a surface with normal vector components `[Nx,Ny,Nz]`. `S` and `V` specify the direction to the light source and to the viewer, respectively. You can specify these directions as three vectors `[x,y,z]` or two vectors `[Theta Phi]` (in spherical coordinates).

The specular highlight is strongest when the normal vector is in the direction of  $(S+V)/2$  where `S` is the source direction, and `V` is the view direction.

The surface spread exponent can be specified by including a sixth argument as in `specular(Nx,Ny,Nz,S,V,spread)`.

# speye

---

**Purpose** Sparse identity matrix

**Syntax**  
S = speye(m,n)  
S = speye([m n])  
S = speye(n)  
S = speye

**Description** S = speye(m,n) and S = speye([m n]) form an m-by-n sparse matrix with 1s on the main diagonal.  
S = speye(n) abbreviates speye(n,n).  
S = speye returns the sparse form of the 1-by-1 identity matrix.

**Examples** I = speye(1000) forms the sparse representation of the 1000-by-1000 identity matrix, which requires only about 16 kilobytes of storage. This is the same final result as I = sparse(eye(1000,1000)), but the latter requires eight megabytes for temporary storage for the full representation.

**See Also** spalloc | spones | spdiags | sprand | sprandn

**Purpose** Apply function to nonzero sparse matrix elements

**Syntax** `f = spfun(fun,S)`

**Description** The `spfun` function selectively applies a function to only the *nonzero* elements of a sparse matrix `S`, preserving the sparsity pattern of the original matrix (except for underflow or if `fun` returns zero for some nonzero elements of `S`).

`f = spfun(fun,S)` evaluates `fun(S)` on the elements of `S` that are nonzero. `fun` is a function handle.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

**Tips** Functions that operate element-by-element, like those in the `elfun` directory, are the most appropriate functions to use with `spfun`.

**Examples** Given the 4-by-4 sparse diagonal matrix

```
S = spdiags([1:4]',0,4,4)
```

```
S =
    (1,1)      1
    (2,2)      2
    (3,3)      3
    (4,4)      4
```

Because `fun` returns nonzero values for all nonzero element of `S`, `f = spfun(@exp,S)` has the same sparsity pattern as `S`.

```
f =
    (1,1)      2.7183
    (2,2)      7.3891
    (3,3)     20.0855
    (4,4)     54.5982
```

whereas `exp(S)` has 1s where `S` has 0s.

```
full(exp(S))
```

```
ans =
```

```
  2.7183    1.0000    1.0000    1.0000  
  1.0000    7.3891    1.0000    1.0000  
  1.0000    1.0000   20.0855    1.0000  
  1.0000    1.0000    1.0000   54.5982
```

## See Also

```
function_handle
```

**Purpose** Transform spherical coordinates to Cartesian

**Syntax** `[x,y,z] = sph2cart(azimuth,elevation,r)`

**Description** `[x,y,z] = sph2cart(azimuth,elevation,r)` transforms the corresponding elements of spherical coordinate arrays to Cartesian, or *xyz*, coordinates. *azimuth*, *elevation*, and *r* must all be the same size (or any of them can be scalar). *azimuth* and *elevation* are angular displacements in radians from the positive *x*-axis and from the *x*-*y* plane, respectively.

**Algorithms** The mapping from spherical coordinates to three-dimensional Cartesian coordinates is

```
x = r .* cos(elevation) .* cos(azimuth)
y = r .* cos(elevation) .* sin(azimuth)
z = r .* sin(elevation)
```

# sphere

---

## Purpose

Generate sphere

## Syntax

```
sphere
sphere(n)
[X,Y,Z] = sphere(n)
```

## Description

The sphere function generates the  $x$ -,  $y$ -, and  $z$ -coordinates of a unit sphere for use with `surf` and `mesh`.

`sphere` generates a sphere consisting of 20-by-20 faces.

`sphere(n)` draws a `surf` plot of an  $n$ -by- $n$  sphere in the current figure.

`[X,Y,Z] = sphere(n)` returns the coordinates of a sphere in three matrices that are  $(n+1)$ -by- $(n+1)$  in size. You draw the sphere with `surf(X,Y,Z)` or `mesh(X,Y,Z)`.

## Examples

Generate and plot a sphere.

```
figure
sphere
axis equal
```

Plot multiple spheres, translating centers away from the origin:

```
figure
[x,y,z] = sphere;
surf(x,y,z) % sphere centered at origin
hold on
surf(x+3,y-2,z) % sphere centered at (3,-2,0)
surf(x,y+1,z-3) % sphere centered at (0,1,-3)
daspect([1 1 1])
```

# sphere

---

| <b>Purpose</b>     | Spin colormap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Syntax</b>      | <code>spinmap</code><br><code>spinmap(t)</code><br><code>spinmap(t,inc)</code><br><code>spinmap('inf')</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | <p>The <code>spinmap</code> function shifts the colormap RGB values by some incremental value. For example, if the increment equals 1, color 1 becomes color 2, color 2 becomes color 3, etc.</p> <p><code>spinmap</code> cyclically rotates the colormap for approximately five seconds using an incremental value of 2.</p> <p><code>spinmap(t)</code> rotates the colormap for approximately <math>10*t</math> seconds. The amount of time specified by <code>t</code> depends on your hardware configuration (e.g., if you are running MATLAB software over a network).</p> <p><code>spinmap(t,inc)</code> rotates the colormap for approximately <math>10*t</math> seconds and specifies an increment <code>inc</code> by which the colormap shifts. When <code>inc</code> is 1, the rotation appears smoother than the default (i.e., 2). Increments greater than 2 are less smooth than the default. A negative increment (e.g., -2) rotates the colormap in a negative direction.</p> <p><code>spinmap('inf')</code> rotates the colormap for an infinite amount of time. To break the loop, press <b>Ctrl+C</b>.</p> |

# spline

---

**Purpose** Cubic spline data interpolation

**Syntax**  
`yy = spline(x,Y,xx)`  
`pp = spline(x,Y)`

**Description** `yy = spline(x,Y,xx)` uses a cubic spline interpolation to find `yy`, the values of the underlying function `Y` at the values of the interpolant `xx`. For the interpolation, the independent variable is assumed to be the final dimension of `Y` with the breakpoints defined by `x`.

The sizes of `xx` and `yy` are related as follows:

- If `Y` is a scalar or vector, `yy` has the same size as `xx`.
- If `Y` is an array that is not a vector,
  - If `xx` is a scalar or vector, `size(yy)` equals `[d1, d2, ..., dk, length(xx)]`.
  - If `xx` is an array of size `[m1,m2,...,mj]`, `size(yy)` equals `[d1,d2,...,dk,m1,m2,...,mj]`.

`pp = spline(x,Y)` returns the piecewise polynomial form of the cubic spline interpolant for later use with `ppval` and the spline utility `unmkpp`. `x` must be a vector. `Y` can be a scalar, a vector, or an array of any dimension, subject to the following conditions:

- If `x` and `Y` are vectors of the same size, the not-a-knot end conditions are used.
- If `x` or `Y` is a scalar, it is expanded to have the same length as the other and the not-a-knot end conditions are used. (See Exceptions (1) below).
- If `Y` is a vector that contains two more values than `x` has entries, the first and last value in `Y` are used as the endslopes for the cubic spline. (See Exceptions (2) below.)

## Exceptions

- 1 If  $Y$  is a vector that contains two more values than  $x$  has entries, the first and last value in  $Y$  are used as the endslopes for the cubic spline. If  $Y$  is a vector, this means
  - $f(x) = Y(2:end-1)$
  - $df(\min(x)) = Y(1)$
  - $df(\max(x)) = Y(\text{end})$
- 2 If  $Y$  is a matrix or an  $N$ -dimensional array with  $\text{size}(Y,N)$  equal to  $\text{length}(x)+2$ , the following hold:
  - $f(x(j))$  matches the value  $Y(:,\dots,:,j+1)$  for  $j=1:\text{length}(x)$
  - $Df(\min(x))$  matches  $Y(:,\dots,:,1)$
  - $Df(\max(x))$  matches  $Y(:,\dots,:,\text{end})$

---

**Note** You can also perform spline interpolation using the `interp1` function with the command `interp1(x,y,xx,'spline')`. Note that while `spline` performs interpolation on rows of an input matrix, `interp1` performs interpolation on columns of an input matrix.

---

## Examples

### Example 1

This generates a sine curve, then samples the spline over a finer mesh.

```
x = 0:10;  
y = sin(x);  
xx = 0:.25:10;  
yy = spline(x,y,xx);  
plot(x,y,'o',xx,yy)
```

## Example 2

This illustrates the use of clamped or complete spline interpolation where end slopes are prescribed. Zero slopes at the ends of an interpolant to the values of a certain distribution are enforced.

```
x = -4:4;  
y = [0 .15 1.12 2.36 2.36 1.46 .49 .06 0];  
cs = spline(x,[0 y 0]);  
xx = linspace(-4,4,101);  
plot(x,y,'o',xx,ppval(cs,xx),'-');
```

### Example 3

The two vectors

```
t = 1900:10:1990;  
p = [ 75.995  91.972  105.711  123.203  131.669 ...  
      150.697  179.323  203.212  226.505  249.633 ];
```

represent the census years from 1900 to 1990 and the corresponding United States population in millions of people. The expression

```
spline(t,p,2000)
```

uses the cubic spline to extrapolate and predict the population in the year 2000. The result is

```
ans =  
    270.6060
```

## Example 4

The statements

```
x = pi*[0:.5:2];  
y = [0 1 0 -1 0 1 0;  
     1 0 1 0 -1 0 1];  
pp = spline(x,y);  
yy = ppval(pp, linspace(0,2*pi,101));  
plot(yy(1,:),yy(2,:),'-b',y(1,2:5),y(2,2:5),'or'), axis equal
```

generate the plot of a circle, with the five data points  $y(:,2), \dots, y(:,6)$  marked with o's. Note that this  $y$  contains two more values (i.e., two more columns) than does  $x$ , hence  $y(:,1)$  and  $y(:,end)$  are used as endslopes.

**Example 5**

The following code generates sine and cosine curves, then samples the splines over a finer mesh.

```
x = 0:.25:1;
Y = [sin(x); cos(x)];
xx = 0:.1:1;
YY = spline(x,Y,xx);
plot(x,Y(1,:), 'o',xx,YY(1,:), '-'); hold on;
plot(x,Y(2,:), 'o',xx,YY(2,:), ':'); hold off;
```

**Algorithms**

A tridiagonal linear system (with, possibly, several right sides) is being solved for the information needed to describe the coefficients of the various cubic polynomials which make up the interpolating spline. `spline` uses the functions `ppval`, `mkpp`, and `unmkpp`. These routines

# spline

---

form a small suite of functions for working with piecewise polynomials. For access to more advanced features, see the `interp1` reference page, the command-line help for these functions, and the Curve Fitting Toolbox spline functions.

# spparms

---

**Purpose** Set parameters for sparse matrix routines

**Syntax**

```
spparms('key',value)
spparms
values = spparms
[keys,values] = spparms
spparms(values)
value = spparms('key')
spparms('default')
spparms('tight')
```

**Description** spparms('key',value) sets one or more of the *tunable* parameters used in the sparse routines. In ordinary use, you should never need to deal with this function.

The meanings of the key parameters are

|                         |                                                                                                        |
|-------------------------|--------------------------------------------------------------------------------------------------------|
| 'spumoni'               | Sparse Monitor flag:                                                                                   |
| 0                       | Produces no diagnostic output, the default                                                             |
| 1                       | Produces information about choice of algorithm based on matrix structure, and about storage allocation |
| 2                       | Also produces very detailed information about the sparse matrix algorithms                             |
| 'thr_rel',<br>'thr_abs' | Minimum degree threshold is thr_rel*mindegree + thr_abs.                                               |
| 'exact_d'               | Nonzero to use exact degrees in minimum degree. Zero to use approximate degrees.                       |
| 'supernd'               | If positive, minimum degree amalgamates the supernodes every supernd stages.                           |
| 'rreduce'               | If positive, minimum degree does row reduction every rreduce stages.                                   |

|           |                                                                                                                                                                                                                                                                                                        |

`spparms`, by itself, prints a description of the current settings.

`values = spparms` returns a vector whose components give the current settings.

`[keys, values] = spparms` returns that vector, and also returns a character matrix whose rows are the keywords for the parameters.

`spparms(values)`, with no output argument, sets all the parameters to the values specified by the argument vector.

`value = spparms('key')` returns the current setting of one parameter.

`spparms('default')` sets all the parameters to their default settings.

`spparms('tight')` sets the minimum degree ordering parameters to their *tight* settings, which can lead to orderings with less fill-in, but which make the ordering functions themselves use more execution time.

The key parameters for `default` and `tight` settings are

# spparms

# sprandn

---

**Purpose** Sparse normally distributed random matrix

**Syntax**  
R = sprandn(S)  
R = sprandn(m,n,density)  
R = sprandn(m,n,density,rc)

**Description** R = sprandn(S) has the same sparsity structure as S, but normally distributed random entries with mean 0 and variance 1.

R = sprandn(m,n,density) is a random, m-by-n, sparse matrix with approximately  $\text{density} * m * n$  normally distributed nonzero entries ( $0 \leq \text{density} \leq 1$ ).

R = sprandn(m,n,density,rc) also has reciprocal condition number approximately equal to rc. R is constructed from a sum of matrices of rank one.

If rc is a vector of length lr, where  $lr \leq \min(m,n)$ , then R has rc as its first lr singular values, all others are zero. In this case, R is generated by random plane rotations applied to a diagonal matrix with the given singular values. It has a great deal of topological and algebraic structure.

**Tips**

- sprandn uses the same random number generator as rand, randi, and randn. You control this generator with rng.

**See Also** sprand | sprandsym

**Purpose**

Sparse symmetric random matrix

**Syntax**

```
R = sprandsym(S)
R = sprandsym(n,density)
R = sprandsym(n,density,rc)
R = sprandsym(n,density,rc,kind)
R = sprandsym(S,[],rc,3)
```

**Description**

`R = sprandsym(S)` returns a symmetric random matrix whose lower triangle and diagonal have the same structure as `S`. Its elements are normally distributed, with mean 0 and variance 1.

`R = sprandsym(n,density)` returns a symmetric random, `n`-by-`n`, sparse matrix with approximately `density*n*n` nonzeros; each entry is the sum of one or more normally distributed random samples, and (`0 <= density <= 1`).

`R = sprandsym(n,density,rc)` returns a matrix with a reciprocal condition number equal to `rc`. The distribution of entries is nonuniform; it is roughly symmetric about 0; all are in `[-1,1]`.

If `rc` is a vector of length `n`, then `R` has eigenvalues `rc`. Thus, if `rc` is a positive (nonnegative) vector then `R` is a positive (nonnegative) definite matrix. In either case, `R` is generated by random Jacobi rotations applied to a diagonal matrix with the given eigenvalues or condition number. It has a great deal of topological and algebraic structure.

`R = sprandsym(n,density,rc,kind)` is positive definite.

- If `kind = 1`, `R` is generated by random Jacobi rotation of a positive definite diagonal matrix. `R` has the desired condition number exactly.
- If `kind = 2`, `R` is a shifted sum of outer products. `R` has the desired condition number only approximately, but has less structure.

`R = sprandsym(S,[],rc,3)` has the same structure as the matrix `S` and approximate condition number `1/rc`.

**Tips**

`sprandsym` uses the same random number generator as `rand`, `randi`, and `randn`. You control this generator with `rng`.

sprand | sprandn

**Purpose** Structural rank

**Syntax** `r = sprank(A)`

**Description** `r = sprank(A)` is the structural rank of the sparse matrix `A`. For all values of `A`,

```
sprank(A) >= rank(full(A))
```

In exact arithmetic, `sprank(A) == rank(full(sprandn(A)))` with a probability of one.

**Examples**

```
A = [1 0 2 0  
     2 0 4 0];
```

```
A = sparse(A);
```

```
sprank(A)
```

```
ans =  
     2
```

```
rank(full(A))
```

```
ans =  
     1
```

`dmperm`

# sprintf

---

**Purpose** Format data into string

**Syntax**  
`str = sprintf(formatSpec,A1,...,An)`  
`[str,errmsg] = sprintf(formatSpec,A1,...,An)`

**Description** `str = sprintf(formatSpec,A1,...,An)` formats the data in arrays `A1,...,An` according to `formatSpec` in column order, and returns the results to string `str`.

`[str,errmsg] = sprintf(formatSpec,A1,...,An)` returns an error message string when the operation is unsuccessful. Otherwise, `errmsg` is empty.

## Input Arguments

### **formatSpec - Format of the output fields**

string

Format of the output fields, specified as a string.

The string can include a percent sign followed by a conversion character. The following table lists the available conversion characters and subtypes.

| Value Type        | Conversion | Details                                      |
|-------------------|------------|----------------------------------------------|
| Integer, signed   | %d or %i   | Base 10                                      |
| Integer, unsigned | %u         | Base 10                                      |
|                   | %o         | Base 8 (octal)                               |
|                   | %x         | Base 16 (hexadecimal), lowercase letters a–f |
|                   | %X         | Same as %x, uppercase letters A–F            |

| Value Type            | Conversion               | Details                                                                                             |
|-----------------------|--------------------------|-----------------------------------------------------------------------------------------------------|
| Floating-point number | %f                       | Fixed-point notation                                                                                |
|                       | %e                       | Exponential notation, such as 3.141593e+00                                                          |
|                       | %E                       | Same as %e, but uppercase, such as 3.141593E+00                                                     |
|                       | %g                       | The more compact of %e or %f, with no trailing zeros                                                |
|                       | %G                       | The more compact of %E or %f, with no trailing zeros                                                |
|                       | %bx or %bX<br>%bo<br>%bu | Double-precision hexadecimal, octal, or decimal value<br>Example: %bx prints pi as 400921fb54442d18 |
|                       | %tx or %tX<br>%to<br>%tu | Single-precision hexadecimal, octal, or decimal value<br>Example: %tx prints pi as 40490fdb         |
| Characters            | %c                       | Single character                                                                                    |
|                       | %s                       | String of characters                                                                                |

The string can include optional operators, which appear in the following order (includes spaces for clarity):

Optional operators include:

# sprintf

---

- Identifier

Order for processing inputs. Use the syntax *n*\$, where *n* represents the position of the value in the input list.

For example, '%3\$s %2\$s %1\$s %2\$s' prints inputs 'A', 'B', 'C' as follows: C B A B.

- Flags

' ' Left-justify. Example: %-5.2f

'+' Print sign character (+) for positive values. Example: %+5.2f

' ' Pad to field width with spaces before the value. Example: % 5.2f

'0' Pad to field width with zeros. Example: %05.2f

'#' Modify selected numeric conversions:

- For %o, %x, or %X, print 0, 0x, or 0X prefix.
- For %f, %e, or %E, print decimal point even when precision is 0.
- For %g or %G, do not remove trailing zeros or decimal point.

Example: %#5.0f

- Field width

Minimum number of characters to print. Can be a number, or an asterisk (\*) to refer to an argument in the input list. For example, the input list ('%12d', intmax) is equivalent to ('%\*d', 12, intmax).

- Precision

For %f, %e, or %E:      Number of digits to the right of the decimal point.  
                                  Example: '%6.4f' prints pi as '3.1416'

For %g or %G              Number of significant digits.  
                                  Example: '%6.4g' prints pi as ' 3.142'

Can be a number, or an asterisk (\*) to refer to an argument in the input list. For example, the input list ('%6.4f', pi) is equivalent to ('%\*.\*f', 6, 4, pi).

The string can also include combinations of the following:

- Literal text to print.
- Escape characters, including:

|             |                              |
|-------------|------------------------------|
| '           | Single quotation mark        |
| %           | Percent character            |
| \           | Backslash                    |
| \a          | Alarm                        |
| \b          | Backspace                    |
| \f          | Form feed                    |
| \n          | New line                     |
| \r          | Carriage return              |
| \t          | Horizontal tab               |
| \v          | Vertical tab                 |
| \x <i>N</i> | Hexadecimal number, <i>N</i> |
| \o <i>N</i> | Octal number, <i>N</i>       |

The following limitations apply to conversions:

- Numeric conversions print only the real component of complex numbers.

# sprintf

---

- If you specify a conversion that does not fit the data, such as a string conversion for a numeric value, MATLAB overrides the specified conversion, and uses %e.
- If you apply a string conversion (%s) to integer values, MATLAB converts values that correspond to valid character codes to characters. For example, '%s' converts [65 66 67] to ABC.

## **A1,...,An - Numeric or character arrays**

scalar | vector | matrix | multidimensional array

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array.

## **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** No

## **Output Arguments**

### **str - Formatted text**

string

Formatted text, returned as a string.

### **errmsg - Error message**

string

Error message, returned as a string, when the operation is unsuccessful. Otherwise, errmsg is empty.

## **Tips**

- The sprintf function is similar to fprintf, but fprintf prints to a file or to the Command Window.
- Format specifiers for the reading functions sscanf and fscanf differ from the formats for the writing functions sprintf and fprintf. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.

## Examples

### Floating-Point Formats

Format a floating-point number using %e, %f, and %g specifiers.

```
A = 1/eps;  
str_e = sprintf('%0.5e',A)  
str_f = sprintf('%0.5f',A)  
str_g = sprintf('%0.5g',A)
```

```
str_e =  
4.50360e+15
```

```
str_f =  
4503599627370496.00000
```

```
str_g =  
4.5036e+15
```

### Literal Text and Array Inputs

Combine literal text with array values to create a string.

```
formatSpec = 'The array is %dx%d.';  
A1 = 2;  
A2 = 3;  
str = sprintf(formatSpec,A1,A2)
```

```
str =  
The array is 2x3.
```

### Integer Format with Floating-Point Inputs

Explicitly convert double-precision values to integers.

```
str = sprintf('%d',round(pi))
```

```
str =  
3
```

## Field Width

Specify the minimum width of the printed value.

```
str = sprintf('%025d',[123456])

str =
00000000000000000000000123456
```

The 0 flag in the %025d format specifier requests leading zeros in the output.

## Position Identifier (n\$)

Reorder the input values using the n\$ position identifier.

```
A1 = 'X';
A2 = 'Y';
A3 = 'Z';
formatSpec = ' %3$s %2$s %1$s';
str = sprintf(formatSpec,A1,A2,A3)

str =
  Z Y X
```

## Cell Array Inputs

Create a string from values in a cell array.

```
C = { 1, 2, 3 ;
      'AA', 'BB', 'CC' };

str = sprintf(' %d %s',C{:})

str =
  1 AA 2 BB 3 CC
```

The syntax C{:} creates a comma-separated list of arrays that contain the contents of each cell from C in column order. For example, C{1}==1 and C{2}=='AA'.

## Concepts

- “Formatting Strings”

**Purpose** Visualize sparsity pattern

**Syntax**

```
spy(S)
spy(S,markersize)
spy(S,'LineStyle')
spy(S,'LineStyle',markersize)
```

**Description** plots the `spy(S)` sparsity pattern of any matrix `S`.

`spy(S,markersize)`, where `markersize` is an integer, plots the sparsity pattern using markers of the specified point size.

`spy(S,'LineStyle')`, where `LineStyle` is a string, uses the specified plot marker type and color.

`spy(S,'LineStyle',markersize)` uses the specified type, color, and size for the plot markers.

`S` is usually a sparse matrix, but full matrices are acceptable, in which case the locations of the nonzero elements are plotted.

---

**Note** `spy` replaces `format +`, which takes much more space to display essentially the same information.

---

**Examples** This example plots the 60-by-60 sparse adjacency matrix of the connectivity graph of the Buckminster Fuller geodesic dome. This matrix also represents the soccer ball and the carbon-60 molecule.

```
B = bucky;
spy(B)
```

# sqrt

---

**Purpose** Square root

**Syntax** `B = sqrt(X)`

**Description** `B = sqrt(X)` returns the square root of each element of the array `X`. For the elements of `X` that are negative or complex, `sqrt(X)` produces complex results.

**Tips** See `sqrtm` for the matrix square root.

**Examples**

```
sqrt((-2:2)')
ans =
    0 + 1.4142i
    0 + 1.0000i
    0
    1.0000
    1.4142
```

| <b>Purpose</b>     | Matrix square root                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Syntax</b>      | <pre>X = sqrtm(A) [X, resnorm] = sqrtm(A) [X, alpha, condest] = sqrtm(A)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p><math>X = \text{sqrtm}(A)</math> is the principal square root of the matrix <math>A</math>, i.e. <math>X^2 = A</math>. <math>X</math> is the unique square root for which every eigenvalue has nonnegative real part. If <math>A</math> has any eigenvalues with negative real parts then a complex result is produced. If <math>A</math> is singular then <math>A</math> may not have a square root. A warning is printed if exact singularity is detected.</p> <p><math>[X, \text{resnorm}] = \text{sqrtm}(A)</math> does not print any warning, and returns the residual, <math>\text{norm}(A - X^2, 'fro') / \text{norm}(A, 'fro')</math>.</p> <p><math>[X, \text{alpha}, \text{condest}] = \text{sqrtm}(A)</math> returns a stability factor <math>\text{alpha}</math> and an estimate <math>\text{condest}</math> of the matrix square root condition number of <math>X</math>. The residual <math>\text{norm}(A - X^2, 'fro') / \text{norm}(A, 'fro')</math> is bounded approximately by <math>n * \text{alpha} * \text{eps}</math> and the Frobenius norm relative error in <math>X</math> is bounded approximately by <math>n * \text{alpha} * \text{condest} * \text{eps}</math>, where <math>n = \max(\text{size}(A))</math>.</p> |
| <b>Tips</b>        | <p>If <math>A</math> is real, symmetric and positive definite, or complex, Hermitian and positive definite, then so is the computed matrix square root.</p> <p>Some matrices, like <math>A = \begin{bmatrix} 0 &amp; 1 \\ 0 &amp; 0 \end{bmatrix}</math>, do not have any square roots, real or complex, and <code>sqrtm</code> cannot be expected to produce one.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Examples</b>    | <p><b>Example 1</b></p> <p>A matrix representation of the fourth difference operator is</p> <pre>A =      5    -4     1     0     0     -4     6    -4     1     0      1    -4     6    -4     1      0     1    -4     6    -4      0     0     1    -4     5</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

This matrix is symmetric and positive definite. Its unique positive definite square root,  $Y = \text{sqrtm}(A)$ , is a representation of the second difference operator.

$$Y = \begin{bmatrix} 2 & -1 & -0 & -0 & -0 \\ -1 & 2 & -1 & 0 & -0 \\ 0 & -1 & 2 & -1 & 0 \\ -0 & 0 & -1 & 2 & -1 \\ -0 & -0 & -0 & -1 & 2 \end{bmatrix}$$

## Example 2

The matrix

$$A = \begin{bmatrix} 7 & 10 \\ 15 & 22 \end{bmatrix}$$

has four square roots. Two of them are

$$Y1 = \begin{bmatrix} 1.5667 & 1.7408 \\ 2.6112 & 4.1779 \end{bmatrix}$$

and

$$Y2 = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}$$

The other two are  $-Y1$  and  $-Y2$ . All four can be obtained from the eigenvalues and vectors of  $A$ .

$$[V,D] = \text{eig}(A);$$
$$D = \begin{bmatrix} 0.1386 & 0 \\ 0 & 28.8614 \end{bmatrix}$$

The four square roots of the diagonal matrix D result from the four choices of sign in

$$S = \begin{pmatrix} -0.3723 & 0 \\ 0 & -5.3723 \end{pmatrix}$$

All four Ys are of the form

$$Y = V*S/V$$

The sqrtm function chooses the two plus signs and produces Y1, even though Y2 is more natural because its entries are integers.

# squeeze

---

**Purpose** Remove singleton dimensions

**Syntax** `B = squeeze(A)`

**Description** `B = squeeze(A)` returns an array `B` with the same elements as `A`, but with all singleton dimensions removed. A singleton dimension is any dimension for which `size(A,dim) = 1`. Two-dimensional arrays are unaffected by `squeeze`; if `A` is a row or column vector or a scalar (1-by-1) value, then `B = A`.

**Examples** Consider the 2-by-1-by-3 array `Y = rand(2,1,3)`. This array has a singleton column dimension — that is, there's only one column per page.

```
Y =  
  
Y(:,:,1) =      Y(:,:,2) =  
    0.5194      0.0346  
    0.8310      0.0535  
  
Y(:,:,3) =  
    0.5297  
    0.6711
```

The command `Z = squeeze(Y)` yields a 2-by-3 matrix:

```
Z =  
    0.5194    0.0346    0.5297  
    0.8310    0.0535    0.6711
```

Consider the 1-by-1-by-5 array `mat= repmat(1,[1,1,5])`. This array has only one scalar value per page.

```
mat =  
  
mat(:,:,1) =  mat(:,:,2) =  
    1          1
```

```
mat(:,:,3) =   mat(:,:,4) =
```

```
    1    1
```

```
mat(:,:,5) =
```

```
    1
```

The command `squeeze(mat)` yields a 5-by-1 matrix:

```
squeeze(mat)
```

```
ans =
```

```
    1  
    1  
    1  
    1  
    1
```

```
size(squeeze(mat))
```

```
ans =
```

```
    5    1
```

[reshape](#) | [shiftdim](#)

**Purpose** Convert state-space filter parameters to transfer function form

**Syntax** `[b,a] = ss2tf(A,B,C,D,iu)`

**Description** `ss2tf` converts a state-space representation of a given system to an equivalent transfer function representation.

`[b,a] = ss2tf(A,B,C,D,iu)` returns the transfer function

$$H(s) = \frac{B(s)}{A(s)} = C(sI - A)^{-1}B + D$$

of the system

$$\dot{x} = Ax + Bu$$

$$y = Cx + Du$$

from the `iu`-th input. Vector `a` contains the coefficients of the denominator in descending powers of  $s$ . The numerator coefficients are returned in array `b` with as many rows as there are outputs  $y$ . `ss2tf` also works with systems in discrete time, in which case it returns the  $z$ -transform representation.

The `ss2tf` function is part of the standard MATLAB language.

## Purpose

Read formatted data from string

## Syntax

```
A = sscanf(str, format)
A = sscanf(str, format, sizeA)
[A, count] = sscanf(...)
[A, count, errmsg] = sscanf(...)
[A, count, errmsg, nextindex] = sscanf(...)
```

## Description

`A = sscanf(str, format)` reads data from string `str`, converts it according to the `format`, and returns the results in array `A`. The `sscanf` function reapplies the `format` until either reaching the end of `str` or failing to match the `format`. If `sscanf` cannot match the `format` to the data, it reads only the portion that matches into `A` and stops processing. If `str` is a character array with more than one row, `sscanf` reads the characters in column order.

`A = sscanf(str, format, sizeA)` reads `sizeA` elements into `A`, where `sizeA` can be an integer or can have the form `[m,n]`.

`[A, count] = sscanf(...)` returns the number of elements that `sscanf` successfully reads.

`[A, count, errmsg] = sscanf(...)` returns an error message string when the operation is unsuccessful. Otherwise, `errmsg` is an empty string.

`[A, count, errmsg, nextindex] = sscanf(...)` returns one more than the number of characters scanned in `str`.

## Tips

- Format specifiers for the reading functions `sscanf` and `fscanf` differ from the formats for the writing functions `sprintf` and `fprintf`. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.

## Input Arguments

### format

String enclosed in single quotation marks that describes each type of element (field). Includes one or more of the following specifiers.

| Field Type            | Specifier     | Details                                                                                                                                   |
|-----------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| Integer, signed       | %d            | Base 10                                                                                                                                   |
|                       | %i            | Base determined from the values. Defaults to base 10. If initial digits are 0x or 0X, it is base 16. If initial digit is 0, it is base 8. |
|                       | %ld or %li    | 64-bit values, base 10, 8, or 16                                                                                                          |
| Integer, unsigned     | %u            | Base 10                                                                                                                                   |
|                       | %o            | Base 8 (octal)                                                                                                                            |
|                       | %x            | Base 16 (hexadecimal)                                                                                                                     |
|                       | %lu, %lo, %lx | 64-bit values, base 10, 8, or 16                                                                                                          |
| Floating-point number | %f            | Floating-point fields can contain any of the following (not case sensitive): Inf, -Inf, NaN, or -NaN.                                     |
|                       | %e            |                                                                                                                                           |
|                       | %g            |                                                                                                                                           |
| Character string      | %s            | Read series of characters, until find white space.                                                                                        |
|                       | %c            | Read any single character, including white space. (To read multiple characters, specify field length.)                                    |
|                       | %[...]        | Read only characters in the brackets, until the first nonmatching character or white space.                                               |

Optionally:

- To skip fields, insert an asterisk (\*) after the percent sign (%). For example, to skip integers, specify %\*d.

- To specify the maximum width of a field, insert a number. For example, %10c reads exactly 10 characters at a time, including white space.
- To skip a specific set of characters, insert the literal characters in the *format*. For example, to read only the floating-point number from 'pi=3.14159', specify a *format* of 'pi=%f'.

**sizeA**

Dimensions of the output array *A*. Specify in one of the following forms:

- inf            Read to the end of the input string. (default)
- n*             Read at most *n* elements.
- [*m*,*n*]        Read at most *m*\**n* elements in column order. *n* can be inf, but *m* cannot.

When the *format* includes %s, *A* can contain more than *n* columns. *n* refers to elements, not characters.

**str**

Character string.

**Output Arguments**

**A**

An array. If the *format* includes:

- Only numeric specifiers, *A* is numeric. If *format* includes only 64-bit signed integer specifiers, *A* is of class int64. Similarly, if *format* includes only 64-bit unsigned integer specifiers, *A* is of class uint64. Otherwise, *A* is of class double. If *sizeA* is inf or *n*, then *A* is a column vector. If the input contains fewer than *sizeA* elements, MATLAB pads *A* with zeros.
- Only character or string specifiers (%c or %s), *A* is a character array. If *sizeA* is inf or *n*, *A* is a row vector. If the input contains fewer than *sizeA* characters, MATLAB pads *A* with char(0).

- A combination of numeric and character specifiers, *A* is numeric, of class `double`. MATLAB converts each character to its numeric equivalent. This conversion occurs even when the *format* explicitly skips all numeric values (for example, a *format* of `'%*d %s'`).

If MATLAB cannot match the input to the *format*, and the *format* contains both numeric and character specifiers, *A* can be numeric or character. The class of *A* depends on the values MATLAB reads before processing stops.

## **count**

Number of elements `sscanf` reads into *A*.

## **errmsg**

An error message string when `sscanf` cannot open the specified file. Otherwise, an empty string.

## **nextindex**

`sscanf` counts the number of characters `sscanf` reads from *str*, and then adds one.

## **Examples**

### **Example 1**

Read multiple floating-point values from a string:

```
s = '2.7183 3.1416';  
A = sscanf(s, '%f ');  
A =  
    2.7183  
    3.1416
```

### **Example 2**

Read an octal integer from a string, identified by the `'0'` prefix, using `%i` to preserve the sign:

```
sscanf('-010', '%i')  
ans =
```

-8

### Example 3

Read numeric values from a two-dimensional character array. By default, `sscanf` reads characters in column order. To preserve the original order of the values, read one row at a time.

```
mixed = ['abc 45 6 ghi'; 'def 7 89 jkl'];

[nrows, ncols] = size(mixed);
for k = 1:nrows
    nums(k,:) = sscanf(mixed(k,:), '%*s %d %d %*s', [1, inf]);
end;

% type the variable name to see the result
nums =
    45     6
     7    89
```

### Example 4

`sscanf` finds one match for `%s`

```
[str count] = sscanf('ThisIsOneString', '%s')
str =
    ThisIsOneString
count =
    1
```

`sscanf` finds four matches for `%s`. Because it does not match space characters, there are no spaces in the output string:

```
[str count] = sscanf('These Are Four Strings', '%s')
str =
    TheseAreFourStrings
count =
    4
```

sscanf finds five word matches for %s and four space character matches for %c. Because the %c specifier does match a space character, the output string does include spaces:

```
[str count] = sscanf('Five strings and four spaces', '%s%c')
str =
    Five strings and four spaces
count =
     9
```

sscanf finds three word matches for %s and two numeric matches for %d. Because the format specifier has a mixed %d and %s format, sscanf converts all nonnumeric characters to numeric:

```
[str count] = sscanf('5 strings and 4 spaces', '%d%s%d%s');
str'
Columns 1 through 9
     5    115    116    114    105    110    103    115     97
Columns 10 through 18
    110    100     4    115    112     97     99    101    115
count
count =
     5
```

## Example 5

```
[str, count] = sscanf('one two three', '%c')
str =
    one two three
count =
    13
```

```
[str, count] = sscanf('one two three', '%13c')
str =
    one two three
count =
     1
```

```
[str, count] = sscanf('one two three', '%s')
str =
    onetwothree
count =
     3
```

```
[str, count] = sscanf('one two three', '%1s')
str =
    onetwothree
count =
    11
```

### Example 6

```
tempString = '78 F 72 F 64 F 66 F 49 F';

degrees = char(176);
tempNumeric = sscanf(tempString, ['%d' degrees 'F'])'
tempNumeric =
     78     72     64     66     49
```

# stairs

---

## Purpose

Stairstep graph

## Syntax

```
stairs(Y)
stairs(X,Y)
stairs(...,LineStyle)
stairs(...,'PropertyName',propertyvalue)
stairs(axes_handle,...)
h = stairs(...)
[xb,yb] = stairs(Y,...)
```

## Description

Stairstep graphs are useful for drawing time-history graphs of digitally sampled data.

`stairs(Y)` draws a stairstep graph of the elements of `Y`, drawing one line per column for matrices. The axes `ColorOrder` property determines the color of the lines.

When `Y` is a vector, the `x`-axis scale ranges from 1 to `length(Y)`. When `Y` is a matrix, the `x`-axis scale ranges from 1 to the number of rows in `Y`.

`stairs(X,Y)` plots the elements in `Y` at the locations specified in `X`.

`X` must be the same size as `Y` or, if `Y` is a matrix, `X` can be a row or a column vector such that

```
length(X) = size(Y,1)
```

`stairs(...,LineStyle)` specifies a line style, marker symbol, and color for the graph. (See `LineStyle` for more information.)

`stairs(...,'PropertyName',propertyvalue)` creates the stairstep graph, applying the specified property settings. See `Stairseries` properties for a description of properties.

`stairs(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes object (`gca`).

`h = stairs(...)` returns the handles of the stairseries objects created (one per matrix column).

`[xb,yb] = stairs(Y,...)` does not draw graphs, but returns vectors `xb` and `yb` such that `plot(xb,yb)` plots the stairstep graph.

## Examples

Create a stairstep plot of a sine wave.

```
x = linspace(-2*pi,2*pi,40);  
stairs(x,sin(x))
```

# stairs

## Purpose

Define stairseries properties

## Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or the Property Editor (`propertyeditor`).

Note that you cannot define default property values for stairseries objects.

See Plot Objects for information on stairseries objects.

## Stairseries Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

### Annotation

`hg.Annotation` object (read-only)

*Control the display of stairseries objects in legends.* Specifies whether this stairseries object is represented in a figure legend.

Querying the Annotation property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the stairseries object is displayed in a figure legend.

| <b>IconDisplayStyle Value</b> | <b>Purpose</b>                                                                        |
|-------------------------------|---------------------------------------------------------------------------------------|
| <code>on</code>               | Include the stairseries object in a legend as one entry, but not its children objects |
| <code>off</code>              | Do not include the stairseries or its children in a legend (default)                  |
| <code>children</code>         | Include only the children of the stairseries as separate entries in the legend        |

# Stairseries Properties

---

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Controlling Legends” for more information and examples.

### BeingDeleted

`on` | `{off}` (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-to-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

### BusyAction

`cancel` | `{queue}`

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the

*running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

### `ButtonDownFcn`

string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

# Stairseries Properties

---

The expression executes in the MATLAB workspace.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## Children

array of graphics object handles

*Children of the stairseries object.* An array containing the handles of all line objects parented to the stairseries object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0, 'ShowHiddenHandles', 'on')
```

## Clipping

{on} | off

*Clipping mode.* MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

## Color

ColorSpec

*Color of the object.* A three-element RGB vector or one of the MATLAB predefined names, specifying the object's color. The default value is `[0 0 0]` (black).

See the [ColorSpec](#) reference page for more information on specifying color. See “Adding Arrows and Lines to Graphs”.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where @*CallbackFcn* is a function handle that references the callback function and *graphicfcn* is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

# Stairseries Properties

---

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DisplayName`  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the stairseries object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

`EraseMode`  
{normal} | none | xor | background

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- **normal** — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- **none** — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- **xor** — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- **background** — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

### Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting

# Stairseries Properties

---

to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## HandleVisibility

`{on} | callback | off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property,

figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to on to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

`HitTest`  
`{on} | off`

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the line objects that compose the stairstep graph. If `HitTest` is off, clicking this object selects the object below it (which is usually the axes containing it).

`HitTestArea`  
`on | {off}`

# Stairseries Properties

---

Select the object by clicking lines or area of extent. Select plot objects by:

- Clicking lines (default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is off, you must click the lines to select the object. When `HitTestArea` is on, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses the stairstep graph).

`Interruptible`  
off | {on}

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.

- If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

`LineStyle`

{-} | -- | : | -. | none

*Line style of stairseries object.*

## Line Style Specifiers Table

| Specifier | Line Style           |
|-----------|----------------------|
| '-'       | Solid line (default) |
| '--'      | Dashed line          |
| ':'       | Dotted line          |

# Stairseries Properties

---

| Specifier | Line Style    |
|-----------|---------------|
| '-.'      | Dash-dot line |
| 'none'    | No line       |

Use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`  
size in points

*Width of linear objects and edges of filled areas.* Specify in points. 1 point =  $\frac{1}{72}$  inch. The default is 0.5 points.

`Marker`  
character (see table)

*Marker symbol.* Specifies marks that display at data points. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

## Marker Specifiers Table

| Specifier        | Marker Type |
|------------------|-------------|
| '+'              | Plus sign   |
| 'o'              | Circle      |
| '*'              | Asterisk    |
| '.'              | Point       |
| 'x'              | Cross       |
| 'square' or 's'  | Square      |
| 'diamond' or 'd' | Diamond     |

| Specifier             | Marker Type                   |
|-----------------------|-------------------------------|
| '^'                   | Upward-pointing triangle      |
| 'v'                   | Downward-pointing triangle    |
| '>'                   | Right-pointing triangle       |
| '<'                   | Left-pointing triangle        |
| 'pentagram' or 'p'    | Five-pointed star (pentagram) |
| 'hexagram' or 'h' ' ' | Six-pointed star (hexagram)   |
| 'none'                | No marker (default)           |

## MarkerEdgeColor

ColorSpec | none | {auto}

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Specifies no color, which makes nonfilled markers invisible.
- `auto` — Uses same color as the `Color` property.

## MarkerFaceColor

ColorSpec | {none} | auto

*Fill color for closed-shape markers.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Makes the interior of the marker transparent, allowing the background to show through.

# Stairseries Properties

---

- `auto` — Sets the fill color to the axes `Color` property. If the axes `Color` property is none (the factory default for axes objects), sets the fill color to the figure `Color`.

`MarkerSize`  
scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

`Parent`  
handle of parent axes, `hgroup`, or `hgtransform`

*Parent of object.* Handle of the object's parent. The parent is normally the axes, `hgroup`, or `hgtransform` object that contains the object.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

`Selected`  
`on` | `{off}`

*Object selection state.* When you set this property to `on`, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

`SelectionHighlight`  
`{on}` | `off`

*Object highlighted when selected.*

- **on** — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- **off** — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

Tag

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an `areaseries` object and set the `Tag` property.

```
t = area(Y, 'Tag', 'area1')
```

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag', 'area1'), 'FaceColor', 'red')
```

Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For stairseries objects, `Type` is `'hggroup'`. The following statement finds all the `hggroup` objects in the current axes object.

```
t = findobj(gca, 'Type', 'hggroup');
```

# Stairseries Properties

---

## UIContextMenu

handle of uicontextmenu object

*Associate context menu with object.* Handle of a uicontextmenu object created in the object's parent figure. Use the uicontextmenu function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

## UserData

array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the set and get commands.

## Visible

{on} | off

*Visibility of object and its children.*

- on — Object and all children of the object are visible unless the child object's Visible property is off.
- off — Object not displayed. However, the object still exists and you can set and query its properties.

## XData

array

*X-axis location of stairs.* The stairs function uses XData to label the  $x$ -axis. XData can be either a matrix equal in size to YData or a vector equal in length to the number of rows in YData. That is,  $\text{length}(\text{XData}) == \text{size}(\text{YData}, 1)$ .

If you do not specify XData (which the input argument X), the stairs function uses the indices of YData to create the stairstep graph. See the XDataMode property for related information.

## XDataMode

{auto} | manual

*Use automatic or user-specified x-axis values.* If you specify XData (by setting the XData property or specifying the X input argument), MATLAB sets this property to manual and uses the specified values to label the x-axis.

If you set XDataMode to auto after specifying XData, MATLAB resets the x-axis ticks to `1:size(YData,1)` or to the column indices of the ZData, overwriting any previous values for XData.

## XDataSource

MATLAB variable, as a string

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the XData. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatabasename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's XDataSource does not change the object's XData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## YData

scalar | vector | matrix

# Stairseries Properties

---

*Stairs plot data.* YData contains the data plotted in the staircase graph. Each value in YData is represented by a marker in the staircase graph. If YData is a matrix, the stairs function creates a line for each column in the matrix.

The input argument Y in the stairs function calling syntax assigns values to YData.

## YDataSource

MATLAB variable, as a string

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the YData. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to refreshdata when you set this property. Changing workspace variables used as an object's YDataSource does not change the object's YData values, but you can use refreshdata to force an update of the object's data. refreshdata also lets you specify that the data source variable be evaluated in the workspace of a function from which you call refreshdata.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

**Purpose** Start timer(s) running

**Syntax** `start(obj)`

**Description** `start(obj)` starts the timer running, represented by the timer object, `obj`. If `obj` is an array of timer objects, `start` starts all the timers. Use the `timer` function to create a timer object.

`start` sets the `Running` property of the timer object, `obj`, to `'on'`, initiates `TimerFcn` callbacks, and executes the `StartFcn` callback.

The timer stops running if one of the following conditions apply:

- The first `TimerFcn` callback completes, if `ExecutionMode` is `'singleShot'`.
- The number of `TimerFcn` callbacks specified in `TasksToExecute` have been executed.
- The `stop(obj)` command is issued.
- An error occurred while executing a `TimerFcn` callback.

**See Also** `timer` | `stop`

# startat

---

**Purpose** Start timer(s) running at specified time

**Syntax**

```
startat(obj, time)
startat(obj, S)
startat(obj, S, pivotyear)
startat(obj, Y, M, D)
startat(obj, [Y, M, D])
startat(obj, Y, M, D, H, MI, S)
startat(obj, [Y, M, D, H, MI, S])
```

**Description** `startat(obj, time)` starts the timer represented by timer object `obj` running at the time specified by the serial date number `time`. If `obj` is an array of timer objects, `startat` starts all the timers running at the specified time. To create a timer object, use the `timer` function. You can set the starting `time` to any serial date number less than or equal to 25 days from the current date.

`startat` sets the `Running` property of the timer object, `obj`, to 'on', initiates `TimerFcn` callbacks, and executes the `StartFcn` callback.

The serial date number, `time`, indicates the number of days that have elapsed since 1-Jan-0000 (starting at 1). See `datenum` for additional information about serial date numbers.

`startat(obj, S)` starts the timer running at the time specified by the date string `S`. The date string must use date format 0, 1, 2, 6, 13, 14, 15, 16, or 23, as defined by the `datestr` function. Date strings with two-character years are interpreted to be within the 100 years centered on the current year.

`startat(obj, S, pivotyear)` uses the specified pivot year as the starting year of the 100-year range in which a two-character year resides. The default pivot year is the current year minus 50 years.

`startat(obj, Y, M, D)` `startat(obj, [Y, M, D])` start the timer at the year (`Y`), month (`M`), and day (`D`) specified. `Y`, `M`, and `D` must be arrays of the same size (or they can be a scalar).

`startat(obj, Y, M, D, H, MI, S)` `startat(obj, [Y, M, D, H, MI, S])` start the timer at the year (`Y`), month (`M`), day (`D`), hour (`H`), minute (`MI`), and

second (S) specified. Y, M, D, H, MI, and S must be arrays of the same size (or they can be a scalar). Values outside the normal range of each array are automatically carried to the next unit (for example, month values greater than 12 are carried to years). Month values less than 1 are set to be 1; all other units can wrap and have valid negative values.

The timer stops running if one of the following conditions apply:

- The number of `TimerFcn` callbacks specified in `TasksToExecute` have been executed.
- The `stop(obj)` command is issued.
- An error occurred while executing a `TimerFcn` callback.

## Examples

This example uses a timer object to execute a function at a specified time.

```
t1=timer('TimerFcn','disp(''it is 10 o''''clock''));  
startat(t1,'10:00:00');
```

This example uses a timer to display a message when an hour has elapsed.

```
t2=timer('TimerFcn','disp(''It has been an hour now.''));  
startat(t2,now+1/24);
```

**Purpose**

Standard deviation

**Syntax**

```
s = std(X)
s = std(X,flag)
s = std(X,flag,dim)
```

**Definitions**

There are two common textbook definitions for the standard deviation  $s$  of a data vector  $X$ .

$$(1) s = \left( \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2 \right)^{\frac{1}{2}}$$

$$(2) s = \left( \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2 \right)^{\frac{1}{2}},$$

where

$$\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i$$

and  $n$  is the number of elements in the sample. The two forms of the equation differ only in  $n - 1$  versus  $n$  in the divisor.

**Description**

`s = std(X)`, where  $X$  is a vector, returns the standard deviation using (1) above. The result  $s$  is the square root of an unbiased estimator of the variance of the population from which  $X$  is drawn, as long as  $X$  consists of independent, identically distributed samples.

If  $X$  is a matrix, `std(X)` returns a row vector containing the standard deviation of the elements of each column of  $X$ . If  $X$  is a multidimensional array, `std(X)` is the standard deviation of the elements along the first nonsingleton dimension of  $X$ .

# std

---

`s = std(X,flag)` for `flag = 0`, is the same as `std(X)`. For `flag = 1`, `std(X,1)` returns the standard deviation using (2) above, producing the second moment of the set of values about their mean.

`s = std(X,flag,dim)` computes the standard deviations along the dimension of `X` specified by scalar `dim`. Set `flag` to 0 to normalize `Y` by  $n-1$ ; set `flag` to 1 to normalize by  $n$ .

The input array, `X`, must be of type `double` or `single` for all syntaxes.

## Examples

For matrix `X`

```
X =
     1     5     9
     7    15    22
s = std(X,0,1)
s =
  4.2426   7.0711   9.1924
s = std(X,0,2)
s =
  4.000
  7.5056
```

## See Also

`corrcoef` | `cov` | `mean` | `median` | `var`

**Purpose** Plot discrete sequence data

## Syntax

```
stem(Y)
stem(X,Y)
stem(...,'fill')
stem(...,LineStyle)
stem(...,'PropertyName',PropertyValue,...)
stem(axes_handle,...)
h = stem(...)
```

## Description

A two-dimensional stem plot displays data as lines extending from a baseline along the  $x$ -axis. A circle (the default) or other marker whose  $y$ -position represents the data value terminates each stem.

`stem(Y)` plots the data sequence  $Y$  as stems that extend from equally spaced and automatically generated values along the  $x$ -axis. When  $Y$  is a matrix, `stem` plots all elements in a row against the same  $x$  value.

`stem(X,Y)` plots  $X$  versus the columns of  $Y$ .  $X$  and  $Y$  must be vectors or matrices of the same size. Additionally,  $X$  can be a row or a column vector and  $Y$  a matrix with `length(X)` rows.

`stem(...,'fill')` specifies whether to color the circle at the end of the stem.

`stem(...,LineStyle)` specifies the line style, marker symbol, and color for the stem and top marker (the baseline is not affected). See `LineStyle` for more information.

`stem(...,'PropertyName',PropertyValue,...)` specifies property name and property value pairs for the `stemseries` objects the function creates.

`stem(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of into the current axes object (`gca`).

`h = stem(...)` returns a vector of `stemseries` object handles in `h`, one handle per column of data in `Y`.

## Examples

### Single Series of Data

This example creates a stem plot representing the cosine of 10 values linearly spaced between 0 and  $2\pi$ . Note that the line style of the baseline is set by first getting its handle from the `stemseries` object's `BaseLine` property.

```
figure
t = linspace(-2*pi,2*pi,10);
h = stem(t,cos(t),'fill','--');
set(get(h,'BaseLine'),'LineStyle',':')
set(h,'MarkerFaceColor','red')
```

If you do not want the baseline to show, you can make the baseline invisible:

```
set(get(h, 'Baseline'), 'Visible', 'off')
```

where `h` is the `stemseries` handle returned by the `stem` function.

Delete the baseline with this command:

```
delete(get(h, 'Baseline'))
```

Use similar code to change the color or style of the baseline, specifying any line property and value, for example,

```
set(get(h, 'Baseline'), 'LineWidth', 3)
```

## Two Series of Data on One Graph

This example creates a stem plot from a two-column matrix. In this case, the `stem` function creates two `stemseries` objects, one for each column of data. Both objects' handles are returned in the output argument `h`.

- `h(1)` is the handle to the `stemseries` object plotting the expression  $\exp(-.07*x) \cdot \cos(x)$ .
- `h(2)` is the handle to the `stemseries` object plotting the expression  $\exp(.05*x) \cdot \cos(x)$ .

```
figure
x = 0:25;
y = [exp(-.07*x) .* cos(x); exp(.05*x) .* cos(x)]';
h = stem(x,y);
set(h(1), 'MarkerFaceColor', 'blue')
set(h(2), 'MarkerFaceColor', 'red', 'Marker', 'square')
```

**See Also**

# stem3

---

## Purpose

Plot 3-D discrete sequence data

## Syntax

```
stem3(Z)
stem3(X,Y,Z)
stem3(...,'fill')
stem3(...,LineStyle)
stem3(...,'PropertyName',PropertyValue,...)
h = stem3(...)
```

## Description

Three-dimensional stem plots display lines extending from the  $x$ - $y$  plane. A circle (the default) or other marker symbol whose  $z$ -position represents the data value terminates each stem.

`stem3(Z)` plots the data sequence  $Z$  as stems that extend from the  $x$ - $y$  plane.  $x$  and  $y$  are generated automatically. When  $Z$  is a row vector, `stem3` plots all elements at equally spaced  $x$  values against the same  $y$  value. When  $Z$  is a column vector, `stem3` plots all elements at equally spaced  $y$  values against the same  $x$  value.

`stem3(X,Y,Z)` plots the data sequence  $Z$  at values specified by  $X$  and  $Y$ .  $X$ ,  $Y$ , and  $Z$  must all be vectors or matrices of the same size.

`stem3(...,'fill')` specifies whether to color the interior of the circle at the end of the stem.

`stem3(...,LineStyle)` specifies the line style, marker symbol, and color for the stems. See `LineStyle` for more information.

`stem3(...,'PropertyName',PropertyValue,...)` specifies property name and property value pairs for the `stemseries` objects the function creates.

`h = stem3(...)` returns handles to `stemseries` graphics objects.

## Examples

Create a three-dimensional stem plot to visualize a function of two variables.

```
figure
X = linspace(0,1,10);
Y = X./2;
Z = sin(X) + cos(Y);
stem3(X,Y,Z,'fill')
view(-25,30)
```

# stem3

---

## How To

- Three-Dimensional Stem Plots

## Purpose

Define stemseries properties

## Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or with the property editor (`propertyeditor`).

Note that you cannot define default properties for stemseries objects.

See Plot Objects for information on stemseries objects.

## Stemseries Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

### Annotation

`hg.Annotation` object (read-only)

*Control the display of stemseries objects in legends.* Specifies whether this stemseries object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the stemseries object is displayed in a figure legend.

| <b>IconDisplayStyle Value</b> | <b>Purpose</b>                                                                       |
|-------------------------------|--------------------------------------------------------------------------------------|
| on                            | Include the stemseries object in a legend as one entry, but not its children objects |
| off                           | Do not include the stemseries or its children in a legend (default)                  |
| children                      | Include only the children of the stemseries as separate entries in the legend        |

# Stemseries Properties

---

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Controlling Legends” for more information and examples.

### BaseLine

handle

*Handle of the baseline object.* Handle of the line object used as the baseline. Set the properties of this line using its handle.

The following example makes the stem plot baseline a dashed, red line:

```
% Create stem plot  
stem_handle = stem(randn(10,1));  
% Obtain handle of baseline from stemseries object  
baseline_handle = get(stem_handle, 'BaseLine');  
% Set line properties  
set(baseline_handle, 'LineStyle', '- -', 'Color', 'red')
```

### BaseValue

y-axis value

*Y-axis value where baseline is drawn.* Specify the value along the y-axis at which the MATLAB software draws the baseline.

### BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`  
`cancel` | `{queue}`

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`  
`string` | `function handle`

# Stemseries Properties

---

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## Children

array of graphics object handles

*Children of the stemseries object.* An array containing the handles of all line objects parented to the stemseries object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0, 'ShowHiddenHandles', 'on')
```

## Clipping

{on} | off

*Clipping mode.* MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

## Color

### ColorSpec

*Color of stem lines.* A three-element RGB vector or one of the MATLAB predefined names, specifying the line color. See the `ColorSpec` reference page for more information on specifying color.

For example, the following statement creates a stem plot with red lines.

```
h = stem(randn(10,1), 'Color', 'r');
```

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function and `graphicfcn` is the plotting function which creates this object.

# Stemseries Properties

---

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

## DisplayName

string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the stemseries object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where  $n$  is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

## EraseMode

`{normal} | none | xor | background`

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.

# Stemseries Properties

---

- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`HandleVisibility`  
{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.

- **callback** — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- **off** — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

# Stemseries Properties

---

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## HitTest

{on} | off

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the line objects that compose the stem plot. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

## HitTestArea

on | {off}

*Select the object by clicking stem lines or area of extent.* Select plot objects by:

- Clicking stem lines (default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is `off`, you must click the stem lines to select the object. When `HitTestArea` is `on`, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses all the stem lines).

## Interruptible

off | {on}

## *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

# Stemseries Properties

---

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

## LineStyle

{-} | -- | : | -. | none

*Line style of stemseries object.*

## Line Style Specifiers Table

| Specifier | Line Style           |
|-----------|----------------------|
| '-'       | Solid line (default) |
| '--'      | Dashed line          |
| ':'       | Dotted line          |
| '-.'      | Dash-dot line        |
| 'none'    | No line              |

Use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

## LineWidth

size in points

*Width of linear objects and edges of filled areas.* Specify in points. 1 point =  $1/72$  inch. The default is 0.5 points.

## Marker

character (see table)

*Marker symbol.* Specifies marks that display at data points. You can set values for the Marker property independently from the LineStyle property. For a list of supported marker symbols, see the following table.

### Marker Specifiers Table

| Specifier              | Marker Type                   |
|------------------------|-------------------------------|
| '+'                    | Plus sign                     |
| 'o'                    | Circle                        |
| '*'                    | Asterisk                      |
| '.'                    | Point                         |
| 'x'                    | Cross                         |
| 'square' or 's'        | Square                        |
| 'diamond' or 'd'       | Diamond                       |
| '^'                    | Upward-pointing triangle      |
| 'v'                    | Downward-pointing triangle    |
| '>'                    | Right-pointing triangle       |
| '<'                    | Left-pointing triangle        |
| 'pentagram' or 'p'     | Five-pointed star (pentagram) |
| 'hexagram' or 'h ' ' ' | Six-pointed star (hexagram)   |
| 'none'                 | No marker (default)           |

## MarkerEdgeColor

ColorSpec | none | {auto}

# Stemseries Properties

---

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Specifies no color, which makes nonfilled markers invisible.
- `auto` — Uses same color as the `Color` property.

`MarkerFaceColor`

`ColorSpec` | `{none}` | `auto`

*Fill color for closed-shape markers.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Sets the fill color to the axes `Color` property. If the axes `Color` property is `none` (the factory default for axes objects), sets the fill color to the figure `Color`.

`MarkerSize`

scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

`Parent`

handle of parent axes, `hgggroup`, or `hgtransform`

*Parent of object.* Handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## Selected

on | {off}

*Object selection state.* When you set this property to on, MATLAB displays selection handles at the corners and midpoints if the SelectionHighlight property is also on (the default). You can, for example, define the ButtonDownFcn callback to set this property to on, thereby indicating that this particular object is selected. This property is also set to on when an object is manually selected in plot edit mode.

## SelectionHighlight

{on} | off

*Object highlighted when selected.*

- on — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- off — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

## Tag

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the Tag property and the findobj function to manipulate specific objects within a plotting hierarchy.

For example, create a stemseries object and set the Tag property:

# Stemseries Properties

---

```
Y = linspace(-2*pi,2*pi,10);  
t = stem(Y, 'Tag', 'stem1')
```

To access the stemseries object, use `findobj` to find the object's handle. The following statement changes the `MarkerFaceColor` property of the object whose `Tag` is `stem1`.

```
set(findobj('Tag', 'stem1'), 'MarkerFaceColor', 'red')
```

## Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For stemseries objects, `Type` is `'hggroup'`. The following statement finds all `hggroup` objects in the current axes object.

```
t = findobj(gca, 'Type', 'hggroup');
```

## UIContextMenu

handle of `uicontextmenu` object

*Associate context menu with object.* Handle of a `uicontextmenu` object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

## UserData

array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## Visible

{on} | off

*Visibility of object and its children.*

- on — Object and all children of the object are visible unless the child object's Visible property is off.
- off — Object not displayed. However, the object still exists and you can set and query its properties.

## XData

array

*X-axis location of stems.* The stem function draws an individual stem at each  $x$ -axis location in the XData array. XData can be either a matrix equal in size to YData or a vector equal in length to the number of rows in YData. That is, `length(XData) == size(YData,1)`. XData does not need to be monotonically increasing.

If you do not specify XData (which is the input argument X), the stem function uses the indices of YData to create the stem plot. See the XDataMode property for related information.

## XDataMode

{auto} | manual

*Use automatic or user-specified x-axis values.* If you specify XData (by setting the XData property or specifying the X input argument), MATLAB sets this property to manual and uses the specified values to label the  $x$ -axis.

If you set XDataMode to auto after specifying XData, MATLAB resets the  $x$ -axis ticks to `1:size(YData,1)` or to the column indices of the ZData, overwriting any previous values for XData.

## XDataSource

MATLAB variable, as a string

# Stemseries Properties

---

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the XData. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's XDataSource does not change the object's XData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## YData

scalar | vector | matrix

*Stem plot data.* YData contains the data plotted as stems. Each value in YData is represented by a marker in the stem plot. If YData is a matrix, MATLAB creates a series of stems for each column in the matrix.

The input argument Y in the `stem` function calling syntax assigns values to YData.

## YDataSource

MATLAB variable, as a string

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the YData. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `YDataSource` does not change the object's `YData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## ZData

vector

*Z-coordinates.* A data defining the stems for 3-D stem graphs. `XData` and `YData` (if specified) must be the same size.

## ZDataSource

MATLAB variable, as a string

*Link ZData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `ZData`. The default value is an empty array.

```
set(h, 'ZDataSource', 'zdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `ZDataSource` does not change the object's `ZData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable

# Stemseries Properties

---

be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

**Purpose** Stop timer(s)

**Syntax** stop(obj)

**Description** stop(obj) stops the timer, represented by the timer object, obj. If obj is an array of timer objects, the stop function stops them all. Use the timer function to create a timer object.

The stop function sets the Running property of the timer object, obj, to 'off', halts further TimerFcn callbacks, and executes the StopFcn callback.

**See Also** timer | start

# stopasync

---

|                    |                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Stop asynchronous read and write operations                                                                                                   |
| <b>Syntax</b>      | <code>stopasync(obj)</code>                                                                                                                   |
| <b>Description</b> | <code>stopasync(obj)</code> stops any asynchronous read or write operation that is in progress for the serial port object, <code>obj</code> . |

**Tips** You can write data asynchronously using the `fprintf` or `fwrite` function. You can read data asynchronously using the `readasync` function, or by configuring the `ReadAsyncMode` property to `continuous`. In-progress asynchronous operations are indicated by the `TransferStatus` property.

If `obj` is an array of serial port objects and one of the objects cannot be stopped, the remaining objects in the array are stopped and a warning is returned. After an object stops:

- Its `TransferStatus` property is configured to `idle`.
- Its `ReadAsyncMode` property is configured to `manual`.
- The data in its output buffer is flushed.

Data in the input buffer is not flushed. You can return this data to the MATLAB workspace using any of the synchronous read functions. If you execute the `readasync` function, or configure the `ReadAsyncMode` property to `continuous`, then the new data is appended to the existing data in the input buffer.

**See Also** `fprintf` | `fwrite` | `readasync` | `ReadAsyncMode` | `TransferStatus`

**Purpose** Convert string to double-precision value

**Syntax**  
`X = str2double('str')`  
`X = str2double(C)`

**Description** `X = str2double('str')` converts the string `str`, which should be an ASCII character representation of a real or complex scalar value, to the MATLAB double-precision representation. The string can contain digits, a comma (thousands separator), a decimal point, a leading + or - sign, an `e` preceding a power of 10 scale factor, and an `i` for a complex unit.

If `str` does not represent a valid scalar value, `str2double` returns NaN.

`X = str2double(C)` converts the strings in the cell array of strings `C` to double precision. The matrix `X` returned will be the same size as `C`.

**Examples** Here are some valid `str2double` conversions.

```
str2double('123.45e7')  
str2double('123 + 45i')  
str2double('3.14159')  
str2double('2.7i - 3.14')  
str2double({'2.71' '3.1415'})  
str2double('1,200.34')
```

**See Also** `char` | `hex2num` | `num2str` | `str2num` | `cast`

# str2func

---

**Purpose** Construct function handle from function name string

**Syntax** `str2func('str')`

**Description** `str2func('str')` constructs a function handle `fhandle` for the function named in the string `'str'`. The contents of `str` can be the name of a file that defines a MATLAB function, or the name of an anonymous function.

You can create a function handle `fh` using any of the following four methods:

- Create a handle to a named function:

```
fh = @functionName;  
fh = str2func(functionName);
```

- Create a handle to an anonymous function:

```
fh = @(x)functionDef(x);  
fh = str2func('@(x)functionDef(x)');
```

You can create an array of function handles from strings by creating the handles individually with `str2func`, and then storing these handles in a cell array.

**Tips** Nested functions are not accessible to `str2func`. To construct a function handle for a nested function, you must use the function handle constructor, `@`.

Any variables and their values originally stored in a function handle when it was created are lost if you convert the function handle to a string and back again using the `func2str` and `str2func` functions.

## Examples **Example 1**

To convert the string, `'sin'`, into a handle for that function, type

```
fh = str2func('sin')
```

```
fh =  
    @sin
```

### Example 2

If you pass a function name string in a variable, the function that receives the variable can convert the function name to a function handle using `str2func`. The example below passes the variable, `funcname`, to function `makeHandle`, which then creates a function handle. Here is the function:

```
function fh = makeHandle(funcname)  
fh = str2func(funcname);
```

This is the code that calls `makeHandle` to construct the function handle:

```
makeHandle('sin')  
ans =  
    @sin
```

### Example 3

To call `str2func` on a cell array of strings, use the `cellfun` function. This returns a cell array of function handles:

```
fh_array = cellfun(@str2func, {'sin' 'cos' 'tan'}, ...  
                  'UniformOutput', false);
```

```
fh_array{2}(5)  
ans =  
    0.2837
```

### Example 4

In the following example, the `myminbnd` function expects to receive either a function handle or string in the first argument. If you pass a string, `myminbnd` constructs a function handle from it using `str2func`, and then uses that handle in a call to `fminbnd`:

```
function myminbnd(fhandle, lower, upper)  
if ischar(fhandle)
```

```
        disp 'converting function string to function handle ...'
        fhandle = str2func(fhandle);
    end
    fminbnd(fhandle, lower, upper)
```

Whether you call `myminbnd` with a function handle or function name string, the function can handle the argument appropriately:

```
myminbnd('humps', 0.3, 1)
converting function string to function handle ...
ans =
    0.6370
```

### Example 5

The `dirByType` function shown here creates an anonymous function called `dirCheck`. What the anonymous function does depends upon the value of the `dirType` argument passed in to the primary function. The example demonstrates one possible use of `str2func` with anonymous functions:

```
function dirByType(dirType)
switch(dirType)
    case 'class', leadchar = '@';
    case 'package', leadchar = '+';
    otherwise disp('ERROR: Unrecognized type'), return;
end

dirfile = @(fs)isdir(fs.name);
dirCheckStr = ['@(fs)strcmp(fs.name(1,1),'', leadchar, '')'];
dirCheckFun = str2func(dirCheckStr);
s = dir;    filecount = length(s);

for k=1:filecount
    fstruct = s(k);
    if dirfile(fstruct) && dirCheckFun(fstruct)
        fprintf('%s folder: %s\n', dirType, fstruct.name)
    end
end
```

Generate a list of class and package folders:

```
dirByType('class')
class folder: @Point
class folder: @asset
class folder: @bond

dirByType('package')
package folder: +containers
package folder: +event
package folder: +mypkg
```

# str2mat

---

**Purpose** Form blank-padded character matrix from strings

---

**Note** str2mat is not recommended. Use char instead.

---

**Syntax** S = str2mat(T1, T2, T3, ...)

**Description** S = str2mat(T1, T2, T3, ...) forms the matrix S containing the text strings T1, T2, T3, ... as rows. The function automatically pads each string with blanks in order to form a valid matrix. Each text parameter, Ti, can itself be a string matrix. This allows the creation of arbitrarily large string matrices. Empty strings are significant.

**Tips** str2mat differs from strvcat in that empty strings produce blank rows in the output. In strvcat, empty strings are ignored.

**Examples** x = str2mat('36842', '39751', '38453', '90307');

```
whos x
  Name      Size      Bytes  Class
  x         4x5         40    char array
```

```
x(2,3)
```

```
ans =
```

```
7
```

**See Also** char

**Purpose** Convert string to number

**Syntax**

```
x = str2num('str')
[x, status] = str2num('str')
```

## Description

---

**Note** str2num uses the eval function to convert the input argument. Side effects can occur if the string contains calls to functions. Using str2double can avoid some of these side effects.

---

`x = str2num('str')` converts the string `str`, which is an ASCII character representation of a numeric value, to numeric representation. `str2num` also converts string matrices to numeric matrices. If the input string does not represent a valid number or matrix, `str2num(str)` returns the empty matrix in `x`.

The input string can contain one or more numbers separated by spaces, commas, or semicolons, such as '5', '10,11,12', or '5,10;15,20'. In addition to numerical values and delimiters, the input string can also include a decimal point, leading + or - signs, the letter e or d preceding a power of 10 scale factor, or the letter i or j indicating a complex or imaginary number.

The following table shows several examples of valid inputs to `str2num`:

| String Input             | Numeric Output                              | Output Class                   |
|--------------------------|---------------------------------------------|--------------------------------|
| '500'                    | 500                                         | 1-by-1 scalar double           |
| '500 250 125 67'         | 500, 250, 125,<br>67                        | 1-by-4 row vector of double    |
| '500; 250; 125;<br>62.5' | 500.0000<br>250.0000<br>125.0000<br>62.5000 | 4-by-1 column vector of double |

# str2num

| String Input       | Numeric Output           | Output Class            |
|--------------------|--------------------------|-------------------------|
| '1 23 6 21; 53:56' | 1 23 6 21<br>53 54 55 56 | 2-by-5 matrix of double |
| '12e-3 5.9e-3'     | 0.0120 0.0059            | vector of double        |
| 'uint16(500)'      | 500                      | 16-bit unsigned integer |

---

**Note** `str2num` does not operate on cell arrays. To convert a cell array of strings to a numeric value, use `str2double`.

---

If the input string does not represent a valid number or matrix, `str2num(str)` returns the empty matrix in `x`.

`[x, status] = str2num('str')` returns the status of the conversion in logical `status`, where `status` equals logical 1 (true) if the conversion succeeds, and logical 0 (false) otherwise.

Space characters can be significant. For instance, `str2num('1+2i')` and `str2num('1 + 2i')` produce `x = 1+2i`, while `str2num('1 +2i')` produces `x = [1 2i]`. You can avoid these problems by using the `str2double` function.

## Examples

Input a character string that contains a single number. The output is a scalar double:

```
A = str2num('500')
A =
    500

class(A)
ans =
    double
```

Repeat this operation, but this time using an unsigned 16-bit integer:

```
A = str2num('uint16(500)')
A =
    500

class(A)
ans =
    uint16
```

Try three different ways of specifying a row vector. Each returns the same answer:

```
str2num('2 4 6 8')           % Separate with spaces.
ans =
     2     4     6     8

str2num('2,4,6,8')           % Separate with commas.
ans =
     2     4     6     8

str2num('[2 4 6 8]')         % Enclose in brackets.
ans =
     2     4     6     8
```

Note that the first two of these commands do not need the MATLAB square bracket operator to create a matrix. The `str2num` function inserts the brackets for you if they are needed.

Use a column vector this time:

```
str2num('2; 4; 6; 8')
ans =
     2
     4
     6
     8
```

And now a 2-by-2 matrix:

# str2num

---

```
str2num('2 4; 6 8')
ans =
     2     4
     6     8
```

| [special characters](#)

**Purpose** Concatenate strings horizontally

**Syntax** `combinedStr = strcat(s1, s2, ..., sN)`

**Description** `combinedStr = strcat(s1, s2, ..., sN)` horizontally concatenates strings in arrays `s1`, `s2`, ..., `sN`. Inputs can be combinations of single strings, strings in scalar cells, character arrays with the same number of rows, and same-sized cell arrays of strings. If any input is a cell array, `combinedStr` is a cell array of strings. Otherwise, `combinedStr` is a character array.

- Tips**
- For character array inputs, `strcat` removes trailing ASCII white-space characters: space, tab, vertical tab, newline, carriage return, and form-feed. To preserve trailing spaces when concatenating character arrays, use horizontal array concatenation, `[s1, s2, ..., sN]`. See the final example in the following section.
  - For cell array inputs, `strcat` does not remove trailing white space.
  - When combining nonscalar cell arrays and multi-row character arrays, cell arrays must be column vectors with the same number of rows as the character arrays.

**Examples** Concatenate two cell arrays:

```
a = {'abcde', 'fghi'};  
b = {'jkl', 'mn'};
```

```
ab = strcat(a, b)
```

MATLAB returns

```
ab =  
    'abcdejkl'    'fghimn'
```

---

Combine cell arrays `a` and `b` from the previous example with a scalar cell:

## strcat

---

```
c = {'Q'};  
abc = strcat(a, b, c)
```

MATLAB returns

```
abc =  
    'abcdejk1Q'    'fghimnQ'
```

---

Compare the use of `strcat` and horizontal array concatenation with strings that contain trailing spaces:

```
a = 'hello  ';  
b = 'goodbye';  
  
using_strcat = strcat(a, b)  
using_arrayop = [a, b]      % Equivalent to horzcat(a, b)
```

MATLAB returns

```
using_strcat =  
hellogoodbye  
  
using_arrayop =  
hello  goodbye
```

**Purpose** Compare strings (case sensitive)

**Syntax** TF = strcmp(string,string)  
TF = strcmp(string,cellstr)  
TF = strcmp(cellstr,cellstr)

**Description** TF = strcmp(string,string) compares two strings for equality. The strings are considered to be equal if the size and content of each are the same. The function returns a scalar logical 1 for equality, or scalar logical 0 for inequality.

TF = strcmp(string,cellstr) compares a string with each element of a cell array of strings. The function returns a logical array the same size as the cellstr input in which logical 1 represents equality. The order of the input arguments is not important.

TF = strcmp(cellstr,cellstr) compares each element of one cell array of strings with the same element of the other. The function returns a logical array the same size as either cell array input.

- Tips**
- The strcmp function is intended for comparison of character data. When used to compare numeric data, it returns logical 0.
  - Use strcmpi for case-insensitive string comparisons.
  - Any leading and trailing blanks in either of the strings are explicitly included in the comparison.
  - The value returned by strcmp is not the same as the C language convention.
  - strcmp supports international character sets.

**Input Arguments** **string**  
A single character string or n-by-1 array of strings.

**cellstr**  
A cell array of strings.

# strcmp

---

## Output Arguments

### TF

When both inputs are character arrays, TF is a scalar logical 1 or 0. This value is logical 1 (true) if the size and content of both arrays are equal, and logical 0 (false) if it is not.

When either or both inputs is a cell array of strings, TF is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (true) for those elements of the input arrays that are a match, and logical 0 (false) for those elements that are not.

## Examples

Perform a simple comparison of two strings:

```
strcmp('Yes', 'No')
ans =
     0
strcmp('Yes', 'Yes')
ans =
     1
```

---

Create two cell arrays of strings and call strcmp to compare them:

```
A = {'Handle Graphics', 'Statistics'; ...
     'Toolboxes', 'MathWorks'};

B = {'Handle Graphics', 'Signal Processing'; ...
     'Toolboxes', 'MATHWORKS'};

match = strcmp(A, B)
match =
     1     0
     0     0
```

The result of comparing the two cell arrays is:

- `match{1,1}` is 1 because “Handle Graphics” in `A{1,1}` matches the same text in `B{1,1}`.

- `match{1,2}` is 0 because “Statistics” in `A{1,2}` does not match “Signal Processing” in `B{1,2}`.
  - `match{2,1}` is 0 because “ Toolboxes”, in `A{2,1}` contains leading space characters that are not in `B{2,1}`.
  - `match{2,2}` is 0 because “MathWorks” in `A{2,2}` uses different letter case than “MATHWORKS” in `B{2,2}`, and `strcmp` does a case-sensitive comparison.
- 

The following example has three parts. It compares

- A string to an array of strings.
- A padded string to a cell array of strings.
- An unpadded string to a cell array of strings.

Start by creating the necessary data structures.

#### 1 Cell array of strings –

Create a 3-element cell array of strings:

```
cellarr = { ...  
    'There are 10 kinds of people in the world,'; ...  
    'those who understand binary math,'; ...  
    'and those who don't.'};
```

#### 2 String array –

From the cell array, create a string array. The string array contains space characters at the end of rows 2 and 3 for the padding needed to make the array rectangular:

```
strarr = char(cellarr)  
strarr =  
There are 10 kinds of people in the world,  
those who understand binary math,  
and those who don't.
```

# strcmp

---

```
%           Each line ends here ^
```

### 3 String vector –

From row 2 of the string array, create a string vector. This string is also padded with spaces at the end:

```
strvec = strarr(2,:)
strvec =
those who understand binary math,
%           Padded line ends here ^
```

Begin the comparisons. Start by comparing the string vector with the string array. When comparing character arrays, `strcmp` does not do a row-by-row comparison. It compares *all* of the 1-by-42 `strvec` with *all* of the 3-by-42 `strarr`. Finding them to be different, the answer is `false` and `strcmp` returns logical 0:

```
strcmp(strvec, strarr)
ans =
    0
```

Compare the string vector to the cell array. Even though `strvec` is essentially the same as row 2 of `cellarr`, it is not a match because of the space padding in `strvec`:

```
strcmp(strvec, cellarr)
ans =
    0
    0
    0
```

Remove the space padding from the string vector and compare it to the cell array. `strcmp` compares `strvec` with each row of the `cellarr`, finding a match with the second row of the latter:

```
strcmp(deblank(strvec), cellarr)
ans =
```

0  
1  
0

**See Also**

`strncmp` | `strcmpi` | `strncmpi` | `strfind` | `regexp` | `regexp` |

# strcmpi

---

**Purpose** Compare strings (case insensitive)

**Syntax**  
TF = strcmpi(string,string)  
TF = strcmpi(string,cellstr)  
TF = strcmpi(cellstr,cellstr)

**Description** TF = strcmpi(string,string) compares two strings for equality, ignoring any differences in letter case. The strings are considered to be equal if the size and content of each are the same. The function returns a scalar logical 1 for equality, or scalar logical 0 for inequality.

TF = strcmpi(string,cellstr) compares a string with each element of a cell array of strings, ignoring letter case. The function returns a logical array the same size as the cellstr input in which logical 1 represents equality. The order of the input arguments is not important.

TF = strcmpi(cellstr,cellstr) compares each element of one cell array of strings with the same element of the other, ignoring letter case. The function returns a logical array the same size as the input arrays.

- Tips**
- The strcmpi function is intended for comparison of character data. When used to compare numeric data, it returns logical 0.
  - Use strcmp for case-sensitive string comparisons.
  - Any leading and trailing blanks in either of the strings are explicitly included in the comparison.
  - The value returned by strcmpi is not the same as the C language convention.
  - strcmpi supports international character sets.

**Input Arguments**

**string**  
A single character string or n-by-1 array of strings.

**cellstr**  
A cell array of strings.

## Output Arguments

### TF

When both inputs are character arrays, TF is a scalar logical value. This value is logical 1 (true) if the size and content of both arrays are equal, and logical 0 (false) if they are not.

When either or both inputs are a cell array of strings, TF is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (true) for those elements of the input arrays that are a match, and logical 0 (false) for those elements that are not.

## Examples

Perform a simple case-insensitive comparison of two strings:

```
strcmapi('Yes', 'No')
ans =
     0
strcmapi('Yes', 'yes')
ans =
     1
```

Create two cell arrays of strings and call `strcmapi` to compare them:

```
A = {'Handle Graphics', 'Statistics'; ...
     'Toolboxes', 'MathWorks'};

B = {'Handle Graphics', 'Signal Processing'; ...
     'Toolboxes', 'MATHWORKS'};

match = strcmapi(A, B)
match =
     1     0
     0     1
```

The result of comparing the two cell arrays is:

- `match{1,1}` is 1 because “Handle Graphics” in `A{1,1}` matches the same text in `B{1,1}`.

## strcmpi

---

- `match{1,2}` is 0 because “Statistics” in `A{1,2}` does not match “Signal Processing” in `B{1,2}`.
- `match{2,1}` is 0 because “ Toolboxes”, in `A{2,1}` contains leading space characters that are not in `B{2,1}`.
- `match{2,2}` is 1 because even though “MathWorks” in `A{2,2}` uses different letter case than “MATHWORKS” in `B{2,2}`, `strcmpi` performs the comparison without sensitivity to letter case.

**Purpose** Compute 2-D streamline data

**Syntax**

```
XY = stream2(x,y,u,v,startx,starty)
XY = stream2(u,v,startx,starty)
XY = stream2(...,options)
```

**Description** `XY = stream2(x,y,u,v,startx,starty)` computes streamlines from vector data `u` and `v`.

The arrays `x` and `y`, which define the coordinates for `u` and `v`, must be monotonic, but do not need to be uniformly spaced. `x` and `y` must have the same number of elements, as if produced by `meshgrid`.

`startx` and `starty` define the starting positions of the streamlines. The section "Specifying Starting Points for Stream Plots" provides more information on defining starting points.

The returned value `XY` contains a cell array of vertex arrays.

`XY = stream2(u,v,startx,starty)` assumes the arrays `x` and `y` are defined as `[x,y] = meshgrid(1:n,1:m)` where `[m,n] = size(u)`.

`XY = stream2(...,options)` specifies the options used when creating the streamlines. Define `options` as a one- or two-element vector containing the step size or the step size and the maximum number of vertices in a streamline:

```
[stepsize]
```

or

```
[stepsize, max_number_vertices]
```

If you do not specify a value, MATLAB software uses the default:

- Step size = 0.1 (one tenth of a cell)
- Maximum number of vertices = 10000

Use the `streamline` command to plot the data returned by `stream2`.

# stream2

---

## Examples

This example draws 2-D streamlines from data representing air currents over regions of North America.

```
load wind
[sx,sy] = meshgrid(80,20:10:50);
streamline(stream2(x(:,:,5),y(:,:,5),u(:,:,5),v(:,:,5),sx,sy));
```

# stream3

---

## Examples

This example draws 3-D streamlines from data representing air currents over regions of North America.

```
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
streamline(stream3(x,y,z,u,v,w,sx,sy,sz))
view(3)
```

## See Also

[coneplot](#) | [stream2](#) | [streamline](#)

## How To

- [Specifying Starting Points for Stream Plots](#)

**Purpose**

Plot streamlines from 2-D or 3-D vector data

**Syntax**

```
streamline(X,Y,Z,U,V,W,startx,starty,startz)
streamline(U,V,W,startx,starty,startz)
streamline(XYZ)
streamline(X,Y,U,V,startx,starty)
streamline(U,V,startx,starty)
streamline(XY)
streamline(...,options)
streamline(axes_handle,...)
h = streamline(...)
```

**Description**

`streamline(X,Y,Z,U,V,W,startx,starty,startz)` draws streamlines from 3-D vector data  $U$ ,  $V$ ,  $W$ .

The arrays  $X$ ,  $Y$ , and  $Z$ , which define the coordinates for  $U$ ,  $V$ , and  $W$ , must be monotonic, but do not need to be uniformly spaced.  $X$ ,  $Y$ , and  $Z$  must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, `startz` define the starting positions of the streamlines. The section [Specifying Starting Points for Stream Plots](#) provides more information on defining starting points.

`streamline(U,V,W,startx,starty,startz)` assumes the arrays  $X$ ,  $Y$ , and  $Z$  are defined as  $[X,Y,Z] = \text{meshgrid}(1:N,1:M,1:P)$ , where  $[M,N,P] = \text{size}(U)$ .

`streamline(XYZ)` assumes  $XYZ$  is a precomputed cell array of vertex arrays (as produced by `stream3`).

`streamline(X,Y,U,V,startx,starty)` draws streamlines from 2-D vector data  $U$ ,  $V$ .

The arrays  $X$  and  $Y$ , which define the coordinates for  $U$  and  $V$ , must be monotonic, but do not need to be uniformly spaced.  $X$  and  $Y$  must have the same number of elements, as if produced by `meshgrid`.

# streamline

---

`startx` and `starty` define the starting positions of the streamlines. The output argument `h` contains a vector of line handles, one handle for each streamline.

`streamline(U,V,startx,starty)` assumes the arrays `X` and `Y` are defined as `[X,Y] = meshgrid(1:N,1:M)`, where `[M,N] = size(U)`.

`streamline(XY)` assumes `XY` is a precomputed cell array of vertex arrays (as produced by `stream2`).

`streamline(...,options)` specifies the options used when creating the streamlines. Define `options` as a one- or two-element vector containing the step size or the step size and the maximum number of vertices in a streamline:

```
[stepsize]
```

or

```
[stepsize, max_number_vertices]
```

If you do not specify values, MATLAB uses the default:

- Step size = 0.1 (one tenth of a cell)
- Maximum number of vertices = 1000

`streamline(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of the into current axes object (`gca`).

`h = streamline(...)` returns a vector of line handles, one handle for each streamline.

## Examples

This example draws streamlines from data representing air currents over a region of North America. Loading the wind data set creates the variables `x`, `y`, `z`, `u`, `v`, and `w` in the MATLAB workspace.

The plane of streamlines indicates the flow of air from the west to the east (the `x`-direction) beginning at `x = 80` (which is close to the minimum value of the `x` coordinates). The `y`- and `z`-coordinate starting points are multivalued and approximately span the range of

these coordinates. `meshgrid` generates the starting positions of the streamlines.

```
load wind
[sx,sy,sz] = meshgrid(80,20:10:50,0:5:15);
h = streamline(x,y,z,u,v,w,sx,sy,sz);
set(h,'Color','red')
view(3)
```

## How To

- [Specifying Starting Points for Stream Plots](#)
- [Stream Line Plots of Vector Data](#)

# streamparticles

---

**Purpose** Plot stream particles

**Syntax**

```
streamparticles(vertices)
streamparticles(vertices,n)
streamparticles(...,'PropertyName',PropertyValue,...)
streamparticles(line_handle,...)
h = streamparticles(...)
```

**Description** `streamparticles(vertices)` draws stream particles of a vector field. Stream particles are usually represented by markers and can show the position and velocity of a streamline. `vertices` is a cell array of 2-D or 3-D vertices (as if produced by `stream2` or `stream3`).

`streamparticles(vertices,n)` uses `n` to determine how many stream particles to draw. The `ParticleAlignment` property controls how `n` is interpreted.

- If `ParticleAlignment` is set to `off` (the default) and `n` is greater than 1, approximately `n` particles are drawn evenly spaced over the streamline vertices.

If `n` is less than or equal to 1, `n` is interpreted as a fraction of the original stream vertices; for example, if `n` is 0.2, approximately 20% of the vertices are used.

`n` determines the upper bound for the number of particles drawn. The actual number of particles can deviate from `n` by as much as a factor of 2.

- If `ParticleAlignment` is `on`, `n` determines the number of particles on the streamline having the most vertices and sets the spacing on the other streamlines to this value. The default value is `n = 1`.

`streamparticles(...,'PropertyName',PropertyValue,...)` controls the stream particles using named properties and specified values. Any unspecified properties have default values. MATLAB ignores the case of property names.

## Stream Particle Properties

`Animate` — Stream particle motion [nonnegative integer]

The number of times to animate the stream particles. The default is 0, which does not animate. `Inf` animates until you enter **Ctrl+C**.

**FrameRate** — Animation frames per second [nonnegative integer]

This property specifies the number of frames per second for the animation. `Inf`, the default, draws the animation as fast as possible. Note that the speed of the animation might be limited by the speed of the computer. In such cases, the value of **FrameRate** cannot necessarily be achieved.

**ParticleAlignment** — Align particles with streamlines [on | {off}]

Set this property to `on` to draw particles at the beginning of each streamline. This property controls how `streamparticles` interprets the argument `n` (number of stream particles).

Stream particles are line objects. In addition to stream particle properties, you can specify any line object property, such as **Marker** and **EraseMode**. `streamparticles` sets the following line properties when called.

| Line Property                | Value Set by <code>streamparticles</code> |
|------------------------------|-------------------------------------------|
| <code>EraseMode</code>       | <code>xor</code>                          |
| <code>LineStyle</code>       | <code>none</code>                         |
| <code>Marker</code>          | <code>o</code>                            |
| <code>MarkerEdgeColor</code> | <code>none</code>                         |
| <code>MarkerFaceColor</code> | <code>red</code>                          |

You can override any of these properties by specifying a property name and value as arguments to `streamparticles`. For example, this statement uses RGB values to set the `MarkerFaceColor` to medium gray:

```
streamparticles(vertices, 'MarkerFaceColor', [.5 .5 .5])
```

# streamparticles

---

`streamparticles(line_handle,...)` uses the line object identified by `line_handle` to draw the stream particles.

`h = streamparticles(...)` returns a vector of handles to the line objects it creates.

## Examples

This example combines streamlines with stream particle animation. The `interpstreamspeed` function determines the vertices along the streamlines where stream particles will be drawn during the animation, thereby controlling the speed of the animation. Setting the axes `DrawMode` property to `fast` provides faster rendering.

```
load wind
[sx sy sz] = meshgrid(80,20:1:55,5);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
sl = streamline(verts);
iverts = interpstreamspeed(x,y,z,u,v,w,verts,.025);
axis tight; view(30,30); daspect([1 1 .125])
camproj perspective; camva(8)
set(gca,'DrawMode','fast')
box on
streamparticles(iverts,35,'animate',10,'ParticleAlignment','on')
```

The following picture is a static view of the animation.

This example uses the streamlines in the  $z = 5$  plane to animate the flow along these lines with streamparticles.

```
load wind
daspect([1 1 1]); view(2)
[verts averts] = streamslice(x,y,z,u,v,w,[],[],[5]);
sl = streamline([verts averts]);
axis tight off;
set(sl,'Visible','off')
iverts = interpstreamspeed(x,y,z,u,v,w,verts,.05);
set(gca,'DrawMode','fast','Position',[0 0 1 1],'ZLim',[4.9 5.1])
set(gcf,'Color','black')
streamparticles(iverts, 200, ...
    'Animate',100,'FrameRate',40, ...
    'MarkerSize',10,'MarkerFaceColor','yellow')
```

## How To

- [Creating Stream Particle Animations](#)
- [Specifying Starting Points for Stream Plots](#)

# streamribbon

---

**Purpose** 3-D stream ribbon plot from vector volume data

**Syntax**

```
streamribbon(X,Y,Z,U,V,W,startx,starty,startz)
streamribbon(U,V,W,startx,starty,startz)
streamribbon(vertices,X,Y,Z,cav,speed)
streamribbon(vertices,cav,speed)
streamribbon(vertices,twistangle)
streamribbon(...,width)
streamribbon(axes_handle,...)
h = streamribbon(...)
```

**Description** `streamribbon(X,Y,Z,U,V,W,startx,starty,startz)` draws stream ribbons from vector volume data `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, and `startz` define the starting positions of the stream ribbons at the center of the ribbons. The section [Specifying Starting Points for Stream Plots](#) provides more information on defining starting points.

The twist of the ribbons is proportional to the curl of the vector field. The width of the ribbons is calculated automatically.

`streamribbon(U,V,W,startx,starty,startz)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamribbon(vertices,X,Y,Z,cav,speed)` assumes precomputed streamline vertices, curl angular velocity, and flow speed. `vertices` is a

cell array of streamline vertices (as produced by `stream3`). `X`, `Y`, `Z`, `cav`, and `speed` are 3-D arrays.

`streamribbon(vertices,cav,speed)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(cav)`.

`streamribbon(vertices,twistangle)` uses the cell array of vectors `twistangle` for the twist of the ribbons (in radians). The size of each corresponding element of `vertices` and `twistangle` must be equal.

`streamribbon(...,width)` sets the width of the ribbons to `width`.

`streamribbon(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of into the current axes object (`gca`).

`h = streamribbon(...)` returns a vector of handles (one per start point) to surface objects.

## Examples

This example uses stream ribbons to indicate the flow in the wind data set. Inputs include the coordinates, vector field components, and starting location for the stream ribbons.

```
figure
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
streamribbon(x,y,z,u,v,w,sx,sy,sz);
% Define viewing and lighting
axis tight
shading interp;
view(3);
camlight; lighting gouraud
```

# streamribbon

This example uses precalculated vertex data (`stream3`), curl average velocity (`curl1`), and speed  $\sqrt{u^2 + v^2 + w^2}$ . Using precalculated data enables you to use values other than those calculated from the single data source. In this case, the speed is reduced by a factor of 10 compared to the previous example.

figure

```
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
cav = curl(x,y,z,u,v,w);
spd = sqrt(u.^2 + v.^2 + w.^2).*0.1;
streamribbon(verts,x,y,z,cav,spd);
% Define viewing and lighting
axis tight
shading interp
view(3)
camlight; lighting gouraud
```

# streamribbon

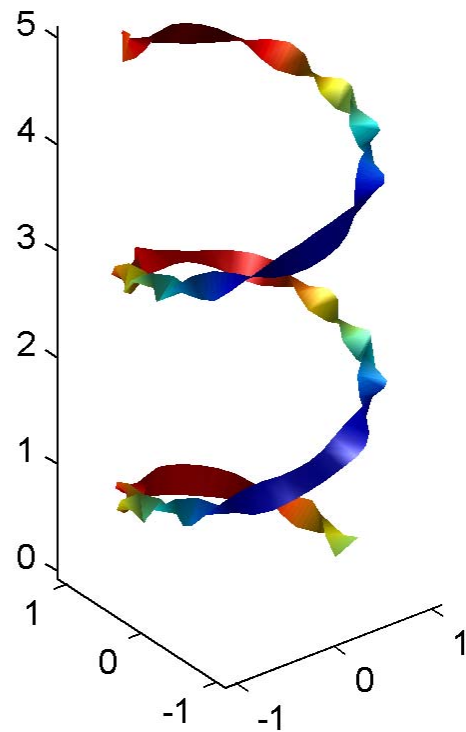

---

This example specifies a twist angle for the stream ribbon.

```
figure
t = 0:.15:15;
verts = {[cos(t)' sin(t)' (t/3)']};
twistangle = {cos(t)'};
streamribbon(verts,twistangle);
% Define viewing and lighting
```

```
axis tight  
shading interp;  
view(3);  
camlight; lighting gouraud
```

This example combines cone plots (coneplot) and stream ribbon plots in one graph.

# streamribbon

---

```
figure
% Define 3-D arrays x, y, z, u, v, w
xmin = -7; xmax = 7;
ymin = -7; ymax = 7;
zmin = -7; zmax = 7;
x = linspace(xmin,xmax,30);
y = linspace(ymin,ymax,20);
z = linspace(zmin,zmax,20);
[x y z] = meshgrid(x,y,z);
u = y; v = -x; w = 0*x+1;
[cx cy cz] = meshgrid(linspace(xmin,xmax,30),...
    linspace(ymin,ymax,30),[-3 4]);
h = coneplot(x,y,z,u,v,w,cx,cy,cz,'quiver');
set(h,'Color','k');

% Plot two sets of streamribbons
[sx sy sz] = meshgrid([-1 0 1],[-1 0 1],-6);
streamribbon(x,y,z,u,v,w,sx,sy,sz);
[sx sy sz] = meshgrid([1:6],[0],-6);
streamribbon(x,y,z,u,v,w,sx,sy,sz);

% Define viewing and lighting
shading interp
view(-30,10) ; axis off tight
camproj perspective; camva(66); camlookat;
camdolly(0,0,.5,'fixtarget')
camlight
```

## How To

- “Volume Visualization”
- [Displaying Curl with Stream Ribbons](#)
- [Specifying Starting Points for Stream Plots](#)

# streamslice

---

## Purpose

Plot streamlines in slice planes

## Syntax

```
streamslice(X,Y,Z,U,V,W,startx,starty,startz)
streamslice(U,V,W,startx,starty,startz)
streamslice(X,Y,U,V)
streamslice(U,V)
streamslice(...,density)
streamslice(...,'arrowsmode')
streamslice(...,'method')
streamslice(axes_handle,...)
h = streamslice(...)
[vertices arrowvertices] = streamslice(...)
```

## Description

`streamslice(X,Y,Z,U,V,W,startx,starty,startz)` draws well-spaced streamlines (with direction arrows) from vector data  $U$ ,  $V$ ,  $W$  in axis aligned  $x$ -,  $y$ -,  $z$ -planes starting at the points in the vectors `startx`, `starty`, `startz`. (The section [Specifying Starting Points for Stream Plots](#) provides more information on defining starting points.)

The arrays  $X$ ,  $Y$ , and  $Z$ , which define the coordinates for  $U$ ,  $V$ , and  $W$ , must be monotonic, but do not need to be uniformly spaced.  $X$ ,  $Y$ , and  $Z$  must have the same number of elements, as if produced by `meshgrid`.  $U$ ,  $V$ ,  $W$  must be  $m$ -by- $n$ -by- $p$  volume arrays.

Do not assume that the flow is parallel to the slice plane. For example, in a stream slice at a constant  $z$ , the  $z$  component of the vector field  $W$  is ignored when you are calculating the streamlines for that plane.

Stream slices are useful for determining where to start streamlines, stream tubes, and stream ribbons.

`streamslice(U,V,W,startx,starty,startz)` assumes  $X$ ,  $Y$ , and  $Z$  are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamslice(X,Y,U,V)` draws well-spaced streamlines (with direction arrows) from vector volume data `U, V`.

The arrays `X` and `Y`, which define the coordinates for `U` and `V`, must be monotonic, but do not need to be uniformly spaced. `X` and `Y` must have the same number of elements, as if produced by `meshgrid`.

`streamslice(U,V)` assumes `X, Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamslice(...,density)` modifies the automatic spacing of the streamlines. `density` must be greater than 0. The default value is 1; higher values produce more streamlines on each plane. For example, 2 produces approximately twice as many streamlines, while 0.5 produces approximately half as many.

`streamslice(...,'arrowmode')` determines if direction arrows are present or not. `arrowmode` can be

- `arrows` — Draw direction arrows on the streamlines (default).
- `noarrows` — Do not draw direction arrows.

`streamslice(...,'method')` specifies the interpolation method to use. `method` can be

- `linear` — Linear interpolation (default)
- `cubic` — Cubic interpolation
- `nearest` — Nearest-neighbor interpolation

See `interp3` for more information on interpolation methods.

`streamslice(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of into the current axes object (`gca`).

# streamslice

---

`h = streamslice(...)` returns a vector of handles to the line objects created.

`[vertices arrowvertices] = streamslice(...)` returns two cell arrays of vertices for drawing the streamlines and the arrows. You can pass these values to any of the streamline drawing functions (`streamline`, `streamribbon`, `streamtube`).

## Examples

This example creates a stream slice in the wind data set at  $z = 5$ .

```
figure
load wind
streamslice(x,y,z,u,v,w,[],[],[5])
axis tight
```

This example uses `streamslic` to calculate vertex data for the streamlines and the direction arrows. This data is then used by `streamline` to plot the lines and arrows. Slice planes illustrating with color the wind speed  $\sqrt{u^2 + v^2 + w^2}$  are drawn by `slice` in the same planes.

figure

## streamslice

---

```
load wind
[verts averts] = streamslice(u,v,w,10,10,10);
streamline([verts averts])
spd = sqrt(u.^2 + v.^2 + w.^2);
hold on;
slice(spd,10,10,10);
colormap(hot)
shading interp
view(30,50); axis(volumebounds(spd));
camlight; material([.5 1 0])
```

This example superimposes contour lines on a surface and then uses `streamslic` to draw lines that indicate the gradient of the surface. `interp2` is used to find the points for the lines that lie on the surface.

```
figure
z = peaks;
surf(z)
shading interp
```

## streamslice

---

```
hold on
[c ch] = contour3(z,20); set(ch,'edgecolor','b')
[u v] = gradient(z);
h = streamslice(-u,-v);
set(h,'color','k')
for i=1:length(h);
    zi = interp2(z,get(h(i),'xdata'),get(h(i),'ydata'));
    set(h(i),'zdata',zi);
end
view(30,50); axis tight
```

## How To

- [Specifying Starting Points for Stream Plots](#)

# streamtube

---

## Purpose

Create 3-D stream tube plot

## Syntax

```
streamtube(X,Y,Z,U,V,W,startx,starty,startz)
streamtube(U,V,W,startx,starty,startz)
streamtube(vertices,X,Y,Z,divergence)
streamtube(vertices,divergence)
streamtube(vertices,width)
streamtube(vertices)
streamtube(...,[scale n])
streamtube(axes_handle,...)
h = streamtube(...z)
```

## Description

`streamtube(X,Y,Z,U,V,W,startx,starty,startz)` draws stream tubes from vector volume data `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, and `startz` define the starting positions of the streamlines at the center of the tubes. The section [Specifying Starting Points for Stream Plots](#) provides more information on defining starting points.

The width of the tubes is proportional to the normalized divergence of the vector field.

`streamtube(U,V,W,startx,starty,startz)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamtube(vertices,X,Y,Z,divergence)` assumes precomputed streamline vertices and divergence. `vertices` is a cell array of

streamline vertices (as produced by `stream3`). `X`, `Y`, `Z`, and divergence are 3-D arrays.

`streamtube(vertices,divergence)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(divergence)`.

`streamtube(vertices,width)` specifies the width of the tubes in the cell array of vectors, `width`. The size of each corresponding element of `vertices` and `width` must be equal. `width` can also be a scalar, specifying a single value for the width of all stream tubes.

`streamtube(vertices)` selects the width automatically.

`streamtube(...,[scale n])` scales the width of the tubes by `scale`. The default is `scale = 1`. When the stream tubes are created, using start points or divergence, specifying `scale = 0` suppresses automatic scaling. `n` is the number of points along the circumference of the tube. The default is `n = 20`.

`streamtube(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of into the current axes object (`gca`).

`h = streamtube(...z)` returns a vector of handles (one per start point) to surface objects used to draw the stream tubes.

## Examples

This example uses stream tubes to indicate the flow in the wind data set. Inputs include the coordinates, vector field components, and starting location for the stream tubes.

```
figure
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
streamtube(x,y,z,u,v,w,sx,sy,sz);
% Define viewing and lighting
view(3)
axis tight
```

# streamtube

```
shading interp;  
camlight; lighting gouraud
```

This example uses precalculated vertex data (`stream3`) and divergence (`divergence`).

```
figure  
load wind
```

```
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
div = divergence(x,y,z,u,v,w);
streamtube(verts,x,y,z,-div);
% Define viewing and lighting
view(3)
axis tight
shading interp
camlight; lighting gouraud
```

# streamtube

---

## How To

- [Displaying Divergence with Stream Tubes](#)
- [Specifying Starting Points for Stream Plots](#)

**Purpose**

Find one string within another

**Syntax**

```
k = strfind(str, pattern)
k = strfind(cellstr, pattern)
```

**Description**

`k = strfind(str, pattern)` searches the string `str` for occurrences of a shorter string, `pattern`, and returns the starting index of each such occurrence in the double array `k`. If `pattern` is not found in `str`, or if `pattern` is longer than `str`, then `strfind` returns the empty array `[]`.

`k = strfind(cellstr, pattern)` searches each string in cell array of strings `cellstr` for occurrences of a shorter string, `pattern`, and returns the starting index of each such occurrence in cell array `k`. If `pattern` is not found in a string or if `pattern` is longer than all strings in the cell array, then `strfind` returns the empty array `[]`, for that string in the cell array.

**Tips**

- The search performed by `strfind` is case sensitive.
- Any leading and trailing blanks in `pattern` or in the strings being searched are explicitly included in the comparison.
- The `strfind` function does not find empty strings ( ' ') within a string.

**Examples**

Use `strfind` to find a two-letter pattern in string `S`:

```
S = 'Find the starting indices of the pattern string';
strfind(S, 'in')
ans =
     2     15     19     45

strfind(S, 'In')
ans =
     []

strfind(S, ' ')
ans =
     5     9     18     26     29     33     41
```

# strfind

---

Use `strfind` on a cell array of strings:

```
cstr = {'How much wood would a woodchuck chuck';  
       'if a woodchuck could chuck wood?'};
```

```
idx = strfind(cstr, 'wood');
```

```
idx{:,:}  
ans =  
    10    23  
ans =  
     6    28
```

This means that 'wood' occurs at indices 10 and 23 in the first string and at indices 6 and 28 in the second.

`strtok` | `strcmp` | `strncmp` | `strcmpi` | `strncmpi` | `regexp` | `regexpr`  
| `regexprep` | `strrep`

**Purpose**

String handling

**Syntax**

```
S = 'Any Characters'  
S = [S1 S2 ...]  
C = {S1 S2 ...}  
S = strcat(S1, S2, ...)  
S = char(S1, S2, ...)  
S = char(X)  
X = double(S)
```

**Description**

`S = 'Any Characters'` creates a character array, or string. The string is actually a vector that contains the numeric codes for the characters (codes 0 to 127 are ASCII). The length of `S` is the number of characters. A quotation within the string is indicated by two quotation marks.

`S = [S1 S2 ...]` concatenates character arrays `S1`, `S2`, etc. into a new character array, `S`.

`C = {S1 S2 ...}` creates a cell array of strings. Separate each row of the cell array with a semicolon (;).

`S = strcat(S1, S2, ...)` horizontally concatenates `S1`, `S2`, etc., which can be character arrays or cell arrays of strings. If the inputs are character arrays, `strcat` removes trailing white space. For more information, see the `strcat` reference page.

`S = char(S1, S2, ...)` vertically concatenates character arrays `S1`, `S2`, etc., padding each input string as needed so that each row contains the same number of characters.

`S = char(X)` converts an array that contains positive integers representing numeric codes into a MATLAB character array.

`X = double(S)` converts the string to its equivalent integer numeric codes.

**Tips**

- To convert between character arrays and cell arrays of strings, use `char` and `cellstr`. Most string functions support both types.

# strings

---

- To determine whether S is a character array or cell array, call `ischar(S)` or `iscellstr(S)`.

## Examples

Create a simple string that includes a single quote.

```
msg = 'You're right!'
```

```
msg =  
You're right!
```

Create the string name using two methods of concatenation.

```
name = ['Thomas' ' R. ' 'Lee']  
name = strcat('Thomas',' R.',' Lee')
```

Create a character array of strings.

```
C = char('Hello','Goodbye','Yes','No')
```

```
C =  
Hello  
Goodbye  
Yes  
No
```

Create a cell array of strings.

```
S = {'Hello' 'Goodbye'; 'Yes' 'No'}
```

```
S =  
    'Hello'    'Goodbye'  
    'Yes'     'No'
```

`iscellstr` | `sprintf` | `sscanf` | `text` | `input`

## Concepts

- “Cell Arrays of Strings”

**Purpose** Justify character array

**Syntax**  
T = strjust(S)  
T = strjust(S, 'right')  
T = strjust(S, 'left')  
T = strjust(S, 'center')

**Description** T = strjust(S) or T = strjust(S, 'right') returns a right-justified version of the character array S.

T = strjust(S, 'left') returns a left-justified version of S.

T = strjust(S, 'center') returns a center-justified version of S.

**See Also** deblank | strtrim

# strmatch

---

## Purpose

Find possible matches for string

---

**Note** `strmatch` is not recommended. Use `strncmp` or `validatestring`, depending on your requirements, instead. `strncmp` returns the numeric index of all array elements that begin with the specified string, whereas `validatestring` returns a single string that represents the best match to the specified string. See Example 2, below.

To find an exact match for a string, use `strcmp`.

---

## Syntax

```
x = strmatch(str, strarray)
x = strmatch(str, strarray, 'exact')
```

## Description

`x = strmatch(str, strarray)` looks through the rows of the character array or cell array of strings `strarray` to find strings that begin with the text contained in `str`, and returns the matching row indices. If `strmatch` does not find `str` in `strarray`, `x` is an empty matrix (`[]`). Any trailing space characters in `str` or `strarray` are ignored when matching. `strmatch` is fastest when `strarray` is a character array.

`x = strmatch(str, strarray, 'exact')` compares `str` with each row of `strarray`, looking for an exact match of the entire strings. Any trailing space characters in `str` or `strarray` are ignored when matching.

## Examples

### Example 1

The statement

```
x = strmatch('max', char('max', 'minimax', 'maximum'))
```

returns `x = [1; 3]` since rows 1 and 3 begin with 'max'. The statement

```
x = strmatch('max', char('max', 'minimax', 'maximum'),'exact')
```

returns `x = 1`, since only row 1 matches 'max' exactly.

## Example 2

This example shows how to replace use of the `strmatch` function with `validatestring` or `strncmp`.

To start with, use `strmatch` to return the index of those elements for which there is a match:

```
list = {'max', 'minimax', 'maximum', 'max'}
x = strmatch('max',list)
x =
     1
     3
     4
```

`validatestring` returns the string representing the best match. If multiple or no matches exist, this statement would return an error:

```
list = {'max', 'minimax', 'maximum', 'max'};
x = validatestring('max', list)
x =
    max
```

`strncmp` returns a logical array indicating which strings match the specified string:

```
list = {'max', 'minimax', 'maximum', 'max'};
x = strncmp('max', list, 3)
x =
     1     0     1     1
```

If you prefer that MATLAB return the numeric indices of `list`, use `find` as follows:

```
list = {'max', 'minimax', 'maximum', 'max'}
x = find(strncmp(list, 'max', 3))
```

# strmatch

---

If your input to `strmatch` is a character matrix, then first convert the matrix to a cell array using `cellstr`. Then, pass the output from `cellstr` to `strncmp` or `validatestring`

| <b>Input Arguments</b> | <p><b>string</b><br/>Single character string or <i>n</i>-by-1 array of strings.</p> <p><b>cellstr</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

# strncmp

---

Cell array of strings.

**n**

Maximum number of characters to compare. Must be a scalar, integer-valued double.

## Output Arguments

**TF**

When both inputs are character arrays, TF is a scalar logical value. This value is logical 1 (true) if the size and content of both arrays are equal, and logical 0 (false) if they are not.

When either or both inputs are a cell array of strings, TF is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (true) for those elements of the input arrays that are a match, and logical 0 (false) for those elements that are not.

## Examples

Before trying the `strncmp` function, use `strcmp` to perform a simple comparison of the two input strings. Because only the first 13 characters are the same, `strcmp` returns logical 0:

```
strcmp('Kansas City, KS', 'Kansas City, MO')
ans =
    0
```

Do the comparison again, but this time using `strncmp` and specifying the number of characters to compare:

```
chars2compare = length('Kansas City, KS') - 2
ans =
    13
strncmp('Kansas City, KS', 'Kansas City, MO', chars2compare)
ans =
    1
```

---

From a list of 10 MATLAB functions, find those that apply to using a camera:

```
function_list = {'calendar' 'case' 'camdolly' 'circshift' ...  
                'caxis' 'camtarget' 'cast' 'camorbit' ...  
                'callib' 'cart2sph'};
```

```
strncmp(function_list, 'cam', 3)
```

```
ans =
```

```
    0    0    1    0    0    1    0    1    0    0
```

```
function_list{strncmp(function_list, 'cam', 3)}
```

```
ans =
```

```
    camdolly
```

```
ans =
```

```
    camtarget
```

```
ans =
```

```
    camorbit
```

---

Create two 5-by-10 string arrays `str1` and `str2` that are equal, except for the element at row 4, column 3. Using linear indexing, this is element 14:

```
str1 = ['AAAAAAAAA'; 'BBBBBBBBBB'; 'CCCCCCCCCC'; ...  
        'DDDDDDDDDD'; 'EEEEEEEEEEE']
```

```
str1 =
```

```
    AAAAAAAAAA
```

```
    BBBBBBBBBB
```

```
    CCCCCCCCCC
```

```
    DDDDDDDDDD
```

```
    EEEEEEEEEE
```

```
str2 = str1;
```

```
str2(4,3) = '-'
```

```
str2 =
```

```
    AAAAAAAAAA
```

# strncmp

---

```
BBBBBBBBBB  
CCCCCCCCC  
DD-DDDDDD  
EEEEEEEEEE
```

Because MATLAB compares the arrays in linear order (that is, column by column rather than row by row), `strncmp` finds only the first 13 elements to be the same:

```
str1  A B C D E A B C D E A B C D E  
str2  A B C D E A B C D E A B C - E  
                                     |  
                                     element 14
```

```
strncmp(str1, str2, 13)  
ans =  
    1
```

```
strncmp(str1, str2, 14)  
ans =  
    0
```

The function returns a logical array the same size as either input array.</p> |
| <b>Tips</b>            | <ul style="list-style-type: none"><li>• The strncmpi function is intended for comparison of character data. When used to compare numeric data, it returns logical 0.</li><li>• Use strcmp for case-sensitive string comparisons.</li><li>• Any leading and trailing blanks in either of the strings are explicitly included in the comparison.</li><li>• The value returned by strncmpi is not the same as the C language convention.</li><li>• strncmpi supports international character sets.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Input Arguments</b> | <p><b>string</b></p> <p>A single character string or <i>n</i>-by-1 array of strings.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

# strncmpi

---

## **cellstr**

A cell array of strings.

## **n**

Maximum number of characters to compare. Must be a scalar, integer-valued double.

## **Output Arguments**

## **TF**

When both inputs are character arrays, TF is a scalar logical value. This value is logical 1 (**true**) if the size and content of both arrays are equal, and logical 0 (**false**) if they are not.

When either or both inputs are a cell array of strings, TF is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (**true**) for those elements of the input arrays that are a match, and logical 0 (**false**) for those elements that are not.

## **Examples**

From a list of 10 MATLAB functions, find those that apply to using a camera. Do the comparison without sensitivity to letter case:

```
function_list = {'calendar' 'case' 'camdolly' 'circshift' ...  
                'caxis' 'Camtarget' 'cast' 'camorbit' ...  
                'callib' 'cart2sph'};
```

```
strncmpi(function_list, 'CAM', 3)  
ans =  
    0    0    1    0    0    1    0    1    0    0
```

```
function_list{strncmpi(function_list, 'CAM', 3)}  
ans =  
    camdolly  
ans =  
    Camtarget  
ans =  
    camorbit
```

# strread

---

## Purpose

Read formatted data from string

---

**Note** `strread` is not recommended. Use `textscan` instead.

---

## Syntax

```
A = strread('str')
[A, B, ...] = strread('str')
[A, B, ...] = strread('str', 'format')
[A, B, ...] = strread('str', 'format', N)
[A, B, ...] = strread('str', 'format', N, param, value, ...)
```

## Description

`A = strread('str')` reads numeric data from input string `str` into a 1-by-`N` vector `A`, where `N` equals the number of whitespace-separated numbers in `str`. Use this form only with strings containing numeric data. See “Example 1” on page 2-4362 below.

`[A, B, ...] = strread('str')` reads numeric data from the string input `str` into scalar output variables `A`, `B`, and so on. The number of output variables must equal the number of whitespace-separated numbers in `str`. Use this form only with strings containing numeric data. See “Example 2” on page 2-4363 below.

`[A, B, ...] = strread('str', 'format')` reads data from `str` into variables `A`, `B`, and so on using the specified format. The number of output variables `A`, `B`, etc. must be equal to the number of format specifiers (e.g., `%s` or `%d`) in the `format` argument. You can read all of the data in `str` to a single output variable as long as you use only one format specifier in the command. See “Example 4” on page 2-4363 and “Example 5” on page 2-4364 below.

The table [Formats for strread](#) on page 2-4359 lists the valid format specifiers. More information on using formats is available under “Formats” on page 2-4362 in the “Tips” on page 2-4361 section below.

`[A, B, ...] = strread('str', 'format', N)` reads data from `str` reusing the format string `N` times, where `N` is an integer greater than zero. If `N` is -1, `strread` reads the entire string. When `str` contains

only numeric data, you can set `format` to the empty string (''). See “Example 3” on page 2-4363 below.

`[A, B, ...] = strread('str', 'format', N, param, value, ...)` customizes `strread` using `param/value` pairs, as listed in the table Parameters and Values for `strread` on page 2-4360 below. When `str` contains only numeric data, you can set `format` to the empty string (''). The `N` argument is optional and may be omitted entirely. See “Example 7” on page 2-4365 below.

**Formats for strread**

| <b>Format</b>                     | <b>Action</b>                                                                                                                                                                                    | <b>Output</b>         |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| Literals<br>(ordinary characters) | Ignore the matching characters. For example, in a string that has Dept followed by a number (for department number), to skip the Dept and read only the number, use 'Dept' in the format string. | None                  |
| %d                                | Read a signed integer value.                                                                                                                                                                     | Double array          |
| %u                                | Read an integer value.                                                                                                                                                                           | Double array          |
| %f                                | Read a floating-point value.                                                                                                                                                                     | Double array          |
| %s                                | Read a white-space separated string.                                                                                                                                                             | Cell array of strings |
| %q                                | Read a double quoted string, ignoring the quotes.                                                                                                                                                | Cell array of strings |
| %c                                | Read characters, including white space.                                                                                                                                                          | Character array       |
| %[...]                            | Read the longest string containing characters specified in the brackets.                                                                                                                         | Cell array of strings |

## Formats for strread (Continued)

| Format    | Action                                                                                                            | Output                |
|-----------|-------------------------------------------------------------------------------------------------------------------|-----------------------|
| %[ ^... ] | Read the longest nonempty string containing characters that are not specified in the brackets.                    | Cell array of strings |
| %*...     | Ignore the characters following *. See “Example 8” on page 2-4365 below.                                          | No output             |
| %w...     | Read field width specified by w. The %f format supports %w.pf, where w is the field width and p is the precision. |                       |

## Parameters and Values for strread

| param      | value                                                                                                                                                              | Action                                                                       |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------|
| whitespace | Any from the list below:<br>\b Backspace<br>\n New line<br>\r Carriage return<br>\t Horizontal tab<br>\\ Backslash<br>%% Percent sign<br>' ' Single quotation mark | Treats vector of characters, *, as white space. Default is \b\r\n\t.         |
| delimiter  | Delimiter character                                                                                                                                                | Specifies delimiter character. Default is one or more whitespace characters. |
| expchars   | Exponent characters                                                                                                                                                | Default is eEdD.                                                             |

**Parameters and Values for strread (Continued)**

| param        | value                                                       | Action                                                          |
|--------------|-------------------------------------------------------------|-----------------------------------------------------------------|
| bufsize      | Positive integer                                            | Specifies the maximum string length, in bytes. Default is 4095. |
| commentstyle | matlab                                                      | Ignores characters after %.                                     |
| commentstyle | shell                                                       | Ignores characters after #.                                     |
| commentstyle | c                                                           | Ignores characters between /* and */.                           |
| commentstyle | c++                                                         | Ignores characters after //.                                    |
| emptyvalue   | Value to return for empty numeric fields in delimited files | Default is NaN.                                                 |

**Tips**

If you terminate the input string with a newline character (\n), strread returns arrays of equal size by padding arrays of lesser size with the emptyvalue character:

```
[A,B,C] = strread(sprintf('5,7,1,9\n'),'%d%d%d', ...
    'delimiter', ',', 'emptyvalue',NaN)
A =
    5
    9
B =
    7
   NaN
C =
    1
   NaN
```

If you remove the `\n` from the input string of this example, array `A` continues to be a 2-by-1 array, but `B` and `C` are now 1-by-1.

## Delimiters

If your data uses a character other than a space as a delimiter, you must use the `strread` parameter `'delimiter'` to specify the delimiter. For example, if the string `str` used a semicolon as a delimiter, you would use this command:

```
[names, types, x, y, answer] = strread(str, '%s %s %f ...  
      %d %s', 'delimiter', ';');
```

## Formats

The format string determines the number and types of return arguments. The number of return arguments must match the number of conversion specifiers in the format string.

The `strread` function continues reading `str` until the entire string is read. If there are fewer format specifiers than there are entities in `str`, `strread` reapplies the format specifiers, starting over at the beginning. See “Example 5” on page 2-4364 below.

The format string supports a subset of the conversion specifiers and conventions of the C language `fscanf` routine. White-space characters in the format string are ignored.

## Preserving White-Space

If you want to preserve leading and trailing spaces in a string, use the `whitespace` parameter as shown here:

```
str = '  An example      of preserving      spaces      ';
```

```
strread(str, '%s', 'whitespace', '')  
ans =  
      '  An example      of preserving      spaces      '
```

## Examples

### Example 1

Read numeric data into a 1-by-5 vector:

```
a = strread('0.41 8.24 3.57 6.24 9.27')
a =
    0.4100    8.2400    3.5700    6.2400    9.2700
```

## Example 2

Read numeric data into separate scalar variables:

```
[a b c d e] = strread('0.41 8.24 3.57 6.24 9.27')
a =
    0.4100
b =
    8.2400
c =
    3.5700
d =
    6.2400
e =
    9.2700
```

## Example 3

Read the only first three numbers in the string, also formatting as floating point:

```
a = strread('0.41 8.24 3.57 6.24 9.27', '%4.2f', 3)

a =
    0.4100
    8.2400
    3.5700
```

## Example 4

Truncate the data to one decimal digit by specifying format `%3.1f`. The second specifier, `%*1d`, tells `strread` not to read in the remaining decimal digit:

```
a = strread('0.41 8.24 3.57 6.24 9.27', '%3.1f %*1d')

a =
```

# strread

---

```
0.4000
8.2000
3.5000
6.2000
9.2000
```

## Example 5

Read six numbers into two variables, reusing the format specifiers:

```
[a b] = strread('0.41 8.24 3.57 6.24 9.27 3.29', '%f %f')
```

```
a =
    0.4100
    3.5700
    9.2700
b =
    8.2400
    6.2400
    3.2900
```

## Example 6

Read string and numeric data to two output variables. Ignore commas in the input string:

```
str = 'Section 4, Page 7, Line 26';

[name value] = strread(str, '%s %d,')
name =
    'Section'
    'Page'
    'Line'
value =
     4
     7
    26
```

## Example 7

Read the string used in the last example, but this time delimiting with commas instead of spaces:

```
str = 'Section 4, Page 7, Line 26';

[a b c] = strread(str, '%s %s %s', 'delimiter', ',')
a =
    'Section 4'
b =
    'Page 7'
c =
    'Line 26'
```

## Example 8

Read selected portions of the input string:

```
str = '<table border=5 width="100%" cellpadding=0>';

[border width space] = strread(str, ...
    '%*s%*s %c %*s "%4s" %*s %c', 'delimiter', '= ')
border =
     5
width =
    '100%'
space =
     0
```

## Example 9

Read the string into two vectors, restricting the Answer values to T and F. Also note that two delimiters (comma and space) are used here:

```
str = 'Answer_1: T, Answer_2: F, Answer_3: F';

[a b] = strread(str, '%s %[TF]', 'delimiter', ', ', ' ')
a =
    'Answer_1:'
```

# strread

---

```
    'Answer_2: '  
    'Answer_3: '  
b =  
    'T'  
    'F'  
    'F'
```

textscan | sscanf

**Purpose** Find and replace substring

**Syntax** `modifiedStr = strrep(origStr, oldSubstr, newSubstr)`

**Description** `modifiedStr = strrep(origStr, oldSubstr, newSubstr)` replaces all occurrences of the string `oldSubstr` within string `origStr` with the string `newSubstr`.

### Tips

- `strrep` accepts input combinations of single strings, strings in scalar cells, and same-sized cell arrays of strings. If any inputs are cell arrays, `strrep` returns a cell array.
- The `strrep` function does not find empty strings for replacement. That is, when `origStr` and `oldSubstr` both contain the empty string (`''`), `strrep` does not replace `''` with the contents of `newSubstr`.
- Before replacing strings, `strrep` finds all instances of `oldSubstr` in `origStr`, like the `strfind` function. For overlapping patterns, `strrep` performs multiple replacements. See the final example in the Examples section.

### Examples

Replace text in a character array:

```
claim = 'This is a good example.';
new_claim = strrep(claim, 'good', 'great')
```

MATLAB returns:

```
new_claim =
This is a great example.
```

---

Replace text in a cell array:

```
c_files = {'c:\cookies.m'; ...
           'c:\candy.m'; ...
           'c:\calories.m'};
d_files = strrep(c_files, 'c:', 'd:')
```

MATLAB returns:

```
d_files =  
    'd:\cookies.m'  
    'd:\candy.m'  
    'd:\calories.m'
```

---

Replace text in a cell array with values in a second cell array:

```
missing_info = {'Start: __'; ...  
               'End: __'};  
  
dates = {'01/01/2001'; ...  
         '12/12/2002'};  
  
complete = strrep(missing_info, '__', dates)
```

MATLAB returns:

```
complete =  
    'Start: 01/01/2001'  
    'End: 12/12/2002'
```

---

Compare the use of `strrep` and `regexprep` to replace a string with a repeated pattern:

```
repeats = 'abc 2 def 22 ghi 222 jkl 2222';  
indices = strfind(repeats, '22')  
  
using_strrep = strrep(repeats, '22', '*')  
using_regexprep = regexprep(repeats, '22', '*')
```

MATLAB returns:

```
indices =  
    11    18    19    26    27    28
```

```
using_strrep =  
abc 2 def * ghi ** jkl ***
```

```
using_regexprep =  
abc 2 def * ghi *2 jkl **
```

**See Also**

[strfind](#) | [regexprep](#)

# strtok

---

**Purpose** Selected parts of string

**Syntax**

```
token = strtok(str)
token = strtok(str, delimiter)
[token, remain] = strtok('str', ...)
```

**Description** `token = strtok(str)` parses input string `str` from left to right, returning part or all of that string in `token`. Using the white-space character as a delimiter, the `token` output begins at the start of `str`, skipping any delimiters that might appear at the start, and includes all characters up to either the next delimiter or the end of the string. White-space characters include space (ASCII 32), tab (ASCII 9), and carriage return (ASCII 13).

The `str` argument can be a string of characters enclosed in single quotation marks, a cell array of strings each enclosed in single quotation marks, or a variable representing either of the two. If `str` is a cell array of `N` strings, then `token` is a cell array of `N` tokens, with `token{1}` derived from `str{1}`, `token{2}` from `str{2}`, and so on.

`token = strtok(str, delimiter)` is the same as the above syntax except that you specify the delimiting character(s) yourself using the `delimiter` character vector input. White-space characters are not considered to be delimiters when using this syntax unless you include them in the `delimiter` argument. If the `delimiter` input specifies more than one character, MATLAB treats each character as a separate delimiter; it does not treat the multiple characters as a delimiting string. The number and order of characters in the `delimiter` argument is unimportant. Do not use escape sequences as delimiters. For example, use `char(9)` rather than `'\t'` for tab.

`[token, remain] = strtok('str', ...)` returns in `remain` that part of `str`, if any, that follows `token`. If no delimiters are found in the body of the input string, then the entire string (excluding any leading delimiting characters) is returned in `token`, and `remain` is an empty string (''). If `str` is a cell array of strings, `token` is a cell array of tokens and `remain` is a cell array of string remainders.

## Examples

### Example 1

This example uses the default white-space delimiter. Note that space characters at the start of the string are not included in the token output, but the space character that follows token is included in remain:

```
s = ' This is a simple example.';
[token, remain] = strtok(s)
```

```
token =
This
remain =
 is a simple example.
```

### Example 2

Take a string of HTML code and break it down into segments delimited by the < and > characters. Write a while loop to parse the string and print each segment:

```
s = sprintf('%s%s%s%s', ...
'<ul class=continued><li class=continued>', ...
'<pre><a name="13474"></a>token = strtok', ...
(''str'', delimiter)<a name="13475"></a>', ...
'token = strtok(''str'')');
```

```
remain = s;
```

```
while true
    [str, remain] = strtok(remain, '<>');
    if isempty(str), break; end
    disp(sprintf('%s', str))
end
```

Here is the output:

```
ul class=continued
li class=continued
pre
```

```
a name="13474"  
/a  
token = strtok('str', delimiter)  
a name="13475"  
/a  
token = strtok('str')
```

### Example 3

Using `strtok` on a cell array of strings returns a cell array of strings in `token` and a character array in `remain`:

```
s = {'all in good time'; ...  
    'my dog has fleas'; ...  
    'leave no stone unturned'};  
  
remain = s;  
  
for k = 1:4  
    [token, remain] = strtok(remain);  
    token  
end
```

Here is the output:

```
token =  
    'all'  
    'my'  
    'leave'  
token =  
    'in'  
    'dog'  
    'no'  
token =  
    'good'  
    'has'  
    'stone'  
token =
```

```
'time'  
'fleas'  
'unturned'
```

## See Also

# strtrim

---

**Purpose** Remove leading and trailing white space from string

**Syntax**  
S = strtrim(str)  
C = strtrim(cstr)

**Description** S = strtrim(str) returns a copy of string str with all leading and trailing white-space characters removed. A white-space character is one for which the isspace function returns logical 1 (true).

C = strtrim(cstr) returns a copy of the cell array of strings cstr with all leading and trailing white-space characters removed from each string in the cell array.

**Examples** Remove the leading white-space characters (spaces and tabs) from str:

```
str = sprintf(' \t Remove leading white-space')
str =
    Remove leading white-space
```

```
str = strtrim(str)
str =
Remove leading white-space
```

Remove leading and trailing white-space from the cell array of strings:

```
cstr = {' Trim leading white-space';
        'Trim trailing white-space '};
```

```
cstr = strtrim(cstr)
cstr =
    'Trim leading white-space'
    'Trim trailing white-space'
```

**See Also** isspace | cellstr | deblank | strjust

**Purpose**

Create structure array

**Syntax**

```
s = struct
s = struct(field,value)
s = struct(field1,value1,...,fieldN,valueN)
s = struct([])

s = struct(obj)
```

**Description**

`s = struct` creates a scalar (1-by-1) structure with no fields.

`s = struct(field,value)` creates a structure array with the specified field and values.

- If `value` is *not* a cell array, then `s` is a scalar structure, where `s.(field) = value`.
- If `value` is a cell array, then `s` is a structure array with the same dimensions as `value`. Each element of `s` contains the corresponding element of `value`. For example, `s = struct('f',{'a','b'})` returns `s(1).f = 'a'` and `s(2).f = 'b'`.
- If `value` is an empty cell array `{}`, then `s` is an empty (0-by-0) structure.

`s = struct(field1,value1,...,fieldN,valueN)` creates a structure array with multiple fields. Any nonscalar cell arrays in the set `value1,...,valueN` must have the same dimensions.

- If none of the `value` inputs is a cell array, or all are scalar cell arrays, then `s` is a scalar structure.
- If any of the `value` inputs are nonscalar cell arrays, then `s` has the same dimensions as the nonscalar cell arrays. For any `value` that is a scalar cell array or an array of any other data type, `struct` inserts the contents of `value` in the relevant field for all elements of `s`.
- If any `value` input is an empty cell array, `{}`, then output `s` is an empty (0-by-0) structure.

# struct

---

`s = struct([])` creates an empty (0-by-0) structure with no fields.

`s = struct(obj)` creates a structure with field names and values that correspond to properties of `obj`. MATLAB does not convert `obj`, but rather creates `s` as a new structure. This structure does not retain the class information, so private, protected, and hidden properties become public fields in `s`. The `struct` function issues a warning when you use this syntax.

## Input Arguments

### field - Field name

string

Field name, specified as a string. Valid field names begin with a letter, and can contain letters, digits, and underscores. The maximum length of a field name is the value that the `namelengthmax` function returns.

### value - Values within structure field

cell array | scalar | vector | multidimensional array

Values within structure field, specified as a cell array or as a scalar, vector, or multidimensional array of any other data type.

If none of the `value` inputs is a cell array, or all of the `value` inputs are scalar cell arrays, then output `s` is a scalar structure. Otherwise, `value` inputs that are nonscalar cell arrays must have the same dimensions, and output `s` also has those dimensions. For any `value` that is a scalar cell array or an array of any other data type, `struct` inserts the contents of `value` in the relevant field for all elements of `s`.

If any `value` input is an empty cell array, `{}`, then output `s` is an empty structure array.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | cell | function\_handle

**Complex Number Support:** Yes

### obj - Object

any nonfundamental class

Object of any class, except the fundamental data types such as double or char.

## Examples

### Structure with One Field

Create a nonscalar structure with one field, `f`.

```
field = 'f';  
value = {'some text';  
        [10, 20, 30];  
        magic(5)};  
s = struct(field,value)
```

```
s =  
3x1 struct array with fields:  
    f
```

View the contents each element.

```
s.f
```

```
ans =  
some text
```

```
ans =  
    10    20    30
```

```
ans =  
    17    24     1     8    15  
    23     5     7    14    16  
     4     6    13    20    22  
    10    12    19    21     3  
    11    18    25     2     9
```

When you access a field of a nonscalar structure, such as `s.f`, MATLAB returns a comma-separated list. In this case, `s.f` is equivalent to `s(1).f`, `s(2).f`, `s(3).f`.

## Structure with Multiple Fields

Create a nonscalar structure with several fields.

```
field1 = 'f1'; value1 = zeros(1,10);  
field2 = 'f2'; value2 = {'a', 'b'};  
field3 = 'f3'; value3 = {pi, pi.^2};  
field4 = 'f4'; value4 = {'fourth'};
```

```
s = struct(field1,value1,field2,value2,field3,value3,field4,value4)
```

```
s =  
1x2 struct array with fields:  
    f1  
    f2  
    f3  
    f4
```

The cell arrays for `value2` and `value3` are 1-by-2, so `s` is also 1-by-2. Because `value1` is a numeric array and not a cell array, both `s(1).f1` and `s(2).f1` have the same contents. Similarly, because the cell array for `value4` has a single element, `s(1).f4` and `s(2).f4` have the same contents.

```
s(1)
```

```
ans =  
    f1: [0 0 0 0 0 0 0 0 0 0]  
    f2: 'a'  
    f3: 3.1416  
    f4: 'fourth'
```

```
s(2)
```

```
ans =  
    f1: [0 0 0 0 0 0 0 0 0 0]  
    f2: 'b'  
    f3: 9.8696  
    f4: 'fourth'
```

### Fields that Contain Cell Arrays

Create a structure with a field that contains a cell array.

```
field = 'mycell';
value = {'a','b','c'};
s = struct(field,value)

s =
    mycell: {'a' 'b' 'c'}
```

### Empty Structure Array

Create an empty structure with several fields.

```
s = struct('a', {}, 'b', {}, 'c', {})

s =
0x0 struct array with fields:
    a
    b
    c
```

### Nested Structure Array

Create a nested structure: a contains field b, which in turn contains fields c and d.

```
a.b = struct('c', {}, 'd', {})

a =
    b: [0x0 struct]
```

View the names of the fields of nested structure a.b.

```
fieldnames(a.b)

ans =
    'c'
    'd'
```

# struct

---

## Related Examples

- “Create a Structure Array”
- “Access Data in a Structure Array”
- “Generate Field Names from Variables”

**Purpose** Convert structure to cell array

**Syntax** `c = struct2cell(s)`

**Description** `c = struct2cell(s)` converts the *m*-by-*n* structure *s* (with *p* fields) into a *p*-by-*m*-by-*n* cell array *c*.

If structure *s* is multidimensional, cell array *c* has size [*p* `size(s)`].

**Examples** The commands

```
clear s, s.category = 'tree';  
s.height = 37.4; s.name = 'birch';
```

create the structure

```
s =  
    category: 'tree'  
    height: 37.4000  
    name: 'birch'
```

Converting the structure to a cell array,

```
c = struct2cell(s)
```

```
c =  
    'tree'  
    [37.4000]  
    'birch'
```

**How To**

- dynamic field names

# structfun

---

**Purpose** Apply function to each field of scalar structure

**Syntax**  
`[A1,...,An] = structfun(func,S)`  
`[A1,...,An] = structfun(func,S,Name,Value)`

**Description** `[A1,...,An] = structfun(func,S)` applies the function specified by function handle `func` to each field of scalar structure `S`. Output arrays `A1,...,An`, where `n` is the number of outputs from function `func`, contain the outputs from the function calls.

`[A1,...,An] = structfun(func,S,Name,Value)` calls function `func` with additional options specified by one or more `Name,Value` pair arguments. Possible values for `Name` are `'UniformOutput'` or `'ErrorHandler'`.

## Input Arguments

### **func**

Handle to a function that accepts a single input argument and returns `n` output arguments.

If function `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

### **S**

Scalar structure.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **UniformOutput**

Logical value, as follows:

- `true` (1) Indicates that for all inputs, each output from function `func` is a cell array or a scalar value that is always of the same type. The `structfun` function combines the outputs in arrays  $A_1, \dots, A_n$ , where  $n$  is the number of function outputs. Each output array is of the same type as the individual function outputs.
- `false` (0) Requests that the `structfun` function combine the outputs into scalar structures  $A_1, \dots, A_n$ , with the same fields as input structure `S`. The outputs of function `func` can be of any size or type.

**Default:** `true`

## ErrorHandler

Handle to a function that catches any errors that occur when MATLAB attempts to execute function `func`. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:
 

|                         |                                                                                             |
|-------------------------|---------------------------------------------------------------------------------------------|
| <code>identifier</code> | Error identifier.                                                                           |
| <code>message</code>    | Error message text.                                                                         |
| <code>index</code>      | Linear index corresponding to the element of the input cell array at the time of the error. |
- The set of input arguments to function `func` at the time of the error.

## Output Arguments

### $A_1, \dots, A_n$

Arrays that collect the  $n$  outputs from function `func`.

If `UniformOutput` is `true` (the default):

# structfun

---

- The individual outputs from function `func` must be scalar values (numeric, logical, character, or structure) or cell arrays.
- The class of a particular output argument must be the same for each input. The class of the corresponding output array is the same as the class of the individual outputs from function `func`.
- Each array `A` is a column vector whose length equals the number of fields in `S`. The `structfun` function applies function `func` to the fields of `S` in the same order as that returned by the `fieldnames` function.

If `UniformOutput` is `false`, each array `A` is a scalar structure with the same fields as input `S`.

## Examples

Create a scalar structure, and count the number of characters in each field.

```
s.f1 = 'Sunday';  
s.f2 = 'Monday';  
s.f3 = 'Tuesday';  
s.f4 = 'Wednesday';  
s.f5 = 'Thursday';  
s.f6 = 'Friday';  
s.f7 = 'Saturday';
```

```
lengths = structfun(@numel, s)
```

---

Shorten the text in each field of `s`, created in the previous example. Because the output is nonscalar, set `UniformOutput` to `false`.

```
shortNames = structfun(@(x) ( x(1:3) ), s, 'UniformOutput', false)
```

The syntax `@(x)` creates an anonymous function.

---

Define and call a custom error handling function.

```
function result = errorfun(errorinfo, field)
```

```
        warning(errorinfo.identifier, errorinfo.message);
        result = NaN;
    end

mystruct.f1 = 'text';
myresult = structfun(@(x) x^2, mystruct, 'ErrorHandler', @errorfun)
```

## Tutorials

- “Anonymous Functions”

# strvcat

---

**Purpose** Concatenate strings vertically

---

**Note** `strvcat` is not recommended. Use `char` instead. Unlike `strvcat`, the `char` function does not ignore empty strings.

---

**Syntax** `S = strvcat(t1, t2, t3, ...)`  
`S = strvcat(c)`

**Description** `S = strvcat(t1, t2, t3, ...)` forms the character array `S` containing the text strings (or string matrices) `t1, t2, t3, ...` as rows. Spaces are appended to each string as necessary to form a valid matrix. Empty arguments are ignored.

`S = strvcat(c)` when `c` is a cell array of strings, passes each element of `c` as an input to `strvcat`. Empty strings in the input are ignored.

**Tips** If each text parameter, `ti`, is itself a character array, `strvcat` appends them vertically to create arbitrarily large string matrices.

**Examples** The command `strvcat('Hello', 'Yes')` is the same as `['Hello'; 'Yes']`, except that `strvcat` performs the padding automatically.

```
t1 = 'first'; t2 = 'string'; t3 = 'matrix'; t4 = 'second';
```

```
S1 = strvcat(t1, t2, t3)          S2 = strvcat(t4, t2, t3)
```

```
S1 =                               S2 =
```

```
first                               second
string                              string
matrix                              matrix
```

```
S3 = strvcat(S1, S2)
```

```
S3 =
```

```
first  
string  
matrix  
second  
string  
matrix
```

# sub2ind

---

**Purpose** Convert subscripts to linear indices

**Syntax** `linearInd = sub2ind(matrixSize, rowSub, colSub)`  
`linearInd = sub2ind(arraySize, dim1Sub, dim2Sub, dim3Sub, ...)`

**Description** `linearInd = sub2ind(matrixSize, rowSub, colSub)` returns the linear index equivalent to the row and column subscripts `rowSub` and `colSub` for a matrix of size `matrixSize`. The `matrixSize` input is a 2-element vector that specifies the number of rows and columns in the matrix as `[nRows, nCols]`. The `rowSub` and `colSub` inputs are positive, whole number scalars or vectors that specify one or more row-column subscript pairs for the matrix. Example 3 demonstrates the use of vectors for the `rowSub` and `colSub` inputs.

`linearInd = sub2ind(arraySize, dim1Sub, dim2Sub, dim3Sub, ...)` returns the linear index equivalent to the specified subscripts for each dimension of an N-dimensional array of size `arraySize`. The `arraySize` input is an n-element vector that specifies the number of dimensions in the array. The `dimNSub` inputs are positive, whole number scalars or vectors that specify one or more row-column subscripts for the matrix.

The `rowSub` and `colSub` inputs must belong to the same class. The `linearInd` output is the same class as the subscript inputs.

If needed, `sub2ind` assumes that unspecified trailing subscripts are 1. See Example 2, below.

## Examples

### Example 1

This example converts the subscripts (2, 1, 2) for three-dimensional array A to a single linear index. Start by creating a 3-by-4-by-2 array A:

```
rng(0,'twister'); % Initialize random number generator.  
A = rand(3, 4, 2)
```

```
A(:, :, 1) =  
    0.8147    0.9134    0.2785    0.9649
```

```

    0.9058    0.6324    0.5469    0.1576
    0.1270    0.0975    0.9575    0.9706
A(:, :, 2) =
    0.9572    0.1419    0.7922    0.0357
    0.4854    0.4218    0.9595    0.8491
    0.8003    0.9157    0.6557    0.9340

```

Find the linear index corresponding to (2, 1, 2):

```

linearInd = sub2ind(size(A), 2, 1, 2)
linearInd =
    14

```

Make sure that these agree:

```

A(2, 1, 2)          A(14)
ans =              and =
    0.4854          0.4854

```

## Example 2

Using the 3-dimensional array A defined in the previous example, specify only 2 of the 3 subscript arguments in the call to sub2ind. The third subscript argument defaults to 1.

The command

```

linearInd = sub2ind(size(A), 2, 4)
ans =
    11

```

is the same as

```

linearInd = sub2ind(size(A), 2, 4, 1)
ans =
    11

```

## Example 3

Using the same 3-dimensional input array A as in Example 1, accomplish the work of five separate `sub2ind` commands with just one.

Replace the following commands:

```
sub2ind(size(A), 3, 3, 2);
sub2ind(size(A), 2, 4, 1);
sub2ind(size(A), 3, 1, 2);
sub2ind(size(A), 1, 3, 2);
sub2ind(size(A), 2, 4, 1);
```

with a single command:

```
sub2ind(size(A), [3 2 3 1 2], [3 4 1 3 4], [2 1 2 2 1])
ans =
    21    11    15    19    11
```

Verify that these linear indices access the same array elements as their subscripted counterparts:

```
[A(3,3,2), A(2,4,1), A(3,1,2), A(1,3,2), A(2,4,1)]
ans =
    0.6557    0.1576    0.8003    0.7922    0.1576
```

```
A([21, 11, 15, 19, 11])
ans =
    0.6557    0.1576    0.8003    0.7922    0.1576
```

## See Also

`ind2sub` | `find` | `size`

**Purpose** Create axes in tiled positions

**Syntax**

```
subplot(m,n,p)
subplot(m,n,p,'replace')
subplot(m,n,p,'align')
subplot(m,n,P)
subplot(h)
subplot('Position',[left bottom width height])
subplot(...,prop1,value1,prop2,value2,...)
h = subplot(...)
```

**Description** subplot divides the current figure into a grid that is numbered row-wise. Each block in the grid can contain an axes object which you can manipulate using [Axes Properties](#). Subsequent plots are output to the current axes.

subplot(m,n,p) breaks the figure window into an m-by-n grid and creates an axes object in the pth location for the current plot, and returns the axes handle. MATLAB numbers the axes along the top row of the figure window, then the second row, etc. For example,

```
subplot(2,1,1), plot(x)
subplot(2,1,2), plot(y)
```

plots *x* on the top half of the window and *y* on the bottom half. The recently created axes becomes the current axes where plot command creates the graph.

subplot(m,n,p,'replace') deletes the specified axes object if it already exists and creates a new axes.

# subplot

---

`subplot(m,n,p, 'align')` places the axes so that the plot boxes are aligned, but does not prevent the labels and ticks from overlapping.

`subplot(m,n,P)`, where `P` is a vector, specifies an axes position that covers all the subplot positions listed in `P`, including those spanned by `P`. For example, `subplot(2,3,[2 5])` creates one axes spanning positions 2 and 5 only (because there are no intervening locations in the grid), while `subplot(2,3,[2 6])` creates one axes spanning positions 2, 3, 5, and 6.

`subplot(h)` makes the axes object with handle `h` the current axes for subsequent plotting commands.

`subplot('Position',[left bottom width height])` creates an axes at the position specified by a four-element vector. The `left`, `bottom`, `width`, and `height` values are normalized coordinates in the range from 0.0 to 1.0.

`subplot(...,prop1,value1,prop2,value2,...)` sets the specified property-value pairs on the subplot axes object. Available property/value pairs are described in `Axes Properties`. To add the subplot to a specific figure or `uipanel`, pass the handle as the value for the `jParent` property. You cannot specify both a `Parent` and a `Position`; that is, `subplot('Position',[left bottom width height], 'Parent',h)` is not a valid syntax.

`h = subplot(...)` returns the handle to the new axes object.

## Tips

If a `subplot` specification causes a new axes object to overlap any existing axes, `subplot` deletes the existing axes object and `uicontrol` objects. However, if the `subplot` specification exactly matches the position of an existing axes object, the matching axes object is not deleted and it becomes the current axes.

`subplot(1,1,1)` or `clf` deletes all axes objects and returns to the default `subplot(1,1,1)` configuration.

You can omit the parentheses and specify `subplot` as

```
subplot mnp
```

where *m* refers to the row, *n* refers to the column, and *p* specifies the grid location.

Be aware when creating subplots from scripts that the `Position` property of subplots is not finalized until either

- A `drawnow` command is issued.
- MATLAB returns to await a user command.

That is, the value obtained for subplot *i* by the command

```
get(h(i), 'position')
```

will not be correct until the script refreshes the plot or exits.

### Special Case: `subplot(111)`

The command `subplot(111)` is not identical in behavior to `subplot(1,1,1)` and exists only for compatibility with previous releases. This syntax does not immediately create an axes object, but instead sets up the figure so that the next graphics command executes a `clf reset` (deleting all figure children) and creates a new axes object in the default position. This syntax does not return a handle, so it is an error to specify a return argument. (MATLAB implements this behavior by setting the figure's `NextPlot` property to `replace`.)

## Examples

### Upper and Lower Subplots with Titles

To plot income in the top half of a figure and outgo in the bottom half,

```
income = [3.2,4.1,5.0,5.6];  
outgo = [2.5,4.0,3.35,4.9];  
subplot(2,1,1); plot(income)  
title('Income')  
subplot(2,1,2); plot(outgo)  
title('Outgo')
```

# subplot

## Subplots in Quadrants

The following illustration shows four subplot regions and indicates the command used to create each.

```
figure
subplot(2,2,1)
text(.5,.5,{ 'subplot(2,2,1)'; 'or subplot 221'},...
     'FontSize',14, 'HorizontalAlignment', 'center')
subplot(2,2,2)
text(.5,.5,{ 'subplot(2,2,2)'; 'or subplot 222'},...
```

```
    'FontSize',14,'HorizontalAlignment','center')
subplot(2,2,3)
text(.5,.5,{'subplot(2,2,3)';'or subplot 223'},...
    'FontSize',14,'HorizontalAlignment','center')
subplot(2,2,4)
text(.5,.5,{'subplot(2,2,4)';'or subplot 224'},...
    'FontSize',14,'HorizontalAlignment','center')
```

## Asymmetrical Subplots

The following combinations produce asymmetrical arrangements of subplots.

```
figure
subplot(2,2,[1 3])
text(.5,.5,'subplot(2,2,[1 3])',...
     'FontSize',14,'HorizontalAlignment','center')
subplot(2,2,2)
text(.5,.5,'subplot(2,2,2)',...
     'FontSize',14,'HorizontalAlignment','center')
subplot(2,2,4)
text(.5,.5,'subplot(2,2,4)',...
     'FontSize',14,'HorizontalAlignment','center')
```

You can also use the colon operator to specify multiple locations if they are in sequence.

```
figure
subplot(2,2,1:2)
text(.5,.5,'subplot(2,2,1:2)',...
     'FontSize',14,'HorizontalAlignment','center')
subplot(2,2,3)
text(.5,.5,'subplot(2,2,3)',...
     'FontSize',14,'HorizontalAlignment','center')
```

# subplot

---

```
subplot(2,2,4)
text(.5,.5,'subplot(2,2,4)',...
     'FontSize',14,'HorizontalAlignment','center')
```

## Suppressing Axis Ticks

When you create many subplots in a figure, the axes tickmarks, which are shown by default, can either be obscured or can cause axes to collapse.

- One way to get around this issue is to enlarge the figure to create enough space to properly display the tick labels.
- Another approach is to eliminate the clutter by suppressing xticks and yticks for subplots as data are plotted into them as,

```
h = subplot(10,1,1);  
set(h,'XTick',[],'YTick',[]);
```

If the subplots are stacked, you can then display tick labels for the bottom axis.

### Plotting Axes Over Subplots

Place a graph in the center, on top of four other graphs, using the axes and subplot functions. Data is random; your graphs can differ.

```
figure  
y = zeros(4,15);  
for k = 1:4  
    y(k,:) = rand(1,15);  
    subplot(2, 2, k)  
    plot(y(k,:));  
end  
hax = axes('Position', [.35, .35, .3, .3]);  
bar(hax,y,'EdgeColor','none')  
set(hax,'XTick',[])
```

# subplot

## Alternatives

To add subplots to a figure, click one of the New Subplot icons in the Figure Palette, and slide right to select an arrangement of subplots. For details, see [Plotting Tools — Interactive Plotting](#).

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>         | Subscripted assignment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Syntax</b>          | <code>A = subsasgn(A, S, B)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b>     | <p><code>A = subsasgn(A, S, B)</code> is called by MATLAB for the syntax <code>A(i) = B</code>, <code>A{i} = B</code>, or <code>A.i = B</code> when <code>A</code> is an object.</p> <p>MATLAB uses the built-in <code>subsasgn</code> function to interpret indexed assignment statements. Modify the indexed assignment behavior of classes by overloading <code>subsasgn</code> in the class.</p> <p>If <code>A</code> is a fundamental class (see “Fundamental MATLAB Classes”), then an indexed reference to <code>A</code> calls the built-in <code>subsasgn</code> function. It does not call a <code>subsasgn</code> method that you have overloaded for that class. Therefore, if <code>A</code> is an array of class <code>double</code>, and there is an <code>@double/subsasgn</code> method on your MATLAB path, the statement <code>A(I) = B</code> calls the MATLAB built-in <code>subsasgn</code> function.</p> |
| <b>Tips</b>            | <p>Within a class’s own methods, MATLAB calls the built-in <code>subsasgn</code>, not the class defined <code>subsasgn</code>. This behavior enables to use the default <code>subsasgn</code> behavior when defining specialized indexing for your class. See “<code>subsref</code> and <code>subsasgn</code> Within Class Methods — Built-In Called” for more information.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Input Arguments</b> | <p><b>A</b><br/>Object</p> <p><b>S</b><br/>struct array with two fields, <code>type</code> and <code>subs</code>.</p> <ul style="list-style-type: none"><li><code>type</code> is a string containing <code>'()''</code>, <code>'{}''</code>, or <code>'.'</code>, where <code>'()''</code> specifies integer subscripts, <code>'{}''</code> specifies cell array subscripts, and <code>'.'</code> specifies subscripted structure fields.</li><li><code>subs</code> is a cell array or string containing the actual subscripts.</li></ul> <p><b>B</b></p>                                                                                                                                                                                                                                                                                                                                                                       |

# subsasgn

---

Assignment value (right-hand side)

## Output Arguments

**A**  
Result of evaluating assignment.

## Examples

See how MATLAB calls `subsasgn` for the expression:

```
A(1:2,:) = B;
```

The syntax `A(1:2,:) = B` calls `A = subsasgn(A,S,B)` where `S` is a 1-by-1 structure with `S.type = '()'` and `S.subs = {1:2, ':'}`. The string `':'` indicates a colon used as a subscript.

---

See how MATLAB calls `subsasgn` for the expression:

```
A{1:2} = B;
```

The syntax `A{1:2} = B` calls `A = subsasgn(A,S,B)` where `S.type = '{}'` and `S.subs = {[1 2]}`.

---

See how MATLAB calls `subsasgn` for the expression:

```
A.field = B;
```

The syntax `A.field = B` calls `A = subsasgn(A,S,B)` where `S.type = '.'` and `S.subs = 'field'`.

---

See how MATLAB calls `subsasgn` for the expression:

```
A(1,2).name(3:5)=B;
```

Simple calls combine in a straightforward way for more complicated indexing expressions. In such cases, `length(S)` is the number of subscripting levels. For instance, `A(1,2).name(3:5)=B` calls `A=subsasgn(A,S,B)` where `S` is a 3-by-1 structure array with the following values:

```
S(1).type = '()'    S(2).type = '.'    S(3).type = '()'
S(1).subs = {1,2}  S(2).subs = 'name'  S(3).subs = {[3 4
                    5]}
```

## Algorithms

In the assignment  $A(J,K,\dots) = B(M,N,\dots)$ , subscripts  $J, K, M, N$ , and so on, can be scalar, vector, or arrays, when all the following are true:

- The number of subscripts specified for  $B$ , excluding trailing subscripts equal to 1, does not exceed the value returned by `ndims(B)`.
- The number of nonscalar subscripts specified for  $A$  equals the number of nonscalar subscripts specified for  $B$ . For example,  $A(5, 1:4, 1, 2) = B(5:8)$  is valid because both sides of the equation use one nonscalar subscript.
- The order and length of all nonscalar subscripts specified for  $A$  matches the order and length of nonscalar subscripts specified for  $B$ . For example,  $A(1:4, 3, 3:9) = B(5:8, 1:7)$  is valid because both sides of the equation (ignoring the one scalar subscript 3) use a 4-element subscript followed by a 7-element subscript.

See `numel` for information concerning the use of `numel` with regards to the overloaded `subsasgn` function.

# subsindex

---

**Purpose**                    Subscript indexing with object

**Syntax**                    `ind = subsindex(A)`

**Description**            `ind = subsindex(A)` called by MATLAB for the expression `X(A)` when `A` is an object, unless such an expression results in a call to an overloaded `subsref` or `subsasgn` method for `X`. `subsindex` must return the value of the object as a zero-based integer index. (`ind` must contain integer values in the range 0 to `prod(size(X))-1`.) Call `subsindex` directly from an overloaded `subsref` or `subsasgn` method.

MATLAB invokes `subsindex` separately on all the subscripts in an expression, such as `X(A,B)`.

| <b>Purpose</b>     | Angle between two subspaces                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Syntax</b>      | <code>theta = subspace(A,B)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | <code>theta = subspace(A,B)</code> finds the angle between two subspaces specified by the columns of A and B. If A and B are column vectors of unit length, this is the same as <code>acos(abs(A'*B))</code> .                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Tips</b>        | If the angle between the two subspaces is small, the two spaces are nearly linearly dependent. In a physical experiment described by some observations A, and a second realization of the experiment described by B, <code>subspace(A,B)</code> gives a measure of the amount of new information afforded by the second experiment not associated with statistical errors of fluctuations.                                                                                                                                                                                                                                     |
| <b>Examples</b>    | <p>Consider two subspaces of a Hadamard matrix, whose columns are orthogonal.</p> <pre>H = hadamard(8); A = H(:,2:4); B = H(:,5:8);</pre> <p>Note that matrices A and B are different sizes — A has three columns and B four. It is not necessary that two subspaces be the same size in order to find the angle between them. Geometrically, this is the angle between two hyperplanes embedded in a higher dimensional space.</p> <pre>theta = subspace(A,B) theta =     1.5708</pre> <p>That A and B are orthogonal is shown by the fact that theta is equal to <math>\pi/2</math>.</p> <pre>theta - pi/2 ans =     0</pre> |

# subsref

---

**Purpose** Redefine subscripted reference for objects

**Syntax** `B = subsref(A,S)`

**Description** `B = subsref(A,S)` is called by MATLAB for the syntax `A(i)`, `A{i}`, or `A.i` when `A` is an object. `S` is a struct array with two fields, `type` and `subs`.

The `type` field is string containing `'()'`, `'{}'`, or `','`, where `'()'` specifies integer subscripts, `'{}'` specifies cell array subscripts, and `','` specifies subscripted structure fields. The `subs` field is a cell array or a string containing the actual subscripts.

`B` is the result of the indexed expression.

MATLAB uses the built-in `subsref` function to interpret indexed references to objects. To modify the indexed reference behavior of objects, overload `subsref` in the class.

If `A` is a fundamental class (see “Fundamental MATLAB Classes”), then an indexed reference to `A` calls the built-in `subsref` function. It does not call a `subsref` method that you have overloaded for that class. Therefore, if `A` is an array of class `double`, and there is an `@double/subsref` method on your MATLAB path, the statement `A(I)` calls the MATLAB built-in `subsref` function.

**Tips** Within a class’s own methods, MATLAB calls the built-in `subsref`, not the class defined `subsref`. This behavior enables to use the default `subsref` behavior when defining specialized indexing for your class. See “`subsref` and `subsasgn` Within Class Methods — Built-In Called” for more information.

**Examples** See how MATLAB calls `subsref` for the expression:

```
A(1:2,:)
```

The syntax `A(1:2,:)` calls `B = subsref(A,S)` where `S` is a 1-by-1 structure with `S.type='()'` and `S.subs={1:2,','}`. The string `','` indicates a colon used as a subscript.

See how MATLAB calls `subsref` for the expression:

```
A{1:2}
```

The syntax `A{1:2}` calls `B = subsref(A,S)` where `S.type='{}'` and `S.subs={1 2}`.

See how MATLAB calls `subsref` for the expression:

```
A.field
```

The syntax `A.field` calls `B = subsref(A,S)` where `S.type='.'` and `S.subs='field'`.

See how MATLAB calls `subsref` for the expression:

```
A(1,2).name(3:5)
```

Simple calls combine in a straightforward way for more complicated indexing expressions. In such cases, `length(S)` is the number of subscript levels. For instance, `A(1,2).name(3:5)` calls `subsref(A,S)` where `S` is a 3-by-1 structure array with the following values:

|                              |                               |                                  |
|------------------------------|-------------------------------|----------------------------------|
| <code>S(1).type='()'</code>  | <code>S(2).type='.'</code>    | <code>S(3).type='()'</code>      |
| <code>S(1).subs={1,2}</code> | <code>S(2).subs='name'</code> | <code>S(3).subs={[3 4 5]}</code> |

## Tutorials

- “Indexed Reference and Assignment”

# substruct

---

**Purpose** Create structure argument for subsasgn or subsref

**Syntax** `S = substruct(type1, subs1, type2, subs2, ...)`

**Description** `S = substruct(type1, subs1, type2, subs2, ...)` creates a structure with the fields required by an overloaded `subsref` or `subsasgn` method. Each `type` string must be one of `.'`, `'()`, or `'{'`. The corresponding `subs` argument must be either a field name (for the `.'` type) or a cell array containing the index vectors (for the `'()` or `'{'` types).

## Output Arguments

**S**

struct with these fields:

- `type`: one of `.'`, `'()`, or `'{'`
- `subs`: subscript values (field name or cell array of index vectors)

## Examples

Call `subsref` with arguments equivalent to the syntax:

```
B = A(3,5).field;
```

where `A` is an object of a class that implements a `subsref` method

Use `substruct` to form the input struct, `S`:

```
S = substruct('()', {3,5}, '.', 'field');
```

Call the class method:

```
B = subsref(A,S);
```

The struct created by `substruct` in this example contains:

```
S(1)
```

```
ans =
```

```
type: '()'  
subs: {[3] [5]}
```

S(2)

ans =

```
type: '.'  
subs: 'field'
```

# subvolume

---

**Purpose** Extract subset of volume data set

**Syntax**

```
[Nx,Ny,Nz,Nv] = subvolume(X,Y,Z,V,limits)
[Nx,Ny,Nz,Nv] = subvolume(V,limits)
Nv = subvolume(...)
```

**Description** `[Nx,Ny,Nz,Nv] = subvolume(X,Y,Z,V,limits)` extracts a subset of the volume data set `V` using the specified axis-aligned `limits`. `limits = [xmin,xmax,ymin, ymax,zmin,zmax]` (Any NaNs in the limits indicate that the volume should not be cropped along that axis.)

The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V`. The subvolume is returned in `NV` and the coordinates of the subvolume are given in `NX`, `NY`, and `NZ`.

`[Nx,Ny,Nz,Nv] = subvolume(V,limits)` assumes the arrays `X`, `Y`, and `Z` are defined as

```
[X,Y,Z] = meshgrid(1:N,1:M,1:P)
```

where `[M,N,P] = size(V)`.

`Nv = subvolume(...)` returns only the subvolume.

## Examples

This example uses a data set that is a collection of MRI slices of a human skull. The data is processed in a variety of ways:

- The 4-D array is squeezed (`squeeze`) into three dimensions and then a subset of the data is extracted (`subvolume`).
- The outline of the skull is an isosurface generated as a patch (`p1`) whose vertex normals are recalculated to improve the appearance when lighting is applied (`patch`, `isosurface`, `isonormals`).
- A second patch (`p2`) with interpolated face color draws the end caps (`FaceColor`, `isocaps`).
- The view of the object is set (`view`, `axis`, `daspect`).
- A 100-element grayscale colormap provides coloring for the end caps (`colormap`).

- Adding lights to the right and left of the camera illuminates the object (camlight, lighting).

```
load mri
D = squeeze(D);
[x,y,z,D] = subvolume(D,[60,80,nan,80,nan,nan]);
p1 = patch(isosurface(x,y,z,D, 5),...
           'FaceColor','red','EdgeColor','none');
isonormals(x,y,z,D,p1);
p2 = patch(isocaps(x,y,z,D, 5),...
           'FaceColor','interp','EdgeColor','none');
view(3); axis tight; daspect([1,1,.4])
colormap(gray(100))
camlight right; camlight left; lighting gouraud
```

# subvolume

---

**Purpose**

Sum of array elements

**Syntax**

```
B = sum(A)
B = sum(A,dim)
B = sum(..., 'double')
B = sum(..., dim,'double')
B = sum(..., 'native')
B = sum(..., dim,'native')
```

**Description**

`B = sum(A)` returns sums along different dimensions of an array. If `A` is floating point, that is double or single, `B` is accumulated natively, that is in the same class as `A`, and `B` has the same class as `A`. If `A` is not floating point, `B` is accumulated in double and `B` has class double.

If `A` is a vector, `sum(A)` returns the sum of the elements.

If `A` is a matrix, `sum(A)` treats the columns of `A` as vectors, returning a row vector of the sums of each column.

If `A` is a multidimensional array, `sum(A)` treats the values along the first non-singleton dimension as vectors, returning an array of row vectors.

`B = sum(A,dim)` sums along the dimension of `A` specified by scalar `dim`. The `dim` input is an integer value from 1 to `N`, where `N` is the number of dimensions in `A`. Set `dim` to 1 to compute the sum of each column, 2 to sum rows, etc.

`B = sum(..., 'double')` and `B = sum(..., dim,'double')` perform additions in double-precision and return an answer of type double, even if `A` has data type single or an integer data type. This is the default for integer data types.

`B = sum(..., 'native')` and `B = sum(..., dim,'native')` perform additions in the native data type of `A` and return an answer of the same data type. This is the default for single and double.

If `A = int8(1:20)` then `sum(A)` accumulates in double and the result is `double(210)` while `sum(A,'native')` accumulates in `int8`, but overflows and saturates to `int8(127)`.

# sum

---

## Tips

`sum(diag(A))` is the trace of A.

## Examples

The magic square of order 3 is:

```
M = magic(3)
M =
     8     1     6
     3     5     7
     4     9     2
```

This is called a magic square because the sums of the elements in each column are the same.

```
sum(M)

ans =

    15    15    15
```

The sums of the elements in each row are also the same. You can sum the elements in each row by transposing M or by using the `dim` argument.

- Transposing M:

```
sum(M')

ans =

    15    15    15
```

- Using the `dim` argument:

```
sum(M,2)

ans =

    15
    15
    15
```

# superclasses

---

**Purpose** Superclass names

**Syntax** `superclasses('ClassName')`  
`superclasses(obj)`  
`s = superclasses(...)`

**Description** `superclasses('ClassName')` displays the names of all visible superclasses of the MATLAB class with the name *ClassName*. Visible classes have a `Hidden` attribute value of `false` (the default).

`superclasses(obj)` `obj` is an instance of a MATLAB class. `obj` can be either a scalar object or an array of objects.

`s = superclasses(...)` returns the superclass names in a cell array of strings.

**Examples** Get the name of the `hgsetget` class superclass:

```
superclasses('hgsetget')
```

Superclasses for class `hgsetget`:

```
handle
```

**Purpose**

3-D shaded surface plot

**Syntax**

```
surf(Z)
surf(Z,C)
surf(X,Y,Z)
surf(X,Y,Z,C)
surf(...,'PropertyName',PropertyValue)
surf(axes_handles,...)
h = surf(...)
```

**Description**

`surf(Z)` creates a three-dimensional shaded surface from the  $z$  components in matrix  $Z$ , using  $x = 1:n$  and  $y = 1:m$ , where  $[m,n] = \text{size}(Z)$ . The height,  $Z$ , is a single-valued function defined over a geometrically rectangular grid.  $Z$  specifies the color data, as well as surface height, so color is proportional to surface height.

`surf(Z,C)` plots the height of  $Z$ , a single-valued function defined over a geometrically rectangular grid, and uses matrix  $C$ , assumed to be the same size as  $Z$ , to color the surface.

`surf(X,Y,Z)` uses  $Z$  for the color data and surface height.  $X$  and  $Y$  are vectors or matrices defining the  $x$  and  $y$  components of a surface. If  $X$  and  $Y$  are vectors,  $\text{length}(X) = n$  and  $\text{length}(Y) = m$ , where  $[m,n] = \text{size}(Z)$ . In this case, the vertices of the surface faces are  $(X(j), Y(i), Z(i,j))$  triples. To create  $X$  and  $Y$  matrices for arbitrary domains, use the `meshgrid` function.

`surf(X,Y,Z,C)` uses  $C$  to define color. MATLAB performs a linear transformation on this data to obtain colors from the current colormap.

`surf(...,'PropertyName',PropertyValue)` specifies surface Surfaceplot along with the data.

`surf(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = surf(...)` returns a handle to a Surfaceplot graphics object.

## Tips

`surf` does not accept complex inputs.

## Algorithms

Consider a parametric surface parameterized by two independent variables,  $i$  and  $j$ , which vary continuously over a rectangle; for example,  $1 \leq i \leq m$  and  $1 \leq j \leq n$ . The three functions  $x(i, j)$ ,  $y(i, j)$ , and  $z(i, j)$  specify the surface. When  $i$  and  $j$  are integer values, they define a rectangular grid with integer grid points. The functions  $x(i, j)$ ,  $y(i, j)$ , and  $z(i, j)$  become three  $m$ -by- $n$  matrices,  $X$ ,  $Y$ , and  $Z$ . Surface color is a fourth function,  $c(i, j)$ , denoted by matrix  $C$ .

Each point in the rectangular grid can be thought of as connected to its four nearest neighbors.

$$\begin{array}{c} i-1, j \\ | \\ i, j-1 - i, j - i, j+1 \\ | \\ i+1, j \end{array}$$

This underlying rectangular grid induces four-sided patches on the surface. To express this another way,  $[X(:) Y(:) Z(:)]$  returns a list of triples specifying points in 3-D space. Each interior point is connected to the four neighbors inherited from the matrix indexing. Points on the edge of the surface have three neighbors. The four points at the corners of the grid have only two neighbors. This defines a mesh of quadrilaterals or a *quad-mesh*.

You can specify surface color in two different ways: at the vertices or at the centers of each patch. In this general setting, the surface need not be a single-valued function of  $x$  and  $y$ . Moreover, the four-sided surface patches need not be planar. For example, you can have surfaces defined in polar, cylindrical, and spherical coordinate systems.

The shading function sets the shading. If the shading is `interp`,  $C$  must be the same size as  $X$ ,  $Y$ , and  $Z$ ; it specifies the colors at the vertices. The color within a surface patch is a bilinear function of the local

coordinates. If the shading is `faceted` (the default) or `flat`, `C(i, j)` specifies the constant color in the surface patch:

$$\begin{array}{ccc} (i, j) & - & (i, j+1) \\ | & C(i, j) & | \\ (i+1, j) & - & (i+1, j+1) \end{array}$$

In this case, `C` can be the same size as `X`, `Y`, and `Z` and its last row and column are ignored. Alternatively, its row and column dimensions can be one less than those of `X`, `Y`, and `Z`.

The `surf` function specifies the viewpoint using `view(3)`.

The range of `X`, `Y`, and `Z` or the current setting of `XLimMode`, `YLimMode`, and `ZLimMode` axes properties determines the axis labels. You can also set these properties using `axis` function.

The range of `C` or the current setting of the `CLim` and `CLimMode` axes properties determines the color scaling. You can also set the properties using `caxis` function. The scaled color values are indices into the current colormap.

## Examples

Color a sphere with the pattern of +1s and -1s in a Hadamard matrix.

```
k = 5;
n = 2^k-1;
[x,y,z] = sphere(n);
c = hadamard(2^k);
surf(x,y,z,c);
colormap([1 1 0; 0 1 1])
axis equal
```

## How To

- “Representing Data as a Surface”
- “Surface Plots of Nonuniformly Sampled Data”
- Coloring Mesh and Surface Plots

**Purpose**

Contour plot under a 3-D shaded surface plot

**Syntax**

```
surf(Z)
surf(Z,C)
surf(X,Y,Z)
surf(X,Y,Z,C)
surf(...,'PropertyName',PropertyValue)
surf(axes_handles,...)
h = surf(...)
```

**Description**

`surf(Z)` creates a contour plot under the three-dimensional shaded surface from the  $z$  components in matrix  $Z$ , using  $x = 1:n$  and  $y = 1:m$ , where  $[m,n] = \text{size}(Z)$ . The height,  $Z$ , is a single-valued function defined over a geometrically rectangular grid.  $Z$  specifies the color data, as well as surface height, so color is proportional to surface height.

`surf(Z,C)` plots the height of  $Z$ , a single-valued function defined over a geometrically rectangular grid, and uses matrix  $C$ , assumed to be the same size as  $Z$ , to color the surface.

`surf(X,Y,Z)` uses  $Z$  for the color data and surface height.  $X$  and  $Y$  are vectors or matrices defining the  $x$  and  $y$  components of a surface. If  $X$  and  $Y$  are vectors,  $\text{length}(X) = n$  and  $\text{length}(Y) = m$ , where  $[m,n] = \text{size}(Z)$ . In this case, the vertices of the surface faces are  $(X(j), Y(i), Z(i,j))$  triples. To create  $X$  and  $Y$  matrices for arbitrary domains, use the `meshgrid` function.

`surf(X,Y,Z,C)` uses  $C$  to define color. MATLAB performs a linear transformation on this data to obtain colors from the current colormap.

`surf(...,'PropertyName',PropertyValue)` specifies surface Surfaceplot along with the data.

`surf(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = surf(...)` returns a handle to a Surfaceplot graphics object.

## Tips

`surf` does not accept complex inputs.

## Algorithms

Consider a parametric surface parameterized by two independent variables,  $i$  and  $j$ , which vary continuously over a rectangle; for example,  $1 \leq i \leq m$  and  $1 \leq j \leq n$ . The three functions  $x(i, j)$ ,  $y(i, j)$ , and  $z(i, j)$  specify the surface. When  $i$  and  $j$  are integer values, they define a rectangular grid with integer grid points. The functions  $x(i, j)$ ,  $y(i, j)$ , and  $z(i, j)$  become three  $m$ -by- $n$  matrices,  $X$ ,  $Y$ , and  $Z$ . Surface color is a fourth function,  $c(i, j)$ , denoted by matrix  $C$ .

Each point in the rectangular grid can be thought of as connected to its four nearest neighbors.

$$\begin{array}{c} i-1, j \\ | \\ i, j-1 - i, j - i, j+1 \\ | \\ i+1, j \end{array}$$

This underlying rectangular grid induces four-sided patches on the surface. To express this another way,  $[X(:) Y(:) Z(:)]$  returns a list of triples specifying points in 3-D space. Each interior point is connected to the four neighbors inherited from the matrix indexing. Points on the edge of the surface have three neighbors. The four points at the corners of the grid have only two neighbors. This defines a mesh of quadrilaterals or a *quad-mesh*.

You can specify surface color in two different ways: at the vertices or at the centers of each patch. In this general setting, the surface need not be a single-valued function of  $x$  and  $y$ . Moreover, the four-sided surface patches need not be planar. For example, you can have surfaces defined in polar, cylindrical, and spherical coordinate systems.

The shading function sets the shading. If the shading is `interp`,  $C$  must be the same size as  $X$ ,  $Y$ , and  $Z$ ; it specifies the colors at the vertices. The color within a surface patch is a bilinear function of the local

coordinates. If the shading is `faceted` (the default) or `flat`, `C(i, j)` specifies the constant color in the surface patch:

$$\begin{array}{ccc} (i, j) & - & (i, j+1) \\ | & C(i, j) & | \\ (i+1, j) & - & (i+1, j+1) \end{array}$$

In this case, `C` can be the same size as `X`, `Y`, and `Z` and its last row and column are ignored. Alternatively, its row and column dimensions can be one less than those of `X`, `Y`, and `Z`.

The `surf` function specifies the viewpoint using `view(3)`.

The range of `X`, `Y`, and `Z` or the current setting of the axes `XLimMode`, `YLimMode`, and `ZLimMode` properties (also set by the `axis` function) determines the axis labels.

The range of `C` or the current setting of the axes `CLim` and `CLimMode` properties (also set by the `caxis` function) determines the color scaling. The scaled color values are used as indices into the current colormap.

## Examples

Display a surface plot and a contour plot of the peaks surface.

```
[X,Y,Z] = peaks(30);
surf(X,Y,Z)
colormap hsv
axis([-3 3 -3 3 -10 5])
```

# surf

## How To

- [Representing a Matrix as a Surface](#)
- [Coloring Mesh and Surface Plots](#)

**Purpose**

Convert surface data to patch data

**Syntax**

```
fvc = surf2patch(Z)
fvc = surf2patch(Z,C)
fvc = surf2patch(X,Y,Z)
fvc = surf2patch(X,Y,Z,C)
fvc = surf2patch(...,'triangles')
[f,v,c] = surf2patch(...)
```

**Description**

```
fvc = surf2patch(h)
```

converts the geometry and color data from the surface object identified by the handle `h` into patch format and returns the face, vertex, and color data in the struct `fvc`. You can pass this struct directly to the `patch` command.

`fvc = surf2patch(Z)` calculates the patch data from the surface's ZData matrix `Z`.

`fvc = surf2patch(Z,C)` calculates the patch data from the surface's ZData and CData matrices `Z` and `C`.

`fvc = surf2patch(X,Y,Z)` calculates the patch data from the surface's XData, YData, and ZData matrices `X`, `Y`, and `Z`.

`fvc = surf2patch(X,Y,Z,C)` calculates the patch data from the surface's XData, YData, ZData, and CData matrices `X`, `Y`, `Z`, and `C`.

`fvc = surf2patch(...,'triangles')` creates triangular faces instead of the quadrilaterals that compose surfaces.

`[f,v,c] = surf2patch(...)` returns the face, vertex, and color data in the three arrays `f`, `v`, and `c` instead of a struct.

**Examples**

The first example uses the `sphere` command to generate the XData, YData, and ZData of a surface, which is then converted to a patch. Note that the ZData (`z`) is passed to `surf2patch` as both the third and fourth arguments — the third argument is the ZData and the fourth argument is taken as the CData. This is because the `patch` command does not

# surf2patch

---

automatically use the  $z$ -coordinate data for the color data, as does the `surface` command.

Also, because `patch` is a low-level command, you must set the `view` to 3-D and `shading` to `faceted` to produce the same results produced by the `surf` command.

```
[x y z] = sphere;  
patch(surf2patch(x,y,z,z));  
shading faceted; view(3)
```

In the second example `surf2patch` calculates face, vertex, and color data from a surface whose handle has been passed as an argument.

```
s = surf(peaks);  
pause  
patch(surf2patch(s));  
delete(s)  
shading faceted; view(3)
```

## See Also

`patch` | `reducepatch` | `shrinkfaces` | `surface` | `surf`

**Purpose**

Create surface object

**Syntax**

```
surface(Z)
surface(Z,C)
surface(X,Y,Z)
surface(X,Y,Z,C)
surface(x,y,Z)
surface(... 'PropertyName',PropertyValue,...)
h = surface(...)
```

**Properties**

For a list of properties, see [Surface Properties](#).

**Description**

`surface` is the low-level function for creating surface graphics objects. Surfaces are plots of matrix data created using the row and column indices of each element as the  $x$ - and  $y$ -coordinates and the value of each element as the  $z$ -coordinate.

`surface(Z)` plots the surface specified by the matrix  $Z$ . Here,  $Z$  is a single-valued function, defined over a geometrically rectangular grid.

`surface(Z,C)` plots the surface specified by  $Z$  and colors it according to the data in  $C$  (see "Examples").

`surface(X,Y,Z)` uses  $C = Z$ , so color is proportional to surface height above the  $x$ - $y$  plane.

`surface(X,Y,Z,C)` plots the parametric surface specified by  $X$ ,  $Y$ , and  $Z$ , with color specified by  $C$ .

`surface(x,y,Z)`, `surface(x,y,Z,C)` replaces the first two matrix arguments with vectors and must have `length(x) = n` and `length(y) = m` where `[m,n] = size(Z)`. In this case, the vertices of the surface facets are the triples  $(x(j), y(i), Z(i,j))$ . Note that  $x$  corresponds to the columns of  $Z$  and  $y$  corresponds to the rows of  $Z$ . For a complete discussion of parametric surfaces, see the `surf` function.

`surface(... 'PropertyName',PropertyValue,...)` follows the  $X$ ,  $Y$ ,  $Z$ , and  $C$  arguments with property name/property value pairs to specify

# surface

---

additional surface properties. For a description of the properties, see [Surface Properties](#).

`h = surface(...)` returns a handle to the created surface object.

## Tips

`surface` does not respect the settings of the figure and axes `NextPlot` properties. It simply adds the surface object to the current axes.

If you do not specify separate color data (`C`), MATLAB uses the matrix (`Z`) to determine the coloring of the surface. In this case, color is proportional to values of `Z`. You can specify a separate matrix to color the surface independently of the data defining the area of the surface.

You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see `set` and `get` for examples of how to specify these data types).

`surface` provides convenience forms that allow you to omit the property name for the `XData`, `YData`, `ZData`, and `CData` properties. For example,

```
surface('XData',X,'YData',Y,'ZData',Z,'CData',C)
```

is equivalent to

```
surface(X,Y,Z,C)
```

When you specify only a single matrix input argument,

```
surface(Z)
```

MATLAB assigns the data properties as if you specified

```
surface('XData',[1:size(Z,2)],...  
       'YData',[1:size(Z,1)],...  
       'ZData',Z,...  
       'CData',Z)
```

The `axis`, `caxis`, `colormap`, `hold`, `shading`, and `view` commands set graphics properties that affect surfaces. You can also set and query

---

surface property values after creating them using the set and get commands.

## Examples

This example creates a surface using `peaks` to generate the data, and colors it using the `clown` image. The `ZData` is a 49-by-49 element matrix, while the `CData` is a 200-by-320 matrix. You must set the surface's `FaceColor` to `texturemap` to use `ZData` and `CData` of different dimensions.

```
load clown
surface(peaks,flipud(X),...
        'FaceColor','texturemap',...
        'EdgeColor','none',...
        'CDataMapping','direct')
colormap(map)
view(-35,45)
```

## surface

Note the use of the `surface(Z,C)` convenience form combined with property name/property value pairs.

Since the clown data (X) is typically viewed with the `image` command, which MATLAB normally displays with 'ij' axis numbering and `direct CDataMapping`, this example reverses the data in the vertical direction using `flipud` and sets the `CDataMapping` property to `direct`.

## Setting Default Properties

You can set default surface properties on the axes, figure, and root object levels:

```
set(0, 'DefaultSurfaceProperty', PropertyValue...)  
set(gcf, 'DefaultSurfaceProperty', PropertyValue...)  
set(gca, 'DefaultSurfaceProperty', PropertyValue...)
```

where *Property* is the name of the surface property whose default value you want to set and *PropertyValue* is the value you are specifying. Use `set` and `get` to access the surface properties.

## Tutorials

For examples, see [Representing a Matrix as a Surface](#).

# Surface Properties

---

## Purpose

Surface properties

## Creating Surface Objects

Use `surface` to create surface objects.

## Modifying Properties

You can set and query graphics object properties in two ways:

- Property Editor is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see [Setting Default Property Values](#).

See “Core Graphics Objects” for general information about this type of object.

## Surface Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

### AlphaData

m-by-n matrix of `double` or `uint8`

*Transparency data.* A matrix of non-NaN values specifying the transparency of each face or vertex of the object. The `AlphaData` can be of class `double` or `uint8`.

MATLAB software determines the transparency in one of the following ways:

- Using the elements of `AlphaData` as transparency values (`AlphaDataMapping` set to `none`)
- Using the elements of `AlphaData` as indices into the current `alphamap` (`AlphaDataMapping` set to `direct`)

- Scaling the elements of `AlphaData` to range between the minimum and maximum values of the axes `ALim` property (`AlphaDataMapping` set to `scaled`, the default)

## `AlphaDataMapping`

`none` | `direct` | `{scaled}`

*Transparency mapping method.* Determines how MATLAB interprets indexed alpha data.

- `none` — The transparency values of `AlphaData` are between 0 and 1 or are clamped to this range (the default).
- `scaled` — Transform the `AlphaData` to span the portion of the `alphamap` indicated by the axes `ALim` property, linearly mapping data values to alpha values.
- `direct` — Use the `AlphaData` as indices directly into the `alphamap`. When not scaled, the data are usually integer values ranging from 1 to `length(alphamap)`. MATLAB maps values less than 1 to the first alpha value in the `alphamap`, and values greater than `length(alphamap)` to the last alpha value in the `alphamap`. Values with a decimal portion are fixed to the nearest lower integer. If `AlphaData` is an array of `uint8` integers, then the indexing begins at 0 (that is, MATLAB maps a value of 0 to the first alpha value in the `alphamap`).

## `AmbientStrength`

scalar  $\geq 0$  and  $\leq 1$

*Strength of ambient light.* Sets the strength of the ambient light, which is a nondirectional light source that illuminates the entire scene. You must have at least one visible light object in the axes for the ambient light to be visible. The axes `AmbientLightColor` property sets the color of the ambient light, which is therefore the same on all objects in the axes.

# Surface Properties

---

You can also set the strength of the diffuse and specular contribution of light objects. See the surface `DiffuseStrength` and `SpecularStrength` properties.

## Annotation

`hg.Annotation` object (read-only)

*Handle of Annotation object.* The `Annotation` property enables you to specify whether this surface object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the surface object is displayed in a figure legend:

| <b>IconDisplayStyle Value</b> | <b>Purpose</b>                                          |
|-------------------------------|---------------------------------------------------------|
| on                            | Represent this surface object in a legend (default)     |
| off                           | Do not include this surface object in a legend          |
| children                      | Same as on because surface objects do not have children |

## Setting the `IconDisplayStyle` property

Set the `IconDisplayStyle` of a graphics object with handle `hobj` to off:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'off')
```

## Using the `IconDisplayStyle` property

See “Controlling Legends” for more information and examples.

### `BackFaceLighting`

`unlit` | `lit` | `{reverselit}`

*Face lighting control.* Determines how faces are lit when their vertex normals point away from the camera.

- `unlit` — Face not lit.
- `lit` — Face lit in normal way.
- `reverselit` — Face lit as if the vertex pointed towards the camera.

Use this property to discriminate between the internal and external surfaces of an object. See “Back Face Lighting” for an example.

### `BeingDeleted`

`on` | `{off}` (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

### `BusyAction`

`cancel` | `{queue}`

*Callback queuing*

# Surface Properties

---

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over the surface object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

Set this property to a function handle that references the callback. The function must define at least two input arguments (handle of object associated with the button down event and an event structure, which is empty for this property).

The following example shows how to access the callback object's handle as well as the handle of the figure that contains the object from the callback function.

```
function button_down(src,evnt)
% src - the object that is the source of the event
```

```
% evt - empty for this property
sel_typ = get(gcf,'SelectionType')
switch sel_typ
    case 'normal'
        disp('User clicked left-mouse button')
        set(src,'Selected','on')
    case 'extend'
        disp('User did a shift-click')
        set(src,'Selected','on')
    case 'alt'
        disp('User did a control-click')
        set(src,'Selected','on')
        set(src,'SelectionHighlight','off')
end
end
```

Suppose `h` is the handle of a surface object and the `button_down` function is on your MATLAB path. The following statement assigns the `button_down` function to the `ButtonDownFcn` property:

```
set(h,'ButtonDownFcn',@button_down)
```

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

**CData**  
matrix (of type double)

*Vertex colors.* Values that specify the color at every point in `ZData`.

## Mapping CData to a Colormap

You can specify color as indexed values or true color. Indexed color data specifies a single value for each vertex. These values are either scaled to map linearly into the current colormap (see `caxis`) or interpreted directly as indices into the colormap, depending on the setting of the `CDataMapping` property.

# Surface Properties

---

## CData as True Color

True color defines an RGB value for each vertex. If the coordinate data (XData, for example) are contained in  $m$ -by- $n$  matrices, then CData must be an  $m$ -by- $n$ -by-3 array. The first page contains the red components, the second the green components, and the third the blue components of the colors.

## Texturemapping the Surface FaceColor

If you set the FaceColor property to texturemap, CData does not need to be the same size as ZData, but must be of type double or uint8. In this case, MATLAB maps CData to conform to the surface defined by ZData.

CDataMapping  
{scaled} | direct

*Direct or scaled color mapping.* Determines how MATLAB interprets indexed color data used to color the surface. (If you use true color specification for CData, this property has no effect.)

- **scaled** — Transform the color data to span the portion of the colormap indicated by the axes CLim property, linearly mapping data values to colors. See the caxis reference page for more information on this mapping.
- **direct** — Use the color data as indices directly into the colormap. The color data should then be integer values ranging from 1 to length(colormap). MATLAB maps values less than 1 to the first color in the colormap, and values greater than length(colormap) to the last color in the colormap. Values with a decimal portion are fixed to the nearest lower integer.

Children  
matrix of handles

Always the empty matrix; surface objects have no children.

## Clipping

{on} | off

*Clipping to axes rectangle.* When `Clipping` is on, MATLAB does not display any portion of the surface that is outside the axes rectangle.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Executes when MATLAB creates a surface object. You must define this property as a default value for surfaces or set the `CreateFcn` property during object creation.

For example, the following statement creates a surface (assuming `x`, `y`, `z`, and `c` are defined), and executes the function referenced by the function handle `@myCreateFcn`.

```
surface(x,y,z,c,'CreateFcn',@myCreateFcn)
```

MATLAB executes this routine after setting all surface properties. Setting this property on an existing surface object has no effect.

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

# Surface Properties

---

*Delete surface callback function.* Executes when you delete the surface object (for example, when you issue a `delete` command or clear the axes `cla` or figure `clf`).

For example, the following function displays object property data before the object is deleted.

```
function delete_fcn(src, evnt)
% src - the object that is the source of the event
% evnt - empty for this property
    obj_tp = get(src, 'Type');
    disp([obj_tp, ' object deleted'])
    disp('Its user data is:')
    disp(get(src, 'UserData'))
end
```

MATLAB executes the function before deleting the object's properties so these values are available to the callback function. The function must define at least two input arguments (handle of object being deleted and an event structure, which is empty for this property).

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

**DiffuseStrength**  
scalar  $\geq 0$  and  $\leq 1$

*Intensity of diffuse light.* Sets the intensity of the diffuse component of the light falling on the surface. Diffuse light comes from light objects in the axes. Default value is 0.6.

You can also set the intensity of the ambient and specular components of the light on the object. See the `AmbientStrength` and `SpecularStrength` properties.

`DisplayName`  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the surface object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where  $n$  is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

`EdgeAlpha`  
{scalar = 1} | flat | interp

*Transparency of the surface edges.*

- scalar — A single non-NaN scalar value between 0 and 1 that controls the transparency of all the edges of the object. 1 (the default) means fully opaque and 0 means completely transparent.

# Surface Properties

---

- `flat` — The alpha data (`AlphaData`) value for the first vertex of the face determines the transparency of the edges.
- `interp` — Linear interpolation of the alpha data (`AlphaData`) values at each vertex determines the transparency of the edge.

Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `EdgeAlpha`.

## EdgeColor

{ColorSpec} | none | flat | interp

*Color of the surface edge.* Determines how MATLAB colors the edges of the individual faces that make up the surface.

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for edges. The default value is `[0 0 0]` (black). See `ColorSpec` for more information on specifying color.
- `none` — Edges not drawn.
- `flat` — The `CData` value of the first vertex for a face determines the color of each edge.

- `interp` — Linear interpolation of the `CData` values at the face vertices determines the edge color.

## EdgeLighting

{none} | flat | gouraud | phong

*Algorithm used for lighting calculations.* Selects the algorithm used to calculate the effect of light objects on surface edges.

- none — Lights do not affect the edges of this object.
- flat — The effect of light objects is uniform across each edge of the surface.
- gouraud — The effect of light objects is calculated at the vertices and then linearly interpolated across the edge lines.
- phong — The effect of light objects is determined by interpolating the vertex normals across each edge line and calculating the reflectance at each pixel. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

## EraseMode

{normal} | none | xor | background

*Erase mode.* Controls the technique MATLAB uses to draw and erase surface objects. Alternative erase modes are useful for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- normal — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- none — Do not erase the surface when it is moved or destroyed. While the object is still visible on the screen after erasing with EraseMode none, you cannot print it because MATLAB stores no information about its former location.

# Surface Properties

---

- `xor` — Draw and erase the surface by performing an exclusive OR (XOR) with each pixel index of the screen behind it. Erasing the surface does not damage the color of the objects behind it. However, surface color depends on the color of the screen behind it and is correctly colored only when over the axes background `Color`, or the figure background `Color` if the axes `Color` is none.
- `background` — Erase the surface by drawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` is set to none. This damages objects that are behind the erased object, but surface objects are always properly colored.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

### FaceAlpha

{`scalar = 1`} | `flat` | `interp` | `texturemap`

*Transparency of the surface faces.*

- `scalar` — A single non-`NaN` scalar value between 0 and 1 that controls the transparency of all the faces of the object. 1 (the default) means fully opaque and 0 means completely transparent (invisible).

- `flat` — The values of the alpha data (`AlphaData`) determine the transparency for each face. The alpha data at the first vertex determine the transparency of the entire face.
- `interp` — Bilinear interpolation of the alpha data (`AlphaData`) at each vertex determines the transparency of each face.
- `texturemap` — Use transparency for the texture map.

Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `FaceAlpha`.

## `FaceColor`

`ColorSpec` | `none` | `{flat}` | `interp` | `texturemap`

*Color of the surface face.*

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for faces. See the `ColorSpec` reference page for more information on specifying color.
- `none` — Do not draw faces. Note that edges are drawn independently of faces.
- `flat` — The values of `CData` determine the color for each face of the surface. The color data at the first vertex determine the color of the entire face.
- `interp` — Bilinear interpolation of the values at each vertex (the `CData`) determines the coloring of each face.
- `texturemap` — Texture map the `CData` to the surface. MATLAB transforms the color data so that it conforms to the surface. (See the texture mapping example.)

## `FaceLighting`

`{none}` | `flat` | `gouraud` | `phong`

*Algorithm used for lighting calculations.* Selects the algorithm used to calculate the effect of light objects on the surface.

# Surface Properties

---

- `none` — Lights do not affect the faces of this object.
- `flat` — The effect of light objects is uniform across the faces of the surface. Select this choice to view faceted objects.
- `gouraud` — The effect of light objects is calculated at the vertices and then linearly interpolated across the faces. Select this choice to view curved surfaces.
- `phong` — The effect of light objects is determined by interpolating the vertex normals across each face and calculating the reflectance at each pixel. Select this choice to view curved surfaces. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

## HandleVisibility

`{on} | callback | off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. This property is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching

the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

**HitTest**  
`{on} | off`

*Selectable by mouse click.* Determines if the surface can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the surface. If `HitTest` is `off`, clicking on the surface selects the object below it (which might be the axes containing it).

**Interruptible**  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is

# Surface Properties

---

the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to `on` (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted.

For more information, see “Control Callback Execution and Interruption”.

## LineStyle

{-} | -- | : | -. | none

*Line style of surface edges.*

### Line Style Specifiers Table

| Specifier | Line Style           |
|-----------|----------------------|
| '-'       | Solid line (default) |
| '--'      | Dashed line          |
| ':'       | Dotted line          |
| '-.'      | Dash-dot line        |
| 'none'    | No line              |

## LineWidth

size in points

*Edge line width.* The width of the lines in points used to draw surface edges. The default width is 0.5 points. 1 point =  $1/72$  inch.

## Marker

character (see table)

*Marker symbol.* Specifies symbols that are displayed at vertices. You can set values for the Marker property independently from the LineStyle property. For a list of supported marker symbols, see the following table.

# Surface Properties

**Marker Specifiers Table**

| Specifier             | Marker Type                   |
|-----------------------|-------------------------------|
| '+'                   | Plus sign                     |
| 'o'                   | Circle                        |
| '*'                   | Asterisk                      |
| '.'                   | Point                         |
| 'x'                   | Cross                         |
| 'square' or 's'       | Square                        |
| 'diamond' or 'd'      | Diamond                       |
| '^'                   | Upward-pointing triangle      |
| 'v'                   | Downward-pointing triangle    |
| '>'                   | Right-pointing triangle       |
| '<'                   | Left-pointing triangle        |
| 'pentagram' or 'p'    | Five-pointed star (pentagram) |
| 'hexagram' or 'h' '1' | Six-pointed star (hexagram)   |
| 'none'                | No marker (default)           |

MarkerEdgeColor

none | {auto} | flat | ColorSpec

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Uses same color as the EdgeColor property.
- flat — Uses the CData value of the vertex to determine the color of the marker edge.

- `ColorSpec` — Defines color to use.

`MarkerFaceColor`

`{none} | auto | flat | ColorSpec`

*Marker face color.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Uses the axes `Color` for the marker face color.
- `flat` — Uses the `CData` value of the vertex to determine the color of the face.
- `ColorSpec` — Defines a single color to use for all markers on the surface.

`MarkerSize`

scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

`MeshStyle`

`{both} | row | column`

*Row and column lines.* Specifies whether to draw all edge lines or just row or column edge lines.

- `both` — Draws edges for both rows and columns.
- `row` — Draws row edges only.
- `column` — Draws column edges only.

# Surface Properties

---

NormalMode  
{auto} | manual

*MATLAB generated or user-specified normal vectors.*

- auto — MATLAB calculates vertex normals based on the coordinate data
- manual — If you specify your own vertex normals, MATLAB sets this property to manual and does not generate its own data.

See also the VertexNormals property.

Parent  
handle of axes, hggroup, or hgtransform

*Parent of surface object.* Contains the handle of the surface object's parent. The parent of a surface object is the axes, hggroup, or hgtransform object that contains it.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

Selected  
on | {off}

*Is object selected?* When this property is on, MATLAB displays a dashed bounding box around the surface if the SelectionHighlight property is also on. You can, for example, define the ButtonDownFcn to set this property, allowing users to select the object with the mouse.

SelectionHighlight  
{on} | off

*Objects are highlighted when selected.* When the Selected property is on, MATLAB indicates the selected state by drawing a dashed bounding box around the surface. When SelectionHighlight is off, MATLAB does not draw the box.

**SpecularColorReflectance**  
scalar in the range 0 to 1

*Color of specularly-reflected light.* When this property is 0, the color of the specularly-reflected light depends on both the color of the object from which it reflects and the color of the light source. When set to 1, the color of the specularly-reflected light depends only on the color of the light source (that is, the light object `Color` property). The proportions vary linearly for values in between.

**SpecularExponent**  
scalar  $\geq 1$

*Harshness of specular reflection.* Controls the size of the specular spot. Most materials have exponents in the range of 5 to 20.

**SpecularStrength**  
scalar  $\geq 0$  and  $\leq 1$

*Intensity of specular light.* Sets the intensity of the specular component of the light falling on the surface. Specular light comes from light objects in the axes.

You can also set the intensity of the ambient and diffuse components of the light on the surface object. See the `AmbientStrength` and `DiffuseStrength` properties. Also see the `material` function.

**Tag**  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

**Type**  
string (read-only)

# Surface Properties

---

*Class of the graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For surface objects, `Type` is always `'surface'`.

## UIContextMenu

handle of `uicontextmenu` object

*Associate a context menu with the surface.* Assign this property the handle of a `uicontextmenu` object created in the same figure as the surface. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the surface.

## UserData

matrix

*User-specified data.* Data you want to associate with the surface object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## VertexNormals

vector | matrix

*Surface normal vectors.* The vertex normals for the surface. MATLAB generates this data to perform lighting calculations. You can supply your own vertex normal data, even if it does not match the coordinate data. This can be useful to produce interesting lighting effects.

## Visible

{on} | off

*Surface object visibility.* By default, all surfaces are visible. When set to `off`, the surface is not visible, but still exists, and you can query and set its properties.

## XData

vector | matrix

*X-coordinates.* The  $x$ -position of the surface points. If you specify a row vector, `surface` replicates the row internally until it has the same number of columns as `ZData`.

`YData`

vector | matrix

*Y-coordinates.* The  $y$ -position of the surface points. If you specify a row vector, `surface` replicates the row internally until it has the same number of rows as `ZData`.

`ZData`

matrix

*Z-coordinates.* The  $z$ -position of the surface data points. See the `Description` section for more information.

`surface`

# Surfaceplot Properties

---

## Purpose

Define surfaceplot properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Editor is an interactive tool that enables you to see and change object property values.
- The set and get commands enable you to set and query the values of properties.

Note that you cannot define default properties for surfaceplot objects.

See Plot Objects for information on surfaceplot objects.

## Surfaceplot Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

### AlphaData

m-by-n matrix of double or uint8

*Transparency data.* A matrix of non-NaN values specifying the transparency of each face or vertex of the object. The AlphaData can be of class double or uint8.

MATLAB software determines the transparency in one of the following ways:

- Using the elements of AlphaData as transparency values (AlphaDataMapping set to none)
- Using the elements of AlphaData as indices into the current alphamap (AlphaDataMapping set to direct)
- Scaling the elements of AlphaData to range between the minimum and maximum values of the axes ALim property (AlphaDataMapping set to scaled, the default)

### AlphaDataMapping

none | direct | {scaled}

*Transparency mapping method.* Determines how MATLAB interprets indexed alpha data. Values for this property are:

- `none` — The transparency values of `AlphaData` are between 0 and 1 or are clamped to this range.
- `scaled` — Transform the `AlphaData` to span the portion of the alphamap indicated by the axes `ALim` property, linearly mapping data values to alpha values (the default).
- `direct` — Use the `AlphaData` as indices directly into the alphamap. When not scaled, the data are usually integer values ranging from 1 to `length(alphamap)`. MATLAB maps values less than 1 to the first alpha value in the alphamap, and values greater than `length(alphamap)` to the last alpha value in the alphamap. Values with a decimal portion are fixed to the nearest, lower integer. If `AlphaData` is an array of `uint8` integers, then the indexing begins at 0 (that is, MATLAB maps a value of 0 to the first alpha value in the alphamap).

## AmbientStrength

scalar  $\geq 0$  and  $\leq 1$

*Strength of ambient light.* Sets the strength of the ambient light, which is a nondirectional light source that illuminates the entire scene. You must have at least one visible light object in the axes for the ambient light to be visible. The axes `AmbientLightColor` property sets the color of the ambient light, which is therefore the same on all objects in the axes.

You can also set the strength of the diffuse and specular contribution of light objects. See the surfaceplot `DiffuseStrength` and `SpecularStrength` properties.

## Annotation

hg.Annotation object (read-only)

# Surfaceplot Properties

---

*Handle of Annotation object.* The Annotation property enables you to specify whether this surfaceplot object is represented in a figure legend.

Querying the Annotation property returns the handle of an hg.Annotation object. The hg.Annotation object has a property called LegendInformation, which contains an hg.LegendEntry object.

Once you have obtained the hg.LegendEntry object, you can set its IconDisplayStyle property to control whether the surfaceplot object is displayed in a figure legend:

| IconDisplayStyle Value | Purpose                                                     |
|------------------------|-------------------------------------------------------------|
| on                     | Represent this surfaceplot object in a legend (default)     |
| off                    | Do not include this surfaceplot object in a legend          |
| children               | Same as on because surfaceplot objects do not have children |

## Setting the IconDisplayStyle property

Set the IconDisplayStyle of a graphics object with handle hobj to off:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'off')
```

## Using the IconDisplayStyle property

See “Controlling Legends” for more information and examples.

## BackFaceLighting

unlit | lit | {reverselit}

*Face lighting control.* Determines how faces are lit when their vertex normals point away from the camera.

- unlit — Face not lit.
- lit — Face lit in normal way.
- reverselit — Face lit as if the vertex pointed towards the camera.

Use this property to discriminate between the internal and external surfaces of an object. See “Back Face Lighting” for an example.

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

## BusyAction

cancel | {queue}

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

# Surfaceplot Properties

---

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## CData

matrix

*Vertex colors.* A matrix containing values that specify the color at every point in ZData. If you set the FaceColor property to texturemap, CData does not need to be the same size as ZData. In this case, MATLAB maps CData to conform to the surfaceplot defined by ZData.

You can specify color as indexed values or true color. Indexed color data specifies a single value for each vertex. These values are either scaled to map linearly into the current colormap (see caxis) or interpreted directly as indices into the colormap, depending on the setting of the CDataMapping property. Note that any non-texture data passed as an input argument must be of type double.

True color defines an RGB value for each vertex. If the coordinate data (XData, for example) are contained in m-by-n matrices, then CData must be an m-by-n-by-3 array. The first page contains the red components, the second the green components, and the third the blue components of the colors.

## CDataMapping

{scaled} | direct

*Direct or scaled color mapping.* Determines how MATLAB interprets indexed color data used to color the surfaceplot. (If you use true color specification for CData, this property has no effect.)

- **scaled** — Transform the color data to span the portion of the colormap indicated by the axes CLim property, linearly mapping data values to colors. See the caxis reference page for more information on this mapping.
- **direct** — Use the color data as indices directly into the colormap. The color data should then be integer values ranging from 1 to length(colormap). MATLAB maps values less than

# Surfaceplot Properties

---

1 to the first color in the colormap, and values greater than `length(colormap)` to the last color in the colormap. Values with a decimal portion are fixed to the nearest lower integer.

## CDataMode

{auto} | manual

*Use automatic or user-specified color data values.* If you specify CData, MATLAB sets this property to manual and uses the CData values to color the surfaceplot.

If you set CDataMode to auto after having specified CData, MATLAB resets the color data of the surfaceplot to that defined by ZData, overwriting any previous values for CData.

## CDataSource

string (MATLAB variable)

*Link CData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the CData.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change CData.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## Children

matrix of handles

Always the empty matrix; surfaceplot objects have no children.

## Clipping

{on} | off

*Clipping to axes rectangle.* When Clipping is on, MATLAB does not display any portion of the surfaceplot that is outside the axes rectangle.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where @CallbackFcn is a function handle that references the callback function and graphicfcn is the plotting function which creates this object.

# Surfaceplot Properties

---

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## `DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

## `DiffuseStrength`

scalar  $\geq 0$  and  $\leq 1$

*Intensity of diffuse light.* Sets the intensity of the diffuse component of the light falling on the surface. Diffuse light comes from light objects in the axes. Default value is `0.6`.

You can also set the intensity of the ambient and specular components of the light on the object. See the `AmbientStrength` and `SpecularStrength` properties.

`DisplayName`  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the surfaceplot object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

`EdgeAlpha`  
{scalar = 1} | flat | interp

*Transparency of the patch and surface edges.*

- scalar — A single non-NaN scalar value between 0 and 1 that controls the transparency of all the edges of the object. 1 (the default) means fully opaque and 0 means completely transparent.

# Surfaceplot Properties

---

- `flat` — The alpha data (`AlphaData`) value for the first vertex of the face determines the transparency of the edges.
- `interp` — Linear interpolation of the alpha data (`AlphaData`) values at each vertex determines the transparency of the edge.

Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `EdgeAlpha`.

Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `EdgeAlpha`.

## `EdgeColor`

`{ColorSpec} | none | flat | interp`

*Color of the surfaceplot edge.* This property determines how MATLAB colors the edges of the individual faces that make up the surface:

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for edges. The default `EdgeColor` is black. See `ColorSpec` for more information on specifying color.
- `none` — Edges are not drawn.
- `flat` — The `CData` value of the first vertex for a face determines the color of each edge.

- `interp` — Linear interpolation of the CData values at the face vertices determines the edge color.

## EdgeLighting

`{none} | flat | gouraud | phong`

*Algorithm used for lighting calculations.* Selects the algorithm used to calculate the effect of light objects on surfaceplot edges.

- `none` — Lights do not affect the edges of this object.
- `flat` — The effect of light objects is uniform across each edge of the surfaceplot.
- `gouraud` — The effect of light objects is calculated at the vertices and then linearly interpolated across the edge lines.
- `phong` — The effect of light objects is determined by interpolating the vertex normals across each edge line and calculating the reflectance at each pixel. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

## EraseMode

`{normal} | none | xor | background`

# Surfaceplot Properties

---

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- **normal** — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- **none** — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- **xor** — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- **background** — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting

to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## FaceAlpha

`{scalar = 1} | flat | interp | texturemap`

*Transparency of the surfaceplot faces.* This property can be any of the following:

- `scalar` — A single non-NaN scalar value between 0 and 1 that controls the transparency of all the faces of the object. 1 (the default) means fully opaque and 0 means completely transparent (invisible).
- `flat` — The values of the alpha data (`AlphaData`) determine the transparency for each face. The alpha data at the first vertex determine the transparency of the entire face.
- `interp` — Bilinear interpolation of the alpha data (`AlphaData`) at each vertex determines the transparency of each face.
- `texturemap` — Use transparency for the texture map.

Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `FaceAlpha`.

## FaceColor

`ColorSpec | none | {flat} | interp`

*Color of the surfaceplot face.* This property can be any of the following:

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for faces. See `ColorSpec` for more information on specifying color.

# Surfaceplot Properties

---

- `none` — Do not draw faces. Note that edges are drawn independently of faces.
- `flat` — The values of `CData` determine the color for each face of the surface. The color data at the first vertex determine the color of the entire face.
- `interp` — Bilinear interpolation of the values at each vertex (the `CData`) determines the coloring of each face.
- `texturemap` — Texture map the `CData` to the surface. MATLAB transforms the color data so that it conforms to the surface. (See the texture mapping example for `surface`.)

## FaceLighting

`{none} | flat | gouraud | phong`

*Algorithm used for lighting calculations.* This property selects the algorithm used to calculate the effect of light objects on the surface. Choices are

- `none` — Lights do not affect the faces of this object.
- `flat` — The effect of light objects is uniform across the faces of the surface. Select this choice to view faceted objects.
- `gouraud` — The effect of light objects is calculated at the vertices and then linearly interpolated across the faces. Select this choice to view curved surfaces.
- `phong` — The effect of light objects is determined by interpolating the vertex normals across each face and calculating the reflectance at each pixel. Select this choice to view curved surfaces. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

## HandleVisibility

`{on} | callback | off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility`

is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

# Surfaceplot Properties

---

## Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## HitTest

{on} | off

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the surface. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

## Interruptible

off | {on}

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

`LineStyle`  
{-} | -- | : | -. | none

# Surfaceplot Properties

---

*Line style of surfaceplot object.*

## Line Style Specifiers Table

| Specifier | Line Style           |
|-----------|----------------------|
| '-'       | Solid line (default) |
| '--'      | Dashed line          |
| '.'       | Dotted line          |
| '-.'      | Dash-dot line        |
| 'none'    | No line              |

Use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`  
size in points

*Width of linear objects and edges of filled areas.* Specify in points. 1 point =  $1/72$  inch. The default is 0.5 points.

`Marker`  
character (see table)

*Marker symbol.* Specifies marks that display at data points. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

## Marker Specifiers Table

| Specifier | Marker Type |
|-----------|-------------|
| '+'       | Plus sign   |
| 'o'       | Circle      |

| Specifier            | Marker Type                   |
|----------------------|-------------------------------|
| '*'                  | Asterisk                      |
| '.'                  | Point                         |
| 'x'                  | Cross                         |
| 'square' or 's'      | Square                        |
| 'diamond' or 'd'     | Diamond                       |
| '^'                  | Upward-pointing triangle      |
| 'v'                  | Downward-pointing triangle    |
| '>'                  | Right-pointing triangle       |
| '<'                  | Left-pointing triangle        |
| 'pentagram' or 'p'   | Five-pointed star (pentagram) |
| 'hexagram' or 'h' '' | Six-pointed star (hexagram)   |
| 'none'               | No marker (default)           |

## MarkerEdgeColor

none | {auto} | flat | ColorSpec

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Uses same color as the EdgeColor property.
- flat — Uses the CData value of the vertex to determine the color of the marker edge.
- ColorSpec — Defines color to use.

## MarkerFaceColor

{none} | auto | flat | ColorSpec

# Surfaceplot Properties

---

*Marker face color.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- none — Makes the interior of the marker transparent, allowing the background to show through.
- auto — Uses the axes Color for the marker face color.
- flat — Uses the CData value of the vertex to determine the color of the face.
- ColorSpec — Defines a single color to use for all markers on the surfaceplot.

MarkerSize  
scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the '.' symbol) at one-third the specified size.

---

MeshStyle  
{both} | row | column

*Row and column lines.* Specifies whether to draw all edge lines or just row or column edge lines.

- both — Draws edges for both rows and columns.
- row — Draws row edges only.
- column — Draws column edges only.

NormalMode  
{auto} | manual

*MATLAB generated or user-specified normal vectors.*

- `auto` — MATLAB calculates vertex normals based on the coordinate data
- `manual` — If you specify your own vertex normals, MATLAB sets this property to `manual` and does not generate its own data.

See also the `VertexNormals` property.

## Parent

handle of parent axes, `hggroup`, or `hgtransform`

*Parent of object.* Handle of the object's parent. The parent is normally the axes, `hggroup`, or `hgtransform` object that contains the object.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## Selected

`on` | `{off}`

*Object selection state.* When you set this property to `on`, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

## SelectionHighlight

`{on}` | `off`

*Selected objects highlighted.*

- `on` — MATLAB indicates the selected state by drawing a dashed bounding box around the surface.
- `off` — MATLAB does not draw the bounding box except when in plot edit mode and objects are selected manually.

# Surfaceplot Properties

---

**SpecularColorReflectance**  
scalar in the range 0 to 1

*Color of specularly-reflected light.* When this property is 0, the color of the specularly-reflected light depends on both the color of the object from which it reflects and the color of the light source. When set to 1, the color of the specularly-reflected light depends only on the color of the light source (that is, the light object `Color` property). The proportions vary linearly for values in between.

**SpecularExponent**  
scalar  $\geq 1$

*Harshness of specular reflection.* Controls the size of the specular spot. Most materials have exponents in the range of 5 to 20.

**SpecularStrength**  
scalar  $\geq 0$  and  $\leq 1$

*Intensity of specular light.* Sets the intensity of the specular component of the light falling on the surfaceplot. Specular light comes from light objects in the axes.

You can also set the intensity of the ambient and diffuse components of the light on the surfaceplot object. See the `AmbientStrength` and `DiffuseStrength` properties. Also see the `material` function.

**Tag**  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an `areaseries` object and set the `Tag` property.

```
t = area(Y, 'Tag', 'area1')
```

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag', 'area1'), 'FaceColor', 'red')
```

## Type

string (read only)

*Class of the graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For surfaceplot objects, `Type` is always the string `'surface'`.

## UIContextMenu

handle of `uicontextmenu` object

*Associate context menu with object.* Handle of a `uicontextmenu` object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

## UserData

array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## VertexNormals

vector | matrix

*Surfaceplot normal vectors.* Contains the vertex normals for the surfaceplot. MATLAB generates this data to perform lighting calculations. You can supply your own vertex normal data, even

# Surfaceplot Properties

---

if it does not match the coordinate data. This can be useful to produce interesting lighting effects.

## Visible

{on} | off

*Visibility of object and its children.*

- on — Object and all children of the object are visible unless the child object's Visible property is off.
- off — Object not displayed. However, the object still exists and you can set and query its properties.

## XData

vector | matrix

*X-coordinates.* The  $x$ -position of the surfaceplot data points. If you specify a row vector, MATLAB replicates the row internally until it has the same number of columns as ZData.

## XDataMode

{auto} | manual

*Use automatic or user-specified x-axis values.* If you specify XData (by setting the XData property or specifying the X input argument), MATLAB sets this property to manual and uses the specified values to label the  $x$ -axis.

If you set XDataMode to auto after specifying XData, MATLAB resets the  $x$ -axis ticks to `1:size(YData,1)` or to the column indices of the ZData, overwriting any previous values for XData.

## XDataSource

MATLAB variable, as a string

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the XData. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `XDataSource` does not change the object's `XData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## YData

vector | matrix

*Y-coordinates.* The *y*-position of the surfaceplot data points. If you specify a row vector, MATLAB replicates the row internally until it has the same number of rows as `ZData`.

## YDataMode

{auto} | manual

*Use automatic or user-specified y-axis values.* If you specify `XData`, MATLAB sets this property to `manual`.

If you set `YDataMode` to `auto` after having specified `YData`, MATLAB resets the *y*-axis ticks and *y*-tick labels to the row indices of the `ZData`, overwriting any previous values for `YData`.

## YDataSource

MATLAB variable, as a string

# Surfaceplot Properties

---

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the YData. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's YDataSource does not change the object's YData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## ZData

matrix

*Z-coordinates.* The *z*-position of the surfaceplot data points. See the Description section for more information.

## ZDataSource

MATLAB variable, as a string

*Link ZData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the ZData. The default value is an empty array.

```
set(h, 'ZDataSource', 'zdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's

ZDataSource does not change the object's ZData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

# surf1

---

## Purpose

Surface plot with colormap-based lighting

## Syntax

```
surf1(Z)
surf1(...,'light')
surf1(...,s)
surf1(X,Y,Z,s,k)
h = surf1(...)
```

## Description

The `surf1` function displays a shaded surface based on a combination of ambient, diffuse, and specular lighting models.

`surf1(Z)` and `surf1(X,Y,Z)` create three-dimensional shaded surfaces using the default direction for the light source and the default lighting coefficients for the shading model. `X`, `Y`, and `Z` are vectors or matrices that define the  $x$ ,  $y$ , and  $z$  components of a surface.

`surf1(...,'light')` produces a colored, lighted surface using a MATLAB light object. This produces results different from the default lighting method, `surf1(...,'cdata')`, which changes the color data for the surface to be the reflectance of the surface.

`surf1(...,s)` specifies the direction of the light source. `s` is a two- or three-element vector that specifies the direction from a surface to a light source. `s = [sx sy sz]` or `s = [azimuth elevation]`. The default `s` is  $45^\circ$  counterclockwise from the current view direction.

`surf1(X,Y,Z,s,k)` specifies the reflectance constant. `k` is a four-element vector defining the relative contributions of ambient light, diffuse reflection, specular reflection, and the specular shine coefficient. `k = [ka kd ks shine]` and defaults to `[.55, .6, .4, 10]`.

`h = surf1(...)` returns a handle to a surface graphics object.

**Tips**

surf1 does not accept complex inputs.

For smoother color transitions, use colormaps that have linear intensity variations (e.g., gray, copper, bone, pink).

The ordering of points in the X, Y, and Z matrices defines the inside and outside of parametric surfaces. If you want the opposite side of the surface to reflect the light source, use surf1(X',Y',Z'). Because of the way surface normal vectors are computed, surf1 requires matrices that are at least 3-by-3.

**Examples**

View peaks using colormap-based lighting.

```
[x,y] = meshgrid(-3:1/8:3);  
z = peaks(x,y);  
surf1(x,y,z);  
shading interp  
colormap(gray);  
axis([-3,3,-3,3,-8,8])
```

# surf1

---

To plot a lighted surface from a view direction other than the default,

```
view([10 10])
grid on
hold on
surf1(peaks)
shading interp
colormap copper
hold off
```

**See Also**

[colormap](#) | [shading](#) | [light](#)

# surfnorm

---

**Purpose** Compute and display 3-D surface normals

**Syntax**

```
surfnorm(Z)
surfnorm(X,Y,Z)
surfnorm(axes_handle, ___)
surfnorm( ___,Name,Value)
[Nx,Ny,Nz] = surfnorm( ___)
```

**Description**

`surfnorm(Z)` plots a surface of the matrix `Z` with `surf` and displays its surface normals as radiating vectors.

`surfnorm(X,Y,Z)` plots a surface and its surface normals from the vectors or matrices `X`, `Y`, and matrix `Z`. `X`, `Y`, and `Z` must be the same size.

`surfnorm(axes_handle, ___)` plots into `axes_handle` instead of `gca` and it can include any of the input arguments in previous syntaxes.

`surfnorm( ___,Name,Value)` can be used to set the value of the specified Surface Properties.

`[Nx,Ny,Nz] = surfnorm( ___)` returns the components of the 3-D surface normals for the surface without plotting the surface or surface normals.

**Tips**

- `surfnorm` does not accept complex inputs.
- Reverse the direction of the normals by calling `surfnorm` with transposed arguments:  

```
surfnorm(X',Y',Z')
```
- The surface normals represent conditions at vertices and are not normalized. Normals for surface elements that face away from the viewer do not display.
- `surf1` uses `surfnorm` to compute surface normals when calculating the reflectance of a surface.

**Input Arguments****Z**

2-D array of real numbers representing a surface

**X**

2-D array of real numbers that defines the  $x$  component of the surface grid

**Y**

2-D array of real numbers that defines the  $y$  component of the surface grid

**axes\_handle**

Handle to the target axes in which to plot the surface

If you do not specify `axes_handle`, MATLAB uses current axes.

**Name,Value**

Specify optional comma-separated pairs of Name,Value arguments, where Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Property names and values of the surface object

See [Surface Properties](#) for description of property names and values.

**Output Arguments****[Nx,Ny,Nz]**

$x$ ,  $y$ , and  $z$  components of the three-dimensional surface normals for the surface

**Definitions****Surface Normal**

An imaginary line perpendicular to a flat surface or perpendicular to the tangent plane at a point on a non-flat surface

# surfnorm

---

## Examples

Plot the normal vectors for a truncated cone.

```
[x,y,z] = cylinder(1:10);  
surfnorm(x,y,z)  
axis([-12 12 -12 12 -0.1 1])
```

---

Get normal vectors of an expression representing a surface.

```
[nx, ny, nz] = surfnorm(peaks);
```

You can use these normals in conjunction with `VertexNormals` property and to apply lighting variations to a plain surface as,

```
b = reshape([nx ny nz], 49,49,3);  
surf(ones(49), 'VertexNormals', b);%Create a plain surface of size equal to the image  
shading interp % remove edge definition from the image  
camlight
```

# surfnorm

---

## Algorithms

After performing a bicubic fit of the data in the  $x$ ,  $y$ , and  $z$  directions, diagonal vectors are computed and crossed to form the normal at each vertex.

## See Also

`surf` | `quiver3` | `surface` | `isonormals` | `surf1`

**Purpose** Singular value decomposition

**Syntax**

```
s = svd(X)
[U,S,V] = svd(X)
[U,S,V] = svd(X,0)
[U,S,V] = svd(X,'econ')
```

**Description** The svd command computes the matrix singular value decomposition. `s = svd(X)` returns a vector of singular values.

`[U,S,V] = svd(X)` produces a diagonal matrix `S` of the same dimension as `X`, with nonnegative diagonal elements in decreasing order, and unitary matrices `U` and `V` so that  $X = U*S*V'$ .

`[U,S,V] = svd(X,0)` produces the “economy size” decomposition. If `X` is `m`-by-`n` with  $m > n$ , then `svd` computes only the first `n` columns of `U` and `S` is `n`-by-`n`.

`[U,S,V] = svd(X,'econ')` also produces the “economy size” decomposition. If `X` is `m`-by-`n` with  $m \geq n$ , it is equivalent to `svd(X,0)`. For  $m < n$ , only the first `m` columns of `V` are computed and `S` is `m`-by-`m`.

**Examples** For the matrix

```
X =
     1     2
     3     4
     5     6
     7     8
```

the statement

```
[U,S,V] = svd(X)
```

produces

```
U =
-0.1525  -0.8226  -0.3945  -0.3800
```

# svd

---

```
-0.3499  -0.4214   0.2428   0.8007
-0.5474  -0.0201   0.6979  -0.4614
-0.7448   0.3812  -0.5462   0.0407
```

```
S =
  14.2691     0
         0   0.6268
         0     0
         0     0
```

```
V =
 -0.6414   0.7672
 -0.7672  -0.6414
```

The economy size decomposition generated by

```
[U,S,V] = svd(X,0)
```

produces

```
U =
 -0.1525  -0.8226
 -0.3499  -0.4214
 -0.5474  -0.0201
 -0.7448   0.3812
```

```
S =
  14.2691     0
         0   0.6268
```

```
V =
 -0.6414   0.7672
 -0.7672  -0.6414
```

## Diagnostics

If the limit of 75 QR step iterations is exhausted while seeking a singular value, this message appears:

```
Solution will not converge.
```

**Purpose** Find singular values and vectors

**Syntax**

```
s = svds(A)
s = svds(A,k)
s = svds(A,k,sigma)
s = svds(A,k,'L')
s = svds(A,k,sigma,options)
[U,S,V] = svds(A,...)
[U,S,V,flag] = svds(A,...)
```

**Description** `s = svds(A)` computes the six largest singular values and associated singular vectors of matrix `A`. If `A` is `m`-by-`n`, `svds(A)` manipulates eigenvalues and vectors returned by `eigs(B)`, where `B = [sparse(m,m) A; A' sparse(n,n)]`, to find a few singular values and vectors of `A`. The positive eigenvalues of the symmetric matrix `B` are the same as the singular values of `A`.

`s = svds(A,k)` computes the `k` largest singular values and associated singular vectors of matrix `A`.

`s = svds(A,k,sigma)` computes the `k` singular values closest to the scalar shift `sigma`. For example, `s = svds(A,k,0)` computes the `k` smallest singular values and associated singular vectors.

`s = svds(A,k,'L')` computes the `k` largest singular values (the default).

`s = svds(A,k,sigma,options)` sets some parameters (see `eigs`):

### Option Structure Fields and Descriptions

| Field name                 | Parameter                                                                  | Default |
|----------------------------|----------------------------------------------------------------------------|---------|
| <code>options.tol</code>   | Convergence tolerance:<br><code>norm(AV-US,1) &lt;= tol * norm(A,1)</code> | 1e-10   |
| <code>options.maxit</code> | Maximum number of iterations                                               | 300     |
| <code>options.disp</code>  | Number of values displayed each iteration                                  | 0       |

`svds` checks the accuracy of the computed singular vectors. If the vectors they are not accurate enough returns fewer singular values than requested. To obtain the requested number of singular values, try decreasing the error tolerance in the options structure.

`[U,S,V] = svds(A,...)` returns three output arguments, and if `A` is `m`-by-`n`:

- `U` is `m`-by-`k` with orthonormal columns
- `S` is `k`-by-`k` diagonal
- `V` is `n`-by-`k` with orthonormal columns
- `U*S*V'` is the closest rank `k` approximation to `A`

`[U,S,V,flag] = svds(A,...)` returns a convergence flag. If `eigs` converged then `norm(A*V-U*S,1) <= tol*norm(A,1)` and `flag` is 0. If `eigs` did not converge, then `flag` is 1.

---

**Note** `svds` is best used to find a few singular values of a large, sparse matrix. To find all the singular values of such a matrix, `svd(full(A))` will usually perform better than `svds(A,min(size(A)))`.

---

## Algorithms

`svds(A,k)` uses `eigs` to find the `k` largest magnitude eigenvalues and corresponding eigenvectors of `B = [0 A; A' 0]`.

`svds(A,k,0)` uses `eigs` to find the `2k` smallest magnitude eigenvalues and corresponding eigenvectors of `B = [0 A; A' 0]`, and then selects the `k` positive eigenvalues and their eigenvectors.

## Examples

`west0479` is a real 479-by-479 sparse matrix. `svd` calculates all 479 singular values. `svds` picks out the largest and smallest singular values.

```
load west0479
s = svd(full(west0479))
s1 = svds(west0479,4)
ss = svds(west0479,6,0)
```

These plots show some of the singular values of west0479 as computed by svd and svds.

The largest singular value of west0479 can be computed a few different ways:

```
svds(west0479,1) =
 3.189517598808622e+05
max(svd(full(west0479))) =
 3.18951759880862e+05
norm(full(west0479)) =
 3.189517598808623e+05
```

and estimated:

```
normest(west0479) =
 3.189385666549991e+05
```

## See Also

svd | eigs

# swapbytes

---

**Purpose** Swap byte ordering

**Syntax** Y = swapbytes(X)

**Description** Y = swapbytes(X) reverses the byte ordering of each element in array X, converting little-endian values to big-endian (and vice versa). The input array must contain all full, noncomplex, numeric elements.

## **Examples** **Example 1**

Reverse the byte order for a scalar 32-bit value, changing hexadecimal 12345678 to 78563412:

```
A = uint32(hex2dec('12345678'));
```

```
B = dec2hex(swapbytes(A))
```

```
B =  
    78563412
```

## **Example 2**

Reverse the byte order for each element of a 1-by-4 matrix:

```
X = uint16([0 1 128 65535])
```

```
X =  
    0         1      128  65535
```

```
Y = swapbytes(X);
```

```
Y =  
    0    256  32768  65535
```

Examining the output in hexadecimal notation shows the byte swapping:

```
format hex
```

```
X, Y
```

```
X =  
    0000    0001    0080    ffff
```

```
Y =  
    0000    0100    8000    ffff
```

### Example 3

Create a three-dimensional array A of 16-bit integers and then swap the bytes of each element:

```
format hex
```

```
A = uint16(magic(3) * 150);  
A(:,:,2) = A * 40;
```

```
A  
A(:,:,1) =  
    04b0    0096    0384  
    01c2    02ee    041a  
    0258    0546    012c  
A(:,:,2) =  
    bb80    1770    8ca0  
    4650    7530    a410  
    5dc0    d2f0    2ee0
```

```
swapbytes(A)  
ans(:,:,1) =  
    b004    9600    8403  
    c201    ee02    1a04  
    5802    4605    2c01  
ans(:,:,2) =  
    80bb    7017    a08c  
    5046    3075    10a4  
    c05d    f0d2    e02e
```

### See Also

```
typecast
```

# switch/case/otherwise

---

**Purpose** Switch among several cases based on expression

**Syntax**

```
switch switch_expression
    case case_expression
        statements
    case case_expression
        statements
    :
    otherwise
        statements
end
```

**Description** A switch block conditionally executes one set of statements from several choices. Each choice is a case.

An evaluated *switch\_expression* is a scalar or string. An evaluated *case\_expression* is a scalar, a string, or a cell array of scalars or strings. The switch block tests each case until one of the cases is true. A case is true when:

- For numbers, `eq(case_expression,switch_expression)`.
- For strings, `strcmp(case_expression,switch_expression)`.
- For objects that support the eq function, `eq(case_expression,switch_expression)`.
- For a cell array *case\_expression*, at least one of the elements of the cell array matches *switch\_expression*, as defined above for numbers, strings, and objects.

When a case is true, MATLAB executes the corresponding statements, and then exits the switch block.

*otherwise* is optional, and executes only when no case is true.

**Tips**

- Unlike the C language switch statement, the MATLAB switch does not fall through. If the first case statement is true, the other case

statements do not execute. Do not use a `break` statement within a `switch` block.

- A *case\_expression* cannot include relational operators such as `<` or `>` to compare against the *switch\_expression*. To test for inequality, use `if-elseif` statements.
- Because MATLAB executes only one case of any `switch` statement, variables defined within one case are not available for other cases. For example, if your current workspace does not contain a variable `x`, only cases that define `x` can use it:

```
switch choice
    case 1
        x = -pi:0.01:pi;
    case 2
        % does not know anything about x
end
```

## Examples

Conditionally display different text depending on a value entered at the command line:

```
mynumber = input('Enter a number:');
```

```
switch mynumber
    case -1
        disp('negative one');
    case 0
        disp('zero');
    case 1
        disp('positive one');
    otherwise
        disp('other value');
end
```

---

Decide which plot to create based on the value of the string `plottype`:

## switch/case/otherwise

---

```
x = [12, 64, 24];
plottype = 'pie3';

switch plottype
    case 'bar'
        bar(x)
        title('Bar Graph')
    case {'pie', 'pie3'}
        pie3(x)
        title('Pie Chart')
        legend('First', 'Second', 'Third')
    otherwise
        warning('Unexpected plot type. No plot created.');
```

---

In MATLAB switch blocks, only the first matching case executes:

```
result = 52;

switch(result)
    case 52
        disp('result is 52')
    case {52, 78}
        disp('result is 52 or 78')
end
```

This code returns

```
result is 52
```

### See Also

```
end | for | if | while
```

**Purpose**

Symmetric approximate minimum degree permutation

**Syntax**

```
p = symamd(S)
p = symamd(S,knobs)
[p,stats] = symamd(...)
```

**Description**

`p = symamd(S)` for a symmetric positive definite matrix `S`, returns the permutation vector `p` such that `S(p,p)` tends to have a sparser Cholesky factor than `S`. To find the ordering for `S`, `symamd` constructs a matrix `M` such that `spones(M'*M) = spones(S)`, and then computes `p = colamd(M)`. The `symamd` function may also work well for symmetric indefinite matrices.

`S` must be square; only the strictly lower triangular part is referenced.

`p = symamd(S,knobs)` where `knobs` is a scalar. If `S` is `n`-by-`n`, rows and columns with more than `knobs*n` entries are removed prior to ordering, and ordered last in the output permutation `p`. If the `knobs` parameter is not present, then `knobs = spparms('wh_frac')`.

`[p,stats] = symamd(...)` produces the optional vector `stats` that provides data about the ordering and the validity of the matrix `S`.

|                       |                                                                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>stats(1)</code> | Number of dense or empty rows ignored by <code>symamd</code>                                                                                                              |
| <code>stats(2)</code> | Number of dense or empty columns ignored by <code>symamd</code>                                                                                                           |
| <code>stats(3)</code> | Number of garbage collections performed on the internal data structure used by <code>symamd</code> (roughly of size $8.4 * \text{nnz}(\text{tril}(S, -1)) + 9n$ integers) |
| <code>stats(4)</code> | 0 if the matrix is valid, or 1 if invalid                                                                                                                                 |
| <code>stats(5)</code> | Rightmost column index that is unsorted or contains duplicate entries, or 0 if no such column exists                                                                      |
| <code>stats(6)</code> | Last seen duplicate or out-of-order row index in the column index given by <code>stats(5)</code> , or 0 if no such row index exists                                       |
| <code>stats(7)</code> | Number of duplicate and out-of-order row indices                                                                                                                          |

Although, MATLAB built-in functions generate valid sparse matrices, a user may construct an invalid sparse matrix using the MATLAB C or Fortran APIs and pass it to `symamd`. For this reason, `symamd` verifies that `S` is valid:

- If a row index appears two or more times in the same column, `symamd` ignores the duplicate entries, continues processing, and provides information about the duplicate entries in `stats(4:7)`.
- If row indices in a column are out of order, `symamd` sorts each column of its internal copy of the matrix `S` (but does not repair the input matrix `S`), continues processing, and provides information about the out-of-order entries in `stats(4:7)`.
- If `S` is invalid in any other way, `symamd` cannot continue. It prints an error message, and returns no output arguments (`p` or `stats`).

The ordering is followed by a symmetric elimination tree post-ordering.

## Examples

Here is a comparison of reverse Cuthill-McKee and minimum degree on the Bucky ball example mentioned in the `symrcm` reference page.

```
B = bucky+4*speye(60);
r = symrcm(B);
p = symamd(B);
R = B(r,r);
S = B(p,p);
subplot(2,2,1), spy(R,4), title('B(r,r)')
subplot(2,2,2), spy(S,4), title('B(s,s)')
subplot(2,2,3), spy(chol(R),4), title('chol(B(r,r))')
subplot(2,2,4), spy(chol(S),4), title('chol(B(s,s))')
```

Even though this is a very small problem, the behavior of both orderings is typical. RCM produces a matrix with a narrow bandwidth which fills in almost completely during the Cholesky factorization. Minimum degree produces a structure with large blocks of contiguous zeros which do not fill in during the factorization. Consequently, the minimum degree ordering requires less time and storage for the factorization.

## References

The authors of the code for `symamd` are Stefan I. Larimore and Timothy A. Davis ([davis@cise.ufl.edu](mailto:davis@cise.ufl.edu)), University of Florida. The algorithm was developed in collaboration with John Gilbert, Xerox PARC, and Esmond Ng, Oak Ridge National Laboratory.

## **See Also**

`colamd` | `colperm` | `spparms` | `symrcm` | `amd`

**Purpose** Symbolic factorization analysis

**Syntax**

```
count = symbfact(A)
count = symbfact(A, 'sym')
count = symbfact(A, 'col')
count = symbfact(A, 'row')
count = symbfact(A, 'lo')
[count, h, parent, post, R] = symbfact(...)
[count, h, parent, post, L] = symbfact(A, type, 'lower')
```

**Description**

`count = symbfact(A)` returns the vector of row counts of  $R = \text{chol}(A)$ . `symbfact` should be much faster than `chol(A)`.

`count = symbfact(A, 'sym')` is the same as `count = symbfact(A)`.

`count = symbfact(A, 'col')` returns row counts of  $R = \text{chol}(A' * A)$  (without forming it explicitly).

`count = symbfact(A, 'row')` returns row counts of  $R = \text{chol}(A * A')$ .

`count = symbfact(A, 'lo')` is the same as `count = symbfact(A)` and uses `tril(A)`.

`[count, h, parent, post, R] = symbfact(...)` has several optional return values.

The flop count for a subsequent Cholesky factorization is `sum(count.^2)`

| Return Value | Description                                                                                                                                                                |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| h            | Height of the elimination tree                                                                                                                                             |
| parent       | The elimination tree itself                                                                                                                                                |
| post         | Postordering of the elimination tree                                                                                                                                       |
| R            | 0-1 matrix having the structure of <code>chol(A)</code> for the symmetric case, <code>chol(A'*A)</code> for the 'col' case, or <code>chol(A*A')</code> for the 'row' case. |

# **symbfact**

---

`symbfact(A)` and `symbfact(A, 'sym')` use the upper triangular part of `A` (`triu(A)`) and assume the lower triangular part is the transpose of the upper triangular part. `symbfact(A, 'lo')` uses `tril(A)` instead.

`[count,h,parent,post,L] = symbfact(A,type,'lower')` where `type` is one of `'sym'`, `'col'`, `'row'`, or `'lo'` returns a lower triangular symbolic factor `L=R'`. This form is quicker and requires less memory.

## **See Also**

`chol` | `etree` | `treelayout`

**Purpose**

Symmetric LQ method

**Syntax**

```

x = symmlq(A,b)
symmlq(A,b,tol)
symmlq(A,b,tol,maxit)
symmlq(A,b,tol,maxit,M)
symmlq(A,b,tol,maxit,M1,M2)
symmlq(A,b,tol,maxit,M1,M2,x0)
[x,flag] = symmlq(A,b,...)
[x,flag,relres] = symmlq(A,b,...)
[x,flag,relres,iter] = symmlq(A,b,...)
[x,flag,relres,iter,resvec] = symmlq(A,b,...)
[x,flag,relres,iter,resvec,resveccg] = symmlq(A,b,...)

```

**Description**

`x = symmlq(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be symmetric but need not be positive definite. It should also be large and sparse. The column vector  $b$  must have length  $n$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x)` returns  $A*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `symmlq` converges, a message to that effect is displayed. If `symmlq` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`symmlq(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `symmlq` uses the default,  $1e-6$ .

`symmlq(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `symmlq` uses the default,  $\min(n,20)$ .

`symmlq(A,b,tol,maxit,M)` and `symmlq(A,b,tol,maxit,M1,M2)` use the symmetric positive definite preconditioner  $M$  or  $M = M1*M2$  and effectively solve the system  $\text{inv}(\text{sqrt}(M))*A*\text{inv}(\text{sqrt}(M))*y =$

# symmlq

---

$\text{inv}(\text{sqrt}(M)) * b$  for  $y$  and then return  $x = \text{in}(\text{sqrt}(M)) * y$ . If  $M$  is  $[]$  then `symmlq` applies no preconditioner.  $M$  can be a function handle `mfun` such that `mfun(x)` returns  $M \backslash x$ .

`symmlq(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If  $x_0$  is  $[]$ , then `symmlq` uses the default, an all-zero vector.

`[x,flag] = symmlq(A,b,...)` also returns a convergence flag.

| Flag | Convergence                                                                                                             |
|------|-------------------------------------------------------------------------------------------------------------------------|
| 0    | <code>symmlq</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.           |
| 1    | <code>symmlq</code> iterated <code>maxit</code> times but did not converge.                                             |
| 2    | Preconditioner $M$ was ill-conditioned.                                                                                 |
| 3    | <code>symmlq</code> stagnated. (Two consecutive iterates were the same.)                                                |
| 4    | One of the scalar quantities calculated during <code>symmlq</code> became too small or too large to continue computing. |
| 5    | Preconditioner $M$ was not symmetric positive definite.                                                                 |

Whenever `flag` is not 0, the solution  $x$  returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = symmlq(A,b,...)` also returns the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = symmlq(A,b,...)` also returns the iteration number at which  $x$  was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = symmlq(A,b,...)` also returns a vector of estimates of the `symmlq` residual norms at each iteration, including  $\text{norm}(b-A*x_0)$ .

`[x,flag,relres,iter,resvec,resveccg] = symmlq(A,b,...)` also returns a vector of estimates of the conjugate gradients residual norms at each iteration.

**Examples****Example 1**

```

n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -2*on],-1:1,n,n);
b = sum(A,2);
tol = 1e-10;
maxit = 50; M1 = spdiags(4*on,0,n,n);

x = symmlq(A,b,tol,maxit,M1);
symmlq converged at iteration 49 to a solution with relative
residual 4.3e-015

```

**Example 2**

This example replaces the matrix *A* in Example 1 with a handle to a matrix-vector product function *afun*. The example is contained in the function *run\_symmlq* that:

- Calls *symmlq* with the function handle *@afun* as its first argument.
- Contains *afun* as a nested function, so that all variables in *run\_symmlq* are available to *afun*.

The following shows the code for *run\_symmlq*:

```

function x1 = run_symmlq
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = symmlq(@afun,b,tol,maxit,M1);

    function y = afun(x)
        y = 4 * x;
        y(2:n) = y(2:n) - 2 * x(1:n-1);

```

```
        y(1:n-1) = y(1:n-1) - 2 * x(2:n);
    end
end
```

When you enter

```
x1=run_symmlq;
```

MATLAB software displays the message

```
symmlq converged at iteration 49 to a solution with relative
residual 4.3e-015
```

### Example 3

Use a symmetric indefinite matrix that fails with pcg.

```
A = diag([20:-1:1,-1:-1:-20]);
b = sum(A,2);          % The true solution is the vector of all ones.
x = pcg(A,b);         % Errors out at the first iteration.
pcg stopped at iteration 1 without converging to the desired
tolerance 1e-006 because a scalar quantity became too small or
too large to continue computing.
The iterate returned (number 0) has relative residual 1
```

However, symmlq can handle the indefinite matrix A.

```
x = symmlq(A,b,1e-6,40);
symmlq converged at iteration 39 to a solution with relative
residual 1.3e-007
```

**Purpose** Sparse reverse Cuthill-McKee ordering

**Syntax** `r = symrcm(S)`

**Description** `r = symrcm(S)` returns the symmetric reverse Cuthill-McKee ordering of  $S$ . This is a permutation  $r$  such that  $S(r,r)$  tends to have its nonzero elements closer to the diagonal. This is a good reordering for LU or Cholesky factorization of matrices that come from long, skinny problems. The ordering works for both symmetric and nonsymmetric  $S$ .  
For a real, symmetric sparse matrix,  $S$ , the eigenvalues of  $S(r,r)$  are the same as those of  $S$ , but `eig(S(r,r))` probably takes less time to compute than `eig(S)`.

**Algorithms** The algorithm first finds a pseudoperipheral vertex of the graph of the matrix. It then generates a level structure by breadth-first search and orders the vertices by decreasing distance from the pseudoperipheral vertex. The implementation is based closely on the SPARSPAK implementation described by George and Liu.

**Examples** The statement

```
B = bucky;
```

uses a function in the `democs` toolbox to generate the adjacency graph of a truncated icosahedron. This is better known as a soccer ball, a Buckminster Fuller geodesic dome (hence the name `bucky`), or, more recently, as a 60-atom carbon molecule. There are 60 vertices. The vertices have been ordered by numbering half of them from one hemisphere, pentagon by pentagon; then reflecting into the other hemisphere and gluing the two halves together. With this numbering, the matrix does not have a particularly narrow bandwidth, as the first spy plot shows

```
subplot(1,2,1),spy(B),title('B')
```

The reverse Cuthill-McKee ordering is obtained with

```
p = symrcm(B);
R = B(p,p);
```

The spy plot shows a much narrower bandwidth.

```
subplot(1,2,2), spy(R), title('B(p,p)')
```

This example is continued in the reference pages for `symamd`.

The bandwidth can also be computed with

```
[i,j] = find(B);
bw = max(i-j) + 1;
```

The bandwidths of `B` and `R` are 35 and 12, respectively.

`colamd` | `colperm` | `symamd`

# symvar

---

**Purpose** Determine symbolic variables in expression

**Syntax**  
`symvar 'expr'`  
`s = symvar('expr')`

**Description** `symvar 'expr'` searches the expression, `expr`, for identifiers other than `i`, `j`, `pi`, `inf`, `nan`, `eps`, and common functions. `symvar` displays those variables that it finds or, if no such variable exists, displays an empty cell array, `{}`.

`s = symvar('expr')` returns the variables in a cell array of strings, `s`. If no such variable exists, `s` is an empty cell array.

**Examples** `symvar` finds variables `beta1` and `x`, but skips `pi` and the `cos` function.

```
symvar 'cos(pi*x - beta1)'
```

```
ans =
```

```
    'beta1'  
    'x'
```

**See Also** `strfind`

**Purpose** Two ways to call MATLAB functions

**Description** You can call MATLAB functions using either *command syntax* or *function syntax*, as described below.

### **Command Syntax**

A function call in this syntax consists of the function name followed by one or more arguments separated by spaces:

```
functionname arg1 arg2 ... argn
```

Command syntax does not allow you to obtain any values that might be returned by the function. Attempting to assign output from the function to a variable using command syntax generates an error. Use function syntax instead.

Examples of command syntax:

```
save mydata.mat x y z
import java.awt.Button java.lang.String
```

Arguments are treated as string literals. See the examples below, under “Argument Passing” on page 2-4520.

### **Function Syntax**

A function call in this syntax consists of the function name followed by one or more arguments separated by commas and enclosed in parentheses:

```
functionname(arg1, arg2, ..., argn)
```

You can assign the output of the function to one or more output values. When assigning to more than one output variable, separate the variables by commas or spaces and enclose them in square brackets ([ ]):

```
[out1,out2,...,outn] = functionname(arg1, arg2, ..., argn)
```

Examples of function syntax:

```
copyfile('srcfile', '..\mytests', 'writable')
[x1,x2,x3,x4] = deal(A{:})
```

Arguments are passed to the function by value. See the examples below, under “Argument Passing” on page 2-4520.

## Argument Passing

When calling a function using command syntax, MATLAB passes the arguments as string literals. When using function syntax, arguments are passed by value.

In the following example, assign a value to A and then call `disp` on the variable to display the value passed. Calling `disp` with command syntax passes the variable name, 'A':

```
A = pi;
disp A
    A
```

while function syntax passes the value assigned to A:

```
A = pi;
disp(A)
    3.1416
```

The next example passes two strings to `strcmp` for comparison. Calling the function with command syntax compares the variable names, 'str1' and 'str2':

```
str1 = 'one';    str2 = 'one';
strcmp str1 str2
ans =
    0           (unequal)
```

while function syntax compares the values assigned to the variables, 'one' and 'one':

```
str1 = 'one';    str2 = 'one';
strcmp(str1, str2)
```

```
ans =  
    1      (equal)
```

### Passing Strings

When using the function syntax to pass a string literal to a function, you must enclose the string in single quotes, ('string'). For example, to create a new folder called `myapptests`, use

```
mkdir('myapptests')
```

On the other hand, variables that contain strings do not need to be enclosed in quotes:

```
folder = 'myapptests';  
mkdir(folder)
```

### See Also

`mlint`

### How To

- “Check Code for Errors and Warnings”

# system

---

**Purpose** Execute operating system command and return result

**Syntax**

```
system('command')  
[status, result] = system('command')  
[status,result] = system('command', '-echo')
```

**Description** `system('command')` calls the operating system to run the given command and directs the output to the MATLAB software. The command executes in a system shell, which might not be the shell from which you launched MATLAB.

`[status, result] = system('command')` returns completion status to the `status` variable and returns the result of the command to the `result` variable.

`[status,result] = system('command', '-echo')` also forces the output to the Command Window.

The ampersand, `&`, character has special meaning. For console programs this causes the console to open. Omitting this character causes console programs to run iconically. For GUI programs, appending this character causes the application to run in the background. MATLAB continues processing.

This function is interchangeable with the `dos` and `unix` functions.

---

**Note** Running `system` on a Microsoft Windows platform with a command that relies on the current folder fails when the current folder is specified using a UNC pathname because DOS does not support UNC pathnames. When this happens, MATLAB displays:

Error using `system`

DOS commands may not be executed when the current directory is a UNC path

To work around this limitation, change the folder to a mapped drive prior to running `system` or a function that calls `system`.

---

**Examples**

On a Windows system, display the current folder by accessing the operating system.

```
[status currdir] = system('cd')
status =
    0
currdir =
    D:\work\matlab\test
```

---

On a UNIX system, if you redirect `stdin` in the script and type at the keyboard while the script executes, MATLAB does not display the type-ahead characters.

```
[a,b] = system('cmd < /dev/null');
```

`computer` | `dos` | `perl` | `unix` | ! (exclamation point)

**How To**

- “Running External Commands, Scripts, and Programs”

# tan

**Purpose** Tangent of argument in radians

**Syntax**  $Y = \tan(X)$

**Description** The tan function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

$Y = \tan(X)$  returns the circular tangent of each element of X.

**Examples** Graph the tangent function over the domain  $-\pi/2 < x < \pi/2$ .

```
x = (-pi/2)+0.01:0.01:(pi/2)-0.01;  
plot(x,tan(x)), grid on
```

The expression  $\tan(\pi/2)$  does not evaluate as infinite but as the reciprocal of the floating point accuracy `eps` since `pi` is only a floating-point approximation to the exact value of  $\pi$ .

# tand

---

## Tangent of vector of complex angles, specified in degrees

```
z = [180+i 15+2i 10+3i];  
y = tand(z)
```

```
y =
```

```
0 + 0.0175i    0.2676 + 0.0374i    0.1758 + 0.0539i
```

## See Also

[atand](#) | [tan](#) | [atan](#)

**Purpose** Hyperbolic tangent

**Syntax**  $Y = \tanh(X)$

**Description** The tanh function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.  
 $Y = \tanh(X)$  returns the hyperbolic tangent of each element of  $X$ .

**Examples** Graph the hyperbolic tangent function over the domain  $-5 \leq x \leq 5$ .

```
x = -5:0.01:5;  
plot(x,tanh(x)), grid on
```

# tar

---

## Purpose

Compress files into tar file

## Syntax

```
tar(tarfilename,files)  
tar(tarfilename,files,rootfolder)  
entrynames = tar(...)
```

## Description

`tar(tarfilename,files)` creates a tar file named *tarfilename* from the list of files and folders specified in *files*. Folders recursively include all of their content. If *files* includes relative paths, the tar file also contains relative paths. The tar file does not include absolute paths.

`tar(tarfilename,files,rootfolder)` specifies the path for *files* relative to *rootfolder* rather than the current folder. Relative paths in the tar file reflect the relative paths in *files*, and do not include path information from *rootfolder*.

`entrynames = tar(...)` returns a string cell array of the names of the files contained in *tarfilename*. If *files* includes relative paths, *entrynames* also contains relative paths.

## Tips

tar cannot compress folders larger than 2 GB.

## Input Arguments

### **tarfilename**

String specifying the name of the tar file. If *tarfilename* has no extension, MATLAB appends the `.tar` extension. The *tarfilename* extension can end in `.tgz` or `.gz`. In this case, *tarfilename* is gzipped.

### **files**

String or cell array of strings containing the list of files or folders included in *tarfilename*.

Individual files that are on the MATLAB path can be specified as partial path names. Otherwise an individual file can be specified relative to the current folder or with an absolute path.

Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with `~/` or `~username/`,

which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character \* can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.

**rootfolder**

String specifying the path for *files*.

**Examples**

Tar all files in the current folder to the file backup.tgz.

```
tar('backup.tgz', '.');
```

# tempdir

---

|                    |                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Name of system's temporary folder                                                                                                               |
| <b>Syntax</b>      | <code>tmp_folder = tempdir</code>                                                                                                               |
| <b>Description</b> | <code>tmp_folder = tempdir</code> returns the name of the system's temporary folder, if one exists. This function does not create a new folder. |
| <b>See Also</b>    | <code>delete</code>   <code>recycle</code>   <code>tempname</code>                                                                              |
| <b>How To</b>      | <ul style="list-style-type: none"><li>• “Creating Temporary Files”</li></ul>                                                                    |

**Purpose** Unique name for temporary file

**Syntax** `tmp_nam = tempname`

**Description** `tmp_nam = tempname` returns a unique string, `tmp_nam`, suitable for use as a temporary filename.

---

**Note** The filename that `tempname` generates is not guaranteed to be unique; however, it is likely to be so.

---

**See Also** `tempdir`

**How To** • “Creating Temporary Files”

# tetramesh

---

**Purpose** Tetrahedron mesh plot

**Syntax**

```
tetramesh(T,X,c)
tetramesh(T,X)
tetramesh(TR)
h = tetramesh(...)
tetramesh(...,'param','value','param','value'...)
```

**Description**

`tetramesh(T,X,c)` displays the tetrahedrons defined in the  $m$ -by-4 matrix  $T$  as mesh.  $T$  is usually the output of a Delaunay triangulation of a 3-D set of points. A row of  $T$  contains indices into  $X$  of the vertices of a tetrahedron.  $X$  is an  $n$ -by-3 matrix, representing  $n$  points in 3 dimension. The tetrahedron colors are defined by the vector  $C$ , which is used as indices into the current colormap.

`tetramesh(T,X)` uses  $C = 1:m$  as the color for the  $m$  tetrahedra. Each tetrahedron has a different color (modulo the number of colors available in the current colormap).

`tetramesh(TR)` displays the tetrahedra in a Triangulation representation.

`h = tetramesh(...)` returns a vector of tetrahedron handles. Each element of  $h$  is a handle to the set of patches forming one tetrahedron. You can use these handles to view a particular tetrahedron by turning the patch 'Visible' property 'on' or 'off'.

`tetramesh(...,'param','value','param','value'...)` allows additional patch property name/property value pairs to be used when displaying the tetrahedrons. For example, the default transparency parameter is set to 0.9. You can overwrite this value by using the property name/property value pair ('FaceAlpha',value) where value is a number between 0 and 1. See Patch Properties for information about the available properties.

**Examples** Generate a 3-D Delaunay triangulation, then use `tetramesh` to visualize the tetrahedrons that form the corresponding simplex.

```
d = [-1 1];
```

```
[x,y,z] = meshgrid(d,d,d); % A cube
x = [x(:);0];
y = [y(:);0];
z = [z(:);0];
% [x,y,z] are corners of a cube plus the center.
dt = DelaunayTri(x,y,z);
Tes = dt(:,:,);
X = [x(:) y(:) z(:)];
tetramesh(Tes,X);
camorbit(20,0)
```

You can also plot the Delaunay triangulation directly.

# tetramesh

---

```
close(gcf);  
tetramesh(dt);
```

## See Also

[trimesh](#) | [trisurf](#) | [patch](#) | [delaunayn](#) | [TriRep](#) | [TriRep.freeBoundary](#)

**Purpose**

Produce TeX format from character string

**Syntax**

```
texlabel(f)
texlabel(f, 'literal')
```

**Description**

`texlabel(f)` converts the MATLAB expression `f` into the TeX equivalent for use in text strings. It processes Greek variable names (e.g., `lambda`, `delta`, etc.) into a string that is displayed as actual Greek letters.

`texlabel(f, 'literal')` prints Greek variable names as literals.

If the string is too long to fit into a figure window, then the center of the expression is replaced with a tilde ellipsis (~~~).

**Examples**

You can use `texlabel` as an argument to the `title`, `xlabel`, `ylabel`, `zlabel`, and `text` commands. For example,

```
figure
title(texlabel('sin(sqrt(x^2 + y^2))/sqrt(x^2 + y^2)'))
```

By default, `texlabel` translates Greek variable names to the equivalent Greek letter. You can select literal interpretation by including the `literal` argument. For example, compare these two commands.

```
text(.5,.5,...
      texlabel('lambda12^(3/2)/pi - pi*delta^(2/3)'))
text(.25,.25,...
      texlabel('lambda12^(3/2)/pi - pi*delta^(2/3)', 'literal'))
```

# textlabel

---

## See Also

text | title | xlabel | ylabel | zlabel | String

**Purpose**

Create text object in current axes

**Syntax**

```
text(x,y,'string')
text(x,y,z,'string')
text(x,y,z,'string','PropertyName',PropertyValue....)
text('PropertyName',PropertyValue....)
h = text(...)
```

**Properties**

For a list of properties, see [Text Properties](#).

**Description**

`text` is the low-level function for creating text graphics objects. Use `text` to place character strings at specified locations.

`text(x,y,'string')` adds the string in quotes to the location specified by the point  $(x,y)$   $x$  and  $y$  must be numbers of class `double`.

`text(x,y,z,'string')` adds the string in 3-D coordinates.  $x$ ,  $y$  and  $z$  must be numbers of class `double`.

`text(x,y,z,'string','PropertyName',PropertyValue....)` adds the string in quotes to the location defined by the coordinates and uses the values for the specified text properties. For a description of the properties, see [Text Properties](#).

`text('PropertyName',PropertyValue....)` omits the coordinates entirely and specifies all properties using property name/property value pairs.

`h = text(...)` returns a column vector of handles to text objects, one handle per object. All forms of the `text` function optionally return this output argument.

See the [String](#) property for a list of symbols, including Greek letters.

**Tips****Position Text Within the Axes**

The default text units are the units used to plot data in the graph. Specify the text location coordinates (the  $x$ ,  $y$ , and  $z$  arguments) in the data units of the current graph (see “Examples” on page 2-4539). You can use other units to position the text by setting the `text Units`

property to normalized or one of the nonrelative units (pixels, inches, centimeters, points, or characters).

Note that the Axes Units property controls the positioning of the Axes within the figure and is not related to the axes data units used for graphing.

The Extent, VerticalAlignment, and HorizontalAlignment properties control the positioning of the character string with regard to the text location point.

If the coordinates are vectors, text writes the string at all locations defined by the list of points. If the character string is an array the same length as x, y, and z, text writes the corresponding row of the string array at each point specified.

## **Multiline Text**

When specifying strings for multiple text objects, the string can be:

- A cell array of strings
- A padded string matrix

Each element of the specified string array creates a different text object.

When specifying the string for a single text object, cell arrays of strings and padded string matrices result in a text object with a multiline string, while vertical slash characters are not interpreted as separators and result in a single line string containing vertical slashes.

## **Behavior of the Text Function**

text is a low-level function that accepts property name/property value pairs as input arguments. However, the convenience form:

```
text(x,y,z,'string')
```

is equivalent to:

```
text('Position',[x,y,z],'String','string')
```

---

You can specify other properties only as property name/property value pairs. For a description of each property, see `Text Properties`. You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see the `set` and `get` reference pages for examples of how to specify these data types).

`text` does not respect the setting of the figure or axes `NextPlot` property. This allows you to add text objects to an existing axes without setting `hold` to `on`.

## Examples

Annotate the point  $(\pi, 0)$  with the string  $\sin(\pi)$  on the following graph:

```
plot(0:pi/20:2*pi,sin(0:pi/20:2*pi))
text(pi,0,' \leftarrow sin(\pi)', 'FontSize', 18)
```

Use embedded TeX sequences to display an equation:

```
axes
text(0.5,0.5,'\ite^{i\omega\tau} = \cos(\omega\tau) + i \sin(\omega\tau)')
```

MATLAB displays:

$$e^{i\omega\tau} = \cos(\omega\tau) + i \sin(\omega\tau)$$

## Setting Default Properties

You can set default text properties on the axes, figure, and root object levels:

```
set(0, 'DefaulttextProperty', PropertyValue...)  
set(gcf, 'DefaulttextProperty', PropertyValue...)  
set(gca, 'DefaulttextProperty', PropertyValue...)
```

Where *Property* is the name of the text property and *PropertyValue* is the value you are specifying. Use `set` and `get` to access text properties.

# Text Properties

---

**Purpose** Text properties

**Creating Text Objects** Use text to create text objects.

**Modifying Properties** You can set and query graphics object properties using the property editor or the set and get commands.

- Property Editor is an interactive tool that enables you to see and change object property values.
- The set and get commands enable you to set and query the values of properties.

To change the default values of properties, see [Setting Default Property Values](#).

See [Core Objects](#) for general information about this type of object.

**Text Property Descriptions** This section provides a description of properties. Curly braces { } enclose default values.

Annotation

hg.Annotation object (read-only)

*Handle of Annotation object.* The Annotation property enables you to specify whether this text object is represented in a figure legend.

Querying the Annotation property returns the handle of an hg.Annotation object. The hg.Annotation object has a property called LegendInformation, which contains an hg.LegendEntry object.

Once you have obtained the hg.LegendEntry object, you can set its IconDisplayStyle property to control whether the text object is displayed in a figure legend:

| IconDisplayStyle Value | Purpose                                              |
|------------------------|------------------------------------------------------|
| on                     | Represent this text object in a legend (default)     |
| off                    | Do not include this text object in a legend          |
| children               | Same as on because text objects do not have children |

## Setting the IconDisplayStyle property

Set the IconDisplayStyle of a graphics object with handle `hobj` to off:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'off')
```

## Using the IconDisplayStyle property

See “Controlling Legends” for more information and examples.

`BackgroundColor`  
`ColorSpec | {none}`

*Color of text extent rectangle.* Defines a color for the rectangle that encloses the text Extent plus the text Margin. For example, the following code creates a text object that labels a plot and sets the background color to light green.

```
text(3*pi/4, sin(3*pi/4), ...  
 ['sin(3*pi/4) = ', num2str(sin(3*pi/4))], ...  
 'HorizontalAlignment', 'center', ...  
 'BackgroundColor', [.7 .9 .7]);
```

# Text Properties

---

For additional features, see the following properties:

- `EdgeColor` — Color of the rectangle's edge (none by default).
- `LineStyle` — Style of the rectangle's edge line (first set `EdgeColor`)
- `LineWidth` — Width of the rectangle's edge line (first set `EdgeColor`)
- `Margin` — Increase the size of the rectangle by adding a margin to the existing text extent rectangle. This margin is added to the text extent rectangle to define the text background area that is enclosed by the `EdgeColor` rectangle. Note that the text extent does not change when you change the margin; only the rectangle displayed when you set the `EdgeColor` property and the area defined by the `BackgroundColor` change.

See also [Drawing Text in a Box](#) in the MATLAB Graphics documentation for an example using background color with contour labels.

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

## BusyAction

cancel | {queue}

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

# Text Properties

---

## ButtonDownFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over the text object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

Set this property to a function handle that references the callback. The function must define at least two input arguments (handle of object associated with the button down event and an event structure, which is empty for this property).

The following example shows how to access the callback object's handle as well as the handle of the figure that contains the object from the callback function.

```
function button_down(src, evnt)
% src - the object that is the source of the event
% evnt - empty for this property
    sel_typ = get(gcf, 'SelectionType')
    switch sel_typ
        case 'normal'
            disp('User clicked left-mouse button')
            set(src, 'Selected', 'on')
        case 'extend'
            disp('User did a shift-click')
            set(src, 'Selected', 'on')
        case 'alt'
            disp('User did a control-click')
            set(src, 'Selected', 'on')
            set(src, 'SelectionHighlight', 'off')
    end
end
```

Suppose `h` is the handle of a text object and the `button_down` function is on your MATLAB path. The following statement assigns the `button_down` function to the `ButtonDownFcn` property:

```
set(h, 'ButtonDownFcn', @button_down)
```

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## Children

matrix (read-only)

The empty matrix; text objects have no children.

## Clipping

on | {off}

*Clipping mode.* When `Clipping` is on, MATLAB does not display any portion of the text that is outside the axes.

## Color

ColorSpec

*Text color.* A three-element RGB vector or one of the predefined names, specifying the text color. The default value is `[0 0 0]` (black). See the `ColorSpec` reference page for more information on specifying color.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Executes when MATLAB creates a text object. You must define this property as a default value for `text` or in a call to the `text` function that creates a new text object. For example, the statement:

```
set(0, 'DefaultTextCreateFcn', @text_create)
```

# Text Properties

---

defines a default value on the root level that sets the figure Pointer property to crosshairs whenever you create a text object. The callback function must be on your MATLAB path when you execute the above statement.

```
function text_create(src,evnt)
% src - the object that is the source of the event
% evnt - empty for this property
    set(gcf,'Pointer','crosshair')
end
```

MATLAB executes this function after setting all text properties. Setting this property on an existing text object has no effect. The function must define at least two input arguments (handle of object created and an event structure, which is empty for this property).

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Delete text callback function.* Executes when you delete the text object (for example, when you issue a `delete` command or clear the axes `cla` or figure `clf`).

For example, the following function displays object property data before the object is deleted.

```
function delete_fcn(src,evnt)
% src - the object that is the source of the event
```

```
% evt - empty for this property
    obj_tp = get(src,'Type');
    disp([obj_tp, ' object deleted'])
    disp('Its user data is:')
    disp(get(src,'UserData'))
end
```

MATLAB executes the function before deleting the object's properties so these values are available to the callback function. The function must define at least two input arguments (handle of object being deleted and an event structure, which is empty for this property).

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

**DisplayName**  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the text object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where  $n$  is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.

# Text Properties

---

- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more information and examples.

## EdgeColor

ColorSpec | {none}

*Color of edge drawn around text extent rectangle plus margin.*  
Specifies the color of a box drawn around the text `Extent` plus the text `Margin`. For example, the following code draws a red rectangle around text that labels a plot.

```
text(3*pi/4,sin(3*pi/4),...  
'\leftarrow sin(t) = .707',...  
'EdgeColor','red');
```

For additional features, see the following properties:

- **BackgroundColor** — Color of the rectangle's interior (none by default)
- **LineStyle** — Style of the rectangle's edge line (first set **EdgeColor**)
- **LineWidth** — Width of the rectangle's edge line (first set **EdgeColor**)
- **Margin** — Increases the size of the rectangle by adding a margin to the area defined by the text extent rectangle. This margin is added to the text extent rectangle to define the text background area that is enclosed by the **EdgeColor** rectangle. Note that the text extent does not change when you change the margin; only the rectangle displayed when you set the **EdgeColor** property and the area defined by the **BackgroundColor** change.

## Editing

on | {off}

*Enable or disable editing mode.* When this property is off (the default), you cannot edit the text string interactively (i.e., you must change the **String** property to change the text). When this property is on, MATLAB places an insert cursor at the end of the text string and enables editing. To apply the new text string,

- 1 Press the **Esc** key.
- 2 Click in any figure window (including the current figure).
- 3 Reset the **Editing** property to off.

MATLAB then updates the **String** property to contain the new text and resets the **Editing** property to off. You must reset the **Editing** property to on to resume editing.

## EraseMode

{normal} | none | xor | background

*Erase mode.* Controls the technique MATLAB uses to draw and erase text objects. Alternative erase modes are useful for creating animated sequences where controlling the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- **normal** — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- **none** — Do not erase the text when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- **xor** — Draw and erase the text by performing an exclusive OR (XOR) with each pixel index of the screen beneath it. When the text is erased, it does not damage the objects beneath it. However, when text is drawn in `xor` mode, its color depends on the color of the screen beneath it. It is correctly colored only when it is over axes background `Color`, or the figure background `Color` if the axes `Color` is `none`.
- **background** — Erase the text by drawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` is `none`. This damages objects that are behind the erased text, but text is always properly colored.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting

to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Extent

position rectangle (read-only)

*Position and size of text.* A four-element vector that defines the size and position of the text string:

```
[left,bottom,width,height]
```

If the `Units` property is `data` (the default), `left` and `bottom` are the  $x$ - and  $y$ -coordinates of the lower left corner of the text `Extent`.

For all other values of `Units`, `left` and `bottom` are the distance from the lower left corner of the axes `Position` rectangle to the lower left corner of the text `Extent`. `width` and `height` are the dimensions of the `Extent` rectangle. All measurements are in units specified by the `Units` property.

## FontAngle

```
{normal} | italic | oblique
```

*Character slant.* MATLAB uses this property to select a font from those available on your particular system. Generally, setting this property to `italic` or `oblique` selects a slanted font.

## FontName

```
name (such as Courier) | FixedWidth
```

*Font family.* Specifies the name of the font to use for the text object. To display and print properly, this must be a font that your system supports. The default font is `Helvetica`.

## Specifying a Fixed-Width Font

If you want text to use a fixed-width font that looks good in any locale, you should set `FontName` to the string `FixedWidth`:

```
set(text_handle, 'FontName', 'FixedWidth')
```

This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding (such as in Japan where multibyte character sets are used). A properly written MATLAB application that needs to use a fixed-width font should set `FontName` to `FixedWidth` (note that this string is case sensitive) and rely on `FixedWidthFontName` to be set correctly in the end user's environment.

End users can adapt a MATLAB application to different locales or personal environments by setting the root `FixedWidthFontName` property to the appropriate value for that locale from `startup.m`.

Note that setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

### FontSize

size in `FontUnits`

*Font size.* Specifies the font size to use for text in units determined by the `FontUnits` property. The default is 10 points. 1 point =  $1/72$  inch.

### FontWeight

{normal} | bold | light | demi

*Weight of text characters.* MATLAB uses this property to select a font from those available on your particular system. Generally, setting this property to `bold` or `demi` causes MATLAB to use a bold font.

## FontUnits

{points} | normalized | inches | centimeters | pixels

*Font size units.* MATLAB uses this property to determine the units used by the `FontSize` property.

- `normalized` — Interpret `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `FontSize` accordingly.
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point =  $\frac{1}{72}$  inch.

Note that if you are setting both the `FontSize` and the `FontUnits` in one function call, you must set the `FontUnits` property first so that MATLAB can correctly interpret the specified `FontSize`.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

# Text Properties

---

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`,

- The object's handle does not appear in its parent's `Children` property.
- Figures do not appear in the root's `CurrentFigure` property.
- Objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property.
- Axes do not appear in their parent's `CurrentAxes` property.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

## HitTest

`{on} | off`

*Selectable by mouse click.* Determines if the text can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the text. If `HitTest` is `off`, clicking the text selects the object below it (which is usually the axes containing it).

For example, suppose you define the button down function of an image (see the `ButtonDownFcn` property) to display text at the location you click with the mouse.

First define the callback routine.

```
function bd_function
pt = get(gca,'CurrentPoint');
text(pt(1,1),pt(1,2),pt(1,3),...
'\fontsize{20}\oplus The spot to label',...
'HitTest','off')
```

Now display an image, setting its `ButtonDownFcn` property to the callback routine.

```
load earth
image(X,'ButtonDownFcn','bd_function'); colormap(map)
```

When you click the image, MATLAB displays the text string at that location. With `HitTest` set to `off`, existing text cannot intercept any subsequent button down events that occur over the text. This enables the image's button down function to execute.

`HorizontalAlignment`  
{left} | center | right

*Horizontal alignment of text.* Specifies the horizontal justification of the text string. It determines where MATLAB places the string with regard to the point specified by the `Position` property. The following picture illustrates the alignment options.

`HorizontalAlignment` viewed with the `VerticalAlignment` set to **middle** (the default).

See the `Extent` property for related information.

See “Text Alignment” for more information and examples.

# Text Properties

---

## Interpreter

latex | {tex} | none

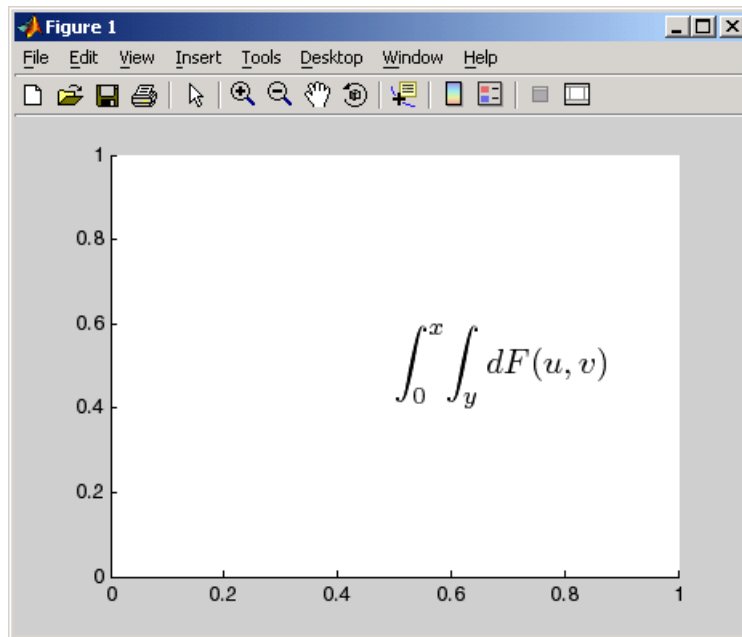

*Interpret TeXinstructions.* Controls whether MATLAB interprets certain characters in the **String** property as TeX instructions (default) or displays all characters literally.

- **latex** — Supports a basic subset of the LaTeX markup language.
- **tex** — Supports a subset of plain TeX markup language. See the **String** property for a list of supported TeX instructions.
- **none** — Displays literal characters.

## LaTeX Interpreter

To enable the LaTeX interpreter for text objects, set the **Interpreter** property to **latex**. For example, the following statement displays an equation in a figure at the point [.5 .5], and enlarges the font to 16 points.

```
text('Interpreter','latex',...  
    'String','$$\int_0^x \! \int_y dF(u,v)$$',...  
    'Position',[.5 .5],...  
    'FontSize',16)
```

---

**Note** The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, reduce this amount by about 10 characters per line.

---

## Information About Using TeX

The following references may be useful to people who are not familiar with TeX.

- Donald E. Knuth, *The TeXbook*, Addison Wesley, 1986.
- The TeX Users Group home page: <http://www.tug.org>

Interruptible  
off | {on}

## *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to `on` (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

## LineStyle

{-} | -- | : | -. | none

*Edge line type.* Specifies the line style used to draw the edges of the text `Extent`.

## Line Style Specifiers Table

| Specifier | Line Style           |
|-----------|----------------------|
| '-'       | Solid line (default) |
| '--'      | Dashed line          |
| ':'       | Dotted line          |
| '-.'      | Dash-dot line        |
| 'none'    | No line              |

For example, the following code draws a red rectangle with a dotted line style around text that labels a plot.

```
text(3*pi/4,sin(3*pi/4),...
     '\leftarrow sin(t) = .707',...
     'EdgeColor','red',...
     'LineWidth',2,...
     'LineStyle',':');
```

# Text Properties

---

For additional features, see the following properties:

- `BackgroundColor` — Color of the rectangle's interior (none by default)
- `EdgeColor` — Color of the rectangle's edge (none by default)
- `LineWidth` — Width of the rectangle's edge line (first set `EdgeColor`)
- `Margin` — Increases the size of the rectangle by adding a margin to the existing text extent rectangle. This margin is added to the text extent rectangle to define the text background area that is enclosed by the `EdgeColor` rectangle. Note that the text extent does not change when you change the margin; only the rectangle displayed when you set the `EdgeColor` property and the area defined by the `BackgroundColor` change.

`LineWidth`  
scalar (points)

*Width of line used to draw text extent rectangle.* When you set the text `EdgeColor` property to a color (the default is none), MATLAB displays a rectangle around the text `Extent`. Use the `LineWidth` property to specify the width of the rectangle edge. For example, the following code draws a red rectangle around text that labels a plot and specifies a line width of 3 points:

```
text(3*pi/4,sin(3*pi/4),...  
'\leftarrow sin(t) = .707',...  
'EdgeColor','red',...  
'LineWidth',3);
```

For additional features, see the following properties:

- `BackgroundColor` — Color of the rectangle's interior (none by default)
- `EdgeColor` — Color of the rectangle's edge (none by default)
- `LineStyle` — Style of the rectangle's edge line (first set `EdgeColor`)

# Text Properties

---

- **Margin** — Increases the size of the rectangle by adding a margin to the existing text extent rectangle. This margin is added to the text extent rectangle to define the text background area that is enclosed by the `EdgeColor` rectangle. Note that the text extent does not change when you change the margin; only the rectangle displayed when you set the `EdgeColor` property and the area defined by the `BackgroundColor` change.

## Margin

scalar (pixels)

*Distance between the text extent and the rectangle edge.* When you specify a color for the `BackgroundColor` or `EdgeColor` text properties, MATLAB draws a rectangle around the area defined by the text `Extent` plus the value specified by the `Margin`. For example, the following code displays a light green rectangle with a 10-pixel margin.

```
text(5*pi/4,sin(5*pi/4),...  
    ['sin(5*pi/4) = ',num2str(sin(5*pi/4))],...  
    'HorizontalAlignment','center',...  
    'BackgroundColor',[.7 .9 .7],...  
    'Margin',10);
```

For additional features, see the following properties:

- **BackgroundColor** — Color of the rectangle's interior (none by default)
- **EdgeColor** — Color of the rectangle's edge (none by default)
- **LineStyle** — Style of the rectangle's edge line (first set **EdgeColor**)
- **LineWidth** — Width of the rectangle's edge line (first set **EdgeColor**)

## See how margin affects text extent properties

This example enables you to change the values of the **Margin** property and observe the effects on the **BackgroundColor** area and the **EdgeColor** rectangle.

[Click to view in editor](#) — This link opens the MATLAB editor with the following example.

[Click to run example](#) — Use your scroll wheel to vary the **Margin**.

# Text Properties

---

## Parent

handle of axes, hggroup, or hgtransform

*Parent of text object.* Handle of the text object's parent. The parent of a text object is the axes, hggroup, or hgtransform object that contains it.

See “Objects That Can Contain Other Objects” for more information on parenting graphics objects.

## Position

[x,y,[z]]

*Location of text.* A two- or three-element vector, [x y [z]], that specifies the location of the text in three dimensions. If you omit the z value, it defaults to 0. All measurements are in units specified by the Units property. Initial value is [0 0 0].

## Rotation

scalar (default = 0)

*Text orientation.* Determines the orientation of the text string. Specify values of rotation in degrees (positive angles cause counterclockwise rotation).

## Selected

on | {off}

*Is object selected?* When this property is on, MATLAB displays selection handles if the SelectionHighlight property is also set to on. You can, for example, define the ButtonDownFcn to set this property, allowing users to select the object with the mouse.

## SelectionHighlight

{on} | off

*Objects are highlighted when selected.* When the Selected property is on, MATLAB indicates the selected state by

drawing four edge handles and four corner handles. When `SelectionHighlight` is off, MATLAB does not draw the handles.

String  
string

*Text string.* Specify this property as a quoted string for single-line strings, or as a cell array of strings, or a padded string matrix for multiline strings. MATLAB displays this string at the specified location. Vertical slash characters are not interpreted as line breaks in text strings, and are drawn as part of the text string. See *Mathematical Symbols*, *Greek Letters*, and *TeX Characters* for an example.

---

**Note** The words `default`, `factory`, and `remove` are reserved words that will not appear in a figure when quoted as a normal string. In order to display any of these words individually, type `'\reserved_word'` instead of `'reserved_word'`.

---

When the text `Interpreter` property is `tex` (the default), you can use a subset of TeX commands embedded in the string to produce special characters such as Greek letters and mathematical symbols. The following table lists these characters and the character sequences used to define them.

**TeX Character Sequence Table**

| Character Sequence  | Symbol   | Character Sequence    | Symbol     | Character Sequence     | Symbol      |
|---------------------|----------|-----------------------|------------|------------------------|-------------|
| <code>\alpha</code> | $\alpha$ | <code>\upsilon</code> | $\upsilon$ | <code>\sim</code>      | $\sim$      |
| <code>\angle</code> | $\angle$ | <code>\phi</code>     | $\Phi$     | <code>\leq</code>      | $\leq$      |
| <code>\ast</code>   | $*$      | <code>\chi</code>     | $\chi$     | <code>\infty</code>    | $\infty$    |
| <code>\beta</code>  | $\beta$  | <code>\psi</code>     | $\psi$     | <code>\clubsuit</code> | $\clubsuit$ |

# Text Properties

| Character Sequence     | Symbol      | Character Sequence     | Symbol      | Character Sequence            | Symbol            |
|------------------------|-------------|------------------------|-------------|-------------------------------|-------------------|
| <code>\gamma</code>    | $\Upsilon$  | <code>\omega</code>    | $\omega$    | <code>\diamondsuit</code>     | $\blacklozenge$   |
| <code>\delta</code>    | $\delta$    | <code>\Gamma</code>    | $\Gamma$    | <code>\heartsuit</code>       | $\heartsuit$      |
| <code>\epsilon</code>  | $\epsilon$  | <code>\Delta</code>    | $\Delta$    | <code>\spadesuit</code>       | $\spadesuit$      |
| <code>\zeta</code>     | $\zeta$     | <code>\Theta</code>    | $\Theta$    | <code>\leftrightharrow</code> | $\leftrightarrow$ |
| <code>\eta</code>      | $\eta$      | <code>\Lambda</code>   | $\Lambda$   | <code>\leftarrow</code>       | $\leftarrow$      |
| <code>\theta</code>    | $\Theta$    | <code>\Xi</code>       | $\Xi$       | <code>\Leftarrow</code>       | $\Leftarrow$      |
| <code>\vartheta</code> |             | <code>\Pi</code>       | $\Pi$       | <code>\uparrow</code>         | $\uparrow$        |
| <code>\iota</code>     | $\iota$     | <code>\Sigma</code>    | $\Sigma$    | <code>\rightarrow</code>      | $\rightarrow$     |
| <code>\kappa</code>    | $\kappa$    | <code>\Upsilon</code>  |             | <code>\Rightarrow</code>      | $\Rightarrow$     |

| <code>\sigma</code>    | $\sigma$    | <code>\cong</code>     | $\cong$     | <code>\bullet</code>          | $\bullet$         |
| <code>\varsigma</code> | $\varsigma$ | <code>\approx</code>   | $\approx$   | <code>\div</code>             | $\div$            |
| <code>\tau</code>      | $\tau$      | <code>\Re</code>       | $\Re$       | <code>\neq</code>             | $\neq$            |
| <code>\equiv</code>    | $\equiv$    | <code>\oplus</code>    | $\oplus$    | <code>\aleph</code>           |                   |
| <code>\Im</code>       | $\Im$       | <code>\cup</code>      | $\cup$      | <code>\wp</code>              | $\wp$             |
| <code>\otimes</code>   | $\otimes$   | <code>\subseteq</code> | $\subseteq$ | <code>\oslash</code>          | $\oslash$         |

| Character Sequence   | Symbol    | Character Sequence   | Symbol    | Character Sequence      | Symbol       |
|----------------------|-----------|----------------------|-----------|-------------------------|--------------|
| <code>\cap</code>    | $\cap$    | <code>\in</code>     | $\in$     | <code>\supseteq</code>  | $\supseteq$  |
| <code>\supset</code> | $\supset$ | <code>\lceil</code>  | $\lceil$  | <code>\subset</code>    | $\subset$    |
| <code>\int</code>    | $\int$    | <code>\cdot</code>   | $\cdot$   | <code>\o</code>         | $\circ$      |
| <code>\rfloor</code> | $\rfloor$ | <code>\neg</code>    | $\neg$    | <code>\nabla</code>     | $\nabla$     |
| <code>\lfloor</code> | $\lfloor$ | <code>\times</code>  | $\times$  | <code>\ldots</code>     | $\dots$      |
| <code>\perp</code>   | $\perp$   | <code>\surd</code>   | $\surd$   | <code>\prime</code>     | $'$          |
| <code>\wedge</code>  | $\wedge$  | <code>\varpi</code>  | $\varpi$  | <code>\0</code>         | $\emptyset$  |
| <code>\rceil</code>  | $\rceil$  | <code>\rangle</code> | $\rangle$ | <code>\mid</code>       | $ $          |
| <code>\vee</code>    | $\vee$    |                      |           | <code>\copyright</code> | $\copyright$ |
| <code>\langle</code> | $\langle$ |                      |           |                         |              |

You can also specify stream modifiers that control font type and color. The first four modifiers are mutually exclusive. However, you can use `\fontname` in combination with one of the other modifiers:

- `\bf` — Bold font
- `\it` — Italic font
- `\sl` — Oblique font (rarely available)
- `\rm` — Normal font
- `\fontname{fontname}` — Specify the name of the font family to use.
- `\fontsize{fontsize}` — Specify the font size in FontUnits.

# Text Properties

---

- `\color{colorSpec}` — Specify color for succeeding characters

Stream modifiers remain in effect until the end of the string or only within the context defined by braces `{ }`.

## Specifying Text Color in TeX Strings

Use the `\color` modifier to change the color of characters following it from the previous color (which is black by default). Syntax is:

- `\color{colorname}` — Use for the eight basic named colors (red, green, yellow, magenta, blue, black, white), and plus the four Simulink colors (gray, darkGreen, orange, and lightBlue).

Note that short names (one-letter abbreviations) for colors are not supported by the `\color` modifier.

- `\color[rgb]{r g b}` — Use to specify an RGB triplet with values between 0 and 1 as a cell array

For example:

```
text(.1,.5,['\fontsize{16}black {\color{magenta}magenta '...  
'\color[rgb]{0 .5 .5}teal \color{red}red} black again'])
```

## Specifying Subscript and Superscript Characters

The subscript character “`_`” and the superscript character “`^`” modify the character or substring defined in braces immediately following.

To print the special characters used to define the TeX strings when `Interpreter` is `tex`, prefix them with the backslash “`\`” character: `\\`, `\{`, `\}`, `\_`, `\^`.

See the “Examples” on page 2-4539 in the text reference page for more information.

When `Interpreter` is `none`, no characters in the `String` are interpreted, and all are displayed when the text is drawn.

When `Interpreter` is `latex`, MATLAB provides a complete LaTeX interpreter for text objects. See the `Interpreter` property for more information.

# Text Properties

---

## Tag

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

## Type

string (read-only)

*Class of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For text objects, `Type` is always `'text'`.

## UIContextMenu

handle of `uicontextmenu` object

*Associate a context menu with the text.* The handle of a `uicontextmenu` object created in the same figure as the text. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the text.

## Units

pixels | normalized | inches |  
| characters | centimeters | points | {data}

*Units of measurement.* Specifies the units MATLAB uses to interpret the `Extent` and `Position` properties. All units are measured from the lower left corner of the axes plot box.

- `normalized` — Units map the lower left corner of the rectangle defined by the axes to (0,0) and the upper right corner to (1.0,1.0).
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point =  $\frac{1}{72}$  inch.

- **characters** — Based on the size of characters in the default system font. The width of one characters unit is the width of the letter x, and the height of one characters unit is the distance between the baselines of two lines of text.
- **data** — Data units of the parent axes as determined by the data graphed (not the axes Units property, which controls the positioning of the axes within the figure window).

If you change the value of Units, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume Units is set to the default value.

## UserData

matrix

*User-specified data.* Data you want to associate with the text object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## VerticalAlignment

top | cap | {middle} | baseline |  
bottom

*Vertical alignment of text.* Specifies the vertical justification of the text string. It determines where MATLAB places the string vertically with regard to the points specified by the Position property.

- **top** — Place the top of the string's Extent rectangle at the specified y-position.
- **cap** — Place the string so that the top of a capital letter is at the specified y-position.
- **middle** — Place the middle of the string at the specified y-position.
- **baseline** — Place font baseline at the specified y-position.

# Text Properties

---

- `bottom` — Place the bottom of the string’s Extent rectangle at the specified *y*-position.

The following picture illustrates the alignment options.

**Text VerticalAlignment property viewed with the HorizontalAlignment property set to left (the default).**

See “Text Alignment” for more information and examples.

`Visible`  
{on} | off

*Text visibility.* By default, all text is visible. When set to `off`, the text is not visible, but still exists, and you can query and set its properties.

**See Also**      `text`

**Purpose** Read data from text file; write to multiple outputs

---

**Note** textread is not recommended. Use textscan instead.

---

**Syntax**

```
[A,B,C,...] = textread(filename,format)
[A,B,C,...] = textread(filename,format,N)
[...] = textread(...,param,value,...)
```

**Description** [A,B,C,...] = textread(filename,format) reads data from the file filename into the variables A,B,C, and so on, using the specified format, until the entire file is read. The filename and format inputs are strings, each enclosed in single quotes. textread is useful for reading text files with a known format. textread handles both fixed and free format files.

---

**Note** When reading large text files, reading from a specific point in a file, or reading file data into a cell array rather than multiple outputs, you might prefer to use the textscan function.

---

textread matches and converts groups of characters from the input. Each input field is defined as a string of non-white-space characters that extends to the next white-space or delimiter character, or to the maximum field width. Repeated delimiter characters are significant, while repeated white-space characters are treated as one.

The format string determines the number and types of return arguments. The number of return arguments is the number of items in the format string. The format string supports a subset of the conversion specifiers and conventions of the C language fscanf routine. Values for the format string are listed in the table below. White-space characters in the format string are ignored.

| format                            | Action                                                                                                                                                                                         | Output                |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| Literals<br>(ordinary characters) | Ignore the matching characters. For example, in a file that has Dept followed by a number (for department number), to skip the Dept and read only the number, use 'Dept' in the format string. | None                  |
| %d                                | Read a signed integer value.                                                                                                                                                                   | Double array          |
| %u                                | Read an integer value.                                                                                                                                                                         | Double array          |
| %f                                | Read a floating-point value.                                                                                                                                                                   | Double array          |
| %s                                | Read a white-space or delimiter-separated string.                                                                                                                                              | Cell array of strings |
| %q                                | Read a double quoted string, ignoring the quotes.                                                                                                                                              | Cell array of strings |
| %c                                | Read characters, including white space.                                                                                                                                                        | Character array       |
| %[...]                            | Read the longest string containing characters specified in the brackets.                                                                                                                       | Cell array of strings |
| %[^...]                           | Read the longest nonempty string containing characters that are not specified in the brackets.                                                                                                 | Cell array of strings |
| %*...<br>instead of %             | Ignore the matching characters specified by *.                                                                                                                                                 | No output             |
| %w...<br>instead of %             | Read field width specified by w. The %f format supports %w.pf, where w is the field width and p is the precision.                                                                              |                       |

[A,B,C,...] = textread(filename,format,N) reads the data, reusing the format string N times, where N is an integer greater than zero. If N is smaller than zero, textread reads the entire file.

[...] = textread(...,param,value,...) customizes textread using param/value pairs, as listed in the table below.

| param        | value                                                                                                                                                                | Action                                                                    |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|
| bufsize      | Positive integer                                                                                                                                                     | Specifies the maximum string length, in bytes. Default is 4095.           |
| commentstyle | matlab                                                                                                                                                               | Ignores characters after %.                                               |
| commentstyle | shell                                                                                                                                                                | Ignores characters after #.                                               |
| commentstyle | c                                                                                                                                                                    | Ignores characters between /* and */.                                     |
| commentstyle | c++                                                                                                                                                                  | Ignores characters after //.                                              |
| delimiter    | One or more characters                                                                                                                                               | Act as delimiters between elements. Default is none.                      |
| emptyvalue   | Scalar double                                                                                                                                                        | Value given to empty cells when reading delimited files. Default is 0.    |
| endofline    | Single character or '\r\n'                                                                                                                                           | Character that denotes the end of a line. Default is determined from file |
| expchars     | Exponent characters                                                                                                                                                  | Default is eEdD.                                                          |
| headerlines  | Positive integer                                                                                                                                                     | Ignores the specified number of lines at the beginning of the file.       |
| whitespace   | Any from the list below:<br>' '           Space<br>\b            Backspace<br>\n            Newline<br>\r            Carriage return<br>\t            Horizontal tab | Treats vector of characters as white space. Default is '\b\t'.            |

---

**Note** When `textread` reads a consecutive series of `whitespace` values, it treats them as one white space. When it reads a consecutive series of `delimiter` values, it treats each as a separate delimiter.

---

## Tips

If you want to preserve leading and trailing spaces in a string, use the `whitespace` parameter as shown here:

```
textread('myfile.txt', '%s', 'whitespace', '')
ans =
    '  An example      of preserving  spaces  '
```

## Examples

### Example 1 – Read All Fields in Free Format File Using %

The first line of `mydata.dat` is

```
Sally   Level1 12.34 45 Yes
```

Read the first line of the file as a free format file using the % format.

```
[names, types, x, y, answer] = textread('mydata.dat', ...
    '%s %s %f %d %s', 1)
```

returns

```
names =
    'Sally'
types =
    'Level1'
x =
    12.340000000000000
y =
    45
answer =
    'Yes'
```

### Example 2 – Read as Fixed Format File, Ignoring the Floating Point Value

The first line of `mydata.dat` is

```
Sally   Level1 12.34 45 Yes
```

Read the first line of the file as a fixed format file, ignoring the floating-point value.

```
[names, types, y, answer] = textread('mydata.dat', ...  
'%9c %6s %*f %2d %3s', 1)
```

returns

```
names =  
Sally  
types =  
    'Level1'  
y =  
    45  
answer =  
    'Yes'
```

`%*f` in the format string causes `textread` to ignore the floating point value, in this case, 12.34.

### Example 3 – Read Using Literal to Ignore Matching Characters

The first line of `mydata.dat` is

```
Sally    Type1 12.34 45 Yes
```

Read the first line of the file, ignoring the characters `Type` in the second field.

```
[names, typenum, x, y, answer] = textread('mydata.dat', ...  
'%s Type%d %f %d %s', 1)
```

returns

```
names =  
    'Sally'  
typenum =  
    1  
x =  
    12.340000000000000  
y =  
    45
```

```
answer =  
    'Yes'
```

Type%d in the format string causes the characters Type in the second field to be ignored, while the rest of the second field is read as a signed integer, in this case, 1.

## Example 4 – Specify Value to Fill Empty Cells

For files with empty cells, use the emptyvalue parameter. Suppose the file data.csv contains:

```
1,2,3,4,,6  
7,8,9,,11,12
```

Read the file using NaN to fill any empty cells:

```
data = textread('data.csv', '', 'delimiter', ',', ...  
    'emptyvalue', NaN);
```

## Example 5 – Read File into a Cell Array of Strings

Read the file fft.m into cell array of strings.

```
file = textread('fft.m', '%s', 'delimiter', '\n', ...  
    'whitespace', '');
```

## See Also

textscan | dlmread | fscanf

**Purpose**

Read formatted data from text file or string

**Syntax**

```
C = textscan(fileID,formatSpec)
C = textscan(fileID,formatSpec,N)
C = textscan(fileID,formatSpec,N,Name,Value)

C = textscan(str,formatSpec,N,Name,Value)

[C,position] = textscan( __ )
```

**Description**

`C = textscan(fileID,formatSpec)` reads data from an open text file into cell array, `C`. The text file is indicated by the file identifier, `fileID`. Use `fopen` to open the file and obtain the `fileID` value. When you finish reading from a file, close the file by calling `fclose(fileID)`.

`textscan` attempts to match the data in the file to `formatSpec`, a string of conversion specifiers.

`C = textscan(fileID,formatSpec,N)` reads file data, using the `formatSpec` `N` times, where `N` is a positive integer. To read additional data from the file after `N` cycles, call `textscan` again using the original `fileID`. If you resume a text scan of a file by calling `textscan` with the same file identifier (`fileID`), then `textscan` automatically resumes reading at the point where it terminated the last read.

`C = textscan(fileID,formatSpec,N,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. You can append `Name,Value` pair arguments to any of the other syntaxes in this syntax group.

`C = textscan(str,formatSpec,N,Name,Value)` reads data from a string, `str`. As with previous syntaxes, use `formatSpec` and optional `N`, and `Name,Value` pair arguments with this syntax. However, for strings, repeated calls to `textscan` restart the scan from the beginning each time. To restart a scan from the last position, request a `position` output.

[C,position] = textscan( \_\_\_ ) returns the file or string position at the end of the scan as the second output argument, using any of the input arguments in the previous syntaxes. For a file, this is the value that ftell(fileID) would return after calling textscan. For a string, position indicates how many characters textscan read.

## Input Arguments

### fileID - File identifier

numeric scalar

File identifier of an open text file, specified as a number. Before reading a file with textscan, you must use fopen to open the file and obtain the fileID.

### Data Types

double

### formatSpec - Format of the data fields

string

Format of the data fields, specified as a string of one or more conversion specifiers. When textscan reads a file or string, it attempts to match the data to the formatSpec string. If textscan fails to match a data field, it stops reading and returns all fields read before the failure.

The number of conversion specifiers determines the number of cells in output array, C.

### Numeric Fields

This table lists available conversion specifiers for numeric inputs.

| Numeric Input Type | Conversion Specifier | Output Class |
|--------------------|----------------------|--------------|
| Integer, signed    | %d                   | int32        |
|                    | %d8                  | int8         |
|                    | %d16                 | int16        |
|                    | %d32                 | int32        |
|                    | %d64                 | int64        |

| <b>Numeric Input Type</b> | <b>Conversion Specifier</b> | <b>Output Class</b> |
|---------------------------|-----------------------------|---------------------|
| Integer, unsigned         | %u                          | uint32              |
|                           | %u8                         | uint8               |
|                           | %u16                        | uint16              |
|                           | %u32                        | uint32              |
|                           | %u64                        | uint64              |
| Floating-point number     | %f                          | double              |
|                           | %f32                        | single              |
|                           | %f64                        | double              |
|                           | %n                          | double              |

### Character Fields

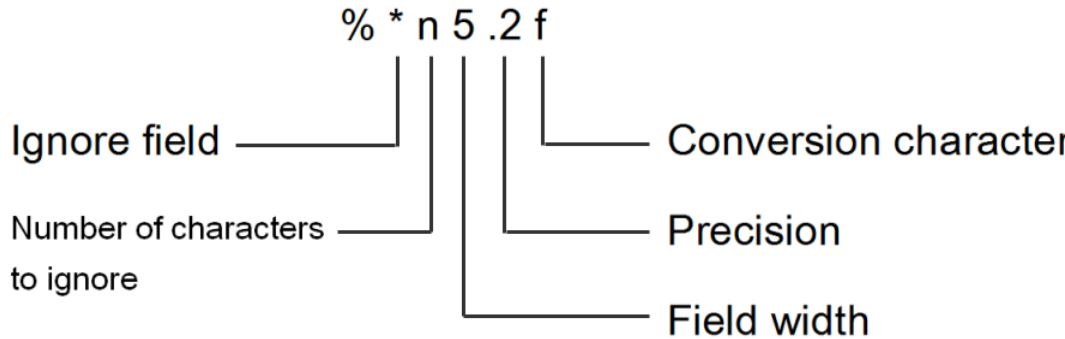

This table lists available conversion specifiers for character inputs.

| <b>Character Strings</b> | <b>Conversion Specifier</b> | <b>Details</b>                                                      |
|--------------------------|-----------------------------|---------------------------------------------------------------------|
| Characters               | %s                          | String                                                              |
|                          | %q                          | String, where double quotation marks indicate text to keep together |
|                          | %c                          | Any single character, including a delimiter                         |

| Character Strings        | Conversion Specifier | Details                                                                                                                                                                                                                          |
|--------------------------|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pattern-matching strings | <code>%[...]</code>  | Read only the characters inside the brackets up to the first nonmatching character. To include <code>]</code> in the set, specify it first: <code>%[...]</code> .<br><br>Example: <code>%[mus]</code> reads 'summer ' as 'summ'. |
|                          | <code>%[^...]</code> | Exclude characters inside the brackets, reading until the first matching character. To exclude <code>]</code> , specify it first: <code>%[^...]</code> .<br><br>Example: <code>%[^xrg]</code> reads 'summer ' as 'summe'.        |

**Optional Operators**

Conversion specifiers in `formatSpec` can include optional operators, which appear in the following order (includes spaces for clarity):

Optional operators include:

- Fields and Characters to Ignore

textscan reads all characters in your file in sequence, unless you tell it to ignore a particular field or a portion of a field.

Use the following operators to skip or read portions of fields.

| Operator         | Action Taken                                                                                                                                                                                                                                                                                                                                                                |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>%*</code>  | <p>Skip the field. textscan does not create an output cell for any field that it skips.</p> <p>Example: <code>'%s %*s %s %s %*s %*s %s'</code> (spaces are optional) converts the string <code>'Blackbird singing in the dead of night'</code> to four output cells with the strings <code>'Blackbird'</code> <code>'in'</code> <code>'the'</code> <code>'night'</code></p> |
| <code>%*n</code> | <p>Ignore <math>n</math> characters of the field, where <math>n</math> is an integer less than or equal to the number of characters in the field.</p> <p>Example: <code>%*4s</code> reads <code>'summer '</code> as <code>'er'</code>.</p>                                                                                                                                  |

- Field Width

textscan reads the number of characters or digits specified by the field width or precision, or up to the first delimiter, whichever comes first. A decimal point is counted as a digit. Specify the field width by inserting a number after the percent character (%) in the conversion specifier.

Example: `%5f` reads `'123.456'` as `123.4`.

---

**Note** When the field width operator is used with single characters (`%c`), textscan also reads delimiter characters.

Example: `%7c` reads 7 characters, including white-space, so `'Day and night'` reads as `'Day and'`.

---

- Precision

For floating-point numbers (%n, %f, %f32, %f64), you can specify the number of decimal digits to read.

Example: %7.2f reads '123.456' as 123.45.

- **Literal Text to Ignore**

textscan ignores specified text appended to the formatSpec string.

Example: Level%u8 reads 'Level1' as 1.

Example: %u8Step reads '2Step' as 2.

## **N - Number of times to apply formatSpec**

integer

Number of times to apply formatSpec, specified as an integer.

## **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32  
| uint64

## **str - Input string**

string

Input string to read.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments, where **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Names are not case sensitive.

**Example:** C =

```
textscan(fileID,formatSpec,'HeaderLines',3,'Delimiter','(',')')  
skips the first three lines of the data, and then reads the remaining  
data, treating commas as a delimiter.
```

## **CollectOutput - Logical indicator determining data concatenation**

false (default) | true

Logical indicator determining data concatenation, specified as the comma-separated pair consisting of 'CollectOutput' and either true or false. If true, then textscan concatenates consecutive output cells of the same fundamental MATLAB class into a single array.

### **CommentStyle - Symbols designating text to ignore**

string | cell array of strings

Symbols designating text to ignore, specified as the comma-separated pair consisting of 'CommentStyle' and a string or cell array of strings.

For example, specify a string such as '%' to ignore characters following the string on the same line. Specify a cell array of two strings, such as {'/\*', '\*/'}, to ignore characters between the strings.

textscan checks for comments only at the start of each field, not within a field.

**Example:** 'CommentStyle',{'/\*', '\*/'}

### **Delimiter - Field delimiter characters**

{' ', '\b', '\t'} (default) | string | cell array of strings

Field delimiter characters, specified as the comma-separated pair consisting of 'Delimiter' and a string or a cell array of strings. Specify multiple delimiters in a cell array of strings.

**Example:** 'delimiter',{';', '\*'}

textscan interprets repeated delimiter characters as separate delimiters, and returns an empty value to the output cell.

Within each row of data, the default field delimiter is white space. White space can be any combination of space (' '), backspace ('\b'), or tab ('\t') characters. If you do not specify a delimiter, textscan interprets repeated white-space characters as a single delimiter.

When you specify one of the following escape sequences as a delimiter, textscan converts that sequence to the corresponding control character:

|                 |                              |
|-----------------|------------------------------|
| <code>\b</code> | Backspace                    |
| <code>\n</code> | Newline                      |
| <code>\r</code> | Carriage return              |
| <code>\t</code> | Tab                          |
| <code>\\</code> | Backslash ( <code>\</code> ) |

## **EmptyValue - Returned value for empty numeric fields**

NaN (default) | scalar

Returned value for empty numeric fields in delimited text files, specified as the comma-separated pair consisting of 'EmptyValue' and a scalar.

## **EndOfLine - End-of-line characters**

string

End-of-line characters, specified as the comma-separated pair consisting of 'EndOfLine' and a string. The default end-of-line sequence depends on the format of your file and can include a newline character (`\n`), a carriage return (`\r`), or a combination of the two (`\r\n`).

If there are missing values and an end-of-line sequence at the end of the last line in a file, then `textscan` returns empty values for those fields. This ensures that individual cells in output cell array, `C`, are the same size.

## **ExpChars - Exponent characters**

'eEdD' (default) | string

Exponent characters, specified as the comma-separated pair consisting of 'ExpChars' and a string. The default exponent characters are `e`, `E`, `d`, and `D`.

## **HeaderLines - Number of header lines**

0 (default) | positive integer

Number of header lines, specified as the comma-separated pair consisting of 'HeaderLines' and a positive integer. textscan skips the header lines, including the remainder of the current line.

### **MultipleDelimsAsOne - Multiple delimiter handling**

0 (false) (default) | 1 (true)

Multiple delimiter handling, specified as the comma-separated pair consisting of 'MultipleDelimsAsOne' and either true or false. If true, textscan treats consecutive delimiters as a single delimiter. Repeated delimiters separated by white-space are also treated as a single delimiter. You must also specify the Delimiter option.

**Example:** 'MultipleDelimsAsOne',1

### **ReturnOnError - Behavior when textscan fails to read or convert**

1 (true) (default) | 0 (false)

Behavior when textscan fails to read or convert, specified as the comma-separated pair consisting of 'ReturnOnError' and either true or false. If true, textscan terminates without an error and returns all fields read. If false, textscan terminates with an error and does not return an output cell array.

### **TreatAsEmpty - Strings to treat as empty value**

string | cell array of strings

Strings to treat as empty values, specified as the comma-separated pair consisting of 'TreatAsEmpty' and a single string or cell array of strings. This option only applies to numeric fields.

### **Whitespace - White-space characters**

' \b\t' (default) | string

White-space characters, specified as the comma-separated pair consisting of 'Whitespace' and a string of one or more characters. textscan adds a space character, char(32), to any specified Whitespace, unless Whitespace is empty ('') and formatSpec includes any string conversion specifier.

When you specify one of the following escape sequences as any white-space character, `textscan` converts that sequence to the corresponding control character:

|                 |                              |
|-----------------|------------------------------|
| <code>\b</code> | Backspace                    |
| <code>\n</code> | Newline                      |
| <code>\r</code> | Carriage return              |
| <code>\t</code> | Tab                          |
| <code>\\</code> | Backslash ( <code>\</code> ) |

## Output Arguments

### **C** - File or string data

cell array

File or string data, returned as a cell array.

For each numeric conversion specifier in `formatSpec`, the `textscan` function returns a K-by-1 MATLAB numeric vector to the output cell array, `C`, where K is the number of times that `textscan` finds a field matching the specifier.

For each string conversion specifier in `formatSpec`, the `textscan` function returns a K-by-1 cell vector of strings, where K is the number of times that `textscan` finds a field matching the specifier. For each character conversion that includes a field width operator, `textscan` returns a K-by-M character array, where M is the field width.

### **position** - File or string position

integer

File or string position at the end of the scan, returned as an integer of class `double`. For a file, `ftell(fileID)` would return the same value after calling `textscan`. For a string, `position` indicates how many characters `textscan` read.

## Examples

### **Read a String**

Read a string of floating-point numbers.

```
str = '0.41 8.24 3.57 6.24 9.27';
```

```
C = textscan(str, '%f');
```

The formatSpec string '%f' tells textscan to match each field in str to a double-precision floating-point number.

Display the contents of cell array C.

```
celldisp(C)
```

```
C{1} =
```

```
0.4100  
8.2400  
3.5700  
6.2400  
9.2700
```

Read the same string, truncating each value to one decimal digit.

```
C = textscan(str, '%3.1f %*1d');
```

The specifier %3.1f indicates a field width of 3 digits and a precision of 1. textscan reads a total of 3 digits, including the decimal point and the 1 digit after the decimal point. The specifier, %\*1d, tells textscan to skip the remaining digit.

Display the contents of cell array C.

```
celldisp(C)
```

```
C{1} =
```

```
0.4000  
8.2000  
3.5000  
6.2000
```

9.2000

## Read Different Types of Data

Using a text editor, create a file `scan1.dat` that contains data in the following form:

```
09/12/2005 Level1 12.34 45 1.23e10 inf Nan Yes 5.1+3i
10/12/2005 Level2 23.54 60 9e19 -inf 0.001 No 2.2-.5i
11/12/2005 Level3 34.90 12 2e5 10 100 No 3.1+.1i
```

Open the file, and read each column with the appropriate conversion specifier.

```
fileID = fopen('scan1.dat');
C = textscan(fileID, '%s %s %f32 %d8 %u %f %f %s %f');
fclose(fileID);
celldisp(C)
```

```
C{1}{1} =
```

```
09/12/2005
```

```
C{1}{2} =
```

```
10/12/2005
```

```
C{1}{3} =
```

```
11/12/2005
```

```
C{2}{1} =
```

```
Level1
```

C{2}{2} =

Level2

C{2}{3} =

Level3

C{3} =

12.3400  
23.5400  
34.9000

C{4} =

45  
60  
12

C{5} =

4294967295  
4294967295  
200000

C{6} =

## textscan

---

```
    Inf  
   -Inf  
     10
```

```
C{7} =
```

```
      NaN  
    0.0010  
   100.0000
```

```
C{8}{1} =
```

```
Yes
```

```
C{8}{2} =
```

```
No
```

```
C{8}{3} =
```

```
No
```

```
C{9} =
```

```
    5.1000 + 3.0000i  
    2.2000 - 0.5000i  
    3.1000 + 0.1000i
```

textscan returns a 1-by-9 cell array C.

View the MATLAB data type of each of the cells in C.

```
C
```

```
C =
```

```
Columns 1 through 5
```

```
{3x1 cell}    {3x1 cell}    [3x1 single]    [3x1 int8]    [3x1 ui
```

```
Columns 6 through 9
```

```
[3x1 double]    [3x1 double]    {3x1 cell}    [3x1 double]
```

For example, C{1} and C{2} are cell arrays. C{5} is of data type uint32, so the first two elements of C{5} are the maximum values for a 32-bit unsigned integer, or intmax('uint32').

### Remove a Literal String

Remove the text 'Level' from each field in the second column of the data from the previous example.

Match the literal string in the formatSpec input.

```
fileID = fopen('scan1.dat');
C = textscan(fileID, '%s Level%d %f32 %d8 %u %f %f %s %f');
fclose(fileID);
C{2}
```

```
ans =
```

```
1
2
3
```

View the MATLAB data type of the second cell in C.

```
class(C{2})
```

```
ans =
```

```
int32
```

The second cell of the 1-by-9 cell array, `C`, is now of data type `int32`.

## Skip the Remainder of a Line

Read the first column of the file in the previous example into a cell array, skipping the rest of the line.

```
fileID = fopen('scan1.dat');  
dates = textscan(fileID, '%s %*[^\\n]');  
fclose(fileID);  
dates{1}
```

```
ans =
```

```
'09/12/2005'
```

```
'10/12/2005'
```

```
'11/12/2005'
```

`textscan` returns a 1-by-1 cell array `dates`.

## Specify Delimiter and Empty Value Conversion

Using a text editor, create a comma-delimited file, `data.csv`, that contains

```
1, 2, 3, 4, , 6  
7, 8, 9, , 11, 12
```

Read the file, converting empty cells to `-Inf`.

```
fileID = fopen('data.csv');  
C = textscan(fileID, '%f %f %f %f %u8 %f', 'delimiter', ',', 'EmptyValue',  
fclose(fileID);  
column4 = C{4}, column5 = C{5}
```

```
column4 =
```

```

        4
    -Inf

column5 =

        0
    11

```

`textscan` returns a 1-by-6 cell array, `C`. The `textscan` function converts the empty value in `C{4}` to `-Inf`, where `C{4}` is associated with a floating-point format. Because MATLAB represents unsigned integer `-Inf` as 0, `textscan` converts the empty value in `C{5}` to 0, and not `-Inf`.

### Read Custom Empty Value Strings and Comments

Using a text editor, create a comma-delimited file, `data2.csv`, that contains the lines

```

abc, 2, NA, 3, 4
// Comment Here
def, na, 5, 6, 7

```

Designate the input that `textscan` should treat as comments or empty values.

```

fileID = fopen('data2.csv');
C = textscan(fileID, '%s %n %n %n %n', 'delimiter', ',', 'treatAsEmpty');
fclose(fileID);
celldisp(C)

```

```

C{1}{1} =
abc

```

```

C{1}{2} =
def

```

```

C{2} =

```

```
      2
      NaN
C{3} =
      NaN
      5
C{4} =
      3
      6
C{5} =
      4
      7
```

## Treat Repeated Delimiters as One

Using a text editor, create a file, `data3.csv`, that contains

```
1,2,3,,4
5,6,7,,8
```

To treat the repeated commas as a single delimiter, use the `MultipleDelimsAsOne` parameter, and set the value to 1 (true).

```
fileID = fopen('data3.csv');
C = textscan(fileID, '%f %f %f %f', 'delimiter', ',', 'MultipleDelimsAsOne', 1);
fclose(fileID);
celldisp(C)
```

```
C{1} =
      1
      5
C{2} =
      2
      6
```

```
C{3} =
     3
     7
```

```
C{4} =
     4
     8
```

### Collect Numeric Data

Using a text editor, create a file, `grades.txt`, that contains:

| Student_ID | Test1 | Test2 | Test3 |
|------------|-------|-------|-------|
| 1          | 91.5  | 89.2  | 77.3  |
| 2          | 88.0  | 67.8  | 91.0  |
| 3          | 76.3  | 78.1  | 92.5  |
| 4          | 96.4  | 81.2  | 84.6  |

Read the column headers using the format `'%s'` four times.

```
fileID = fopen('grades.txt');

formatSpec = '%s';
N = 4;
C_text = textscan(fileID, formatSpec, N, 'delimiter', '|');
```

Read the numeric data in the file.

```
C_data0 = textscan(fileID, '%d %f %f %f')
```

```
C_data0 =
     [4x1 int32]     [4x1 double]     [4x1 double]     [4x1 double]
```

The default value for `CollectOutput` is 0 (`false`), so `textscan` returns each column of the numeric data in a separate array.

Set `CollectOutput` to 1 (true) to collect the consecutive columns of the same class into a single array.

```
frewind(fileID);

C_text = textscan(fileID, '%s', N, 'delimiter', '|');

C_data1 = textscan(fileID, '%d %f %f %f', 'CollectOutput', 1)

C_data1 =
    [4x1 int32]    [4x3 double]
```

The test scores, which are all double, are collected into a single 4-by-3 array.

Close the file, `grades.txt`.

```
fclose(fileID);
```

### Read Nondefault Control Characters

Use `sprintf` to convert nondefault escape sequences in your data.

Create a string that includes a form feed character, `\f`. Then, to read the string using `textscan`, call `sprintf` to explicitly convert the form feed.

```
lyric = sprintf('Blackbird\f\singing\f\in\fthe\fdead\fof\fnight');
C = textscan(lyric, '%s', 'delimiter', sprintf('\f'));
C{1}
```

```
ans =

    'Blackbird'
    'singing'
    'in'
    'the'
    'dead'
    'of'
    'night'
```

textscan returns a 1-by-1 cell array, C.

### Resume a Text Scan of a String

Resume a scan of a string from a position other than the beginning.

If you resume a text scan of a string, textscan reads from the beginning of the string each time. To resume a scan from any other position in the string, use the two-output argument syntax in your initial call to textscan.

For example, create a string called lyric. Read the first word of the string, and then resume the scan.

```
lyric = 'Blackbird singing in the dead of night';
[firstword, pos] = textscan(lyric,'%9c', 1);
lastpart = textscan(lyric(pos+1:end), '%s');
```

## Algorithms

textscan converts numeric fields to the specified output type according to MATLAB rules regarding overflow, truncation, and the use of NaN, Inf, and -Inf. For example, MATLAB represents an integer NaN as zero. If textscan finds an empty field associated with an integer format specifier (such as %d or %u), it returns the empty value as zero and not NaN.

textscan does not include leading white-space characters in the processing of any data fields. When processing numeric data, textscan also ignores trailing white space.

textscan imports any complex number as a whole into a complex numeric field, converting the real and imaginary parts to the specified numeric type (such as %d or %f). Valid forms for a complex number are:

|                                                                |                   |
|----------------------------------------------------------------|-------------------|
| $\pm\langle\text{real}\rangle\pm\langle\text{imag}\rangle i j$ | Example: 5.7-3.1i |
| $\pm\langle\text{imag}\rangle i j$                             | Example: -7j      |

Do not include embedded white space in a complex number. textscan interprets embedded white space as a field delimiter.

# textscan

| <b>Purpose</b>     | Wrapped string matrix for given uicontrol                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Syntax</b>      | <pre>outstring = textwrap(h,instring) outstring = textwrap(h,instring,columns) [outstring,position] = textwrap(...)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p><code>outstring = textwrap(h,instring)</code> returns a wrapped string cell array, <code>outstring</code>, that fits inside the uicontrol with handle <code>h</code>. <code>instring</code> is a cell array, with each cell containing a single line of text. <code>outstring</code> is the wrapped string matrix in cell array format. Each cell of the input string is considered a paragraph.</p> <p><code>outstring = textwrap(h,instring,columns)</code> returns an <code>outstring</code> with each line wrapped at <code>columns</code> characters. Spaces are included in the character count.</p> <p><code>[outstring,position] = textwrap(...)</code> returns the recommended position of the uicontrol in the units of the uicontrol. <code>position</code> considers the extent of the multiline text in the <code>x</code> and <code>y</code> directions.</p> <p><code>textwrap</code> maintains the original line breaks in the input cell array and adds new ones. It can calculate uicontrol positions with any type of Units, including normalized units.</p> |
| <b>Tips</b>        | When programming a GUI, do not call <code>copyobj</code> or <code>textwrap</code> (which calls <code>copyobj</code> ) inside a <code>CreateFcn</code> . The act of copying the uicontrol object fires the <code>CreateFcn</code> repeatedly, which raises a series of error messages after exceeding the root object's <code>RecursionLimit</code> property.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Examples</b>    | <p>Place two text-wrapped strings in text uicontrols. The left one has a <code>Position</code> calculated by <code>textwrap</code> in Units of pixels; the right one's <code>Position</code> is calculated manually in Units of characters:</p> <pre>figure('Position',[560 528 350 250]); % Make a text uicontrol to wrap in Units of Pixels % Create it in Units of Pixels, 100 wide, 10 high pos = [10 100 100 10]; ht = uicontrol('Style','Text','Position',pos);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## textwrap

---

```
string = {'This is a string for the left text uicontrol.',...
         'to be wrapped in Units of Pixels,',...
         'with a position determined by TEXTWRAP.'};
% Wrap string, also returning a new position for ht
[outstring,newpos] = textwrap(ht,string) %#ok<NOPRT>

outstring =
    'This is a string for'
    'the left text'
    'uicontrol.'
    'to be wrapped in'
    'Units of Pixels,'
    'with a position'
    'determined by'
    'TEXTWRAP.'

newpos =
    10    100    91    124

set(ht,'String',outstring,'Position',newpos)

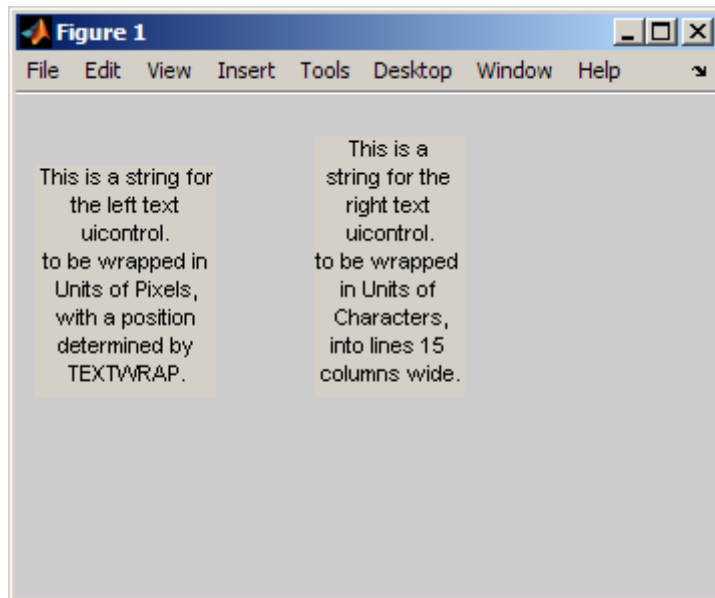

% Make another text uicontrol to wrap to a column width of 15
colwidth = 15;
% Create it in Units of Pixels, 100 wide, 10 high
pos1 = [150 100 100 10];
ht1 = uicontrol('Style','Text','Position',pos1);
string1 = {'This is a string for the right text uicontrol.',...
          'to be wrapped in Units of Characters,',...
          'into lines 15 columns wide.'};
outstring1 = textwrap(ht1,string1,colwidth);
% Reset Units of ht1 to Characters to use the result
set(ht1,'Units','characters')
newpos1 = get(ht1,'Position')

newpos1 =
    29.8000    7.6154    20.0000    0.7692
```

```
% Set new Position in Characters to be specified colwidth
% with height the length of the outstring1 cell array + 1.
newpos1(3) = colwidth;
newpos1(4) = length(outstring1)+1

newpos1 =
    29.8000    7.6154   15.0000   10.0000

set(ht1,'String',outstring1,'Position',newpos1)
```

**See Also** [align](#) | [uicontrol](#)

**Purpose** Transpose-free quasi-minimal residual method

**Syntax**

```
x = tfqmr(A,b)
x = tfqmr(afun,b)
x = tfqmr(a,b,tol)
x = tfqmr(a,b,tol,maxit)
x = tfqmr(a,b,tol,maxit,m)
x = tfqmr(a,b,tol,maxit,m1,m2,x0)
[x,flag] = tfqmr(A,B,...)
[x,flag,relres] = tfqmr(A,b,...)
[x,flag,relres,y]y(A,b,...)
[x,flag,relres,iter,resvec] = tfqmr(A,b,...)
```

**Description** `x = tfqmr(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and the right-hand side column vector  $b$  must have length  $n$ .

`x = tfqmr(afun,b)` accepts a function handle, `afun`, instead of the matrix  $A$ . The function, `afun(x)`, accepts a vector input  $x$  and returns the matrix-vector product  $A*x$ . In all of the following syntaxes, you can replace  $A$  by `afun`. “Parameterizing Functions” explains how to provide additional parameters to the function `afun`.

`x = tfqmr(a,b,tol)` specifies the tolerance of the method. If `tol` is `[]` then `tfqmr` uses the default,  $1e-6$ .

`x = tfqmr(a,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]` then `tfqmr` uses the default,  $\min(N,20)$ .

`x = tfqmr(a,b,tol,maxit,m)` and `x = tfqmr(a,b,tol,maxit,m1,m2)` use preconditioners  $m$  or  $m=m1*m2$  and effectively solve the system  $A*inv(M)*x = B$  for  $x$ . If  $M$  is `[]` then a preconditioner is not applied.  $M$  may be a function handle `mfun` such that `mfun(x)` returns  $m \setminus x$ .

`x = tfqmr(a,b,tol,maxit,m1,m2,x0)` specifies the initial guess. If `x0` is `[]` then `tfqmr` uses the default, an all zero vector.

`[x,flag] = tfqmr(A,B,...)` also returns a convergence flag:

| Flag | Convergence                                                                                               |
|------|-----------------------------------------------------------------------------------------------------------|
| 0    | tfqmr converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.           |
| 1    | tfqmr iterated <code>maxit</code> times but did not converge.                                             |
| 2    | Preconditioner <code>m</code> was ill-conditioned.                                                        |
| 3    | tfqmr stagnated. (Two consecutive iterates were the same.)                                                |
| 4    | One of the scalar quantities calculated during tfqmr became too small or too large to continue computing. |

`[x,flag,relres] = tfqmr(A,b,...)` also returns the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$ . If `flag` is 0, then `relres`  $\leq$  `tol`.

`[x,flag,relres,y]y(A,b,...)` also returns the iteration number at which `x` was computed:  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = tfqmr(A,b,...)` also returns a vector of the residual norms at each iteration, including  $\text{norm}(b-A*x_0)$ .

## Examples

### Example 1

This example shows how to use `tfqmr` with a matrix input and with a function input.

```
n = 100; on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x = tfqmr(A,b,tol,maxit,M1,M2,[]);
```

You can also use a matrix-vector product function as input:

```
function y = afun(x,n)
```

```
y = 4 * x;  
y(2:n) = y(2:n) - 2 * x(1:n-1);  
y(1:n-1) = y(1:n-1) - x(2:n);  
x1 = tfqmr(@(x)afun(x,n),b,tol,maxit,M1,M2);
```

If `applyOp` is a function suitable for use with `qmr`, it may be used with `tfqmr` by wrapping it in an anonymous function:

```
x1 = tfqmr(@(x)applyOp(x,'notransp'),b,tol,maxit,M1,M2);
```

## Example 2

This example demonstrates the use of a preconditioner.

**1**

Load `A = west0479`, a real 479-by-479 nonsymmetric sparse matrix:

```
load west0479;  
A = west0479;
```

**2**

Define `b` so that the true solution is a vector of all ones:

```
b = full(sum(A,2));
```

**3**

Set the tolerance and maximum number of iterations:

```
tol = 1e-12; maxit = 20;
```

**4**

Use `tfqmr` to find a solution at the requested tolerance and number of iterations:

```
[x0,f10,rr0,it0,rv0] = tfqmr(A,b,tol,maxit);
```

`f10` is 1 because `tfqmr` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. The seventeenth iterate is the

best approximate solution and is the one returned as indicated by `it0 = 17`. MATLAB stores the residual history in `rv0`.

## 5

Plot the behavior of `tfqmr`:

```
semilogy(0:maxit,rv0/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

Note that like `bicgstab`, `tfqmr` keeps track of half iterations. The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

## 6

Create the preconditioner with `ilu`, since the matrix `A` is nonsymmetric:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));  
Error using ilu  
There is a pivot equal to zero. Consider decreasing  
the drop tolerance or consider using the 'udiag' option.
```

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

## 7

You can try again with a reduced drop tolerance, as indicated by the error message:

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));  
[x1,f11,rr1,it1,rv1] = tfqmr(A,b,tol,maxit,L,U);
```

`f11` is 0 because `tfqmr` drives the relative residual to  $4.1410e-014$  (the value of `rr1`). The relative residual is less than the prescribed tolerance of  $1e-12$  at the sixth iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of  $1e-6$ . The output `rv1(1)` is `norm(b)`, and the output `rv1(7)` is `norm(b-A*x2)`.

## 8

You can follow the progress of `tfqmr` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0):

```
semilogy(0:it1,rv1/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

# throw (MException)

---

**Purpose** Issue exception and terminate function

**Syntax** `throw(exception)`

**Description** `throw(exception)` issues an exception based on the information contained in *exception*. The exception terminates the currently running function and returns control to its caller. The *exception* argument is scalar object of the MException class that contains information on the cause of the error and where it occurred. The `throw` function passes *exception* back to the caller of the currently running function, and eventually back to the Command Window when the program terminates. The exception is made available to any calling function by means of the `catch` function, and to the Command Window by means of the `MException.last` function.

Unlike `throwAsCaller` and `rethrow`, the `throw` function also sets the *stack* field of the *exception* to the location from which `throw` was called.

**Tips** There are four ways to throw an exception in MATLAB (see the list below). Use the first of these when testing the outcome of some action for failure and reporting the failure to MATLAB. Use one of the remaining three techniques to throw an existing exception.

- 1** Test the result of some action taken by your program. If the result is found to be incorrect or unexpected, compose an appropriate message and message identifier, and pass these to MATLAB using the `error` function.
- 2** Reissue the original exception by throwing the initial exception unmodified. Use the `MException.rethrow` method to do this.
- 3** Collect additional information on the cause of the error, store it in a new or modified exception, and issue a new exception based on that record. Use the `MException.addCause` and `throw` methods to do this.

- 4 Make it appear that the error originated in the caller of the currently running function. Use the MException throwAsCaller method to do this.

## Examples

### Example 1

This example tests the output of function `evaluate_plots` and throws an exception if it is not acceptable:

```
[minval, maxval] = evaluate_plots(p24, p28, p41);
if minval < lower_bound || maxval > upper_bound
    exception = MException('VerifyOutput:OutOfBounds', ...
        'Results are outside the allowable limits');
    throw(exception);
end
```

### Example 2

This example attempts to open a file in a folder that is not on the MATLAB path. It uses a nested try-catch block to give the user the opportunity to extend the path. If the file still cannot be found, the program issues an exception with the first error appended to the second using `addCause`:

```
function data = read_it(filename);
try
    % Attempt to open and read from a file.
    fid = fopen(filename, 'r');
    data = fread(fid);
catch exception1
    % If the error was caused by an invalid file ID, try
    % reading from another location.
    if strcmp(exception1.identifier, 'MATLAB:FileIO:InvalidFid')
        msg = sprintf( ...
            '\nCannot open file %s. Try another location? ', ...
            filename);
        reply = input(msg, 's')
        if reply(1) == 'y'
            newFolder = input('Enter folder name: ', 's');
```

## throw (MException)

---

```
        else
            throw(exception1);
        end
        oldpath = addpath(newFolder);
        try
            fid = fopen(filename, 'r');
            data = fread(fid);
        catch exception2
            exception3 = addCause(exception2, exception1)
            path(oldpath);
            throw(exception3);
        end
        path(oldpath);
    end
end
fclose(fid);

try
    d = read_it('anytextfile.txt');
catch exception
end

exception
exception =
    MException object with properties:

        identifier: 'MATLAB:FileIO:InvalidFid'
        message: 'Invalid file identifier. Use fopen
                to generate a valid file identifier.'
        stack: [1x1 struct]
        cause: {[1x1 MException]}

    Cannot open file anytextfile.txt. Try another location?y
Enter folder name: xxxxxxx
Warning: Name is nonexistent or not a directory: xxxxxxx.
> In path at 110
    In addpath at 89
```

# throwAsCaller (MException)

---

**Purpose** Throw exception as if from calling function

**Syntax** `throwAsCaller(exception)`

**Description** `throwAsCaller(exception)` throws an exception from the currently running function based on the *exception* input, a scalar object of the `MException` class. The MATLAB software exits the currently running function and returns control to either the keyboard or an enclosing catch block in a calling function. Unlike the `throw` function, MATLAB omits the current stack frame from the `stack` field of the `MException`, thus making the exception look as if it is being thrown by the caller of the function.

In some cases, it is not relevant to show the person running your program the true location that generated an exception, but is better to point to the calling function where the problem really lies. You might also find `throwAsCaller` useful when you want to simplify the error display, or when you have code that you do not want made public.

**Tips** There are four ways to throw an exception in MATLAB (see the list below). Use the first of these when testing the outcome of some action for failure and reporting the failure to MATLAB. Use one of the remaining three techniques to throw an existing exception.

- 1** Test the result of some action taken by your program. If the result is found to be incorrect or unexpected, compose an appropriate message and message identifier, and pass these to MATLAB using the `error` function.
- 2** Reissue the original exception by throwing the initial exception unmodified. Use the `MException` `rethrow` method to do this.
- 3** Collect additional information on the cause of the error, store it in a new or modified exception, and issue a new exception based on that record. Use the `MException` `addCause` and `throw` methods to do this.

- 4 Make it appear that the error originated in the caller of the currently running function. Use the MException throwAsCaller method to do this.

### Examples

The function `klein_bottle`, in this example, generates a Klein Bottle figure by revolving the figure-eight curve defined by `XYKLEIN`. It defines a few variables and calls the function `draw_klein`, which executes three functions in a try-catch block. If there is an error, the catch block issues an exception using either `throw` or `throwAsCaller`:

```
function klein_bottle(pq)
ab = [0 2*pi];
rtr = [2 0.5 1];
box = [-3 3 -3 3 -2 2];
vue = [55 60];
draw_klein(ab, rtr, pq, box, vue)

function draw_klein(ab, rtr, pq, box, vue)
clf
try
    tube('xyklein',ab, rtr, pq, box, vue);
    shading interp
    colormap(pink);
catch exception
    throw(exception)
%    throwAsCaller(exception)
end
```

Call the `klein_bottle` function, passing a vector, and the function completes normally by drawing the figure.

```
klein_bottle([40 40])
```

Call the function again, this time passing a scalar value. Because the catch block issues the exception using `throw`, MATLAB displays error messages for line 16 of function `draw_klein`, and for line 6 of function `klein_bottle`:

## throwAsCaller (MException)

---

```
klein_bottle(40)
Error using klein_bottle>draw_klein (line 16)
Attempted to access pq(2); index out of bounds because numel(pq)=1.

Error in klein_bottle (line 6)
draw_klein(ab, rtr, pq, box, vue)
```

Run the function again, this time changing the `klein_bottle.m` file so that the catch block uses `throwAsCaller` instead of `throw`. This time, MATLAB only displays the error at line 6 of the main program:

```
klein_bottle(40)
Error using klein_bottle (line 6)
Attempted to access pq(2); index out of bounds because numel(pq)=1.
```

| <b>Input Arguments</b>  | <p><b>ticID</b></p> <p>Identifier generated by a previous call to <code>tic</code> with an output argument.</p>                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Output Arguments</b> | <p><b>elapsedTime</b></p> <p>Scalar <code>double</code> representing the time elapsed between <code>tic</code> and <code>toc</code> commands, in seconds.</p>                                                                                                                                                                                                                                                                                                                                                |
| <b>Examples</b>         | <p>Measure how the time required to solve a linear system varies with the order of a matrix:</p> <pre>t = zeros(1,100); for n = 1:100</pre>                                                                                                                                                                                                                                                                                                                                                                  |

```
A = rand(n,n);
b = rand(n,1);
tic
x = A\b;
t(n) = toc;
end
plot(t)
```

---

Measure the minimum and average time to compute a summation of Bessel functions:

```
REPS = 1000;  minTime = Inf;  nsum = 10;
tic;

for i=1:REPS
    tStart = tic;  total = 0;
    for j=1:nsum,
        total = total + besselj(j,REPS);
    end

    tElapsed = toc(tStart);
    minTime = min(tElapsed, minTime);
end
averageTime = toc/REPS;
```

## Purpose

MATLAB Gateway to LibTIFF library routines

## Description

The `Tiff` class represents a connection to a Tagged Image File Format (TIFF) file and provides access to many of the capabilities of the LibTIFF library. Use the methods of the `Tiff` object to call routines in the LibTIFF library. While you can use the `imread` and `imwrite` functions to read and write TIFF files, the `Tiff` class offers capabilities that these functions don't provide, such as reading subimages, writing tiles and strips of image data, and modifying individual TIFF tags.

In most cases, the syntax of the `Tiff` method is similar to the syntax of the corresponding LibTIFF library function. To get the most out of the `Tiff` object, you must be familiar with the LibTIFF API, as well as the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

MATLAB supports LibTIFF version 4.0.0.

For copyright information, see the `libtiffcopyright.txt` file.

## Construction

`obj = Tiff(filename,mode)` creates a `Tiff` object associated with the TIFF file `filename`. `mode` specifies the type of access to the file.

A TIFF file is made up of one or more image file directories (IFDs). An IFD contains image data and associated metadata. IFDs can also contain subIFDs which also contain image data and metadata. When you open a TIFF file for reading, the `Tiff` object makes the first IFD in the file the *current* IFD. `Tiff` methods operate on the current IFD. You can use `Tiff` object methods to navigate among the IFDs and the subIFDs in a TIFF file.

When you open a TIFF file for writing or appending, the `Tiff` object automatically creates a IFD in the file for writing subsequent data. This IFD has all the default values specified in TIFF Revision 6.0.

When creating a new TIFF file, before writing any image to the file, you must create certain required fields (tags) in the file. These tags include `ImageWidth`, `ImageHeight`, `BitsPerSample`, `SamplesPerPixel`, `Compression`, `PlanarConfiguration`, and `Photometric`. If the image data has a stripped layout, the IFD contains the `RowsPerStrip` tag. If

the image data has a tiled layout, the IFD contains the `TileWidth` and `TileHeight` tags. Use the `setTag` method to define values for these tags.

## Input Arguments

### filename

Text string specifying name of file.

### mode

One of the following text strings specifying the type of access to the TIFF file.

## Supported Values

| Parameter | Description                                                     |
|-----------|-----------------------------------------------------------------|
| 'r'       | Open file for reading                                           |
| 'w'       | Open file for writing; discard existing contents                |
| 'w8'      | Open file for writing a BigTIFF file; discard existing contents |
| 'a'       | Open or create file for writing; append data to end of file.    |
| 'r+'      | Open (do not create) file for reading and writing               |

## Properties

### Compression

Specify scheme used to compress image data

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

### Supported Values

|                                |
|--------------------------------|
| None                           |
| CCITTRLE (Read-only)           |
| CCITTFax3                      |
| CCITTFax4                      |
| LZW                            |
| JPEG                           |
| CCITTRLEW (Read-only)          |
| PackBits                       |
| SGILog                         |
| SGILog24                       |
| Deflate                        |
| AdobeDeflate (Same as deflate) |

Example: Set the Compression tag to the value JPEG. Note how you use the property to specify the value.

```
tiffobj.setTag('Compression', Tiff.Compression.JPEG);
```

### ExtraSamples

Describe extra components

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

### Supported Values

|                   |
|-------------------|
| Unspecified       |
| AssociatedAlpha   |
| UnassociatedAlpha |

Example: Set the `ExtraSamples` tag to the value `AssociatedAlpha`. Note how you use the property to specify the value.

```
tiffobj.setTag('ExtraSamples', Tiff.ExtraSamples.AssociatedAlpha);
```

## InkSet

Specify set of inks used in separated image.

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

In this context, separated refers to photometric interpretation, not the planar configuration.

## Supported Values

|          |                                                                                                                                                                                                                                                                                                         |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMYK     | Order of components: cyan, magenta, yellow, black. Usually, a value of 0 represents 0% ink coverage and a value of 255 represents 100% ink coverage for that component, but consult the TIFF specification for <code>DotRange</code> . When you specify CMYK, do not set the <code>InkNames</code> tag. |
| MultiInk | Any ordering other than CMYK. Consult the TIFF specification for <code>InkNames</code> field for a description of the inks used.                                                                                                                                                                        |

Example:

```
tiffobj.setTag('InkSet', Tiff.InkSet.CMYK);
```

## Orientation

Specify visual orientation of the image data.

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

The first row represents the top of the image, and the first column represents the left side. Support for this tag is for informational purposes only, and it does not affect how MATLAB reads or writes the image data.

### Supported Values

|             |
|-------------|
| TopLeft     |
| TopRight    |
| BottomRight |
| BottomLeft  |
| LeftTop     |
| RightTop    |
| RightBottom |
| LeftBottom  |

Example:

```
tiffobj.setTag('Orientation', Tiff.Orientation.TopRight);
```

### Photometric

Specify color space of image data

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

### Supported Values

|            |
|------------|
| MinIsWhite |
| MinIsBlack |
| RGB        |
| Palette    |

|                  |
|------------------|
| Mask             |
| Separated (CMYK) |
| YCbCr            |
| CIELab           |
| ICCLab           |
| ITULab           |
| LogL             |
| LogLUV           |
| CFA              |
| LinearRaw        |

Example:

```
tiffobj.setTag('Photometric', Tiff.Photometric.RGB);
```

## PlanarConfiguration

Specifies how image data components are stored on disk

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

## Supported Values

|          |                                                                                                                                                                                                                              |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Chunky   | Store component values for each pixel contiguously. For example, in the case of RGB data, the first three pixels would be stored in the file as RGBRGBRGB etc. Almost all TIFF images have contiguous planar configurations. |
| Separate | Store component values for each pixel separately. For example, in the case of RGB data, the red component would be stored                                                                                                    |

|  |                                                            |
|--|------------------------------------------------------------|
|  | separately in the file from the green and blue components. |
|--|------------------------------------------------------------|

Example:

```
tiffobj.setTag('PlanarConfiguration', Tiff.PlanarConfiguration.CH
```

### ResolutionUnit

Specify unit of measure used to interpret the XResolution and YResolution tags.

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

#### Supported Values

|                |
|----------------|
| None (default) |
| Inch           |
| Centimeter     |

Example: Set `ResolutionUnit` tag to the value `Inch`. Then, setting `XResolution` tag to 300 means pixels per inch.

```
tiffObj.setTag('ResolutionUnit', Tiff.ResolutionUnit.Inch);
tiffObj.setTag('XResolution', 300);
tiffObj.setTag('YResolution', 300);
```

### SampleFormat

Specify how to interpret each pixel sample

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

## Supported Values

|               |
|---------------|
| Uint          |
| Int           |
| IEEEFP        |
| Void          |
| ComplexInt    |
| ComplexIEEEFP |

Example:

```
tiffobj.setTag('SampleFormat', Tiff.SampleFormat.IEEFP);
```

## SGILogDataFmt

Specify control of client data for SGILog codec

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

These enumerated values should only be used when the photometric interpretation value is `LogL` or `LogLUV`. The `BitsPerSample`, `SamplesPerPixel`, and `SampleFormat` tags should not be set if the image type is `LogL` or `LogLuv`. The choice of `SGILogDataFmt` will set these tags automatically. The `Float` and `Bits8` settings imply a `SamplesPerPixel` value of 3 for `LogLUV` images, but only 1 for `LogL` images.

## Supported Values

|       |                           |
|-------|---------------------------|
| Float | Single precision samples  |
| Bits8 | uint8 samples (read only) |

This tag can be set only once per instance of a `LogL/LogLuv Tiff` image object instance.

Example:

```
tiffobj = Tiff('example.tif','r');
tiffobj.setDirectory(3); % image three is a LogLuv image
tiffobj.setTag('SGILogDataFmt', Tiff.SGILogDataFmt.Float);
imdata = tiffobj.read();
```

### SubFileType

Specify type of image

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

SubFileType is a bitmask that indicates the type of the image.

### Supported Values

|              |                                                                                                                                |
|--------------|--------------------------------------------------------------------------------------------------------------------------------|
| Default      | Default value for single image file or first image.                                                                            |
| ReducedImage | The current image is a thumbnail or reduced-resolution image that typically would be found in a sub-IFD.                       |
| Page         | The image is a single image of a multi-image (or multipage) file.                                                              |
| Mask         | The image is a transparency mask for another image in the file. The photometric interpretation value must be Photometric.Mask. |

Example:

```
tiffobj.setTag('SubFileType', Tiff.SubFileType.Mask);
```

### TagID

List of recognized TIFF tag names with their ID numbers

This property identifies all the supported TIFF tags with their ID numbers. Use this property to specify a tag when using the

setTag method. For example, `Tiff.TagID.ImageWidth` returns the ID of the `ImageWidth` tag. To get a list of the names of supported tags, use the `getTagNames` method.

Example:

```
tiffobj.setTag(Tiff.TagID.ImageWidth, 300);
```

## Thresholding

Specifies technique used to convert from gray to black and white pixels.

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

### Supported Values

|                   |
|-------------------|
| BiLevel (default) |
| HalfTone          |
| ErrorDiffuse      |

Example:

```
tiffobj.setTag('Thresholding', Tiff.Thresholding.HalfTone);
```

## YCbCrPositioning

Specify relative positioning of chrominance samples

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

This property identifies all supported values for the `YCbCrPositioning` tag.

### Supported Values

|          |                                                                                                |
|----------|------------------------------------------------------------------------------------------------|
| Centered | Specify for compatibility with industry standards such as PostScript Level 2                   |
| Cosited  | Specify for compatibility with most digital video standards such as CCIR Recommendation 601-1. |

Example:

```
tiffobj.setTag('YCbCrPositioning', Tiff.YCbCrPositioning.Centered)
```

### Methods

|                  |                                                       |
|------------------|-------------------------------------------------------|
| close            | Close Tiff object                                     |
| computeStrip     | Index number of strip containing specified coordinate |
| computeTile      | Index number of tile containing specified coordinates |
| currentDirectory | Index of current IFD                                  |
| getTag           | Value of specified tag                                |
| getTagNames      | List of recognized TIFF tags                          |
| getVersion       | LibTIFF library version                               |
| isTiled          | Determine if tiled image                              |
| lastDirectory    | Determine if current IFD is last in file              |
| nextDirectory    | Make next IFD current IFD                             |
| numberOfStrips   | Total number of strips in image                       |
| numberOfTiles    | Total number of tiles in image                        |
| read             | Read entire image                                     |
| readEncodedStrip | Read data from specified strip                        |

# Tiff

---

|                                |                                                  |
|--------------------------------|--------------------------------------------------|
| <code>readEncodedTile</code>   | Read data from specified tile                    |
| <code>rewriteDirectory</code>  | Write modified metadata to existing IFD          |
| <code>setDirectory</code>      | Make specified IFD current IFD                   |
| <code>setSubDirectory</code>   | Make subIFD specified by byte offset current IFD |
| <code>setTag</code>            | Set value of tag                                 |
| <code>write</code>             | Write entire image                               |
| <code>writeDirectory</code>    | Create new IFD and make it current IFD           |
| <code>writeEncodedStrip</code> | Write data to specified strip                    |
| <code>writeEncodedTile</code>  | Write data to specified tile                     |

## Examples

Create a new TIFF file using the `Tiff` object. To run this example, your directory must be writable.

```
t = Tiff('myfile.tif', 'w');  
%  
% Close the Tiff object  
t.close();
```

- “Reading Image Data and Metadata from TIFF Files”

**Purpose**

Construct timer object

**Syntax**

```
T = timer
T = timer('PropertyName1', PropertyValue1, 'PropertyName2',
          PropertyValue2,...)
```

**Description**

T = timer constructs a timer object with default attributes.

T = timer('PropertyName1', PropertyValue1, 'PropertyName2', PropertyValue2,...) constructs a timer object in which the given property name/value pairs are set on the object. See “Timer Object Properties” on page 2-4635 for a list of all the properties supported by the timer object.

Note that the property name/property value pairs can be in any format supported by the set function, i.e., property/value string pairs, structures, and property/value cell array pairs.

---

**Note** The timer object is subject to the limitations of your hardware, operating system, and software. It is not intended to be used for real-time applications.

---

**Timer  
Object  
Properties**

The timer object supports the following properties that control its attributes. The table includes information about the data type of each property and its default value.

To view the value of the properties of a particular timer object, use the `get(timer)` function. To set the value of the properties of a timer object, use the `set(timer)` function.

# timer

| Property Name | Property Description                                                                                                                                                                                                                                                            | Data Types, Values, Defaults, Access |                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|---------------------------------------------|
| AveragePeriod | Average time between TimerFcn executions since the timer started.<br><br>Note: Value is NaN until timer executes two timer callbacks.                                                                                                                                           | Data type                            | double                                      |
|               |                                                                                                                                                                                                                                                                                 | Default                              | NaN                                         |
|               |                                                                                                                                                                                                                                                                                 | Read only                            | Always                                      |
| BusyMode      | Action taken when a timer has to execute TimerFcn before the completion of previous execution of TimerFcn.<br><br>'drop' — Do not execute the function.<br><br>'error' — Generate an error. Requires ErrorFcn to be set.<br><br>'queue' — Execute function at next opportunity. | Data type                            | Enumerated string                           |
|               |                                                                                                                                                                                                                                                                                 | Values                               | 'drop'<br>'error'<br>'queue'                |
|               |                                                                                                                                                                                                                                                                                 | Default                              | 'drop'                                      |
|               |                                                                                                                                                                                                                                                                                 | Read only                            | While Running = 'on'                        |
| ErrorFcn      | Function that the timer executes when an error occurs. This function executes before the StopFcn. See “Creating Callback Functions” for more information.                                                                                                                       | Data type                            | Text string, function handle, or cell array |
|               |                                                                                                                                                                                                                                                                                 | Default                              | None                                        |
|               |                                                                                                                                                                                                                                                                                 | Read only                            | Never                                       |

| Property Name | Property Description                                                                                             | Data Types, Values, Defaults, Access |                                                                                                                                                                                      |

# timer

| Property Name    | Property Description                                                                                                                                                                                                                                                                                                                                                                                                | Data Types, Values, Defaults, Access |                         |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|-------------------------|
| ObjectVisibility | Provides a way for application developers to prevent end-user access to the timer objects created by their application. The <code>timerfind</code> function does not return an object whose <code>ObjectVisibility</code> property is set to 'off'. Objects that are not visible are still valid. If you have access to the object (for example, from within the file that created it), you can set its properties. | Data type                            | Enumerated string       |
|                  |                                                                                                                                                                                                                                                                                                                                                                                                                     | Values                               | 'off'<br>'on'           |

|               |                                                                                                                                                                                                                                                                                                                                                                   | Read only                            | While Running = 'on'                        |
| StartFcn      | Function the timer calls when it starts. See “Creating Callback Functions” for more information.                                                                                                                                                                                                                                                                  | Data type                            | Text string, function handle, or cell array |
|               |                                                                                                                                                                                                                                                                                                                                                                   | Default                              | None                                        |
|               |                                                                                                                                                                                                                                                                                                                                                                   | Read only                            | Never                                       |
| StopFcn       | Function the timer calls when it stops. The timer stops when <ul style="list-style-type: none"> <li>• You call the timer stop function</li> <li>• The timer finishes executing TimerFcn, i.e., the value of TasksExecuted reaches the limit set by TasksToExecute.</li> <li>• An error occurs (The ErrorFcn is called first, followed by the StopFcn.)</li> </ul> | Data type                            | Text string, function handle, or cell array |
|               |                                                                                                                                                                                                                                                                                                                                                                   | Default                              | None                                        |
|               |                                                                                                                                                                                                                                                                                                                                                                   | Read only                            | Never                                       |

# timer

| Property Name  | Property Description                                                                                    | Data Types, Values, Defaults, Access |                                             |
|----------------|---------------------------------------------------------------------------------------------------------|--------------------------------------|---------------------------------------------|
|                | See “Creating Callback Functions” for more information.                                                 |                                      |                                             |
| Tag            | User supplied label.                                                                                    | Data type                            | Text string                                 |
|                |                                                                                                         | Default                              | Empty string ( ' ' )                        |
|                |                                                                                                         | Read only                            | Never                                       |
| TasksToExecute | Specifies the number of times the timer should execute the function specified in the TimerFcn property. | Data type                            | double                                      |
|                |                                                                                                         | Values                               | Any number > 0                              |
|                |                                                                                                         | Default                              | Inf                                         |
|                |                                                                                                         | Read only                            | Never                                       |
| TasksExecuted  | The number of times the timer has called TimerFcn since the timer was started.                          | Data type                            | double                                      |
|                |                                                                                                         | Values                               | Any number >= 0                             |
|                |                                                                                                         | Default                              | 0                                           |
|                |                                                                                                         | Read only                            | Always                                      |
| TimerFcn       | Timer callback function. See “Creating Callback Functions” for more information.                        | Data type                            | Text string, function handle, or cell array |
|                |                                                                                                         | Default                              | None                                        |
|                |                                                                                                         | Read only                            | Never                                       |

| Property Name | Property Description        | Data Types, Values, Defaults, Access |              |
|---------------|-----------------------------|--------------------------------------|--------------|
| Type          | Identifies the object type. | Data type                            | Text string  |
|               |                             | Values                               | 'timer'      |
|               |                             | Read only                            | Always       |
| UserData      | User-supplied data.         | Data type                            | User-defined |
|               |                             | Default                              | []           |
|               |                             | Read only                            | Never        |

**Examples**

This example constructs a timer object with a timer callback function handle, `mycallback`, and a 10 second interval.

```
t = timer('TimerFcn',@mycallback, 'Period', 10.0);
```

**See Also**

```
delete(timer) | disp(timer) | get(timer) | isvalid(timer) |
set(timer) | start | startat | stop | timerfind | timerfindall
| wait
```

# timerfind

---

**Purpose** Find timer objects

**Syntax**

```
out = timerfind
out = timerfind('P1', V1, 'P2', V2,...)
out = timerfind(S)
out = timerfind(obj, 'P1', V1, 'P2', V2,...)
```

**Description** `out = timerfind` returns an array, `out`, of all the timer objects that exist in memory.

`out = timerfind('P1', V1, 'P2', V2,...)` returns an array, `out`, of timer objects whose property values match those passed as parameter/value pairs, `P1, V1, P2, V2`. Parameter/value pairs may be specified as a cell array.

`out = timerfind(S)` returns an array, `out`, of timer objects whose property values match those defined in the structure, `S`. The field names of `S` are timer object property names and the field values are the corresponding property values.

`out = timerfind(obj, 'P1', V1, 'P2', V2,...)` restricts the search for matching parameter/value pairs to the timer objects listed in `obj`. `obj` can be an array of timer objects.

---

**Note** When specifying parameter/value pairs, you can use any mixture of strings, structures, and cell arrays in the same call to `timerfind`.

---

Note that, for most properties, `timerfind` performs case-sensitive searches of property values. For example, if the value of an object's `Name` property is `'MyObject'`, `timerfind` will not find a match if you specify `'myobject'`. Use the `get` function to determine the exact format of a property value. However, properties that have an enumerated list of possible values are not case sensitive. For example, `timerfind` will find an object with an `ExecutionMode` property value of `'singleShot'` or `'singleshot'`.

## Examples

These examples use `timerfind` to find timer objects with the specified property values.

```
t1 = timer('Tag', 'broadcastProgress', 'Period', 5);
t2 = timer('Tag', 'displayProgress');
out1 = timerfind('Tag', 'displayProgress')
out2 = timerfind({'Period', 'Tag'}, {5, 'broadcastProgress'})
```

## See Also

`get(timer)` | `timer` | `timerfindall`

# timerfindall

---

**Purpose** Find timer objects, including invisible objects

**Syntax**

```
out = timerfindall
out = timerfindall('P1', V1, 'P2', V2,...)
out = timerfindall(S)
out = timerfindall(obj, 'P1', V1, 'P2', V2,...)
```

**Description** `out = timerfindall` returns an array, `out`, containing all the timer objects that exist in memory, regardless of the value of the object's `ObjectVisibility` property.

`out = timerfindall('P1', V1, 'P2', V2,...)` returns an array, `out`, of timer objects whose property values match those passed as parameter/value pairs, `P1, V1, P2, V2`. Parameter/value pairs may be specified as a cell array.

`out = timerfindall(S)` returns an array, `out`, of timer objects whose property values match those defined in the structure, `S`. The field names of `S` are timer object property names and the field values are the corresponding property values.

`out = timerfindall(obj, 'P1', V1, 'P2', V2,...)` restricts the search for matching parameter/value pairs to the timer objects listed in `obj`. `obj` can be an array of timer objects.

---

**Note** When specifying parameter/value pairs, you can use any mixture of strings, structures, and cell arrays in the same call to `timerfindall`.

---

Note that, for most properties, `timerfindall` performs case-sensitive searches of property values. For example, if the value of an object's `Name` property is `'MyObject'`, `timerfindall` will not find a match if you specify `'myobject'`. Use the `get` function to determine the exact format of a property value. However, properties that have an enumerated list of possible values are not case sensitive. For example, `timerfindall` will find an object with an `ExecutionMode` property value of `'singleShot'` or `'singleshot'`.

**Examples**

Create several timer objects.

```
t1 = timer;
t2 = timer;
t3 = timer;
```

Set the `ObjectVisibility` property of one of the objects to 'off'.

```
t2.ObjectVisibility = 'off';
```

Use `timerfind` to get a listing of all the timer objects in memory. Note that the listing does not include the timer object (timer-2) whose `ObjectVisibility` property is set to 'off'.

```
timerfind
```

Timer Object Array

| Index: | ExecutionMode: | Period: | TimerFcn: | Name:   |
|--------|----------------|---------|-----------|---------|
| 1      | singleShot     | 1       | ''        | timer-1 |
| 2      | singleShot     | 1       | ''        | timer-3 |

Use `timerfindall` to get a listing of all the timer objects in memory. This listing includes the timer object whose `ObjectVisibility` property is set to 'off'.

```
timerfindall
```

Timer Object Array

| Index: | ExecutionMode: | Period: | TimerFcn: | Name:   |
|--------|----------------|---------|-----------|---------|
| 1      | singleShot     | 1       | ''        | timer-1 |
| 2      | singleShot     | 1       | ''        | timer-2 |
| 3      | singleShot     | 1       | ''        | timer-3 |

**See Also**

`get(timer)` | `timer` | `timerfind`

# times

---

**Purpose**            Array multiply

**Syntax**            `c = a.*b`  
                      `c = times(a,b)`

**Description**        `c = a.*b` multiplies arrays `a` and `b` element-by-element and returns the result in `c`. Inputs `a` and `b` must have the same size unless one is a scalar.  
  
`c = times(a,b)` is called for the syntax `a.*b` when `a` or `b` is an object.

**See Also**            `mtimes`

**Purpose**

Add title to current axes

**Syntax**

```
title('string')
title(fname)
title(...,'PropertyName',PropertyValue,...)
title(axes_handle,...)
h = title(...)
```

**Description**

Each axes graphics object can have one title. The title is located at the top and in the center of the axes.

`title('string')` outputs the string at the top and in the center of the current axes.

`title(fname)` evaluates the function that returns a string and displays the string at the top and in the center of the current axes.

`title(...,'PropertyName',PropertyValue,...)` specifies property name and property value pairs for the text graphics object that `title` creates. Do not use the 'String' text property to set the title string; the content of the title should be given by the first argument.

`title(axes_handle,...)` adds the title to the specified axes.

`h = title(...)` returns the handle to the text object used as the title.

---

**Note** The words `default`, `factory`, and `remove` are reserved words that will not appear in a title when quoted as a normal string. In order to display any of these words individually, type `'\reserved_word'` instead of `'reserved_word'`.

---

**Examples**

Display today's date in the current axes:

```
title(date)
```

Include a variable's value in a title:

# title

---

```
f = 70;
c = (f-32)/1.8;
title(['Temperature is ',num2str(c),'C'])
```

Make a multi-colored title:

```
title(['\fontsize{16}black {\color{magenta}magenta '...
'\color[rgb]{0 .5 .5}teal \color{red}red} black again'])
```

Include a variable's value in a title and set the color of the title to yellow:

```
n = 3;
title(['Case number #',int2str(n)], 'Color', 'y')
```

Include Greek symbols in a title:

```
title('\ite^{\omega\tau} = cos(\omega\tau) + isin(\omega\tau)')
```

Include a superscript character in a title:

```
title('\alpha^2')
```

Include a subscript character in a title:

```
title('X_1')
```

The text object String property lists the available symbols.

Create a multiline title using a multiline cell array.

```
title({'First line';'Second line'})
```

To change the default interpreter from Tex, set the Interpreter property as:

```
title('X_1', 'Interpreter', 'none');
```

This displays the string `X_1` in the title of the figure instead of making `1` subscript of `X`. See `Interpreter` for other options for the property and also `Text Properties` for other text properties.

**Tips**

`title` sets the `Title` property of the current axes graphics object to a new text graphics object. See the text `String` property for more information.

**Alternatives**

To create or modify a plot's title from a GUI, use **Insert Title** from the figure menu. Use the `Property Editor`, one of the plotting tools , to modify the position, font, and other properties of a legend. For details, see `The Property Editor`.

**How To**

- `Adding Titles to Graphs`

# todatenum

---

**Purpose** Convert CDF epoch object to MATLAB datenum

**Syntax** `n = todatenum(obj)`

**Description** `n = todatenum(obj)` converts the CDF epoch object `ep_obj` into a MATLAB serial date number. Note that a CDF epoch is the number of milliseconds since 01-Jan-0000 whereas a MATLAB datenum is the number of days since 00-Jan-0000.

**Examples** Construct a CDF epoch object from a date string, and then convert the object back into a MATLAB date string:

```
dstr = datestr(today)
dstr =
    08-Oct-2003

obj = cdfepoch(dstr)
obj =
    cdfepoch object:
    08-Oct-2003 00:00:00

dstr2 = datestr(todatenum(obj))
dstr2 =
    08-Oct-2003
```

**See Also** `cdfepoch` | `cdfinfo` | `cdfread` | `cdfwrite` | `datenum`

**Purpose** Toeplitz matrix

**Syntax** `T = toeplitz(c,r)`  
`T = toeplitz(r)`

**Description** A *Toeplitz* matrix is defined by one row and one column. A *symmetric Toeplitz* matrix is defined by just one row. `toeplitz` generates Toeplitz matrices given just the row or row and column description.

`T = toeplitz(c,r)` returns a nonsymmetric Toeplitz matrix `T` having `c` as its first column and `r` as its first row. If the first elements of `c` and `r` are different, a message is printed and the column element is used.

For a real vector `r`, `T = toeplitz(r)` returns the symmetric Toeplitz matrix formed from vector `r`, where `r` defines the first row of the matrix. For a complex vector `r` with a real first element, `T = toeplitz(r)` returns the Hermitian Toeplitz matrix formed from `r`, where `r` defines the first row of the matrix and `r'` defines the first column. When the first element of `r` is not real, the resulting matrix is Hermitian off the main diagonal, i.e.,  $T_{ij} = \text{conj}(T_{ji})$  for  $i \neq j$ .

**Examples** A Toeplitz matrix with diagonal disagreement is

```
c = [1 2 3 4 5];
r = [1.5 2.5 3.5 4.5 5.5];
toeplitz(c,r)
Column wins diagonal conflict:
ans =
    1.000    2.500    3.500    4.500    5.500
    2.000    1.000    2.500    3.500    4.500
    3.000    2.000    1.000    2.500    3.500
    4.000    3.000    2.000    1.000    2.500
    5.000    4.000    3.000    2.000    1.000
```

**See Also** `hankel` | `kron`

# toolboxdir

---

**Purpose** Root folder for specified toolbox

**Syntax**

```
toolboxdir('tbxFolderName')
s = toolboxdir('tbxFolderName')
s = toolboxdir tbxFolderName
```

**Description** `toolboxdir('tbxFolderName')` returns a string that is the absolute path to the specified toolbox, `tbxFolderName`, where `tbxFolderName` is the folder name for the toolbox.

`s = toolboxdir('tbxFolderName')` returns the absolute path to the specified toolbox to the output argument, `s`.

`s = toolboxdir tbxFolderName` is the command form of the syntax.

**Tips** `toolboxdir` is particularly useful for MATLAB Compiler software. The base folder of all toolboxes installed with MATLAB software is:

```
matlabroot/toolbox/tbxFolderName
```

However, in deployed mode, the base folders of the toolboxes are different. `toolboxdir` returns the correct root folder, whether running from MATLAB or from an application deployed with the MATLAB Compiler software.

To determine the folder name for a given toolbox, run the following code, substituting the name of a product function for *toolboxfcn*:

```
n = 'toolboxfcn';
pat = '(?<=^.+[\\\/]toolbox[\\\/])[^\\\/]+';
regexp(which(n), pat, 'match', 'once')
```

For example, to determine the product name for Control System Toolbox set `n` to the name of a function unique to Control System Toolbox, such as `dss`:

```
n = 'dss'
pat = '(?<=^.+[\\\/]toolbox[\\\/])[^\\\/]+'
regexp(which(n), pat, 'match', 'once')
```

`control`

**Examples**

Obtain the path for the Control System Toolbox software:

```
s = toolboxdir('control')
```

MATLAB returns:

```
s = C:\Program Files\MATLAB\R2012a\toolbox\control
```

# trace

---

|                    |                                                                                |
|--------------------|--------------------------------------------------------------------------------|
| <b>Purpose</b>     | Sum of diagonal elements                                                       |
| <b>Syntax</b>      | <code>b = trace(A)</code>                                                      |
| <b>Description</b> | <code>b = trace(A)</code> is the sum of the diagonal elements of the matrix A. |
| <b>Algorithms</b>  | <code>t = sum(diag(A));</code>                                                 |
| <b>See Also</b>    | <code>det</code>   <code>eig</code>                                            |

**Purpose**

Transpose

**Syntax**

```
b = a.'  
b = transpose(a)
```

**Description**

`b = a.'` computes the non-conjugate transpose of matrix `a` and returns the result in `b`.

`b = transpose(a)` is called for the syntax `a.'` when `a` is an object.

**See Also**

`ctranspose` | `permute`

# trapz

---

**Purpose** Trapezoidal numerical integration

**Syntax**  
`Z = trapz(Y)`  
`Z = trapz(X,Y)`  
`Z = trapz(...,dim)`

**Description** `Z = trapz(Y)` computes an approximation of the integral of `Y` via the trapezoidal method (with unit spacing). To compute the integral for spacing other than one, multiply `Z` by the spacing increment. Input `Y` can be complex.

If `Y` is a vector, `trapz(Y)` is the integral of `Y`.

If `Y` is a matrix, `trapz(Y)` is a row vector with the integral over each column.

If `Y` is a multidimensional array, `trapz(Y)` works across the first nonsingleton dimension.

`Z = trapz(X,Y)` computes the integral of `Y` with respect to `X` using trapezoidal integration. Inputs `X` and `Y` can be complex.

If `X` is a column vector and `Y` an array whose first nonsingleton dimension is `length(X)`, `trapz(X,Y)` operates across this dimension.

`Z = trapz(...,dim)` integrates across the dimension of `Y` specified by scalar `dim`. The length of `X`, if given, must be the same as `size(Y,dim)`.

## Examples

### Example 1

The exact value of  $\int_0^{\pi} \sin(x) dx$  is 2.

To approximate this numerically on a uniformly spaced grid, use

```
X = 0:pi/100:pi;  
Y = sin(X);
```

Then both

```
Z = trapz(X,Y)
```

and

```
Z = pi/100*trapz(Y)
```

produce

```
Z =  
    1.9998
```

### Example 2

A nonuniformly spaced example is generated by

```
X = sort(rand(1,101)*pi);  
Y = sin(X);  
Z = trapz(X,Y);
```

The result is not as accurate as the uniformly spaced grid. One random sample produced

```
Z =  
    1.9984
```

### Example 3

This example uses two complex inputs:

```
z = exp(1i*pi*(0:100)/100);  
  
trapz(z, 1./z)  
ans =  
    0.0000 + 3.1411i
```

# treelayout

---

**Purpose** Lay out tree or forest

**Syntax** `[x,y] = treelayout(parent,post)`  
`[x,y,h,s] = treelayout(parent,post)`

**Description** `[x,y] = treelayout(parent,post)` lays out a tree or a forest. `parent` is the vector of parent pointers, with 0 for a root. `post` is an optional postorder permutation on the tree nodes. If you omit `post`, `treelayout` computes it. `x` and `y` are vectors of coordinates in the unit square at which to lay out the nodes of the tree to make a nice picture.

`[x,y,h,s] = treelayout(parent,post)` also returns the height of the tree `h` and the number of vertices `s` in the top-level separator.

**See Also** `etree` | `treepplot` | `etreeplot` | `symbfact`

**Purpose**

Plot picture of tree

**Syntax**

```
treeplot(p)
treeplot(p,nodeSpec,edgeSpec)
```

**Description**

`treeplot(p)` plots a picture of a tree given a vector of parent pointers, with  $p(i) = 0$  for a root.

`treeplot(p,nodeSpec,edgeSpec)` allows optional parameters `nodeSpec` and `edgeSpec` to set the node or edge color, marker, and linestyle. Use `' '` to omit one or both.

**Examples**

To plot a tree with 12 nodes, call `treeplot` with a 12-element input vector. The index of each element in the vector is shown adjacent to each node in the figure below. (These indices are shown only for the point of illustrating the example; they are not part of the `treeplot` output.)

To generate this plot, set the value of each element in the nodes vector to the index of its parent, (setting the parent of the root node to zero).

# treeplot

---

The node marked 1 in the figure is represented by `nodes(1)` in the input vector, and because this is the root node which has a parent of zero, you set its value to zero:

```
nodes(1) = 0;      % Root node
```

`nodes(2)` and `nodes(8)` are children of `nodes(1)`, so set these elements of the input vector to 1:

```
nodes(2) = 1;      nodes(8) = 1;
```

`nodes(5:7)` are children of `nodes(4)`, so set these elements to 4:

```
nodes(5) = 4;      nodes(6) = 4;      nodes(7) = 4;
```

Continue in this manner until each element of the vector identifies its parent. For the plot shown above, the `nodes` vector now looks like this:

```
nodes = [0 1 2 2 4 4 4 1 8 8 10 10];
```

Now call `treeplot` to generate the plot:

```
treeplot(nodes)
```

## See Also

[etree](#) | [etreeplot](#) | [treelayout](#)

**Purpose** Lower triangular part of matrix

**Syntax**  $L = \text{tril}(X)$   
 $L = \text{tril}(X,k)$

**Description**  $L = \text{tril}(X)$  returns the lower triangular part of  $X$ .  
 $L = \text{tril}(X,k)$  returns the elements on and below the  $k$ th diagonal of  $X$ .  $k = 0$  is the main diagonal,  $k > 0$  is above the main diagonal, and  $k < 0$  is below the main diagonal.

**Examples** `tril(ones(4,4), -1)`

ans =

```

0  0  0  0
1  0  0  0
1  1  0  0
1  1  1  0

```

**See Also** `diag` | `triu`

# trimesh

---

**Purpose** Triangular mesh plot

**Syntax**

```
trimesh(Tri,X,Y,Z,C)
trimesh(Tri,X,Y,Z)
trimesh(Tri, X, Y)
trimesh(TR)
trimesh(...'PropertyName',PropertyValue...)
h = trimesh(...)
```

**Description** `trimesh(Tri,X,Y,Z,C)` displays triangles defined in the  $m$ -by-3 face matrix `Tri` as a mesh. Each row of `Tri` defines a single triangular face by indexing into the vectors or matrices that contain the  $X$ ,  $Y$ , and  $Z$  vertices. The edge color is defined by the vector `C`.

`trimesh(Tri,X,Y,Z)` uses `C = Z` so color is proportional to surface height.

`trimesh(Tri, X, Y)` displays the triangles in a 2-D plot.

`trimesh(TR)` displays the triangles in a `TriRep` triangulation representation.

`trimesh(...'PropertyName',PropertyValue...)` specifies additional patch property names and values for the patch graphics object created by the function.

`h = trimesh(...)` returns a handle to the displayed triangles.

**Examples** Create vertex vectors and a face matrix, then create a triangular mesh plot.

```
[x,y]=meshgrid(1:15,1:15);
tri = delaunay(x,y);
z = peaks(15);
trimesh(tri,x,y,z)
```

If the surface is already a triangulation representation it may be plotted as follows:

```
tr = TriRep(tri, x(:), y(:), z(:));
```

```
trimesh(tr)
```

## See Also

[patch](#) | [trisurf](#) | [delaunay](#) | [DelaunayTri](#) | [TriRep](#)

# triplequad

---

**Purpose** Numerically evaluate triple integral

**Syntax**

```
q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax)
q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol)
q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol,method)
```

**Description** `q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax)` evaluates the triple integral  $\text{fun}(x,y,z)$  over the three dimensional rectangular region  $x_{\min} \leq x \leq x_{\max}$ ,  $y_{\min} \leq y \leq y_{\max}$ ,  $z_{\min} \leq z \leq z_{\max}$ . The first input, `fun`, is a function handle. `fun(x,y,z)` must accept a vector `x` and scalars `y` and `z`, and return a vector of values of the integrand.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol)` uses a tolerance `tol` instead of the default, which is  $1.0e-6$ .

`q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol,method)` uses the quadrature function specified as `method`, instead of the default `quad`. Valid values for `method` are `@quad1` or the function handle of a user-defined quadrature method that has the same calling sequence as `quad` and `quad1`.

**Examples** Pass function handle `@integrnd` to `triplequad`:P

```
Q = triplequad(@integrnd,0,pi,0,1,-1,1);
```

where the file `integrnd.m` is

```
function f = integrnd(x,y,z)
f = y*sin(x)+z*cos(x);
```

Pass anonymous function handle `F` to `triplequad`:

```
F = @(x,y,z)y*sin(x)+z*cos(x);
Q = triplequad(F,0,pi,0,1,-1,1);
```

This example integrates  $y*\sin(x)+z*\cos(x)$  over the region  $0 \leq x \leq \pi, 0 \leq y \leq 1, -1 \leq z \leq 1$ . Note that the integrand can be evaluated with a vector  $x$  and scalars  $y$  and  $z$ .

## How To

- “Anonymous Functions”

# triplot

---

**Purpose** 2-D triangular plot

**Syntax**

```
triplot(TRI,x,y)
triplot(TRI,x,y,color)
h = triplot(...)
triplot(...,'param','value','param','value'...)
```

**Description** `triplot(TRI,x,y)` displays the triangles defined in the m-by-3 matrix TRI. A row of TRI contains indices into the vectors x and y that define a single triangle. The default line color is blue.

`triplot(TRI,x,y,color)` uses the string color as the line color. color can also be a line specification. See `ColorSpec` for a list of valid color strings. See `LineStyle` for information about line specifications.

`h = triplot(...)` returns a vector of handles to the displayed triangles.

`triplot(...,'param','value','param','value'...)` allows additional line property name/property value pairs to be used when creating the plot. See `Line Properties` for information about the available properties.

**Examples** Plot a Delaunay triangulation for 10 randomly generated points.

```
X = rand(10,2);
dt = DelaunayTri(X);
triplot(dt)
```

Plot the Delaunay triangulation in face-vertex format.

```
tri = dt(:,:,);
triplot(tri, X(:,1), X(:,2));
```

**See Also**

[DelaunayTri](#) | [delaunay](#) | [trimesh](#) | [trisurf](#)

**Purpose** Triangulation representation

**Description** TriRep provides topological and geometric queries for triangulations in 2-D and 3-D space. For example, for triangular meshes you can query triangles attached to a vertex, triangles that share an edge, neighbor information, circumcenters, or other features. You can create a TriRep directly using existing triangulation data. Alternatively, you can create a Delaunay triangulation, via `DelaunayTri`, which provides access to the TriRep functionality.

**Construction** TriRep Triangulation representation

|                |                              |                                                         |

## Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

## Indexing

TriRep objects support indexing into the triangulation using parentheses (). The syntax is the same as for arrays.

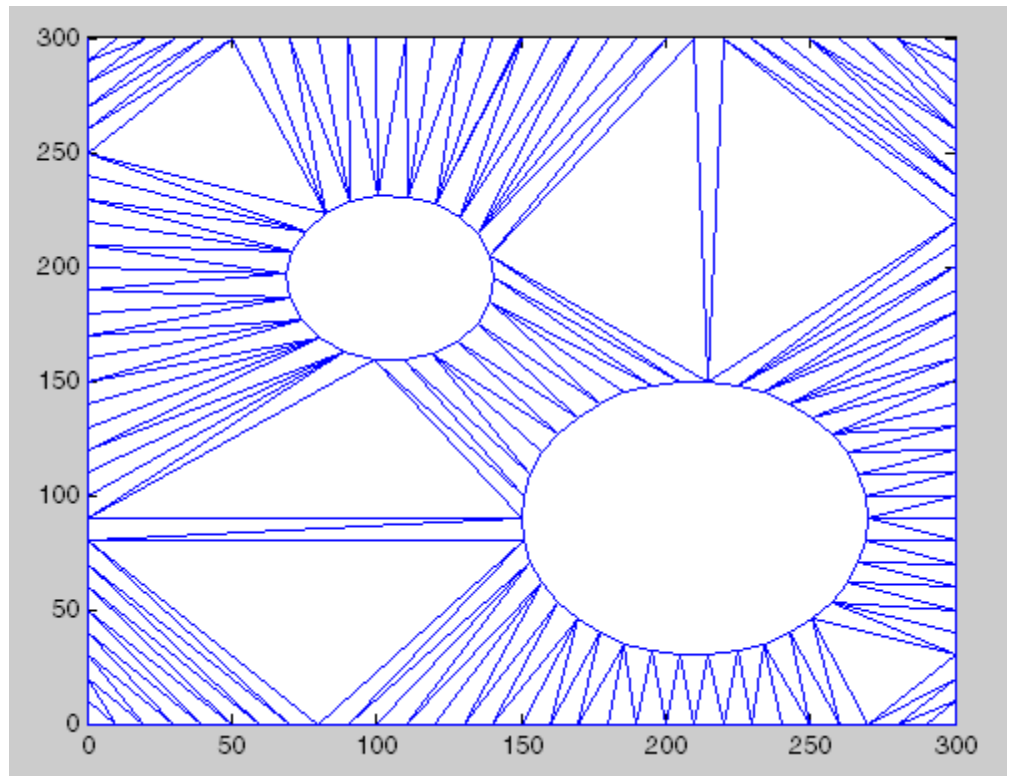

## Examples

Load a 2-D triangulation and use the TriRep constructor to build an array of the free boundary edges:

```
load trimesh2d
```

This loads triangulation `tri` and vertex coordinates `x, y`:

```
trep = TriRep(tri, x,y);
fe = freeBoundary(trep)';
triplot(trep);
```

You can add the free edges `fe` to the plot:

```
hold on;  
plot(x(fe), y(fe), 'r', 'LineWidth', 2);  
hold off;  
axis([-50 350 -50 350]);  
axis equal;
```

**See Also**

[DelaunayTri](#) | [TriScatteredInterp](#)

**Purpose**            Triangulation representation

**Syntax**            `TR = TriRep(TRI, X, Y)`  
`TR = TriRep(TRI, X, Y, Z)`  
`TR = TriRep(TRI, X)`

**Description**      `TR = TriRep(TRI, X, Y)` creates a 2-D triangulation representation from the triangulation matrix `TRI` and the vertex coordinates  $(X, Y)$ . `TRI` is an  $m$ -by-3 matrix that defines the triangulation in face-vertex format, where  $m$  is the number of triangles. Each row of `TRI` is a triangle defined by indices into the column vector of vertex coordinates  $(X, Y)$ .

`TR = TriRep(TRI, X, Y, Z)` creates a 3-D triangulation representation from the triangulation matrix `TRI` and the vertex coordinates  $(X, Y, Z)$ . `TRI` is an  $m$ -by-3 or  $m$ -by-4 matrix that defines the triangulation in simplex-vertex format, where  $m$  is the number of simplices; triangles or tetrahedra in this case. Each row of `TRI` is a simplex defined by indices into the column vector of vertex coordinates  $(X, Y, Z)$ .

`TR = TriRep(TRI, X)` creates a triangulation representation from the triangulation matrix `TRI` and the vertex coordinates `X`. `TRI` is an  $m$ -by- $n$  matrix that defines the triangulation in simplex-vertex format, where  $m$  is the number of simplices and  $n$  is the number of vertices per simplex. Each row of `TRI` is a simplex defined by indices into the array of vertex coordinates `X`. `X` is an  $mpts$ -by- $ndim$  matrix where  $mpts$  is the number of points and  $ndim$  is the dimension of the space where the points reside, where  $2 \leq ndim \leq 3$ .

**Examples**            Load a 3-D tetrahedral triangulation compute the free boundary. First, load triangulation `tet` and vertex coordinates `X`.

```
load tetmesh
```

Create the triangulation representation and compute the free boundary.

```
trep = TriRep(tet, X);  
[tri, Xb] = freeBoundary(trep);
```

**See Also**

TriScatteredInterp

# TriScatteredInterp

---

**Purpose** Interpolate scattered data

**Description** TriScatteredInterp is used to perform interpolation on a scattered dataset that resides in 2-D or 3-D space. A scattered data set defined by locations  $X$  and corresponding values  $V$  can be interpolated using a Delaunay triangulation of  $X$ . This produces a surface of the form  $V = F(X)$ . The surface can be evaluated at any query location  $QX$ , using  $QV = F(QX)$ , where  $QX$  lies within the convex hull of  $X$ . The interpolant  $F$  always goes through the data points specified by the sample.

**Definitions** The *Delaunay triangulation* of a set of points is a triangulation such that the unique circle circumscribed about each triangle contains no other points in the set. The *convex hull* of a set of points is the smallest convex set containing all points of the original set. These definitions extend naturally to higher dimensions.

**Construction** TriScatteredInterp Interpolate scattered data

## Properties

|        |                                                                 |                                |
|--------|-----------------------------------------------------------------|--------------------------------|

|        | nearest                                                         | Nearest neighbor interpolation |

## Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

## Examples

Create a data set:

```
x = rand(100,1)*4-2;  
y = rand(100,1)*4-2;  
z = x.*exp(-x.^2-y.^2);
```

Construct the interpolant:

```
F = TriScatteredInterp(x,y,z);
```

Evaluate the interpolant at the locations (qx, qy). The corresponding value at these locations is qz:

```
ti = -2:.25:2;  
[qx,qy] = meshgrid(ti,ti);  
qz = F(qx,qy);  
mesh(qx,qy,qz);  
hold on;  
plot3(x,y,z, 'o');
```

# TriScatteredInterp

---

## See Also

[DelaunayTri](#) | [interp1](#) | [interp2](#) | [interp3](#) | [meshgrid](#)

## Purpose

Interpolate scattered data

## Syntax

```
F = TriScatteredInterp()  
F = TriScatteredInterp(X, V)  
F = TriScatteredInterp(X, Y, V)  
F = TriScatteredInterp(X, Y, Z, V)  
F = TriScatteredInterp(DT, V)  
F = TriScatteredInterp(..., method)
```

## Description

`F = TriScatteredInterp()` creates an empty scattered data interpolant. This can subsequently be initialized with sample data points and values (`Xdata`, `Vdata`) via `F.X = Xdata` and `F.V = Vdata`.

`F = TriScatteredInterp(X, V)` creates an interpolant that fits a surface of the form  $V = F(X)$  to the scattered data in  $(X, V)$ . `X` is a matrix of size `mpts-by-ndim`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside (`ndim` is 2 or 3). The column vector `V` defines the values at `X`, where the length of `V` equals `mpts`.

`F = TriScatteredInterp(X, Y, V)` and `F = TriScatteredInterp(X, Y, Z, V)` allow the data point locations to be specified in alternative column vector format when working in 2-D and 3-D.

`F = TriScatteredInterp(DT, V)` uses the specified DelaunayTri object `DT` as a basis for computing the interpolant. `DT` is a Delaunay triangulation of the scattered data locations, `DT.X`. The matrix `DT.X` is of size `mpts-by-ndim`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside,  $2 \leq \text{ndim} \leq 3$ . `V` is a column vector that defines the values at `DT.X`, where the length of `V` equals `mpts`.

`F = TriScatteredInterp(..., method)` allows selection of the technique `method` used to interpolate the data.

# TriScatteredInterp

## Input Arguments

|        |                                                                                                                                                                                                                                           |                                |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|
| X      | Matrix of size <code>mpts-by-ndim</code> , where <code>mpts</code> is the number of points and <code>ndim</code> is the dimension of the space where the points reside. Input may also be specified as column vectors (X, Y) or (X, Y, Z) |                                |
| V      | Column vector that defines the values at X, where the length of V equals <code>mpts</code> .                                                                                                                                              |                                |
| DT     | Delaunay triangulation of the scattered data locations                                                                                                                                                                                    |                                |
| method | natural                                                                                                                                                                                                                                   | Natural neighbor interpolation |
|        | linear                                                                                                                                                                                                                                    | Linear interpolation (default) |
|        | nearest                                                                                                                                                                                                                                   | Nearest-neighbor interpolation |

## Output Arguments

|   |                                                                                          |  |
|---|------------------------------------------------------------------------------------------|--|
| F | Creates an interpolant that fits a surface of the form $V = F(X)$ to the scattered data. |  |
|---|------------------------------------------------------------------------------------------|--|

## Evaluation

To evaluate the interpolant, express the statement in Monge's form  $V_q = F(X_q)$ ,  $V_q = F(X_q, Y_q)$ , or  $V_q = F(X_q, Y_q, Z_q)$  where  $V_q$  is the value of the interpolant at the query location and  $X_q$ ,  $Y_q$ , and  $Z_q$  are the vectors of point locations.

## Definitions

The *Delaunay triangulation* of a set of points is a triangulation such that the unique circle circumscribed about each triangle contains no other points in the set.

## Examples

Create a data set:

```
x = rand(100,1)*4-2;  
y = rand(100,1)*4-2;  
z = x.*exp(-x.^2-y.^2);
```

Construct the interpolant:

```
F = TriScatteredInterp(x,y,z);
```

Evaluate the interpolant at the locations (qx, qy). The corresponding value at these locations is qz .

```
ti = -2:.25:2;  
[qx,qy] = meshgrid(ti,ti);  
qz = F(qx,qy);  
mesh(qx,qy,qz);  
hold on;  
plot3(x,y,z, 'o');
```

## See Also

[DelaunayTri](#) | [interp1](#) | [interp2](#) | [interp3](#) | [meshgrid](#)

# trisurf

---

**Purpose** Triangular surface plot

**Syntax**

```
trisurf(Tri,X,Y,Z,C)
trisurf(Tri,X,Y,Z)
trisurf(tr)
trisurf(...'PropertyName',PropertyValue...)
h = trisurf(...)
```

**Description** `trisurf(Tri,X,Y,Z,C)` displays triangles defined in the  $m$ -by-3 face matrix `Tri` as a surface. Each row of `Tri` defines a single triangular face by indexing into the vectors or matrices that contain the  $X$ ,  $Y$ , and  $Z$  vertices. The color is defined by the vector `C`.

`trisurf(Tri,X,Y,Z)` uses `C=Z` so color is proportional to surface height.

`trisurf(tr)` displays the triangles in a `TriRep` triangulation representation. It uses `C = TR.X(:,3)` so surface color is proportional to height.

`trisurf(...'PropertyName',PropertyValue...)` specifies additional patch property names and values for the patch graphics object created by the function.

`h = trisurf(...)` returns a patch handle.

**Examples** Create vertex vectors and a face matrix, then create a triangular surface plot.

```
[x,y]=meshgrid(1:15,1:15);
tri = delaunay(x,y);
z = peaks(15);
trisurf(tri,x,y,z)
```

If the surface is in the form of a `TriRep` triangulation representation, plot it as follows:

```
tr = TriRep(tri, x(:), y(:), z(:));
trisurf(tr)
```

| `DelaunayTri`

# triu

**Purpose** Upper triangular part of matrix

**Syntax**  
`U = triu(X)`  
`U = triu(X,k)`

**Description** `U = triu(X)` returns the upper triangular part of `X`.  
`U = triu(X,k)` returns the element on and above the `k`th diagonal of `X`.  
`k = 0` is the main diagonal, `k > 0` is above the main diagonal, and `k < 0` is below the main diagonal.

**Examples** `triu(ones(4,4), -1)`

```
ans =  
  
    1    1    1    1  
    1    1    1    1  
    0    1    1    1  
    0    0    1    1
```

**See Also** `diag` | `tril`

**Purpose** Logical 1 (true)

**Syntax**

```
true
true(n)
true(m, n)
true(m, n, p, ...)
true(size(A))
```

**Description**

`true` is shorthand for `logical(1)`.

`true(n)` is an  $n$ -by- $n$  matrix of logical ones.

`true(m, n)` or `true([m, n])` is an  $m$ -by- $n$  matrix of logical ones.

`true(m, n, p, ...)` or `true([m n p ...])` is an  $m$ -by- $n$ -by- $p$ -by-... array of logical ones.

---

**Note** The size inputs  $m, n, p, \dots$  should be nonnegative integers. Negative integers are treated as 0.

---

`true(size(A))` is an array of logical ones that is the same size as array `A`.

**Tips**

`true(n)` is much faster and more memory efficient than `logical(ones(n))`.

**See Also** `false` | `logical`

# try/catch

---

**Purpose** Execute statements and catch resulting errors

**Syntax**

```
try
    statements
catch exception
    statements
end
```

**Description** try and catch blocks allow you to override the default error behavior for a set of program statements. If any statement in a try block generates an error, program control goes immediately to the catch block, which contains your error handling statements.

*exception* is an optional MException object input to the catch block that allows you to identify the error.

Both try and catch blocks can contain nested try/catch statements.

**Examples** Provide more information about a dimension mismatch error:

```
A = rand(3);
B = ones(5);

try
    C = [A; B];
catch err

    % Give more information for mismatch.
    if (strcmp(err.identifier, 'MATLAB:catenate:dimensionMismatch'))

        msg = sprintf('%s', ...
            'Dimension mismatch occurred: First argument has ', ...
            num2str(size(A,2)), ' columns while second has ', ...
            num2str(size(B,2)), ' columns. ');
        error('MATLAB:myCode:dimensions', msg);

    % Display any other errors as usual.
    else
```

```
        rethrow(err);
    end

end % end try/catch
```

---

Catch an error when reading an image file, and try adjusting the file extension to resolve the error (.jpg and .jpeg are similar, as are .tif and .tiff):

```
function imageData = readImage(filename)
try
    imageData = imread(filename);
catch exception

    % Is the error because MATLAB could not find the file?
    if ~exist(filename, 'file')

        % Check for common typos in the extension.
        [~, ~, extension] = fileparts(filename);
        switch extension
            case '.jpg'
                altFilename = strrep(filename, '.jpg', '.jpeg');
            case '.jpeg'
                altFilename = strrep(filename, '.jpeg', '.jpg');
            case '.tif'
                altFilename = strrep(filename, '.tif', '.tiff');
            case '.tiff'
                altFilename = strrep(filename, '.tiff', '.tif');
            otherwise
                rethrow(exception);
        end

        % Try again, with modified filename.
        try
            imageData = imread(altFilename);
        catch exception2
```

# try/catch

---

```
        % Rethrow original error.  
        rethrow(exception)  
    end  
  
    else  
        rethrow(exception)  
    end  
  
end
```

error | assert | MException

**Purpose** Create tscollection object

**Syntax**

```
tsc = tscollection(TimeSeries)
tsc = tscollection(Time)
tsc = tscollection(...,'Parameter',Value,...)
```

**Description**

`tsc = tscollection(TimeSeries)` creates a `tscollection` object `tsc` with one or more `timeseries` objects already in the MATLAB workspace. The argument `TimeSeries` can be a

- Single `timeseries` object
- Cell array of `timeseries` objects

`tsc = tscollection(Time)` creates an empty `tscollection` object with the time vector `Time`. When time values are date strings, you must specify `Time` as a cell array of date strings.

`tsc = tscollection(...,'Parameter',Value,...)` creates a `tscollection` object with optional parameter-value pairs you enter after specifying either a time vector or a `timeseries` object. You can specify the following parameter:

- `Name` — String that specifies the name of this `tscollection` object

## Tips

### Definition: Time Series Collection

A time series collection object is a MATLAB variable that groups several time series with a common time vector. The time series that you include in the collection are called members of this collection.

### Properties of Time Series Collection Objects

This table lists the properties of the `tscollection` object. You can specify the `Time`, `TimeSeries`, and `Name` properties as input arguments in the constructor.

# tscollection

---

| Property | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Name     | tscollection name as a string. This can differ from the tscollection name in the MATLAB workspace.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Time     | <p>When <code>TimeInfo.StartDate</code> is empty, values are measured relative to 0 . When <code>TimeInfo.StartDate</code> is defined, values represent date strings measured relative to the <code>StartDate</code>.</p> <p>The length of <code>Time</code> must be the same as the first or the last dimension of <code>Data</code> for each collection .</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| TimeInfo | <p>Contains fields for contextual information about <code>Time</code>:</p> <ul style="list-style-type: none"><li>• <code>Units</code> — Time units with any of the following values: 'weeks', 'days', 'hours', 'minutes', 'seconds', 'milliseconds', 'microseconds', 'nanoseconds'</li><li>• <code>Start</code> — Start time</li><li>• <code>End</code> — End time (read only)</li><li>• <code>Increment</code> — Interval between subsequent time values. NaN when times are not uniformly sampled.</li><li>• <code>Length</code> — Length of the time vector (read only)</li><li>• <code>Format</code> — String defining the date string display format. See <code>datestr</code>.</li><li>• <code>StartDate</code> — Date string defining the reference date. See <code>setabstime (tscollection)</code>.</li><li>• <code>UserData</code> — Any additional user-defined information</li></ul> |

## Examples

The following example shows how to create a `tscollection` object.

1 Import the sample data.

```
load count.dat
```

**2** Create three `timeseries` objects to store each set of data:

```
count1 = timeseries(count(:,1),1:24,'name', 'ts1');  
count2 = timeseries(count(:,2),1:24,'name', 'ts2');  
count3 = timeseries(count(:,3),1:24,'name', 'ts3');
```

**3** Create a `tscollection` object named `tsc` and add to it two out of three time series already in the MATLAB workspace, by using the following syntax:

```
tsc = tscollection({count1 count2},'name','tsc')
```

# tsdata.event

---

**Purpose** Construct event object for timeseries object

**Syntax**  
`e = tsdata.event(Name,Time)`  
`e = tsdata.event(Name,Time,'Datenum')`

**Description** `e = tsdata.event(Name,Time)` creates an event object with the specified Name that occurs at the time Time. Time can either be a real value or a date string.

`e = tsdata.event(Name,Time,'Datenum')` uses 'Datenum' to indicate that the Time value is a serial date number generated by the datenum function. The Time value is converted to a date string after the event is created.

**Tips** You add events by using the addevent method.

Fields of the `tsdata.event` object include the following:

- **EventData** — MATLAB array that stores any user-defined information about the event
- **Name** — String that specifies the name of the event
- **Time** — Time value when this event occurs, specified as a real number
- **Units** — Time units
- **StartDate** — A reference date, specified in MATLAB datestr format. StartDate is empty when you have a numerical (non-date-string) time vector.

**Purpose** Search for enclosing Delaunay triangle

---

**Note** tsearch has been removed. Use DelaunayTri/pointLocation instead.

---

**Syntax** `T = tsearch(x,y,TRI,xi,yi)`

**Description** `T = tsearch(x,y,TRI,xi,yi)` returns an index into the rows of TRI for each point in xi, yi. The tsearch command returns NaN for all points outside the convex hull. Requires a triangulation TRI of the points x,y obtained from delaunay.

**See Also** DelaunayTri | delaunay | delaunayn | tsearchn

# tsearchn

---

**Purpose** N-D closest simplex search

**Syntax**  
`t = tsearchn(X,TRI,XI)`  
`[t,P] = tsearchn(X,TRI,XI)`

**Description** `t = tsearchn(X,TRI,XI)` returns the indices `t` of the enclosing simplex of the Delaunay triangulation `TRI` for each point in `XI`. `X` is an `m`-by-`n` matrix, representing `m` points in `N`-dimensional space. `XI` is a `p`-by-`n` matrix, representing `p` points in `N`-dimensional space. `tsearchn` returns `NaN` for all points outside the convex hull of `X`. `tsearchn` requires a triangulation `TRI` of the points `X` obtained from `delaunayn`.

`[t,P] = tsearchn(X,TRI,XI)` also returns the barycentric coordinate `P` of `XI` in the simplex `TRI`. `P` is a `p`-by-`n+1` matrix. Each row of `P` is the barycentric coordinate of the corresponding point in `XI`. It is useful for interpolation.

**See Also** [DelaunayTri](#) | [tsearch](#)

**Purpose** Open Time Series Tools GUI

**Syntax**  
`tstool`  
`tstool(ts)`  
`tstool(tsc)`

---

**Note** `tstool(sldata)` and `tstool(ModelDataLogs, 'replace')` have been removed. To view logged signal data, use the Simulink Simulation Data Inspector instead.

---

**Description**

`tstool` starts the Time Series Tools GUI without loading any data.

`tstool(ts)` starts the Time Series Tools GUI and loads the time-series object `ts` from the MATLAB workspace.

`tstool(tsc)` starts the Time Series Tools GUI and loads the time-series collection object `tsc` from the MATLAB workspace.

**See Also** `timeseries` | `tscollection`

**How To**

- “View Logged Signal Data with the Simulation Data Inspector”

# type

---

**Purpose** Display contents of file

**Syntax** `type('filename')`  
`type filename`

**Description** `type('filename')` displays the contents of the specified file in the MATLAB Command Window. Use the full path for `filename`, or use a MATLAB relative partial path.

If you do not specify a file extension and there is no `filename` file without an extension, the `type` function adds the `.m` extension by default. The `type` function checks the folders specified in the MATLAB search path, which makes it convenient for listing the contents of files on the screen. Use `type` with `more` on to see the listing one screen at a time.

`type filename` is the command form of the syntax.

**Examples** `type('foo.bar')` lists the contents of the file `foo.bar`.

`type foo` lists the contents of the file `foo`. If `foo` does not exist, `type foo` lists the contents of the file `foo.m`.

**See Also** `cd` | `dbtype` | `delete` | `dir` | `more` | `path` | `what` | `who`

**Purpose** Convert data types without changing underlying data

**Syntax** `Y = typecast(X, type)`

**Description** `Y = typecast(X, type)` converts a numeric value in `X` to the data type specified by `type`. Input `X` must be a full, noncomplex, numeric scalar or vector. The `type` input is a string set to one of the following: 'uint8', 'int8', 'uint16', 'int16', 'uint32', 'int32', 'uint64', 'int64', 'single', or 'double'.

`typecast` is different from the MATLAB `cast` function in that it does not alter the input data. `typecast` always returns the same number of bytes in the output `Y` as were in the input `X`. For example, casting the 16-bit integer 1000 to `uint8` with `typecast` returns the full 16 bits in two 8-bit segments (3 and 232) thus keeping its original value ( $3 \times 256 + 232 = 1000$ ). The `cast` function, on the other hand, truncates the input value to 255.

The output of `typecast` can be formatted differently depending on what system you use it on. Some computer systems store data starting with its most significant byte (an ordering called *big-endian*), while others start with the least significant byte (called *little-endian*).

---

**Note** MATLAB issues an error if `X` contains fewer values than are needed to make an output value.

---

## Examples

### Example 1

This example converts between data types of the same size:

```
typecast(uint8(255), 'int8')
ans =
    -1
```

```
typecast(int16(-1), 'uint16')
ans =
```

65535

## Example 2

Set X to a 1-by-3 vector of 32-bit integers, then cast it to an 8-bit integer type:

```
X = uint32([1 255 256])
X =
     1     255     256
```

Running this on a little-endian system produces the following results. Each 32-bit value is divided up into four 8-bit segments:

```
Y = typecast(X, 'uint8')
Y =
     1     0     0     0    255     0     0     0     0     1     0     0
```

The third element of X, 256, exceeds the 8 bits that it is being converted to in Y(9) and thus overflows to Y(10):

```
Y(9:12)
ans =
     0     1     0     0
```

Note that `length(Y)` is equal to `4.*length(X)`. Also note the difference between the output of `typecast` versus that of `cast`:

```
Z = cast(X, 'uint8')
Z =
     1    255    255
```

## Example 3

This example casts a smaller data type (`uint8`) into a larger one (`uint16`). Displaying the numbers in hexadecimal format makes it easier to see just how the data is being rearranged:

```
format hex
X = uint8([44 55 66 77])
X =
```

```
2c 37 42 4d
```

The first `typecast` is done on a big-endian system. The four 8-bit segments of the input data are combined to produce two 16-bit segments:

```
Y = typecast(X, 'uint16')
Y =
    2c37    424d
```

The second is done on a little-endian system. Note the difference in byte ordering:

```
Y = typecast(X, 'uint16')
Y =
    372c    4d42
```

You can format the little-endian output into big-endian (and vice versa) using the `swapbytes` function:

```
Y = swapbytes(typecast(X, 'uint16'))
Y =
    2c37    424d
```

## Example 4

This example attempts to make a 32-bit value from a vector of three 8-bit values. MATLAB issues an error because there are an insufficient number of bytes in the input:

```
format hex
typecast(uint8([120 86 52]), 'uint32')
```

Error using `typecast`  
Too few input values to make output type.

Repeat the example, but with a vector of four 8-bit values, and it returns the expected answer:

```
typecast(uint8([120 86 52 18]), 'uint32')
ans =
```

# typecast

---

12345678

| <b>Description</b> | <p>A <code>uibuttongroup</code> groups components and manages exclusive selection behavior for radio buttons and toggle buttons that it contains. It can also contain other user interface controls, axes, <code>uipanel</code>s, and <code>uibuttongroups</code>. It cannot contain ActiveX controls.</p> <pre>uibuttongroup('PropertyName1',Value1,'PropertyName2',Value2,...)</pre> creates a visible container component in the current figure window. This component manages exclusive selection behavior for <code>uicontrol</code> s of style <code>radiobutton</code> and <code>togglebutton</code> . |
|                    | <pre>handle = uibuttongroup(...)</pre> creates a <code>uibuttongroup</code> object and returns a handle to it in <code>handle</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                    | A <code>uibuttongroup</code> object can have axes, <code>uicontrol</code> , <code>uipanel</code> , and <code>uibuttongroup</code> objects as children. However, only <code>uicontrol</code> s of style <code>radiobutton</code> and <code>togglebutton</code> are managed by the component.                                                                                                                                                                                                                                                                                                                   |
|                    | When programming a button group, you do not code callbacks for the individual buttons; instead, use its <code>SelectionChangeFcn</code> callback to manage responses to selections. The following example illustrates how you use <code>uibuttongroup</code> event data to do this.                                                                                                                                                                                                                                                                                                                           |
|                    | For the children of a <code>uibuttongroup</code> object, the <code>Position</code> property is interpreted relative to the button group. If you move the button group, the children automatically move with it and maintain their positions in the button group.                                                                                                                                                                                                                                                                                                                                              |
|                    | If you have a button group that contains a set of radio buttons and toggle buttons and you want:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                    | <ul style="list-style-type: none"><li>• An immediate action to occur when a radio button or toggle button is selected, you must include the code to control the radio and toggle buttons in the button group's <code>SelectionChangeFcn</code> callback function,</li></ul>                                                                                                                                                                                                                                                                                                                                   |

# uibbuttongroup

---

not in the individual toggle button `Callback` functions. See the `SelectionChangeFcn` property and the example on this reference page for more information.

- Another component such as a push button to base its action on the selection, then that component's `Callback` callback can get the handle of the selected radio button or toggle button from the button group's `SelectedObject` property.

Use the `Parent` property to specify the parent as a figure, `uipanel`, or `uibbuttongroup`. If you do not specify a parent, `uibbuttongroup` adds the button group to the current figure. If no figure exists, one is created.

See the `Uibbuttongroup Properties` reference page for more information.

After creating a `uibbuttongroup`, you can set and query its property values using `set` and `get`. Run `get(handle)` to see a list of properties and their current values. Run `set(handle)` to see a list of object properties you can set and their legal values.

## Tips

If you set the `Visible` property of a `uibbuttongroup` object to `'off'`, any child objects it contains (buttons, button groups, etc.) become invisible along with the `uibbuttongroup` panel itself. However, doing this does *not* affect the settings of the `Visible` property of any of its child objects, even though all of them remain invisible until the button group's visibility is set to `'on'`. `uipanel` components also behave in this manner.

Do not use the `CreateFcn` of a button group to create the buttons it contains. You can toggle buttons created in the button group `CreateFcn` on and off, but clicking them does not trigger the button group `SelectionChangeCallback` and the buttons do not display the expected mutually-exclusive behavior.

## Examples

This example creates a `uibbuttongroup` with three radio buttons. It manages the radio buttons with the `SelectionChangeFcn` callback, `selcbk`.

When you select a new radio button, `selcbk` displays the `uibbuttongroup` handle on one line, the `EventName`, `OldValue`, and `NewValue` fields

of the event data structure on a second line, and the value of the SelectedObject property on a third line.

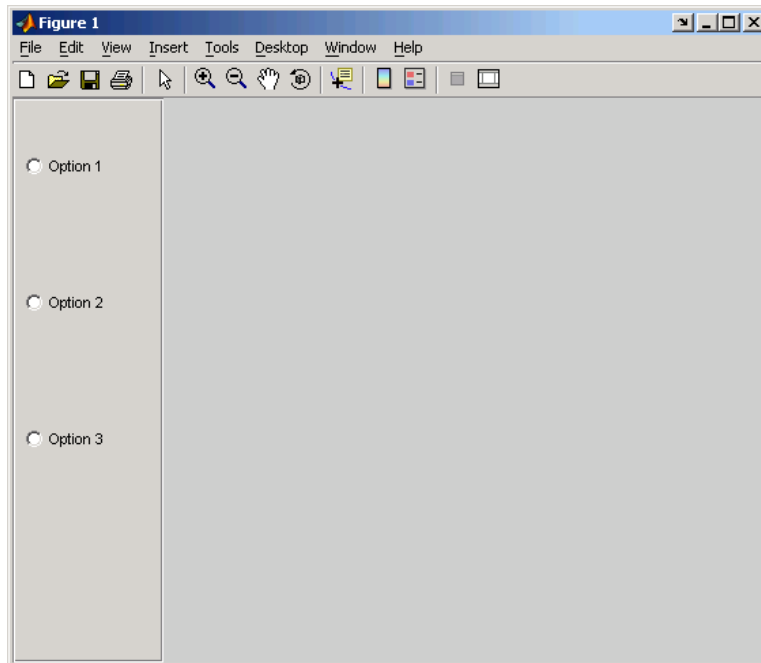

```
% Create the button group.
h = uibuttongroup('visible','off','Position',[0 0 .2 1]);
% Create three radio buttons in the button group.
u0 = uicontrol('Style','radiobutton','String','Option 1',...
    'pos',[10 350 100 30],'parent',h,'HandleVisibility','off');
u1 = uicontrol('Style','radiobutton','String','Option 2',...
    'pos',[10 250 100 30],'parent',h,'HandleVisibility','off');
u2 = uicontrol('Style','radiobutton','String','Option 3',...
    'pos',[10 150 100 30],'parent',h,'HandleVisibility','off');
% Initialize some button group properties.
set(h,'SelectionChangeFcn',@selcbk);
set(h,'SelectedObject',[]); % No selection
set(h,'Visible','on');
```

For the SelectionChangeFcn callback, selcbk, the source and event data structure arguments are available only if selcbk is called using a function handle. See SelectionChangeFcn for more information.

```
function selcbk(source,eventdata)
disp(source);
disp([ eventdata.EventName, ' ',...
    get(eventdata.OldValue,'String'),' ', ...
    get(eventdata.NewValue,'String')]);
disp(get(get(source,'SelectedObject'),'String'));
```

# uibuttongroup

---

If you click Option 2 with no option selected, the SelectionChangeFcn callback, selcbk, displays:

```
3.0011
```

```
SelectionChanged    Option 2  
Option 2
```

If you then click Option 1, the SelectionChangeFcn callback, selcbk, displays:

```
3.0011
```

```
SelectionChanged    Option 2    Option 1  
Option 1
```

# Uibuttongroup Properties

---

## Purpose

Describe button group properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

Uibuttongroup takes its default property values from `uipanel`. To set a uibuttongroup default property value, set the default for the corresponding `uipanel` property. Note that you can set no default values for the uibuttongroup `SelectedObject` and `SelectionChangeFcn` properties.

For more information about changing the default value of a property see “Setting Default Property Values”. For an example, see the `CreateFcn` property.

## Uibuttongroup Properties

This section describes all properties useful to uibuttongroup objects and lists valid values. Curly braces { } enclose default values.

| Property Name                | Description                                |
|------------------------------|--------------------------------------------|
| <code>BackgroundColor</code> | Color of the button group background       |
| <code>BeingDeleted</code>    | This object is being deleted               |
| <code>BorderType</code>      | Type of border around the button group     |
| <code>BorderWidth</code>     | Width of the button group border in pixels |
| <code>BusyAction</code>      | Interruption of other callback routines    |
| <code>ButtonDownFcn</code>   | Button-press callback routine              |
| <code>Children</code>        | All children of the button group           |

# Uibuttongroup Properties

| Property Name      | Description                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------|
| Clipping           | Clipping of child axes, panels, and button groups to the button group. Does not affect child user interface controls (uicontrol) |
| CreateFcn          | Callback routine executed during object creation                                                                                 |
| DeleteFcn          | Callback routine executed during object deletion                                                                                 |
| FontAngle          | Title font angle                                                                                                                 |
| FontName           | Title font name                                                                                                                  |
| FontSize           | Title font size                                                                                                                  |
| FontUnits          | Title font units                                                                                                                 |
| FontWeight         | Title font weight                                                                                                                |
| ForegroundColor    | Title font color and color of 2-D border line                                                                                    |
| HandleVisibility   | Handle accessibility from command line and GUIs                                                                                  |
| HighlightColor     | 3-D frame highlight color                                                                                                        |
| Interruptible      | Callback routine interruption mode                                                                                               |
| Parent             | uibuttongroup object's parent                                                                                                    |
| Position           | Button group position relative to parent figure, panel, or button group                                                          |
| ResizeFcn          | User-specified resize routine                                                                                                    |
| Selected           | Whether object is selected                                                                                                       |
| SelectedObject     | Currently selected uicontrol of style radiobutton or togglebutton                                                                |
| SelectionChangeFcn | Callback routine executed when the selected radio button or toggle button changes                                                |
| SelectionHighlight | Object highlighted when selected                                                                                                 |

# Uibuttongroup Properties

---

| Property Name | Description                                                                                                                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ShadowColor   | 3-D frame shadow color                                                                                                                                                                                         |
| Tag           | User-specified object identifier                                                                                                                                                                               |
| Title         | Title string                                                                                                                                                                                                   |
| TitlePosition | Location of title string in relation to the button group                                                                                                                                                       |
| Type          | Object class                                                                                                                                                                                                   |
| UIContextMenu | Associate context menu with the button group                                                                                                                                                                   |
| Units         | Units used to interpret the position vector                                                                                                                                                                    |
| UserData      | User-specified data                                                                                                                                                                                            |
| Visible       | Button group visibility<br><br><b>Note</b> Controls the visibility of a uibuttongroup and of its child axes, uibuttongroups, uipanel, and child uicontrols. Setting it does not change their Visible property. |

BackgroundColor  
ColorSpec

*Color of the uibuttongroup background.* A three-element RGB vector or one of the MATLAB predefined names, specifying the background color. See the ColorSpec reference page for more information on specifying color.

BeingDeleted  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the BeingDeleted property to on when the object's delete function callback is called

(see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

## BorderType

`none` | `{etchedin}` | `etchedout` |  
`beveledin` | `beveledout` | `line`

*Border of the uibuttongroup area.* Used to define the button group area graphically. Etched and beveled borders provide a 3-D look. Use the `HighlightColor` and `ShadowColor` properties to specify the border color of etched and beveled borders. A line border is 2-D. Use the `ForegroundColor` property to specify its color.

## BorderWidth

integer

*Width of the button group border.* The width of the button group borders in pixels. The default border width is 1 pixel. 3-D borders wider than 3 may not appear correctly at the corners.

## BusyAction

`cancel` | `{queue}`

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

# Uibuttongroup Properties

---

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## ButtonDownFcn

string or function handle

*Button-press callback routine.* A callback routine that executes when you press a mouse button while the pointer is in a 5-pixel wide border around the `uibuttongroup`. This is useful for implementing actions to interactively modify object properties, such as size and position, when they are clicked on (using the `selectmoveresize` function, for example).

If you define this routine as a string, the string can be a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

## Children

vector of handles

*Children of the uibuttongroup.* A vector containing the handles of all children of the `uibuttongroup`. Although a `uibuttongroup` manages only `uicontrols` of style `radiobutton` and `togglebutton`, its children can be axes, `uipanel`s, `uibuttongroup`s, and other `uicontrol`s. You can use this property to reorder the children.

## Clipping

{on} | off

*Clipping mode.* By default, MATLAB clips a `uibuttongroup`'s child axes, `uipanel`s, and `uibuttongroup`s to the `uibuttongroup` rectangle. If you set `Clipping` to `off`, the axis, `uipanel`, or

`uibuttongroup` is displayed outside the button group rectangle. This property does not affect child `uicontrols` which, by default, can display outside the button group rectangle.

## CreateFcn

string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a `uibuttongroup` object. MATLAB sets all property values for the `uibuttongroup` before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcb0` to get the handle of the `uibuttongroup` being created.

Setting this property on an existing `uibuttongroup` object has no effect.

To define a default `CreateFcn` callback for all new `uibuttongroups` you must define the same default for all `uipanel`s. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uibuttongroup`. For example, the code

```
set(0, 'DefaultUipanelCreateFcn', 'set(gcb0, ...  
    ' 'FontName', 'arial', 'FontSize', 12)')
```

creates a default `CreateFcn` callback that runs whenever you create a new panel or button group. It sets the default font name and font size of the `uipanel` or `uibuttongroup` title.

To override this default and create a button group whose `FontName` and `FontSize` properties are set to different values, call `uibuttongroup` with code similar to

```
hpt = uibuttongroup(..., 'CreateFcn', 'set(gcb0, ...  
    ' 'FontName', 'times', 'FontSize', 14)')
```

# Uibuttongroup Properties

---

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uibuttongroup` call. In the example above, if instead of redefining the `CreateFcn` property for this `uibuttongroup`, you had explicitly set `FontSize` to 14, the default `CreateFcn` callback would have set `FontSize` back to the system dependent default.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

`DeleteFcn`  
string or function handle

*Callback routine executed during object deletion.* A callback routine that executes when you delete the `uibuttongroup` object (e.g., when you issue a delete command or clear the figure containing the `uibuttongroup`). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine. The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

`FontAngle`  
{normal} | italic | oblique

*Character slant used in the Title.* MATLAB uses this property to select a font from those available on your particular system.

Setting this property to *italic* or *oblique* selects a slanted version of the font, when it is available on your system.

FontName  
string

*Font family used in the Title.* The name of the font in which to display the `Title`. To display and print properly, this must be a font that your system supports. The default font is system dependent. To eliminate the need to hard code the name of a fixed-width font, which may not display text properly on systems that do not use ASCII character encoding (such as in Japan), set `FontName` to the string `FixedWidth`. This string value is case insensitive.

```
set(uicontrol_handle,'FontName','FixedWidth')
```

This then uses the value of the root `FixedWidthFontName` property, which can be set to the appropriate value for a locale from `startup.m` in the end user's environment. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

FontSize  
integer

*Title font size.* A number specifying the size of the font in which to display the `Title`, in units determined by the `FontUnits` property. The default size is system dependent.

FontUnits  
inches | centimeters | normalized |  
{points} | pixels

*Title font size units.* Normalized units interpret `FontSize` as a fraction of the height of the `uibuttongroup`. When you resize the `uibuttongroup`, MATLAB modifies the screen `FontSize` accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).

# Uibuttongroup Properties

---

## FontWeight

light | {normal} | demi | bold

*Weight of characters in the title.* MATLAB uses this property to select a font from those available on your particular system. Setting this property to bold causes MATLAB to use a bold version of the font, when it is available on your system.

## ForegroundColor

ColorSpec

*Color used for title font and 2-D border line.* A three-element RGB vector or one of the MATLAB predefined names, specifying the font or line color. See the ColorSpec reference page for more information on specifying color.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is on.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.

- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

---

**Note** Uicontrols of style `radiobutton` and `togglebutton` that are managed by a `uibuttongroup` should not be accessed outside the button group. Set the `HandleVisibility` of such radio buttons and toggle buttons to `off` or `callback` to prevent inadvertent access.

---

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HighlightColor`  
`ColorSpec`

*3-D frame highlight color.* A three-element RGB vector or one of the MATLAB predefined names, specifying the highlight color. See the `ColorSpec` reference page for more information on specifying color.

`Interruptible`  
`off` | `{on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

# Uibuttongroup Properties

---

- ButtonDownFcn
- KeyPressFcn
- KeyReleaseFcn
- WindowButtonDownFcn
- WindowButtonMotionFcn
- WindowButtonUpFcn
- WindowKeyPressFcn
- WindowKeyReleaseFcn
- WindowScrollWheelFcn

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to on (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure’s `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object’s `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object’s `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

## Parent

handle

*Uibuttongroup parent.* The handle of the `uibuttongroup`’s parent figure, `uipanel`, or `uibuttongroup`. You can move a `uibuttongroup` object to another figure, `uipanel`, or `uibuttongroup` by setting this property to the handle of the new parent.

## Position

position rectangle

# Uibuttongroup Properties

---

*Size and location of uibuttongroup relative to parent.* The rectangle defined by this property specifies the size and location of the button group within the parent figure window, uipanel, or uibuttongroup. Specify `Position` as

```
[left bottom width height]
```

`left` and `bottom` are the distance from the lower-left corner of the parent object to the lower-left corner of the `uibuttongroup` object. `width` and `height` are the dimensions of the `uibuttongroup` rectangle, including the title. All measurements are in units specified by the `Units` property.

`ResizeFcn`  
string or function handle

*Resize callback routine.* MATLAB executes this callback routine whenever a user resizes the `uibuttongroup` and the figure `Resize` property is set to `on`, or in GUIDE, the **Resize behavior** option is set to `Other`. You can query the `uibuttongroup Position` property to determine its new size and position. During execution of the callback routine, the handle to the figure being resized is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

You can use `ResizeFcn` to maintain a GUI layout that is not directly supported by the MATLAB `Position/Units` paradigm.

For example, consider a GUI layout that maintains an object at a constant height in pixels and attached to the top of the figure, but always matches the width of the figure. The following `ResizeFcn` accomplishes this; it keeps the `uicontrol` whose `Tag` is `'StatusBar'` 20 pixels high, as wide as the figure, and attached to the top of the figure. Note the use of the `Tag` property to retrieve the `uicontrol` handle, and the `gcbo` function to retrieve the figure handle. Also note the defensive programming regarding figure `Units`, which the callback requires to be in pixels in order to work

correctly, but which the callback also restores to their previous value afterwards.

```
u = findobj('Tag','StatusBar');
fig = gcbo;
old_units = get(fig,'Units');
set(fig,'Units','pixels');
figpos = get(fig,'Position');
upos = [0, figpos(4) - 20, figpos(3), 20];
set(u,'Position',upos);
set(fig,'Units',old_units);
```

You can change the figure `Position` from within the `ResizeFcn` callback; however, the `ResizeFcn` is not called again as a result.

Note that the `print` command can cause the `ResizeFcn` to be called if the `PaperPositionMode` property is set to `manual` and you have defined a resize function. If you do not want your resize function called by `print`, set the `PaperPositionMode` to `auto`.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

## Selected

on | off (read only)

*Is object selected?* This property indicates whether the button group is selected. When this property is on, MATLAB displays selection handles if the `SelectionHighlight` property is also on. You can, for example, define the `ButtonDownFcn` function to set this property, allowing users to select the object with the mouse.

## SelectedObject

scalar handle

*Currently selected radio button or toggle button uicontrol* in the managed group of components. Use this property to determine the currently selected component or to initialize selection of one of

# Uibuttongroup Properties

---

the radio buttons or toggle buttons. By default, `SelectedObject` is set to the first uicontrol radio button or toggle button that is added. Set it to `[]` if you want no selection. Note that `SelectionChangeFcn` does not execute when this property is set by the user.

`SelectionChangeFcn`  
string or function handle

Callback routine executed when the selected radio button or toggle button changes. If this routine is called as a function handle, `uibuttongroup` passes it two arguments. The first argument, `source`, is the handle of the `uibuttongroup`. The second argument, `eventdata`, is an event data structure that contains the fields shown in the following table.

| Event Data Structure Field | Description                                                                            |
|----------------------------|----------------------------------------------------------------------------------------|
| <code>EventName</code>     | 'SelectionChanged'                                                                     |
| <code>OldValue</code>      | Handle of the object selected before this event. <code>[]</code> if none was selected. |
| <code>NewValue</code>      | Handle of the currently selected object.                                               |

If you have a button group that contains a set of radio buttons and/or toggle buttons and you want an immediate action to occur when a radio button or toggle button is selected, you must include the code to control the radio and toggle buttons in the button group's `SelectionChangeFcn` callback function, not in the individual toggle button `Callback` functions.

If you want another component such as a push button to base its action on the selection, then that component's `Callback` callback can get the handle of the selected radio button or toggle button from the button group's `SelectedObject` property.

---

**Note** For GUIDE GUIs, `hObject` contains the handle of the selected radio button or toggle button. See “Add Code for Components in Callbacks” for more information.

---

## SelectionHighlight

{on} | off

*Object highlighted when selected.* When the `Selected` property is on, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is off, MATLAB does not draw the handles.

## ShadowColor

ColorSpec

*3-D frame shadow color.* `ShadowColor` is a three-element RGB vector or one of the MATLAB predefined names, specifying the shadow color. See the `ColorSpec` reference page for more information on specifying color.

## Tag

string

*User-specified object identifier.* The `Tag` property provides a means to identify graphics objects with a user-specified label. You can define `Tag` as any string.

With the `findobj` function, you can locate an object with a given `Tag` property value. This saves you from defining object handles as global variables. For example, this function call returns the handles of all children (of the specified figures) that have the `Tag` value `'FormatTb'`.

```
h = findobj(figurehandles,'Tag','FormatTb')
```

# Uibuttongroup Properties

---

## Title

string

*Title string.* The text displayed in the button group title. You can position the title using the `TitlePosition` property.

If the string value is specified as a cell array of strings or padded string matrix, only the first string in the cell array or padded string matrix is displayed; the rest are ignored. Vertical slash (`|`) characters are not interpreted as line breaks and instead show up in the text displayed in the `uibuttongroup` title.

Setting a property value to `default`, `remove`, or `factory` produces the effect described in “Defining Default Values”. To set `Title` to one of these words, you must precede the word with the backslash character. For example,

```
hp = uibuttongroup(...,'Title','\Default');
```

## TitlePosition

{lefttop} | centertop | righttop |  
leftbottom | centerbottom | rightbottom

*Location of the title.* This property determines the location of the title string, in relation to the `uibuttongroup`.

## Type

string (read-only)

*Object class.* This property identifies the kind of graphics object. For `uibuttongroup` objects, `Type` is always the string `'uipanel'`, because its default properties derive from `uipanel`.

## UIContextMenu

handle

*Associate a context menu with a uibuttongroup.* Assign this property the handle of a `Uicontextmenu` object. MATLAB displays

# Uibuttongroup Properties

---

the context menu whenever you right-click the `uibuttongroup`. Use the `uicontextmenu` function to create the context menu.

## Units

`inches` | `centimeters` | `{normalized}` |  
`points` | `pixels` | `characters`

*Units of measurement.* MATLAB uses these units to interpret the `Position` property. For the button group itself, units are measured from the lower-left corner of its parent figure window, panel, or button group. For children of the button group, they are measured from the lower-left corner of the button group.

- Normalized units map the lower-left corner of the button group or figure window to (0,0) and the upper-right corner to (1.0,1.0).
- pixels, inches, centimeters, and points are absolute units (1 point = 1/72 inch).
- Character units are characters using the default system font; the width of one character is the width of the letter x, the height of one character is the distance between the baselines of two lines of text.

If you change the value of `Units`, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume `Units` is set to the default value.

## UserData

matrix

*User-specified data.* Any data you want to associate with the `uibuttongroup` object. MATLAB does not use this data, but you can access it using `set` and `get`.

## Visible

`{on}` | `off`

# Uibuttongroup Properties

---

*Uibuttongroup visibility.* By default, a `uibuttongroup` object is visible. When set to 'off', the `uibuttongroup` is not visible, as are all child objects of the button group. When a button group is hidden in this manner, you can still query and set its properties.

---

**Note** The value of a `uibuttongroup`'s `Visible` property determines whether its child components, such as axes, buttons, `uipanel`s, and other `uibuttongroup`s, are visible. However, changing the `Visible` property of a button group does *not* change the settings of the `Visible` property of its child components even though hiding the button group causes them to be hidden.

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Create context menu                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Syntax</b>      | <code>handle = uicontextmenu('PropertyName',PropertyValue,...)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p><code>handle = uicontextmenu('PropertyName',PropertyValue,...)</code> creates a context menu, which is a menu that appears when the user right-clicks on a graphics object. See Uicontextmenu Properties for more information.</p> <p>In its initial state, a context menu has no menu items. You create menu items within the context menu using the <code>uimenu</code> function. Menu items appear in the order in which the <code>uimenu</code> statements appear. You then associate a context menu with an object by specifying the handle of the context menu as the value for its <code>UIContextMenu</code> property.</p>                                                                                                                                                                                                                                                                                                                  |
| <b>Examples</b>    | <p>The following statements define a context menu associated with a line on a graph. The menu items enable you to change the line style.</p> <pre>% Create axes and save handle hax = axes; % Plot three lines plot(rand(20,3)); % Define a context menu; it is not attached to anything hcmenu = uicontextmenu; % Define callbacks for context menu items that change linestyle hcb1 = ['set(gcf, ''LineStyle'', ''--'')']; hcb2 = ['set(gcf, ''LineStyle'', '':''')']; hcb3 = ['set(gcf, ''LineStyle'', ''-'')']; % Define the context menu items and install their callbacks item1 = uimenu(hcmenu, 'Label', 'dashed', 'Callback', hcb1); item2 = uimenu(hcmenu, 'Label', 'dotted', 'Callback', hcb2); item3 = uimenu(hcmenu, 'Label', 'solid', 'Callback', hcb3); % Locate line objects hlines = findall(hax,'Type','line'); % Attach the context menu to each line for line = 1:length(hlines)     set(hlines(line),'uicontextmenu',hcmenu)</pre> |

## uicontextmenu

---

end

When you right-click on any line (or, on a Macintosh computer with a one-button mouse, press the **Ctrl** key and click), the context menu appears, as shown in the following figure.

To make context menus available immediately, attach them to lines at the time they are plotted. Therefore, when creating a GUI that uses such context menus, place code like the preceding in the callbacks that perform plotting for the GUI.

A best practice is to use function handles for callbacks. Only define callbacks as strings for simple actions. For example, you can add check marks to menu items (using the `Checked` uimenu property) to indicate the current style for each line. To manage the check marks, define the menu item callbacks as function handles. Place the code for the functions in the GUI code file rather than placing callback strings in the figure.

Generally, you need to attach context menus to lines at the time they are plotted in order to be sure that the menus are immediately available. Therefore, code such as the above could be placed in or called from the callbacks that perform plotting for the GUI.

# Uicontextmenu Properties

---

## Purpose

Describe context menu properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

For more information about changing the default value of a property see “Setting Default Property Values”. For an example, see the `CreateFcn` property.

## Uicontextmenu Properties

This section lists all properties useful to `uicontextmenu` objects along with valid values and descriptions of their use. Curly braces `{}` enclose default values.

| Property                      | Purpose                                                              |
|-------------------------------|----------------------------------------------------------------------|
| <code>BeingDeleted</code>     | This object is being deleted                                         |
| <code>BusyAction</code>       | Callback routine interruption                                        |
| <code>Callback</code>         | Control action                                                       |
| <code>Children</code>         | The <code>uimenu</code> s defined for the <code>uicontextmenu</code> |
| <code>CreateFcn</code>        | Callback routine executed during object creation                     |
| <code>DeleteFcn</code>        | Callback routine executed during object deletion                     |
| <code>HandleVisibility</code> | Whether handle is accessible from command line and GUIs              |
| <code>Interruptible</code>    | Callback routine interruption mode                                   |
| <code>Parent</code>           | <code>Uicontextmenu</code> object's parent                           |

| Property | Purpose                                      |
|----------|----------------------------------------------|
| Position | Location of uicontextmenu when Visible is on |
| Tag      | User-specified object identifier             |
| Type     | Class of graphics object                     |
| UserData | User-specified data                          |
| Visible  | Uicontextmenu visibility                     |

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the **BeingDeleted** property to **on** when the object's delete function callback is called (see the **DeleteFcn** property). It remains set to **on** while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's **BeingDeleted** property before acting.

## BusyAction

cancel | {queue}

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The **BusyAction** property of the *interrupting* callback determines how MATLAB handles its execution. When the **BusyAction** property is set to:

# Uicontextmenu Properties

---

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

**Callback**  
string

*Control action.* A routine that executes whenever you right-click an object for which a context menu is defined. The routine executes immediately before the context menu is posted. Define this routine as a string that is a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

**Children**  
matrix

The `uimenu` items defined for the `uicontextmenu`.

**CreateFcn**  
string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a `uicontextmenu` object. MATLAB sets all property values for the `uicontextmenu` before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcb0` to get the handle of the `uicontextmenu` being created.

Setting this property on an existing `uicontextmenu` object has no effect.

You can define a default `CreateFcn` callback for all new `uicontextmenus`. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uicontextmenu`. For example, the code

```
set(0,'DefaultUicontextmenuCreateFcn','set(gcbo,...  
    'Visible','on'))
```

creates a default `CreateFcn` callback that runs whenever you create a new context menu. It sets the default `Visible` property of a context menu.

To override this default and create a context menu whose `Visible` property is set to a different value, call `uicontextmenu` with code similar to

```
hpt = uicontextmenu(...,'CreateFcn','set(gcbo,...  
    'Visible','off'))
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uicontextmenu` call. In the example above, if instead of redefining the `CreateFcn` property for this `uicontextmenu`, you had explicitly set `Visible` to `off`, the default `CreateFcn` callback would have set `Visible` back to the default, i.e., `on`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

# Uicontextmenu Properties

---

## DeleteFcn

string or function handle

*Delete uicontextmenu callback routine.* A callback routine that executes when you delete the `uicontextmenu` object (for example, when you issue a `delete` command or clear the figure containing the `uicontextmenu`). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define the callback function.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from

command-line users, while allowing callback routines to have complete access to object handles.

- Setting `HandleVisibility` to `off` makes handles invisible at all times. This might be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`Interruptible`  
`off | {on}`

### *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

# Uicontextmenu Properties

---

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted.

For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure’s `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object’s `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object’s `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

## Parent

handle

*Uicontextmenu’s parent.* The handle of the `uicontextmenu`’s parent object, which must be a figure.

## Position

vector

*Uicontextmenu’s position.* A two-element vector that defines the location of a context menu posted by setting the `Visible` property value to `on`. Specify `Position` as

[x y]

where vector elements represent the horizontal and vertical distances in pixels from the bottom left corner of the figure window, panel, or button group to the top left corner of the context menu.

## Tag

string

# Uicontextmenu Properties

---

*User-specified object label.* The `Tag` property provides a means to identify graphics objects with a user-specified label. This is particularly useful when constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callback routines. You can define `Tag` as any string.

**Type**  
string

*Class of graphics object.* For `uicontextmenu` objects, `Type` is always the string `'uicontextmenu'`.

**UserData**  
matrix

*User-specified data.* Any data you want to associate with the `uicontextmenu` object. MATLAB does not use this data, but you can access it using `set` and `get`.

**Visible**  
on | {off}

*Uicontextmenu visibility.* The `Visible` property can be used in two ways:

- Its value indicates whether the context menu is currently posted. While the context menu is posted, the property value is `on`; when the context menu is not posted, its value is `off`.
- Its value can be set to `on` to force the posting of the context menu. Similarly, setting the value to `off` forces the context menu to be removed. When used in this way, the `Position` property determines the location of the posted context menu.

**See Also**      `uicontextmenu`

**Purpose**

Create user interface control object

**Syntax**

```
handle = uicontrol('Name',Value,...)
handle = uicontrol(parent,'Name',Value,...)
handle = uicontrol
uicontrol(uich)
```

**Description**

`handle = uicontrol('Name',Value,...)` creates a `uicontrol` and assigns the specified properties and values to it. It assigns the default values to any properties you do not specify. The default `uicontrol` style is `pushbutton`. The default parent is the current figure. See the `Uicontrol Properties` reference page for more information.

`handle = uicontrol(parent,'Name',Value,...)` creates a `uicontrol` in the object specified by the handle, `parent`. If you also specify a different value for the `Parent` property, the value of the `Parent` property takes precedence. `parent` can be the handle of a figure, `uipanel`, or `uibuttongroup`.

`handle = uicontrol` creates a push button in the current figure. The `uicontrol` function assigns all properties their default values.

`uicontrol(uich)` gives focus to the `uicontrol` specified by the handle, `uich`.

`uicontrol` creates a `uicontrol` graphics objects (user interface controls), which you use to implement graphical user interfaces.

**Specifying the Uicontrol Style**

When selected, most `uicontrol` objects perform a predefined action. To create a specific type of `uicontrol`, set the `Style` property as one of the strings that follow. You can specify a partial string if it is unique among all the styles. For example, instead of `'radiobutton'`, you can specify `'radio'`.

- `'checkbox'` – A check box generates an action when you select it. Use check boxes to provide a number of independent choices. To activate a check box, click the mouse button on the object. The check box updates its appearance when its state changes.

- 'edit' – Editable text fields enable you to enter or modify text values. Use editable text when you want free text as input. To enable multiple lines of text, set `Max-Min>1`. Multiline edit boxes provide a vertical scroll bar for scrolling. The arrow keys also provide a way to scroll. Obtain the current text by getting the `String` property. The `String` property does not update as you type in an edit box. To execute the callback routine for an edit text control, type in the desired text and then do one of the following:
  - Click another component, the menu bar, or the background of the GUI.
  - For a single line editable text box, press **Enter**.
  - For a multiline editable text box, press **Ctrl+Enter**.
- 'frame'

---

**Note** MathWorks recommends you use `uipanel` or `uibuttongroup` instead of frames.

GUIDE continues to support frames in those GUIs that contain them, but the frame component does not appear in the GUIDE Layout Editor component palette.

---

- 'listbox' – List boxes display a list of items, from which you can select one or more items. Unlike pop-up menus, list boxes do not expand when clicked. The `Min` and `Max` properties control the selection mode:
  - To enable multiple selection of items, set `Max-Min > 1`.
  - To enable selection of only one item at a time, set `Max-Min <= 1`.

The `Value` property stores the row indexes of currently selected list box items, and is a vector value when you select multiple items. After any mouse button up event that changes the `Value` property, MATLAB evaluates the list box's callback routine. To delay action

when multiple items can be selected, you can associate a "Done" push button with the list box. Use the callback for that button to evaluate the list box `Value` property.

List boxes with the `Enable` property set to `on` differentiate between single and double left clicks. MATLAB sets the figure `SelectionType` property to `normal` or `open` accordingly before evaluating the list box `Callback` property. For enabled list boxes, **Ctrl**-left click and **Shift**-left click also set the figure `SelectionType` property to `normal` or `open`, respectively indicating a single or double click.

- `'popupmenu'` – Pop-up menus (also known as drop-down menus or combo boxes) display a list of choices when you open them with a button-press. When closed, a pop-up menu indicates the current choice. Pop-up menus are useful when you want to provide a number of mutually exclusive choices, but do not want to take up the amount of space that a group of radio buttons requires.
- `'pushbutton'` – Push buttons generate an action when activated. Left-click a push button to activate it. The button appears to depress until you release the mouse button. The callback activates when you release the mouse button while still pointing within the push button.
- `'radiobutton'` – Radio buttons are similar to check boxes, but are intended to be mutually exclusive within a group of related radio buttons. When used this way, you can only select one radio button at any given time). To activate a radio button, click and release the mouse button over it. The easiest way to implement mutually exclusive behavior for a set of radio buttons is to place them within a `uibuttongroup`.
- `'slider'` – Sliders accept numeric input within a specific range when you move the “thumb” button along a bar. The location of the thumb indicates a numeric value, assigned to the `Value` property when you release the mouse button. You can set the minimum, maximum, and current values, and step sizes of a slider.

Move the thumb by doing any one of the following:

- Press the mouse button on the thumb, and drag it along the bar.

- Click in the bar or on arrow buttons located at both ends of the bar.
- Click the keyboard arrow keys when the slider is in focus.
- 'text' – Static text boxes display lines of text. You typically use static text to label other controls, provide information to the user, or indicate values associated with a slider. Users cannot change static text interactively. Static text controls do not activate callback routines when clicked.
- 'togglebutton' – Toggle buttons are similar in appearance to push buttons, but they visually indicate their state, either on (pressed down) or off (up). Clicking a toggle button changes its state, and switches its Value property between Min and Max.

## Tips

- To simulate activation on static text by a mouse click, set the text *object's* Enable property to Inactive, and set its ButtonDownFcn callback to perform an action. For example, the following code displays 'Pressed' in the Command Window when you click on theClick me! text in the running GUI. (Without the set command, it would do nothing.)

```
h = uicontrol('Style','text','String','Click Me!');
set(h,'Enable','Inactive','ButtonDownFcn',...
    'disp(''Text was clicked'')')
```
- Adding a uicontrol to a figure removes the figure toolbar when the figure Toolbar property is 'auto' (which is the default). To prevent this from happening, set the Toolbar property to 'figure'. You can restore the toolbar by selecting **Figure Toolbar** from the **View** menu regardless of this property setting.
- The uicontrol function accepts property name/property value pairs, structures, and cell arrays as input arguments and optionally returns the handle of the created object. You can also use the set and get functions to set and query property values after creating the control.
- A uicontrol object is a child of a figure, uipanel, or uibuttongroup. Therefore, the uicontrol object does not require an axes to exist when placed in a figure window, uipanel, or uibuttongroup.

- When you pause MATLAB and a uicontrol has focus, pressing a keyboard key does not cause MATLAB to resume. Click anywhere outside a uicontrol and then press any key. For more information, see the `pause` function.

## Examples

Create a figure and an axes to contain a 3-D surface plot.

```
figure
hax = axes('Units','pixels');
surf(peaks)
```

Place a uicontrol object to let users change the colormap with a pop-up menu. Supply a function handle as the object's `Callback` property:

```
uicontrol('Style', 'popup',...
         'String', 'jet|hsv|hot|cool|gray',...
         'Position', [20 340 100 50],...
         'Callback', @setmap); % Popup function handle callback
                               % Implemented as a local function
```

Add a different uicontrol. Create a push button that clears the current axes when pressed. Position the button inside the axes at the lower left. All uicontrols have default units of pixels. In this example, the axes has units of pixels, as well.

```
uicontrol('Style', 'pushbutton', 'String', 'Clear',...  
         'Position', [20 20 50 20],...  
         'Callback', 'cla');           % Pushbutton string callback  
                                       % that calls a MATLAB function
```

Add a slider uicontrol to control the vertical scaling of the surface object. Position it at the bottom right corner of the figure. Then add a text uicontrol as a label for the slider.

```
uicontrol('Style', 'slider',...
         'Min',1,'Max',50,'Value',41,...
         'Position', [400 20 120 20],...
         'Callback', {@surfzlim,hax});
% Uses cell array function handle callback
% Implemented as a local function with an argument
```

```
uicontrol('Style','text',...  
         'Position',[400 45 120 20],...  
         'String','Vertical Exaggeration')
```

To operate the controls, you need callback functions. The callback for the pop-up menu is a local function called `setmap` that contains the following code.

```
function setmap(hObject,event) %#ok<INUSD>
```

```

    % Called when user activates popup menu
    val = get(hObj, 'Value');
    if val == 1
        colormap(jet)
    elseif val == 2
        colormap(hsv)
    elseif val == 3
        colormap(hot)
    elseif val == 4
        colormap(cool)
    elseif val == 5
        colormap(gray)
    end
end

```

The callback for the slider is also a local function in the same file, and contains the following code.

```

function surfzlim(hObj,event,ax) %#ok<INUSL>
    % Called to set zlim of surface in figure axes
    % when user moves the slider control
    val = 51 - get(hObj, 'Value');
    zlim(ax, [-val val]);
end

```

To use the uicontrols in the example, you need to put all the functions in a MATLAB code file. Copy the following code and paste it into a new file. Save the file as `ex_uicontrol.m` on your search path, and then run it.

```

function ex_uicontrol
    % Example code for uicontrol reference page

    % Create a figure and an axes to contain a 3-D surface plot.
    figure
    hax = axes('Units','pixels');
    surf(peaks)
    % Create a uicontrol object to let users change the colormap

```

```
% with a pop-up menu. Supply a function handle as the object's
% Callback:
uicontrol('Style', 'popup',...
          'String', 'hsv|hot|cool|gray',...
          'Position', [20 340 100 50],...
          'Callback', @setmap);    % Popup function handle callback
                                   % Implemented as a local function

% Add a different uicontrol. Create a push button that clears
% the current axes when pressed. Position the button inside
% the axes at the lower left. All uicontrols have default units
% of pixels. In this example, the axes does as well.
uicontrol('Style', 'pushbutton', 'String', 'Clear',...
          'Position', [20 20 50 20],...
          'Callback', 'cla');      % Pushbutton string callback
                                   % that calls a MATLAB function

% Add a slider uicontrol to control the vertical scaling of the
% surface object. Position it under the Clear button.
uicontrol('Style', 'slider',...
          'Min',1,'Max',50,'Value',41,...
          'Position', [400 20 120 20],...
          'Callback', {@surfzlim,hax});
% Slider function handle callback
% Implemented as a local function

% Add a text uicontrol to label the slider.
uicontrol('Style','text',...
          'Position',[400 45 120 20],...
          'String','Vertical Exaggeration')
end

function setmap(hObj,event) %#ok<INUSD>
% Called when user activates popup menu
val = get(hObj,'Value');
if val ==1
```

```
        colormap(jet)
elseif val == 2
    colormap(hsv)
elseif val == 3
    colormap(hot)
elseif val == 4
    colormap(cool)
elseif val == 5
    colormap(gray)
end
end

function surfzlim(hObject,event,ax) %#ok<INUSL>
% Called to set zlim of surface in figure axes
% when user moves the slider control
val = 51 - get(hObject,'Value');
zlim(ax,[-val val]);
end
```

# Uicontrol Properties

---

## Purpose

Describe user interface control (`uicontrol`) properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` commands enable you to set and query the values of properties

To change the default value of properties see “Setting Default Property Values”. You can also set default `uicontrol` properties on the root and figure levels:

```
set(0, 'DefaultUicontrolProperty', PropertyValue...)  
set(gcf, 'DefaultUicontrolProperty', PropertyValue...)
```

where *Property* is the name of the `uicontrol` property whose default value you want to set and *PropertyValue* is the value you are specifying as the default. Use `set` and `get` to access `uicontrol` properties.

For information on using these `uicontrols` within GUIDE, the MATLAB GUI development environment, see Programming GUI Components in the MATLAB Creating GUIs documentation.

## Uicontrol Properties

This section lists all properties useful to `uicontrol` objects along with valid values and descriptions of their use. Curly braces `{}` enclose default values.

| Property                     | Purpose                       |
|------------------------------|-------------------------------|
| <code>BackgroundColor</code> | Object background color       |
| <code>BeingDeleted</code>    | This object is being deleted  |
| <code>BusyAction</code>      | Callback routine interruption |
| <code>ButtonDownFcn</code>   | Button-press callback routine |

# Uicontrol Properties

| <b>Property</b>     | <b>Purpose</b>                                          |
|---------------------|---------------------------------------------------------|
| Callback            | Control action                                          |
| CData               | Truecolor image displayed on the control                |
| Children            | Uicontrol objects have no children                      |
| CreateFcn           | Callback routine executed during object creation        |
| DeleteFcn           | Callback routine executed during object deletion        |
| Enable              | Enable or disable the uicontrol                         |
| Extent              | position rectangle (read only)                          |
| FontAngle           | Character slant                                         |
| FontName            | Font family                                             |
| FontSize            | Font size                                               |
| FontUnits           | Font size units                                         |
| FontWeight          | Weight of text characters                               |
| ForegroundColor     | Color of text                                           |
| HandleVisibility    | Whether handle is accessible from command line and GUIs |
| HitTest             | Whether selectable by mouse click                       |
| HorizontalAlignment | Alignment of label string                               |
| Interruptible       | Callback routine interruption mode                      |
| KeyPressFcn         | Key press callback routine                              |
| ListboxTop          | Index of top-most string displayed in list box          |
| Max                 | Maximum value (depends on uicontrol object)             |
| Min                 | Minimum value (depends on uicontrol object)             |

# Uicontrol Properties

---

| Property           | Purpose                                                     |
|--------------------|-------------------------------------------------------------|
| Parent             | Uicontrol object's parent                                   |
| Position           | Size and location of uicontrol object                       |
| Selected           | Whether object is selected                                  |
| SelectionHighlight | Object highlighted when selected                            |
| SliderStep         | Slider step size                                            |
| String             | Uicontrol object label, also list box and pop-up menu items |
| Style              | Type of uicontrol object                                    |
| Tag                | User-specified object identifier                            |
| TooltipString      | Content of object's tooltip                                 |
| Type               | Class of graphics object                                    |
| UIContextMenu      | Uicontextmenu object associated with the uicontrol          |
| Units              | Units to interpret position vector                          |
| UserData           | User-specified data                                         |
| Value              | Current value of uicontrol object                           |
| Visible            | Uicontrol visibility                                        |

BackgroundColor  
ColorSpec

*Object background color.* The color used to fill the uicontrol rectangle. Specify a color using a three-element RGB vector or one of the MATLAB predefined names. The default color is determined by system settings. See ColorSpec for more information on specifying color.

BeingDeleted  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`  
`cancel` | `{queue}`

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- `'cancel'` — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`  
string or function handle (GUIDE sets this property)

# Uicontrol Properties

---

*Button-press callback routine.* A callback routine that can execute when you press a mouse button while the pointer is on or near a uicontrol. Specifically:

- If the uicontrol's `Enable` property is set to `on`, the `ButtonDownFcn` callback executes when you click the right or left mouse button in a 5-pixel border around the uicontrol or when you click the right mouse button on the control itself.
- If the uicontrol's `Enable` property is set to `inactive` or `off`, the `ButtonDownFcn` executes when you click the right or left mouse button in the 5-pixel border or on the control itself.

This is useful for implementing actions to interactively modify control object properties, such as size and position, when they are clicked on (using `selectmoveresize`, for example).

Define this routine as a string that is a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

To add a `ButtonDownFcn` callback in GUIDE, select **View Callbacks** from the Layout Editor **View** menu, then select `ButtonDownFcn`. GUIDE sets this property to the appropriate string and adds the callback to the code file the next time you save the GUI. Alternatively, you can set this property to the string `%automatic`. The next time you save the GUI, GUIDE sets this property to the appropriate string and adds the callback to the code file.

Use the `Callback` property to specify the callback routine that executes when you activate the enabled uicontrol (e.g., click a push button).

**Callback**

string or function handle (GUIDE sets this property)

*Control action.* A routine that executes whenever you activate the uicontrol object (e.g., when you click on a push button or move a slider). Define this routine as a string that is a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

For examples of `Callback` callbacks for each style of component:

- For GUIDE GUIs, see “Add Code for Components in Callbacks”.
- For programmatically created GUIs, see “Examples: Program GUI Components”.

## `CData`

matrix

*Truecolor image displayed on control.* A three-dimensional matrix of RGB values that defines a truecolor image displayed on a control, which must be a **push button** or **toggle button**. Each value must be between 0.0 and 1.0. Setting `CData` on a **radio button** or **checkbox** will replace the default `CData` on these controls. The control will continue to work as expected, but its state is not reflected by its appearance when clicked.

For **push buttons** and **toggle buttons**, `CData` overlaps the `String`. In the case of **radio buttons** and **checkboxes**, `CData` takes precedence over `String` and, depending on its size, it can displace the text.

Setting `CData` to `[]` restores the default `CData` for **radio buttons** and **checkboxes**.

## `Children`

matrix

The empty matrix; uicontrol objects have no children.

## `Clipping`

{on} | off

# Uicontrol Properties

---

This property has no effect on `uicontrol` objects.

`CreateFcn`  
string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a `uicontrol` object. MATLAB sets all property values for the `uicontrol` before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the `uicontrol` being created.

Setting this property on an existing `uicontrol` object has no effect.

You can define a default `CreateFcn` callback for all new `uicontrol`s. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uicontrol`. For example, the code

```
set(0, 'DefaultUicontrolCreateFcn', 'set(gcbo, ...  
    'BackgroundColor', 'white')')
```

creates a default `CreateFcn` callback that runs whenever you create a new `uicontrol`. It sets the default background color of all new `uicontrol`s.

To override this default and create a `uicontrol` whose `BackgroundColor` is set to a different value, call `uicontrol` with code similar to

```
hpt = uicontrol(..., 'CreateFcn', 'set(gcbo, ...  
    'BackgroundColor', 'blue')')
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uicontrol` call. In the example above, if instead of redefining the `CreateFcn` property for this `uicontrol`, you had explicitly set `BackgroundColor` to `blue`, the default `CreateFcn` callback would have set `BackgroundColor` back to the default, i.e., `white`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## DeleteFcn

string or function handle

*Delete uicontrol callback routine.* A callback routine that executes when you delete the `uicontrol` object (e.g., when you issue a `delete` command or clear the figure containing the `uicontrol`). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## Enable

{on} | inactive | off

# Uicontrol Properties

---

*Enable or disable the uicontrol.* This property controls how uicontrols respond to mouse button clicks, including which callback routines execute.

- **on** – The uicontrol is operational (the default).
- **inactive** – The uicontrol is not operational, but looks the same as when **Enable** is on.
- **off** – The uicontrol is not operational and its image (set by the **Cdata** property) is grayed out.

When you left-click on a uicontrol whose **Enable** property is on, MATLAB performs these actions in this order:

- 1** Sets the figure **SelectionType** property.
- 2** Executes the uicontrol **Callback** routine, if any. (Static text components do not use callbacks.)
- 3** Does *not* set the figure **CurrentPoint** property and does *not* execute either the uicontrol **ButtonDownFcn** or the figure **WindowButtonDownFcn** callback.

Single-clicking or double-clicking an enabled uicontrol with the left mouse button sets the figure **SelectionType** property to normal, unless the uicontrol **Style** is **listbox**. For list boxes, double-clicking sets the figure **SelectionType** property to open on the second of the two clicks, enabling the list box callback to detect a set of multiple choices.

When you left-click on a uicontrol whose **Enable** property is **off** or **inactive**, or when you right-click a uicontrol whose **Enable** property has any value, MATLAB performs these actions in this order:

- 1** Sets the figure **SelectionType** property.
- 2** Sets the figure **CurrentPoint** property.
- 3** Executes the figure **WindowButtonDownFcn** callback, if provided.

**4** Executes the uicontrol `ButtonDownFcn` callback, if provided.

## Extent

position rectangle (read only)

*Size of uicontrol character string.* A four-element vector that defines the size and position of the character string used to label the uicontrol. It has the form:

```
[0,0,width,height]
```

The first two elements are always zero. `width` and `height` are the dimensions of the rectangle. All measurements are in units specified by the `Units` property.

Since the `Extent` property is defined in the same units as the uicontrol itself, you can use this property to determine proper sizing for the uicontrol with regard to its label. Do this by

- Defining the `String` property and selecting the font using the relevant properties.
- Getting the value of the `Extent` property.
- Defining the `width` and `height` of the `Position` property to be somewhat larger than the `width` and `height` of the `Extent`.

For multiline strings, the `Extent` rectangle encompasses all the lines of text. For single line strings, the `height` element of the `Extent` property returned always indicates the height of a single line, and its `width` element always indicates the width of the longest line, even if the string wraps when displayed on the control. Edit boxes are considered multiline if `Max - Min > 1`.

## FontAngle

```
{normal} | italic | oblique
```

*Character slant.* MATLAB uses this property to select a font from those available on your particular system. Setting this property

# Uicontrol Properties

---

to *italic* or *oblique* selects a slanted version of the font, when it is available on your system.

FontName  
string

*Font family.* The name of the font in which to display the String. To display and print properly, this must be a font that your system supports. The default font is system dependent.

---

**Note** MATLAB GUIs do not support the Marlett and Symbol font families.

---

To use a fixed-width font that looks good in any locale (and displays properly in Japan, where multibyte character sets are used), set FontName to the string FixedWidth (this string value is case sensitive):

```
set(uicontrol_handle, 'FontName', 'FixedWidth')
```

This parameter value eliminates the need to hard code the name of a fixed-width font, which may not display text properly on systems that do not use ASCII character encoding (such as in Japan). A properly written MATLAB application that needs to use a fixed-width font should set FontName to FixedWidth and rely on the root FixedWidthFontName property to be set correctly in the end user's environment.

End users can adapt a MATLAB application to different locales or personal environments by setting the root FixedWidthFontName property to the appropriate value for that locale from startup.m. Setting the root FixedWidthFontName property causes an immediate update of the display to use the new font.

---

**Tip** To determine what fonts exist on your system (which can differ from the GUI user's system), use the `uisetfont` GUI to select a font and return its name and other characteristics in a MATLAB structure.

---

**FontSize**  
size in `FontUnits`

*Font size.* A number specifying the size of the font in which to display the String, in units determined by the `FontUnits` property. The default point size is system dependent.

**FontUnits**  
{points} | normalized | inches |  
centimeters | pixels

*Font size units.* This property determines the units used by the `FontSize` property. Normalized units interpret `FontSize` as a fraction of the height of the uicontrol. When you resize the uicontrol, MATLAB modifies the screen `FontSize` accordingly. pixels, inches, centimeters, and points are absolute units (1 point =  $\frac{1}{72}$  inch).

**FontWeight**  
light | {normal} | demi | bold

*Weight of text characters.* MATLAB uses this property to select a font from those available on your particular system. Setting this property to `bold` causes MATLAB to use a bold version of the font, when it is available on your system.

**ForegroundColor**  
`ColorSpec`

*Color of text.* This property determines the color of the text defined for the String property (the uicontrol label). Specify a

# Uicontrol Properties

---

color using a three-element RGB vector or one of the MATLAB predefined names. The default text color is black. See `ColorSpec` for more information on specifying color.

---

**Note** If you change the `ForegroundColor` for a uicontrol listbox, MATLAB uses that color for all listbox items *except* selected listbox items. For selected items MATLAB uses a color that ensures good contrast between the text of selected items and the color that indicates a selection.

---

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is on.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI

(such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

---

**Note** Radio buttons and toggle buttons that are managed by a `uibuttongroup` should not be accessed outside the button group. Set the `HandleVisibility` of such radio buttons and toggle buttons to `off` to prevent inadvertent access.

---

## HitTest

`{on} | off`

*Selectable by mouse click.* This property has no effect on uicontrol objects.

## HorizontalAlignment

`left | {center} | right`

*Horizontal alignment of label string.* This property determines the justification of the text defined for the `String` property (the uicontrol label):

- `left` — Text is left justified with respect to the uicontrol.
- `center` — Text is centered with respect to the uicontrol.
- `right` — Text is right justified with respect to the uicontrol.

The contents of `edit` and `text` uicontrols are always vertically aligned to the top of the rectangle.

# Uicontrol Properties

---

---

**Note** On Microsoft Windows systems, although this property can be specified on all uicontrols, it affects only edit and text uicontrols.

---

Interruptible  
off | {on}

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a *drawnow*, *figure*, *getframe*, *waitfor*, or *pause* command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

# Uicontrol Properties

---

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object's `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

## `KeyPressFcn`

string or function handle

*Key press callback function.* A callback routine invoked by a key press when the callback's uicontrol object has focus. Focus is denoted by a border or a dotted border, respectively, in UNIX and Microsoft Windows. If no uicontrol has focus, the figure's key press callback function, if any, is invoked. `KeyPressFcn` can be a function handle, the name of a code file, or any legal MATLAB expression.

If the specified value is the name of a code file, the callback routine can query the figure's `CurrentCharacter` property to determine what particular key was pressed and thereby limit the callback execution to specific keys.

If the specified value is a function handle, the callback routine can retrieve information about the key that was pressed from its event data structure argument.

| Event Data Structure Field | Description                                                                         | Examples:  |            |           |           |
|----------------------------|-------------------------------------------------------------------------------------|------------|------------|-----------|-----------|
|                            |                                                                                     | a          | =          | Shift     | Shift/a   |
| Character                  | Character interpretation of the key that was pressed.                               | 'a'        | '='        | ' '       | 'A'       |
| Modifier                   | Current modifier, such as 'control', or an empty cell array if there is no modifier | {1x0 cell} | {1x0 cell} | {'shift'} | {'shift'} |
| Key                        | Name of the key that was pressed.                                                   | 'a'        | 'equal'    | 'shift'   | 'a'       |

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

**ListboxTop**  
scalar

*Index of top-most string displayed in list box.* This property applies only to the `listbox` style of uicontrol. It specifies which string appears in the top-most position in a list box that is not large enough to display all list entries. `ListboxTop` is an index into the array of strings defined by the `String` property and must have a value between 1 and the number of strings. Noninteger values are fixed to the next lowest integer.

**Max**  
scalar

*Maximum value.* This property specifies the largest value allowed for the `Value` property. Different styles of uicontrols interpret `Max` differently:

- Check boxes – `Max` is the setting of the `Value` property while the check box is selected.
- Editable text – The `Value` property does not apply. If `Max - Min > 1`, then editable text boxes accept multiline input. If `Max - Min`

# Uicontrol Properties

---

$\leq 1$ , then editable text boxes accept only single line input. The absolute values of `Max` and `Min` have no effect on the number of lines an edit box can contain; a multiline edit box can contain any number of lines.

- List boxes – If  $\text{Max} - \text{Min} > 1$ , then list boxes allow multiple item selection. If  $\text{Max} - \text{Min} \leq 1$ , then list boxes do not allow multiple item selection. When they do, `Value` can be a vector of indices.
- Radio buttons – `Max` is the setting of the `Value` property when the radio button is selected.
- Sliders – `Max` is the maximum slider value and must be greater than the `Min` property. The default is 1.
- Toggle buttons – `Max` is the value of the `Value` property when the toggle button is selected. The default is 1.
- Pop-up menus, push buttons, and static text do not use the `Max` property.

`Min`

scalar

*Minimum value.* This property specifies the smallest value allowed for the `Value` property. Different styles of uicontrols interpret `Min` differently:

- Check boxes – `Min` is the setting of the `Value` property while the check box is not selected.
- Editable text – The `Value` property does not apply. If  $\text{Max} - \text{Min} > 1$ , then editable text boxes accept multiline input. If  $\text{Max} - \text{Min} \leq 1$ , then editable text boxes accept only single line input. The absolute values of `Max` and `Min` have no effect on the number of lines an edit box can contain; a multiline edit box can contain any number of lines.
- List boxes – If  $\text{Max} - \text{Min} > 1$ , then list boxes allow multiple item selection. If  $\text{Max} - \text{Min} \leq 1$ , then list boxes allow only single item selection. When they do, `Value` can be a vector of indices.

- Radio buttons – Min is the setting of the Value property when the radio button is not selected.
- Sliders – Min is the minimum slider value and must be less than Max. The default is 0.
- Toggle buttons – Min is the value of the Value property when the toggle button is not selected. The default is 0.
- Pop-up menus, push buttons, and static text do not use the Min property.

## Parent

handle

*Uicontrol parent.* The handle of the uicontrol's parent object. You can move a uicontrol object to another figure, uipanel, or uibuttongroup by setting this property to the handle of the new parent.

## Position

position rectangle

*Size and location of uicontrol.* The rectangle defined by this property specifies the size and location of the control within the parent figure window, uipanel, or uibuttongroup. Specify Position as

```
[left bottom width height]
```

left and bottom are the distance from the lower-left corner of the parent object to the lower-left corner of the uicontrol object. width and height are the dimensions of the uicontrol rectangle. All measurements are in units specified by the Units property.

On Microsoft Windows systems, the height of pop-up menus is automatically determined by the size of the font. The value you specify for the height of the Position property has no effect.

# Uicontrol Properties

---

The width and height values determine the orientation of sliders. If width is greater than height, then the slider is oriented horizontally. If height is greater than width, then the slider is oriented vertically.

---

**Note** The height of a pop-up menu is determined by the font size. The height you set in the position vector is ignored. The height element of the position vector is not changed.

On Mac platforms, the height of a horizontal slider is constrained. If the height you set in the position vector exceeds this constraint, the displayed height of the slider is the maximum allowed. The height element of the position vector is not changed.

---

## Selected

on | {off} (read only)

*Is object selected.* When this property is on, MATLAB displays selection handles if the SelectionHighlight property is also on. You can, for example, define the ButtonDownFcn to set this property, allowing users to select the object with the mouse.

## SelectionHighlight

{on} | off

*Object highlight when selected.* When the Selected property is on, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When SelectionHighlight is off, MATLAB does not draw the handles.

## SliderStep

[minor\_step major\_step]

*Slider step size,* a two-element vector of positive values that indicates the size of the major and minor steps as a percent change in slider value. Both steps should be greater than  $1e-6$ ,

and `minor_step` should be less than or equal to `major_step`. The slider `Value` changes up or down by `minor_step` when you click the arrow button, and up or down by `major_step` when you click the slider trough, also called the channel.

The actual step size is a function of the specified `SliderStep` and the total slider range (`Max - Min`). The default, `[0.01 0.10]`, provides a 1 percent change for clicks on the arrow button and a 10 percent change for clicks in the trough.

For example, if you create the following slider,

```
uicontrol('Style','slider','Min',1,'Max',7,...  
         'Value',2,'SliderStep',[0.1 0.6])
```

clicking an arrow button moves the thumb indicator toward it by `minor_step*(max-min)`:

```
0.1*(7-1)  
ans =  
    0.6000
```

Clicking the trough moves the thumb indicator toward the mouse pointer by `major_step*(max-min)`:

```
0.6*(7-1)  
ans =  
    3.6000
```

If clicking moves the slider to a value outside the range, the thumb indicator moves only to the `Max` or `Min` value.

As `major_step` increases, the slider thumb indicator grows longer. When `major_step` is 1, the thumb is half as long as the trough. When `major_step` is greater than 1, the thumb continues to grow, slowly approaching the full length of the trough.

See also the `Max`, `Min`, and `Value` properties.

# Uicontrol Properties

---

String  
string

*Uicontrol label, list box items, pop-up menu choices.*

**For check boxes, editable text, push buttons, radio buttons, static text, and toggle buttons**, the text displayed on the object. For list boxes and pop-up menus, the set of entries or items displayed in the object.

---

**Note** If you specify a numerical value for `String`, MATLAB converts it to `char` but the result may not be what you expect. If you have numerical data, you should first convert it to a string, e.g., using `num2str`, before assigning it to the `String` property.

---

**For uicontrol objects that display only one line of text** (check box, push button, radio button, toggle button), if the string value is specified as a cell array of strings or padded string matrix, only the first string of a cell array or of a padded string matrix is displayed; the rest are ignored. Vertical slash (`'|'`) characters are not interpreted as line breaks and instead show up in the text displayed in the uicontrol.

**For multiple line editable text or static text controls**, line breaks occur between each row of the string matrix, and each cell of a cell array of strings. Vertical slash (`'|'`) characters and `\n` characters are not interpreted as line breaks, and instead show up in the text displayed in the uicontrol. Text in edit text and static text boxes is always vertically top-aligned. For **editable text**, the `String` property value is set to the string entered by the user when the control loses focus. The `String` property for **static text** can only be set programmatically (or when authoring a GUI in GUIDE).

To place multiple items on a list box or pop-up menu, you can specify the items in any of the formats shown in the following table.

| String Property Format                                     | Example                                    |
|------------------------------------------------------------|--------------------------------------------|
| Cell array of strings                                      | <code>{'one' 'two' 'three'}</code>         |
| Padded string column matrix                                | <code>['one ' '; 'two ' '; 'three']</code> |
| String vector using vertical slash ( ) as a line separator | <code>['one two three']</code>             |

If you specify a component width that is too small to accommodate one or more of the specified strings, MATLAB truncates those strings with an ellipsis. Use the `Value` property to set the index of the initial item selected.

For **check boxes**, **push buttons**, **radio buttons**, **toggle buttons**, and the selected item in **popup menus**, when the specified text is clipped because it is too long for the uicontrol, an ellipsis (...) is appended to the text in the active GUI to indicate that it has been clipped.

For **push buttons** and **toggle buttons**, `CData` overlaps the `String`. In the case of **radio buttons** and **checkboxes**, `CData` takes precedence over `String` and, depending on its size, can displace the text.

# Uicontrol Properties

---

---

**Reserved Words** There are three reserved words: `default`, `remove`, `factory` (case sensitive). If you want to use one of these reserved words in the `String` property, you must precede it with a backslash (`'\'`) character. For example,

```
h = uicontrol('Style','edit','String','\default');
```

---

## Style

`{pushbutton} | togglebutton | radiobutton | checkbox | edit | text | slider | frame | listbox | popupmenu`

*Style of uicontrol object to create.* The `Style` property specifies the kind of uicontrol to create. See the `uicontrol` Description section for information on each type.

## Tag

string (GUIDE sets this property)

*User-specified object label.* The `Tag` property provides a means to identify graphics objects with a user-specified label. This is particularly useful when constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callback routines. You can define `Tag` as any string.

## TooltipString

string

*Content of tooltip for object.* The `TooltipString` property specifies the text of the tooltip associated with the uicontrol. When the user moves the mouse pointer over the control and leaves it there, the tooltip is displayed.

To create a tooltip that has more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the `TooltipString` to that value. For example:

```
h = uicontrol('Style','pushbutton');  
s = sprintf('Button tooltip line 1\nButton tooltip line 2');  
set(h,'TooltipString',s)
```

## Type

string (read only)

*Class of graphics object.* For uicontrol objects, `Type` is always the string `'uicontrol'`.

## UIContextMenu

handle

*Associate a context menu with uicontrol.* Assign this property the handle of a `uicontextmenu` object. MATLAB displays the context menu whenever you right-click over the uicontrol. Use the `uicontextmenu` function to create the context menu.

## Units

{pixels} | normalized | inches | centimeters | points | characters (GUIDE default: normalized)

*Units of measurement.* MATLAB uses these units to interpret the `Extent` and `Position` properties. All units are measured from the lower-left corner of the parent object.

- Normalized units map the lower-left corner of the parent object to (0,0) and the upper-right corner to (1.0,1.0).
- pixels, inches, centimeters, and points are absolute units (1 point = 1/72 inch).
- Character units are characters using the default system font; the width of one character is the width of the letter x, the height of one character is the distance between the baselines of two lines of text.

# Uicontrol Properties

---

If you change the value of `Units`, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume `Units` is set to the default value.

`UserData`  
matrix

*User-specified data.* Any data you want to associate with the uicontrol object. MATLAB does not use this data, but you can access it using `set` and `get`.

`Value`  
scalar or vector

*Current value of uicontrol.* The uicontrol style determines the possible values this property can have:

- Check boxes set `Value` to `Max` when they are on (when selected) and `Min` when off (not selected).
- List boxes set `Value` to a vector of indices corresponding to the selected list entries, where 1 corresponds to the first item in the list.
- Pop-up menus set `Value` to the index of the item selected, where 1 corresponds to the first item in the menu. The `Examples` section shows how to use the `Value` property to determine which item has been selected.
- Radio buttons set `Value` to `Max` when they are on (when selected) and `Min` when off (not selected).
- Sliders set `Value` to the number indicated by the slider bar.
- Toggle buttons set `Value` to `Max` when they are down (selected) and `Min` when up (not selected).
- Editable text, push buttons, and static text do not set this property.

Set the `Value` property either interactively with the mouse or through a call to the `set` function. The display reflects changes made to `Value`.

`Visible`

`{on} | off`

*Uicontrol visibility.* By default, all uicontrols are visible. When set to `off`, the uicontrol is not visible, but still exists and you can query and set its properties.

---

**Note** Setting `Visible` to `off` for uicontrols that are not displayed initially in the GUI, can result in faster startup time for the GUI.

---

# uigetdir

---

**Purpose** Open standard dialog box for selecting directory

**Syntax**

```
folder_name = uigetdir
folder_name = uigetdir(start_path)
folder_name = uigetdir(start_path,dialog_title)
```

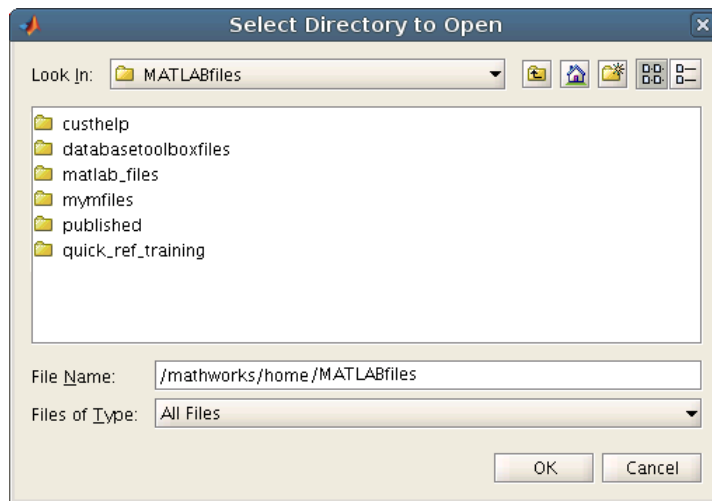

**Description** `folder_name = uigetdir` displays a modal dialog box enabling you to navigate the folder hierarchy and select a folder or type the name of a folder. If the folder exists, `uigetdir` returns the selected path when you click **OK**. If you type the name of a folder that does not exist, `uigetdir` returns the name of the current folder. If you click **Cancel**, or close the dialog box, `uigetdir` returns 0. On Microsoft Windows platforms, `uigetdir` opens a dialog box in the base folder (the Windows desktop) with the current folder selected.

`folder_name = uigetdir(start_path)` opens a dialog box with the folder specified by `start_path` selected. If `start_path` is a valid path, the dialog box opens in the specified folder. If `start_path` is an empty string ( ' ') or is not a valid path, the dialog box opens in the current folder.

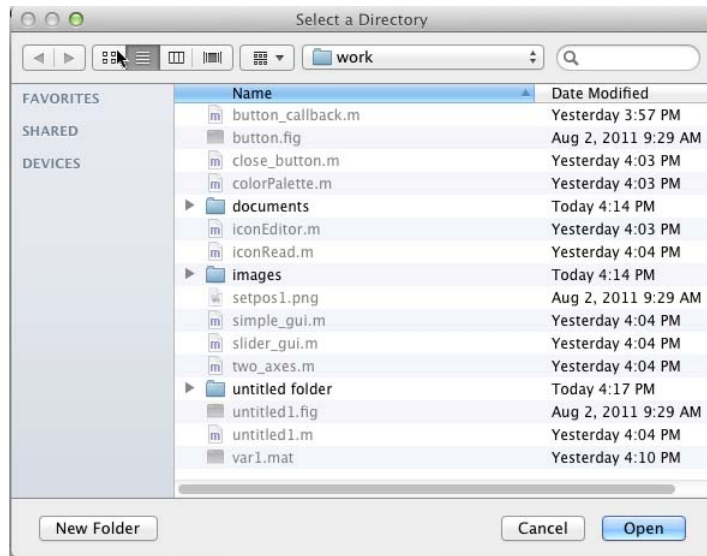

`folder_name = uigetdir(start_path,dialog_title)` opens a dialog box with the specified title. On Windows and UNIX platforms, the string replaces the default caption inside the dialog box for specifying instructions to the user. The default `dialog_title` is **Select folder to Open**.

On Windows platforms, you can click the **New Folder** button to add a new folder to the folder hierarchy displayed. You can also drag and drop existing directories into different folders.

On UNIX platforms, `uigetdir` opens a dialog box in the startup folder (the one you are in when you start MATLAB), with the current directory selected. The `dialog_title` string replaces the default title of the dialog box. The dialog box looks similar to the following figure.

On Mac platforms, `uigetdir` opens a dialog box in the startup folder (the one you are in when you start MATLAB), with the current directory selected. The dialog box looks similar to the following figure.

---

**Note** A modal dialog box prevents you from interacting with other MATLAB windows before responding. To block MATLAB program execution as well, use the `uiwait` function. For more information about modal dialog boxes, see `WindowState` in the MATLAB Figure Properties.

---

The `pwd` and `cd` functions return the name of the current folder.

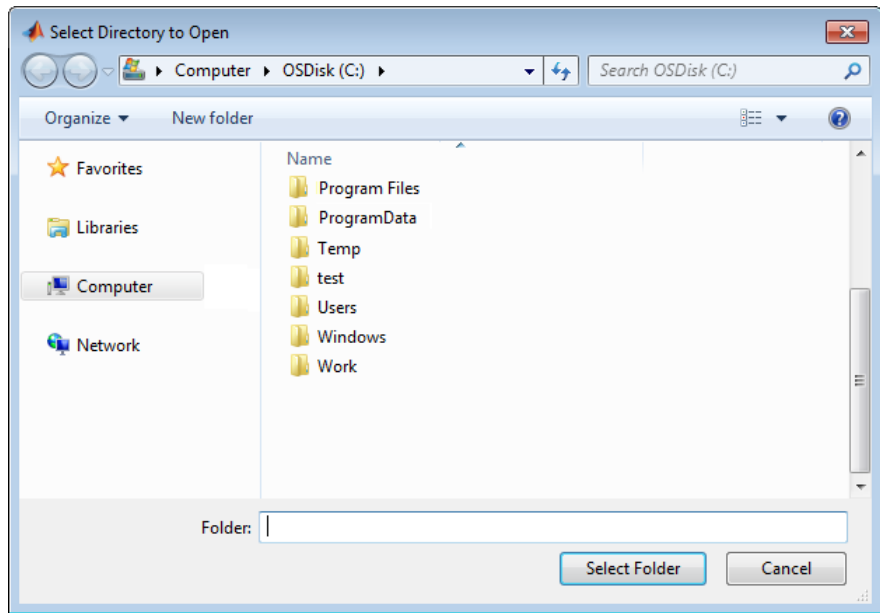

## Examples

The following statement displays directories on the C: drive.

```
dname = uigetdir('C:\');
```

A dialog box such as the following displays (on Windows).

If you double-click the Program Files folder, and the MATLAB subfolder, and then click **Select Folder**, `uigetdir` returns `C:\Program Files\MATLAB` to `dname`:

The following statement uses `matlabroot` to display the MATLAB root folder in the dialog box:

```
uigetdir(matlabroot, 'MATLAB Root Directory')
```

Assuming that MATLAB is installed on drive `C:\`, selecting the folder `MATLAB\R2012b\notebook\pc` from the dialog box, returns this string:

```
C:\Program Files\MATLAB\R2012b\notebook\pc
```

## See Also

`uigetfile` | `uiputfile`

# uigetfile

---

**Purpose** Open standard dialog box for retrieving files

**Syntax**

```
filename = uigetfile
[FileName,PathName,FilterIndex] = uigetfile(FilterSpec)
[FileName,PathName,FilterIndex] = uigetfile(FilterSpec,
    DialogTitle)
[FileName,PathName,FilterIndex] = uigetfile(FilterSpec,
    DialogTitle,DefaultName)
[FileName,PathName,FilterIndex] = uigetfile(...,'MultiSelect',
    selectmode)
```

**Description** filename = uigetfile displays a modal dialog box that lists files in the current folder and enables you to select or enter the name of a file. If the file name is valid and the file exists, uigetfile returns the file name as a string when you click **Open**. Otherwise uigetfile displays an appropriate error message, after which control returns to the dialog box. You can then enter another file name or click **Cancel**. If you click **Cancel** or close the dialog window, uigetfile returns 0.

---

**Note** Successful execution of uigetfile does not open a file; it only returns the name of an existing file that you identify.

---

[FileName,PathName,FilterIndex] = uigetfile(FilterSpec) displays only those files with extensions that match FilterSpec. On some platforms uigetfile also displays in gray the files that do not match FilterSpec. The uigetfile function appends 'All Files' to the list of file types. FilterSpec can be a string or a cell array of strings, and can include the \* wildcard.

- If FilterSpec is a file name, that file name displays, selected in the **File name** field. The extension of the file is the default filter.
- FilterSpec can include a path. That path can contain '.', '..', '\', '/', or '~'. For example, '../\*.\*m' lists all code files in the folder above the current folder.

- If `FilterSpec` is a folder name, `uigetfile` displays the contents of that folder, the **File name** field is empty, and no filter applies. To specify a folder name, make the last character of `FilterSpec` either `'\'` or `'/'`.
- If `FilterSpec` is a cell array of strings, it can include two columns. The first column contains a list of file extensions. The optional second column contains a corresponding list of descriptions. These descriptions replace standard descriptions in the **Files of type** field. A description cannot be an empty string. The second and third examples illustrate use of a cell array as `FilterSpec`.

If `FilterSpec` is missing or empty, `uigetfile` uses the default list of file types (for example, all MATLAB files).

After you click **Open** and if the file name exists, `uigetfile` returns the name of the file in `FileName` and its path in `PathName`. If you click **Cancel** or close the dialog window, the function sets `FileName` and `PathName` to 0.

`FilterIndex` is the index of the filter selected in the dialog box. Indexing starts at 1. If you click **Cancel** or close the dialog window, the function sets `FilterIndex` to 0.

```
[FileName,PathName,FilterIndex] =  
uigetfile(FilterSpec,DialogTitle) displays a dialog box that has  
the title DialogTitle. To use the default file types and specify a  
dialog title, enter
```

```
uigetfile(' ',DialogTitle)
```

```
[FileName,PathName,FilterIndex] =  
uigetfile(FilterSpec,DialogTitle,DefaultName) displays a dialog  
box in which the file name specified by DefaultName appears in the  
File name field. DefaultName can also be a path or a path/filename. In  
this case, uigetfile opens the dialog box in the folder specified by the  
path. You can use '.', '..', '\', or '/' in the DefaultName argument.  
To specify a folder name, make the last character of DefaultName either  
'\ ' or '/ '. If the specified path does not exist, uigetfile opens the  
dialog box in the current folder.
```

# uigetfile

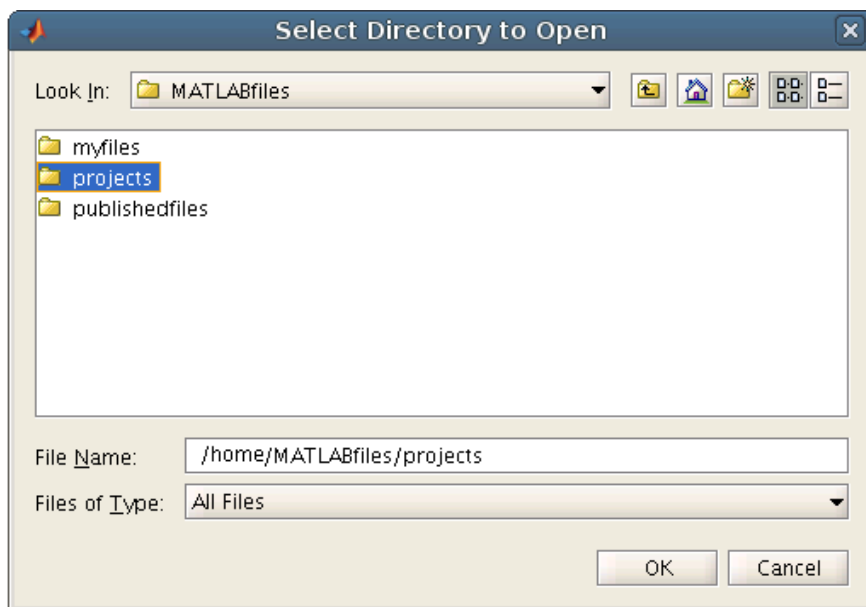

---

`[FileName,PathName,FilterIndex] = uigetfile(...,'MultiSelect',selectmode)` opens the dialog box in *multiselect* mode. Valid values for *selectmode* are 'on' and 'off' (the default, which allows single selection only). If 'MultiSelect' is 'on' and you select more than one file in the dialog box, then `FileName` is a cell array of strings. Each array element contains the name of a selected file. File names in the cell array are sorted in the order your platform uses. If you select multiple files, they must be in the same folder, otherwise MATLAB displays a warning dialog box. Be aware that Microsoft Windows libraries can span multiple folders. `PathName` is a string identifying the folder containing the files.

If you include either of the wildcard characters, '\*' or '?', in a file name, `uigetfile` does not respond to clicking **Open**. The dialog box remains open until you cancel it or remove the wildcard characters. This restriction applies to all platforms, even to file systems that permit these characters in file names.

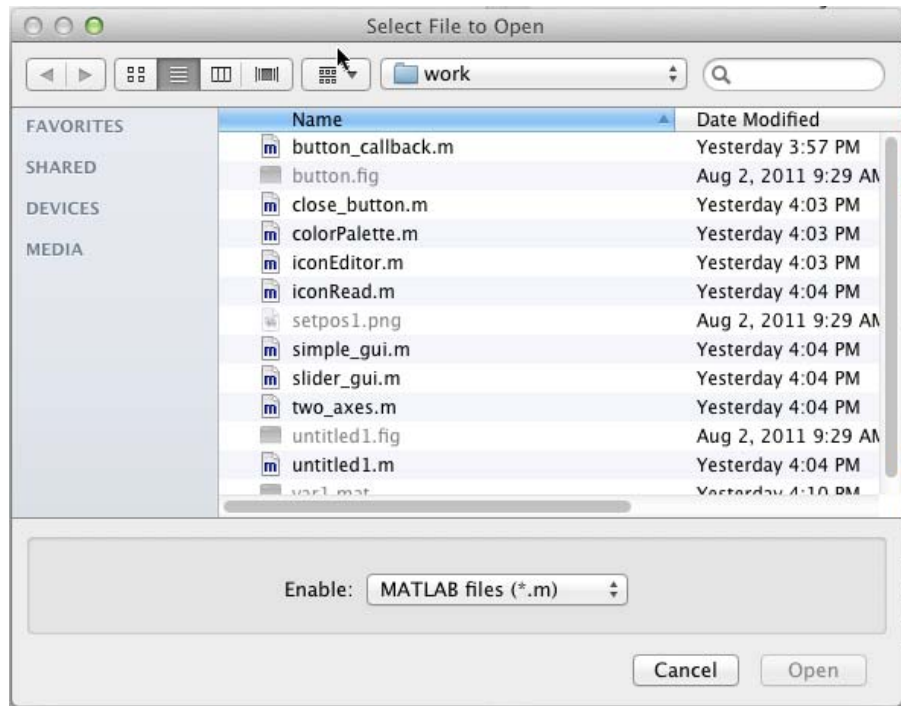

For Windows platforms, the dialog box is the Windows dialog box native to your platform. Depending on your version of Windows, dialogs you see can differ from the figures shown in following examples.

For UNIX platforms, the dialog box is like the one shown in the following figure.

For Mac platforms, the dialog box is like the one shown in the following figure.

# uigetfile

---

**Note** A modal dialog box prevents you from interacting with other windows before responding. To block MATLAB program execution, use the `uiwait` function. For more information about modal dialog boxes, see `WindowState` in the MATLAB Figure Properties.

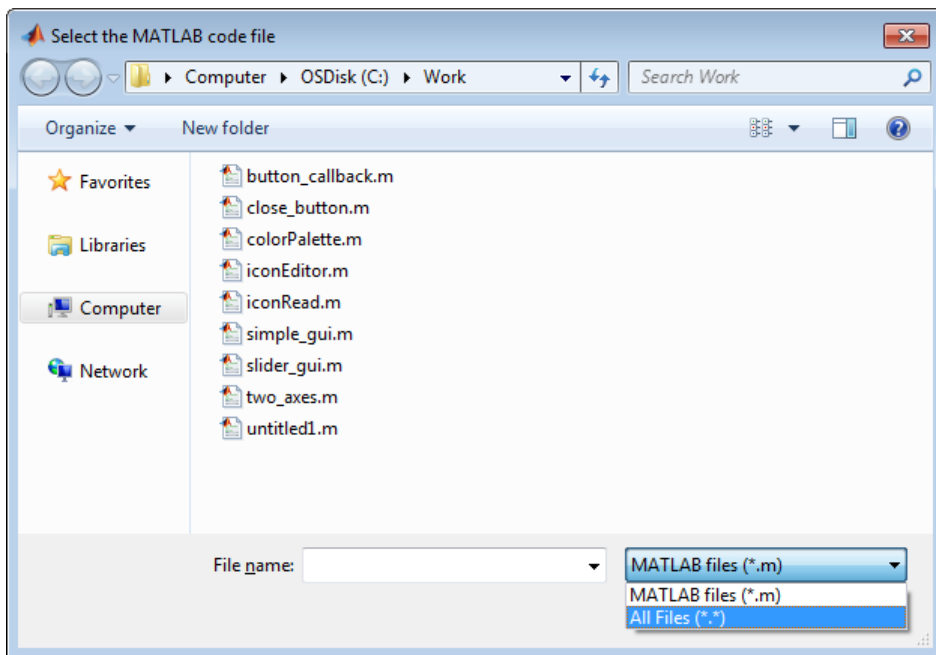

---

## Examples

The following statement displays a dialog box for retrieving a file. The dialog box lists all MATLAB code files within a selected directory. `uigetfile` returns the name and path of the selected file in `FileName` and `PathName`. `uigetfile` appends `All Files (*.*)` to the file types when `FilterSpec` is a string.

```
[FileName,PathName] = uigetfile('*.m','Select the MATLAB code file');
```

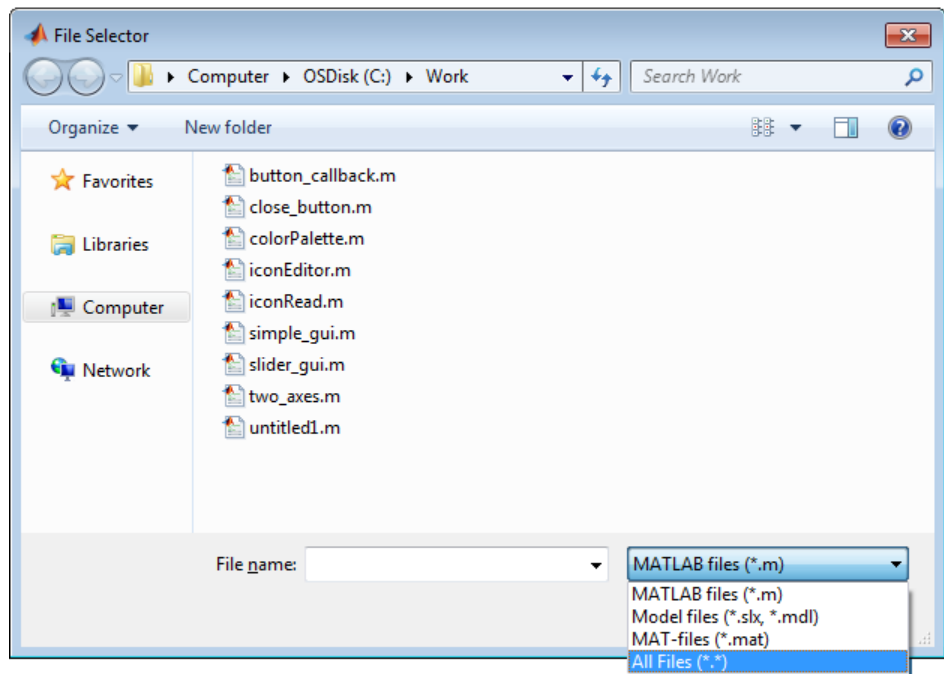

The following figure shows the dialog box with the file type drop-down list open.

To create a list of file types that appears in the file type drop-down list, separate the file extensions with semicolons, as in the following code. `uigetfile` displays a default description for each known file type, such as "Model files" for Simulink `.slx` and `.mdl` files.

```
[filename, pathname] = ...  
    uigetfile({'*.m'; '*.slx'; '*.mat'; '*.*'}, 'File Selector');
```

# uigetfile

If you want to create a list of file types and give them descriptions that are different from the defaults, use a cell array, as in the following code. This example also associates multiple file types with the 'MATLAB Files' and 'Models' descriptions.

```
[filename, pathname] = uigetfile( ...  
{ '*.m;*.fig;*.mat;*.slx;*.mdl', 'MATLAB Files (*.m,*.fig,*.mat,*.slx,*.mdl)';  
  '*.m', 'Code files (*.m)'; ...  
  '*.fig', 'Figures (*.fig)'; ...  
  '*.mat', 'MAT-files (*.mat)'; ...  
  '*.mdl;*.slx', 'Models (*.slx, *.mdl)'; ...  
  '*.*', 'All Files (*.*)' }, ...  
  'Pick a file');
```

The first column of the cell array contains the file extensions, while the second contains your descriptions of the file types. In this example, the first entry of column one contains several extensions, separated by semicolons, which are all associated with the description 'MATLAB Files (\*.m;\*.fig;\*.mat;\*.mdl)'. The code produces the dialog box shown in the following figure.

The following code lets you select a file and then displays a message in the Command Window that summarizes the result.

```
[filename, pathname] = uigetfile('*.*', 'Select a MATLAB code file');
if isequal(filename,0)
    disp('User selected Cancel')
```

# uigetfile

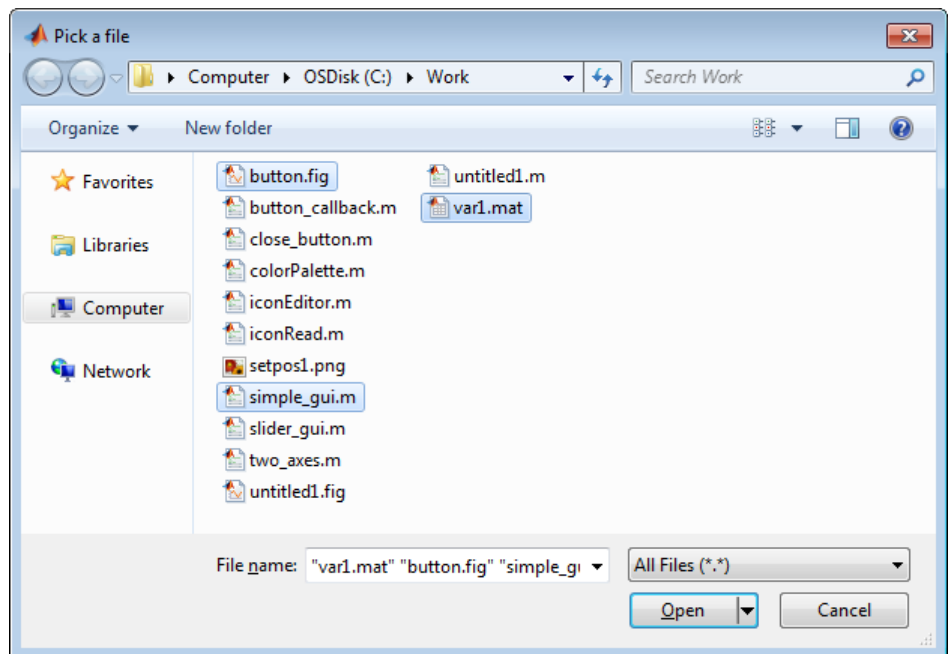

---

```
else
    disp(['User selected ', fullfile(pathname, filename)])
end
```

---

This code creates a list of file types and gives them descriptions that are different from the defaults. It also enables multiple-file selection. Select multiple files by holding down the **Shift** or **Ctrl** key and clicking on additional file names.

```
[filename, pathname, filterindex] = uigetfile( ...
{ '*.mat', 'MAT-files (*.mat)'; ...
  '*.slx;*.mdl', 'Models (*.slx, *.mdl)'; ...
  *.*', 'All Files (*.*)'}, ...
'Pick a file', ...
'MultiSelect', 'on');
```

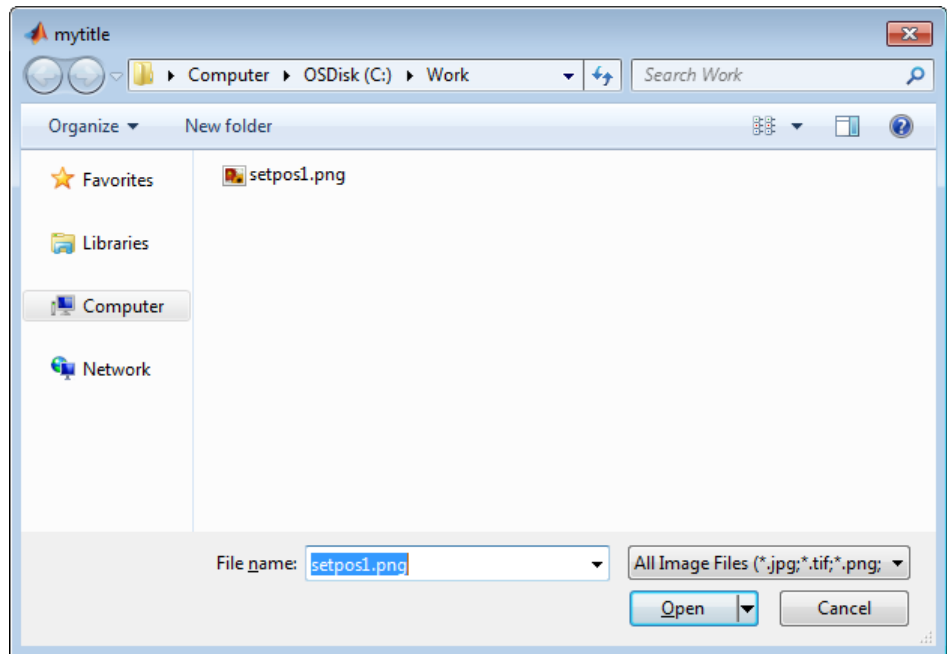

As mentioned previously, `uigetfile` does not open the file or files you select.

You can use the `DefaultName` argument to specify a start path and a default file name for the dialog box.

```
uigetfile({'*.jpg;*.tif;*.png;*.gif', 'All Image Files';...  
         '*.*', 'All Files' }, 'mytitle', ...  
         'C:\myfiles\my_examples\gbtools\setpos1.png')
```

# uigetfile

## Alternatives

Use the `dir` function to return a filtered or unfiltered list of files in your current folder or a folder you specify. `dir` also can return file attributes.

| <b>Tips</b>        | <ul style="list-style-type: none"><li>• You must supply all input arguments up to and including <code>pref_choices</code>.</li><li>• <code>uigetpref</code> creates specified groups and preferences, if they do not currently exist. To delete a preference group you no longer need, use <code>rmpref</code>.</li><li>• The string returned in <code>pref_value</code> is a preference name (as specified in <code>pref</code>), not its button label (as specified in <code>pref_choices</code>).</li><li>• After you select the check box <b>Do not show this dialog again</b> and close the dialog box, the dialog box does not display again for the same preference. To reenable dialogs that are being suppressed by preferences, use the command:</li></ul>                                                                                                             |

# uigetpref

---

```
uigetpref('clearall')
```

Executing `uigetpref` with this command re-enables *all* preference dialogs you have defined with `uigetpref`, not just the most recent one.

## Input Arguments

### **group**

String specifying the name of the preference group that preference `pref` belongs to. If the group does not already exist, `uigetpref` creates it.

**Default:** None

### **pref**

String specifying the name of the preference that controls whether the dialog displays. If the preference does not already exist, `uigetpref` creates it.

**Default:** None

### **title**

String to display in the dialog box title bar

### **question**

String or cell array of strings specifying a descriptive paragraph for the dialog to display. Use `question` to define what you are asking the user to decide. Clearly state the alternatives and the consequences of choosing among them. The dialog box that `uigetpref` generates inserts line breaks between rows of the string array, between elements of the cell array of strings, and between `'|'` or newline characters within a string vector.

**Default:** None

### **pref\_choices**

String, cell array of strings, or ' | '-separated strings specifying the labels for the dialog box push buttons. The string on the selected push button is returned.

If the internal preference values are different from the strings displayed on the push buttons, provide a 2-by-n cell array of strings. The first row contains the preference strings, and the second row contains the associated push button strings. When `pref_choices` is not a 2-by-n cell array, MATLAB constructs lowercase versions of the button labels and returns them in `pref_value`. If your code tests returned values, make sure it compares them against the appropriate strings.

**Default:** None

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### **CheckboxState**

State of check box when dialog box opens:

- `false` or `0`: Check box is not initially selected.
- `true` or `1`: Check box is initially selected.

**Default:** 0

### **CheckboxString**

String specifying the label for the check box.

**Default:** 'Do not show this dialog again'

### **HelpString**

String specifying the label for **Help** button.

**Default:** No **Help** button displays.

## **HelpFcn**

String or function handle specifying the callback that executes when you click the **Help** button. Also, to have a button to trigger the callback, you must specify the **HelpString** option.

**Default:** `doc('uigetpref')`

## **ExtraOptions**

String or cell array of strings specifying extra buttons. The additional buttons are not mapped to any preference settings. If you click any of these buttons, the dialog closes and **uigetpref** returns the string in value.

**Default:** `{}`

## **DefaultButton**

String specifying the value that **uigetpref** returns if you close the dialog without clicking a button. This string does not have to correspond to any preference or **ExtraOption**.

**Default:** The first button specified in `pref_choices`

## **Output Arguments**

### **pref\_value**

String containing the preference corresponding to the button you press. If you cancel the dialog by clicking its close box, **uigetpref** returns the label of the first button specified in `pref_choices` or the value for **DefaultButton**, if specified. After you select the **Do not show this dialog again** check box, **uigetpref** does not display a dialog box when you call it with the same `group` and `pref` arguments. Instead, it returns the last choice you made (your registered preference) in `pref_value` immediately.

### **dlgshown**

Logical value that specifies the state of the check box when the dialog box closed. The value is 1 if selected, 0 if not selected. After you select the **Do not show this dialog again** check box, `uigetpref` does not display a dialog box when you call it with the same `group` and `pref` arguments. Instead, it returns 0 in `dlgshown` immediately.

## Definitions

### Preferences

Preferences provide the ability to specify how applications behave and how users interact with them. For example, you can set a preference for which products display their documentation in the Help browser, or which messages the Code Analyzer displays. In MathWorks software products, preferences persist across sessions and are stored in a preference data base, the location of which is system-dependent. Use the **Preferences** option on the **File** menu to access all built-in preferences.

`uigetpref` uses the same preference data base as `addpref`, `getpref`, `ispref`, `rmpref`, and `setpref`. However, `uigetpref` registers the preferences it sets as a separate list, so that it and `uisetpref` can manage those preferences.

To modify preferences registered with `uigetpref`, you can use `setpref` and `uisetpref` to explicitly change preference values to 'ask'. If you specify a preference that does not already exist in the preference data base, `uigetpref` creates it.

## Examples

Create a preference dialog for the 'savefigurebeforeclosing' preference in the 'mygraphics' group of preferences.

Call `uigetpref` to display the dialog (or not) from a figure window `CloseRequestFcn` callback. The callback code takes action via a switch statement. The action (to delete or not to delete the figure) depends on whether the answer returned by `uigetpref` was `'always'` or `'never'`:

```
function save_figure_perhaps
% Closes figure conditionally, asking whether to save it first.
% User can suppress the dialog from UIGETPREF permanently by selecting
% "Do not show this dialog again".

fig = gcf;
[selectedButton dlgshown] = uigetpref(...
    'mygraphics',...           % Group
    'savefigurebeforeclosing',... % Preference
    'Closing Figure',...      % Window title
    {'Do you want to save your figure before closing?'
    ''
    'You can save your figure manually by typing ''hgsave(gcf)'''},...
    {'always','never';'Yes','No'},... % Values and button strings
    'ExtraOptions','Cancel',... % Additional button
    'DefaultButton','Cancel',... % Default choice
    'HelpString','Help',... % String for Help button
    'HelpFcn','doc(''closereq'');'); % Callback for Help button
switch selectedButton
case 'always' % Open a Save dialog (without testing if saved before)
    [fileName,pathName,filterIndex] = uinputfile('fig', ...
        'Save current figure', ...
```

```
                                'untitled.fig');
if filterIndex == 0             % User cancelled save or named no file
    delete(fig);
else                             % Use filename returned from UIPUTFILE
    saveas(fig,[pathName fileName])
    delete(fig);
end
case 'never'                     % Close the figure without saving it
    delete(fig);
case 'cancel'                   % Do not close the figure
    return
end
```

To execute the example, copy it and paste the code into a new program file. Name the file `save_figure_perhaps.m` and place it on your search path. To use the function as a `CloseRequestFcn`, create a figure as follows:

```
figure('CloseRequestFcn','save_figure_perhaps');
```

Clicking the figure close box or selecting **File > Close** displays the dialog box until you select **Do not show this dialog again**.

# uiimport

---

**Purpose** Import data interactively

**Syntax**

```
uiimport
uiimport(filename)
uiimport('-file')
uiimport('-pastespecial')
S = uiimport( __ )
```

**Description** `uiimport` opens a dialog to interactively load data from a file or the clipboard. MATLAB displays a preview of the data in the file.

`uiimport(filename)` opens the file specified in `filename`.

`uiimport('-file')` presents the file selection dialog first.

`uiimport('-pastespecial')` presents the clipboard contents first.

`S = uiimport( __ )` stores the resulting variables as fields in the struct `S`.

| <b>Purpose</b>     | Create menus and menu items on figure windows                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Syntax</b>      | <pre>handle = uimenu('PropertyName',PropertyValue,...) handle = uimenu(parent,'PropertyName',PropertyValue,...)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | <p><code>handle = uimenu('PropertyName',PropertyValue,...)</code> creates a menu in the current figure's menu bar using the values of the specified properties and assigns the menu handle to <code>handle</code>.</p> <p><code>handle = uimenu(parent,'PropertyName',PropertyValue,...)</code> creates a submenu of a parent menu or a menu item on a context menu specified by <code>parent</code> and assigns the menu handle to <code>handle</code>. If <code>parent</code> refers to a figure instead of another <code>uimenu</code> object or a <code>uicontextmenu</code>, MATLAB software creates a new menu on the referenced figure's menu bar.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Tips</b>        | <p>MATLAB adds the new menu to the existing menu bar. If the figure does not have a menu bar, MATLAB creates one. Each menu choice can itself be a menu that displays its items when you select it. <code>uimenu</code> accepts property name/property value pairs as well as structures and cell arrays of properties as input arguments.</p> <p>Use the <code>uimenu</code> <code>Callback</code> property to define the action taken when you activate the created menu item.</p> <p>Uimenu only appear in figures whose <code>Window Style</code> is <code>normal</code>. If a figure containing <code>uimenu</code> children is changed to <code>modal</code>, the <code>uimenu</code> children still exist and are contained in the <code>Children</code> list of the figure, but are not displayed until the <code>WindowStyle</code> is changed to <code>normal</code>.</p> <p>The value of the figure <code>MenuBar</code> property affects the content of the figure menu bar. When <code>MenuBar</code> is <code>figure</code>, a set of built-in menus precedes any user-created <code>uimenu</code>s on the menu bar (MATLAB controls the built-in menus and their handles are not available to the user). When <code>MenuBar</code> is <code>none</code>, <code>uimenu</code>s are the only items on the menu bar (that is, the built-in menus do not appear).</p> |

# uimenu

See the Uimenu Properties reference page for more information. You can set and query property values after creating a menu with the `set` and `get` functions.

## Examples

This example creates a menu labeled **Workspace** with menu options for creating a new figure window, saving workspace variables, and exiting MATLAB. In addition, it defines an accelerator key for the Quit option.

```
f = uimenu('Label', 'Workspace');
    uimenu(f, 'Label', 'New Figure', 'Callback', 'figure');
    uimenu(f, 'Label', 'Save', 'Callback', 'save');
    uimenu(f, 'Label', 'Quit', 'Callback', 'exit', ...
           'Separator', 'on', 'Accelerator', 'Q');
```

This example creates a new figure with a menu bar that excludes the built-in menus. It creates a **Find** menu with options **Find & Replace**, and **Variable**. For the Variable option, it creates a submenu with options of **Name** and **Value**.

```
f=figure('MenuBar', 'None');
mh = uimenu(f, 'Label', 'Find');
frh = uimenu(mh, 'Label', 'Find and Replace ...', ...
             'Callback', 'goto');
frh = uimenu(mh, 'Label', 'Variable');
uimenu(frh, 'Label', 'Name...', ...
       'Callback', 'variable');
```

```
uimenu(frh,'Label','Value...', ...
       'Callback','value');
```

This example creates a context menu, **Font**, on a figure with menu options **Helvetica** and **Monospace**. When you run the code and then right-click anywhere within the figure window, the context menu displays.

```
% Create the UICONTEXTMENU
cmenu = uicontextmenu;

% Create the parent menu
fontmenu = uimenu(cmenu, 'label','Font');

% Create the submenus
font1 = uimenu(fontmenu, 'label','Helvetica','Callback', 'HelvFont');
font2 = uimenu(fontmenu, 'label','Monospace','Callback', 'MonoFont');
set(gcf,'uicontextmenu',cmenu);
```

# uimenu

## Purpose

Describe menu properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` commands enable you to set and query the values of properties

You can set default Uimenu properties on the root, figure and menu levels:

```
set(0, 'DefaultUimenuPropertyName', PropertyValue...)  
set(gcf, 'DefaultUimenuPropertyName', PropertyValue...)  
set(menu_handle, 'DefaultUimenuPropertyName', PropertyValue...)
```

Where *PropertyName* is the name of the Uimenu property and *PropertyValue* is the value you specify as the default for that property.

For more information about changing the default value of property see “Setting Default Property Values”

## Uimenu Properties

This section lists all properties useful to `uimenu` objects along with valid values and instructions for their use. Curly braces `{ }` enclose default values.

| Property Name | Property Description          |
|---------------|-------------------------------|
| Accelerator   | Keyboard equivalent           |
| BeingDeleted  | This object is being deleted  |
| BusyAction    | Callback routine interruption |
| Callback      | Control action                |
| Checked       | Menu check indicator          |
| Children      | Handles of submenus           |

# Uimenu Properties

---

| Property Name    | Property Description                                    |
|------------------|---------------------------------------------------------|
| CreateFcn        | Callback routine executed during object creation        |
| DeleteFcn        | Callback routine executed during object deletion        |
| Enable           | Enable or disable the uimenu                            |
| ForegroundColor  | Color of text                                           |
| HandleVisibility | Whether handle is accessible from command line and GUIs |
| Interruptible    | Callback routine interruption mode                      |
| Label            | Menu label                                              |
| Parent           | Uimenu object's parent                                  |
| Position         | Relative uimenu position                                |

Accelerator  
character

*Keyboard equivalent.* An alphabetic character specifying the keyboard equivalent for the menu item. This allows users to select a particular menu choice by pressing the specified character in conjunction with another key, instead of selecting the menu item with the mouse. The key sequence is platform specific:

- For Microsoft Windows systems, the sequence is **Ctrl+Accelerator**. Windows reserves these keys for default

menu items: **c**, **v**, and **x**. For more information, see Keyboard shortcuts for Windows on the Microsoft support Web site.

- For Macintosh systems, the sequence is **Cmd**+Accelerator. Apple reserves these keys for default menu items: **a**, **c**, **v**, and **x**. For more information, see Mac OS X keyboard shortcuts on the Apple Computer support Web site.
- For UNIX systems, the sequence is **Ctrl**+Accelerator. These keys are reserved for default menu items: **o**, **p**, **s**, and **w**. Many UNIX applications also use **a**, **c**, **v**, and **x** in the same manner as the other platforms.

Accelerated menu items do not have to be displayed for the accelerator key to work (you can accelerate a submenu). However, some restrictions apply:

- You can define an accelerator only for menu items that do not have children menus.
- Accelerators work only for menu items that directly execute a callback routine.
- The figure must be in focus when entering the accelerator key sequence.

To remove an accelerator, set `Accelerator` to an empty string, `''`.

For a cross-platform comparison of accelerators, see the article [Table of Keyboard Shortcuts](#).

`BeingDeleted`  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

# Uimenu Properties

---

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

## BusyAction

cancel | {queue}

*Callback routine interruption.* If a callback is executing and the user triggers an event (such as a mouse click) on an object for which a callback is defined, the callback associated with the new event uses the value of `BusyAction` to decide whether or not to attempt to interrupt the executing callback.

- If the value is `cancel`, the event is discarded and the second callback does not execute.
- If the value is `queue`, and the `Interruptible` property of the first callback is `on`, the second callback is added to the event queue and executes in its turn after the first callback finishes execution.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. See the `Interruptible` property for information about controlling a callback's interruptibility.

---

## Callback

string or function handle

*Menu action.* A callback routine that executes whenever you activate the menu or its submenu (if one exists). Activation is platform dependent. Typically, it is clicking the menu or, if the menu has one, its submenu. Define this routine as a string that

is a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB base workspace.

---

**Caution** Do not use a uimenu callback to dynamically change menu items. Deleting, adding, and replacing menu items in a callback can result in a blank menu on some platforms. You can hide, show, and disable menu items in a callback to achieve the same effect. To fully repopulate menu items, delete and create them outside the callback.

---

Checked

on | {off}

*Menu check indicator.* Setting this property to `on` places a check mark next to the corresponding menu item. Setting it to `off` removes the check mark. You can use this feature to create menus that indicate the state of a particular option. For example, suppose you have a menu item called **Show axes** that toggles the visibility of an axes between visible and invisible each time the user selects the menu item. If you want a check to appear next to the menu item when the axes are visible, add the following code to the callback for the **Show axes** menu item:

```
if strcmp(get(gcbo, 'Checked'), 'on')
    set(gcbo, 'Checked', 'off');
else
    set(gcbo, 'Checked', 'on');
end
```

This changes the value of the `Checked` property of the menu item from `on` to `off` or vice versa each time a user selects the menu item.

Note that there is no formal mechanism for indicating that an unchecked menu item will become checked when selected.

# Uimenu Properties

---

---

**Note** This property is ignored for top level and parent menus.

---

## Children

vector of handles

*Handles of submenus.* A vector containing the handles of all children of the uimenu object. The children objects of uimenu are other uimenu objects, which function as submenus. You can use this property to reorder the menus.

## CreateFcn

string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a uimenu object. MATLAB sets all property values for the uimenu before executing the CreateFcn callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the uimenu being created.

Setting this property on an existing uimenu object has no effect.

You can define a default CreateFcn callback for all new uimenu objects. This default applies unless you override it by specifying a different CreateFcn callback when you call `uimenu`. For example, the code

```
set(0, 'DefaultUimenuCreateFcn', 'set(gcbo, ...  
    'Visible','on')')
```

creates a default CreateFcn callback that runs whenever you create a new menu. It sets the default Visible property of a uimenu object.

To override this default and create a menu whose Visible property is set to a different value, call `uimenu` with code similar to

```
hpt = uimenu(...,'CreateFcn','set(gcbo,...  
'Visible','off'))
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uimenu` call. In the example above, if instead of redefining the `CreateFcn` property for this `uimenu`, you had explicitly set `Visible` to `off`, the default `CreateFcn` callback would have set `Visible` back to the default, i.e., `on`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## DeleteFcn

string or function handle

*Delete uimenu callback routine.* A callback routine that executes when you delete the `uimenu` object (e.g., when you issue a `delete` command or cause the figure containing the `uimenu` to reset). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which is more simply queried using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

# Uimenu Properties

---

## Enable

{on} | off

*Enable or disable the uimenu.* This property controls whether a menu item can be selected. When not enabled (set to `off`), the menu `Label` appears dimmed, indicating the user cannot select it.

## ForegroundColor

ColorSpec X-Windows only

*Color of menu label string.* This property determines color of the text defined for the `Label` property. Specify a color using a three-element RGB vector or one of the MATLAB predefined names. The default text color is black. See `ColorSpec` for more information on specifying color.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.

- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

## Interruptible

`{on} | off`

*Callback routine interruption mode.* If a callback is executing and the user triggers an event (such as a mouse click) on an object for which a callback is defined, that callback attempts to interrupt the first callback. MATLAB processes the callbacks according to these factors:

- The `Interruptible` property of the object whose callback is executing
- Whether the executing callback contains `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statements
- The `BusyAction` property of the object whose callback is waiting to execute

If the `Interruptible` property of the object whose callback is executing is `on` (the default), the callback can be interrupted. Whenever the callback calls one of the `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` functions, the function processes any events in the event queue, including the waiting callback, before performing its defined task.

If the `Interruptible` property of the object whose callback is executing is `off`, the callback cannot be interrupted (except by certain callbacks; see the note below). The `BusyAction` property

# Uimenu Properties

---

of the object whose callback is waiting to execute determines what happens to the callback.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. A figure's `WindowButtonDownFcn` callback routine, or an object's `ButtonDownFcn` or `Callback` routine are processed according to the rules described above.

---

## Label

string

*Menu label.* A string specifying the text label on the menu item. You can specify a mnemonic for the label using the '&' character. Except as noted below, the character that follows the '&' in the string appears underlined and selects the menu item when you type **Alt+** followed by that character while the menu is visible. The '&' character is not displayed. To display the '&' character in a label, use two '&' characters in the string:

'O&pen selection' yields **Open selection**

'Save && Go' yields **Save & Go**

'Save&&Go' yields **Save & Go**

'Save& Go' yields **Save& Go** (the space is not a mnemonic)

---

**Tip** Avoid specifying mnemonics for applications designed to run on Macintosh computers. Accessing menus with mnemonics violates the principles of Apple Human Interface Guidelines. However, you can set the `Accelerator` property to access individual menu items with key sequences on a Mac.

---

Avoid including the reserved words, `default`, `remove`, and `factory`, in menu labels unless you escape them. They are case sensitive. To use one of these words in the `Label` property, escape it by preceding it with a backslash (`'\'`) character. For example:

`'\remove'` yields **remove**

`'\default'` yields **default**

`'\factory'` yields **factory**

## Parent

handle

*Uimenu's parent.* The handle of the `uimenu`'s parent object. The parent of a `uimenu` object is the figure on whose menu bar it displays, or the `uimenu` of which it is a submenu. You can move a `uimenu` object to another figure by setting this property to the handle of the new parent.

## Position

scalar

*Relative menu position.* The value of `Position` indicates placement on the menu bar or within a menu. Top-level menus are placed from left to right on the menu bar according to the value of their `Position` property, with 1 representing the left-most position. The individual items within a given menu are placed from top to bottom according to the value of their `Position` property, with 1 representing the top-most position.

# Uimenu Properties

---

## Separator

on | {off}

*Separator line mode.* Setting this property to on draws a dividing line above the menu item.

## Tag

string

*User-specified object label.* The Tag property provides a means to identify graphics objects with a user-specified label. This is particularly useful when constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callback routines. You can define Tag as any string.

## Type

string (read only)

*Class of graphics object.* For uimenu objects, Type is always the string 'uimenu'.

## UserData

matrix

*User-specified data.* Any matrix you want to associate with the uimenu object. MATLAB does not use this data, but you can access it using the set and get commands.

## Visible

{on} | off

*Uimenu visibility.* By default, all uimenus are visible. When set to off, the uimenu is not visible, but still exists and you can query and set its properties.

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Convert to 8-bit unsigned integer                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Syntax</b>           | <code>intArray = uint8(array)</code>                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b>      | <code>intArray = uint8(array)</code> converts the elements of an array into unsigned 8-bit (1-byte) integers of class <code>uint8</code> .                                                                                                                                                                                                                                                                     |
| <b>Input Arguments</b>  | <p><b>array</b></p> <p>Array of any numeric class, such as <code>single</code> or <code>double</code>. If <code>array</code> is already of class <code>uint8</code>, the <code>uint8</code> function has no effect.</p>                                                                                                                                                                                        |
| <b>Output Arguments</b> | <p><b>intArray</b></p> <p>Array of class <code>uint8</code>. Values range from 0 to <math>2^8 - 1</math>.</p> <p>The <code>uint8</code> function maps any values in <code>array</code> that are outside the limit to the nearest endpoint. For example,</p> <pre>uint8(2^8)    % 2^8 = 256</pre> <p>returns</p> <pre>ans =     255</pre>                                                                       |
| <b>Examples</b>         | <p>Convert a double array to <code>uint8</code>:</p> <pre>mydata = uint8(magic(10));</pre>                                                                                                                                                                                                                                                                                                                     |
| <b>Alternatives</b>     | <p>When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as <code>zeros</code>, <code>ones</code> or <code>eye</code>), rather than calling an integer conversion function. For example,</p> <pre>I = uint8(zeros(100));    % Creates an intermediate array</pre> <p>is not as efficient as</p> <pre>I = zeros(100, 'uint8');  % Preferred</pre> |

# uint8

| <b>Description</b>      | <code>intArray = uint16(array)</code> converts the elements of an array into unsigned 16-bit (2-byte) integers of class <code>uint16</code> .                                                                                                                                                                                                                                                                |
| <b>Input Arguments</b>  | <p><b>array</b></p> <p>Array of any numeric class, such as <code>single</code> or <code>double</code>. If array is already of class <code>uint16</code>, the <code>uint16</code> function has no effect.</p>                                                                                                                                                                                                 |
| <b>Output Arguments</b> | <p><b>intArray</b></p> <p>Array of class <code>uint16</code>. Values range from 0 to <math>2^{16} - 1</math>.</p> <p>The <code>uint16</code> function maps any values in array that are outside the limit to the nearest endpoint. For example,</p> <pre>uint16(2^16) % 2^16 = 65536</pre> <p>returns</p> <pre>ans =     65535</pre>                                                                         |
| <b>Examples</b>         | <p>Convert a double array to <code>uint16</code>:</p> <pre>mydata = uint16(magic(100));</pre>                                                                                                                                                                                                                                                                                                                |
| <b>Alternatives</b>     | <p>When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as <code>zeros</code>, <code>ones</code> or <code>eye</code>), rather than calling an integer conversion function. For example,</p> <pre>I = uint16(zeros(100)); % Creates an intermediate array</pre> <p>is not as efficient as</p> <pre>I = zeros(100, 'uint16'); % Preferred</pre> |

|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Convert to 64-bit unsigned integer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Syntax</b>           | <code>intArray = uint64(array)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b>      | <code>intArray = uint64(array)</code> converts the elements of an array into unsigned 64-bit (8-byte) integers of class <code>uint64</code> .                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Tips</b>             | <p>Double-precision floating-point numbers have only 52 bits in the mantissa. Therefore, <code>double</code> values cannot represent all integers greater than <math>2^{53}</math> correctly. Before performing arithmetic operations on values larger than <math>2^{53}</math> in magnitude, convert the values to 64-bit integers. For example,</p> <pre>x = uint64(2^53+1);    % Floating-point arithmetic, loses precision</pre> <p>is not as accurate as the 64-bit integer arithmetic operation:</p> <pre>x = uint64(2^53) + 1; % Preferred</pre> |
| <b>Input Arguments</b>  | <p><b>array</b></p> <p>Array of any numeric class, such as <code>single</code> or <code>double</code>. If <code>array</code> is already of class <code>uint64</code>, the <code>uint64</code> function has no effect.</p>                                                                                                                                                                                                                                                                                                                               |
| <b>Output Arguments</b> | <p><b>intArray</b></p> <p>Array of class <code>uint64</code>. Values range from 0 to <math>2^{64} - 1</math>.</p> <p>The <code>uint64</code> function maps any values in <code>array</code> that are outside the limit to the nearest endpoint. For example,</p> <pre>uint64(2^64)    % 2^64 = 18446744073709551616</pre> <p>returns</p> <pre>ans =<br/>    18446744073709551615</pre>                                                                                                                                                                  |

# uint64

---

## Examples

Convert a literal value to uint64:

```
x = uint64(9007199254740993);
```

## Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = uint64(zeros(100));    % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'uint64'); % Preferred
```

## Tutorials

- “Integers”
- “Arithmetic Operations on Integer Classes”

**Purpose** Interactively select file to open and load data

**Syntax**

```
uiopen  
uiopen(type)  
uiopen(filename)  
uiopen(filename, TF)
```

**Description** `uiopen` displays the dialog box with the file filter set to all MATLAB files (with file extensions `*.m`, `*.mat`, `*.fig`, `*.mdl`, and `*.slx`).  
`uiopen(type)` sets the file filter according to the `type`.  
`uiopen(filename)` displays `filename` as the default value for **File name** in the dialog box and lists only files having the same extension.  
`uiopen(filename, TF)` directly opens file `filename` without displaying a dialog box if `TF` is true, and displays the dialog box if `TF` is false.

**Tips** When you select a file and click **open**, `uiopen` does the following:

- Gets the file using `uigetfile`.
- Opens the file using the `open` command.
  - Files with a file extension of `.m` open in the Editor.
  - Variables stored in files with a file extension of `.mat` appear in the caller's workspace.
  - Files with a file extension of `.fig` open as figure windows.
  - Files with a file extension of `.mdl` or `.slx` open as models in Simulink.
- `uiopen('load')` is the only the form of `uiopen` that you can compile into a standalone application. You can create a file selection dialog box that you can compile using `uigetfile`.
- The `uiopen` dialog box is modal. A modal dialog box prevents you from interacting with other windows until you respond to the modal one.

- `uiopen` displays the same dialog box that opens when you use the MATLAB desktop toolstrip to open a file. (On the **Home** tab, in the **File** section, click **Open** )

## Input Arguments

### **type**

String that specifies the kind of file to show in the dialog box (the file filter). Acceptable values for `type` are the following.

| Type string           | Files Displayed                                                                                                                                    |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>matlab</code>   | All MATLAB files (with file extensions <code>*.m</code> , <code>*.mat</code> , <code>*.fig</code> , <code>*.mdl</code> , and <code>*.slx</code> .) |
| <code>load</code>     | All MAT-files ( <code>*.mat</code> )                                                                                                               |
| <code>figure</code>   | All figure files ( <code>*.fig</code> )                                                                                                            |
| <code>simulink</code> | All Simulink model files ( <code>*.mdl</code> and <code>*.slx</code> )                                                                             |
| <code>editor</code>   | All MATLAB files except for <code>.mat</code> , <code>.fig</code> , and <code>.slx</code> files.                                                   |

### **filename**

A string, including the file extension, naming a file to open. The `filename` can be a wildcard character plus extension. For example, `*.txt` displays a list of all files with the file extension `.txt`.

### **TF**

A MATLAB expression that evaluates to true or false. If true, `filename` opens directly, without displaying the dialog.

## Definitions

### **Modal Dialog**

A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

## Examples

Filter to display only FIG-files by setting the **Files of type** field to Figures (\*.fig):

```
uiopen('figure')
```

## Alternatives

In MATLAB code or in a command:

- To open a file appropriately based on its file extension, use the `open` function.
- To open a file in the Editor, use the `edit` function.
- To open a MAT-file and load its contents into the workspace, use the `load` function.
- To open a FIG-file, use the `openfig` function.
- To open a file in an application in Microsoft Windows, use the `winopen` function.

# uiopen

---

## **See Also**

`uigetfile` | `uiputfile` | `uisave`

**Purpose**

Create panel container object

**Syntax**

```
h = uipanel('PropertyName1',value1,'PropertyName2',value2,
... )
h = uipanel(parent,'PropertyName1',value1,'PropertyName2',
value2,...)
```

**Description**

A uipanel groups components. It can contain user interface controls with which the user interacts directly. It can also contain axes, other uipanels, and uibuttongroups. It cannot contain ActiveX controls.

```
h =
uipanel('PropertyName1',value1,'PropertyName2',value2,...)
creates a uipanel container object in a figure, uipanel, or
uibuttongroup. Use the Parent property to specify the parent figure,
uipanel, or uibuttongroup. If you do not specify a parent, uipanel adds
the panel to the current figure. If no figure exists, one is created. See
the Uipanel Properties reference page for more information.
```

```
h =
uipanel(parent,'PropertyName1',value1,'PropertyName2',value2,...)
creates a uipanel in the object specified by the handle, parent. If you
also specify a different value for the Parent property, the value
of the Parent property takes precedence. parent must be a
figure, uipanel, or uibuttongroup.
```

A uipanel object can have axes, uicontrol, uipanel, and uibuttongroup objects as children. For the children of a uipanel, the Position property is interpreted relative to the uipanel. If you move the panel, the children automatically move with it and maintain their positions relative to the panel.

After creating a uipanel object, you can set and query its property values using set and get.

**Tips**

If you set the Visible property of a uipanel object to 'off', any child objects it contains (buttons, button groups, axes, etc.) become invisible along with the panel itself. However, doing this does *not* affect the

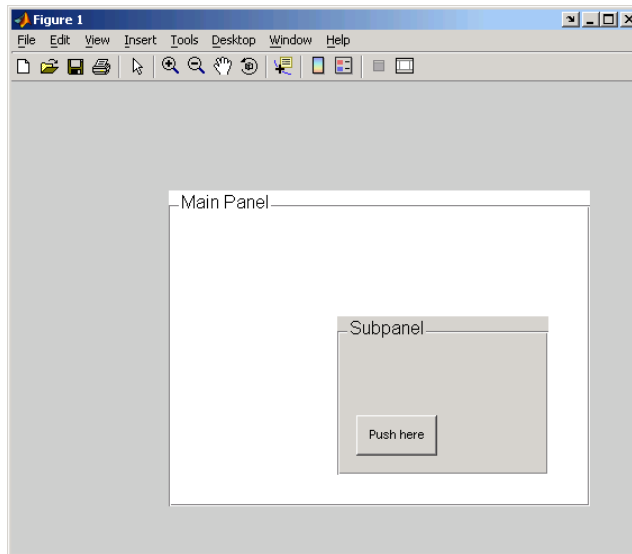

# uipanel

settings of the `Visible` property of any of its child objects, even though all of them remain invisible until the `uipanel`'s visibility is set to `'on'`. `uibuttongroup` components also behave in this manner.

## Examples

This example creates a `uipanel` in a figure, then creates a subpanel in the first panel. Finally, it adds a `pushbutton` to the subpanel. Both panels use the default `Units` property value, `normalized`. Note that default `Units` for the `uicontrol` `pushbutton` is `pixels`.

```
h = figure;  
hp = uipanel('Title','Main Panel','FontSize',12,...  
            'BackgroundColor','white',...  
            'Position',[.25 .1 .67 .67]);  
hsp = uipanel('Parent',hp,'Title','Subpanel','FontSize',12,...  
             'Position',[.4 .1 .5 .5]);  
hbsp = uicontrol('Parent',hsp,'String','Push here',...  
                'Position',[18 18 72 36]);
```

# Uipanel Properties

---

## Purpose

Describe panel properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default uipanel properties by typing:

```
set(h, 'DefaultUipanelPropertyName', PropertyValue...)
```

Where `h` can be the root handle (0), a figure handle, or a uipanel handle. `PropertyName` is the name of the uipanel property and `PropertyValue` is the value you specify as the default for that property.

---

**Note** Default properties you set for uipanel also apply to `uibuttongroups`.

---

For more information about changing the default value of a property see “Setting Default Property Values”. For an example, see the `CreateFcn` property.

## Uipanel Properties

This section lists all properties useful to `uipanel` objects along with valid values and a descriptions of their use. Curly braces `{ }` enclose default values.

| Property Name                | Description                             |
|------------------------------|-----------------------------------------|
| <code>BackgroundColor</code> | Color of the uipanel background         |
| <code>BeingDeleted</code>    | This object is being deleted            |
| <code>BorderType</code>      | Type of border around the uipanel area. |

# Uipanel Properties

| Property Name    | Description                                                                                           |
|------------------|-------------------------------------------------------------------------------------------------------|
| BorderWidth      | Width of the panel border.                                                                            |
| BusyAction       | Interruption of other callback routines                                                               |
| ButtonDownFcn    | Button-press callback routine                                                                         |
| Children         | All children of the uipanel                                                                           |
| Clipping         | Clipping of child axes, uipanel, and uibuttongroups to the uipanel. Does not affect child uicontrols. |
| CreateFcn        | Callback routine executed during object creation                                                      |
| DeleteFcn        | Callback routine executed during object deletion                                                      |
| FontAngle        | Title font angle                                                                                      |
| FontName         | Title font name                                                                                       |
| FontSize         | Title font size                                                                                       |
| FontUnits        | Title font units                                                                                      |
| FontWeight       | Title font weight                                                                                     |
| ForegroundColor  | Title font color and/or color of 2-D border line                                                      |
| HandleVisibility | Handle accessibility from commandline and GUIs                                                        |
| HighlightColor   | 3-D frame highlight color                                                                             |
| HitTest          | Selectable by mouse click                                                                             |
| Interruptible    | Callback routine interruption mode                                                                    |
| Parent           | Uipanel object's parent                                                                               |
| Position         | Panel position relative to parent figure or uipanel                                                   |
| ResizeFcn        | User-specified resize routine                                                                         |

# Uipanel Properties

---

| Property Name      | Description                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Selected           | Whether object is selected                                                                                                                                                                                   |
| SelectionHighlight | Object highlighted when selected                                                                                                                                                                             |
| ShadowColor        | 3-D frame shadow color                                                                                                                                                                                       |
| Tag                | User-specified object identifier                                                                                                                                                                             |
| Title              | Title string                                                                                                                                                                                                 |
| TitlePosition      | Location of title string in relation to the panel                                                                                                                                                            |
| Type               | Object class                                                                                                                                                                                                 |
| UIContextMenu      | Associates uicontextmenu with the uipanel                                                                                                                                                                    |
| Units              | Units used to interpret the position vector                                                                                                                                                                  |
| UserData           | User-specified data                                                                                                                                                                                          |
| Visible            | Uipanel visibility.<br><hr/> <b>Note</b> Controls the visibility of a uipanel and of its child axes, uibuttongroups, uipanel, and child uicontrols. Setting it does not change their Visible property. <hr/> |

BackgroundColor  
ColorSpec

*Color of the uipanel background.* A three-element RGB vector or one of the MATLAB predefined names, specifying the background color. See the ColorSpec reference page for more information on specifying color.

BeingDeleted  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

## BorderType

`none` | `{etchedin}` | `etchedout` | `beveledin` | `beveledout`  
| `line`

*Border of the uipanel area.* Used to define the panel area graphically. Etched and beveled borders provide a 3-D look. Use the `HighlightColor` and `ShadowColor` properties to specify the border color of etched and beveled borders. A line border is 2-D. Use the `ForegroundColor` property to specify its color.

## BorderWidth

integer

*Width of the panel border.* The width of the panel borders in pixels. The default border width is 1 pixel. 3-D borders wider than 3 may not appear correctly at the corners.

## BusyAction

`cancel` | `{queue}`

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the

# Uipanel Properties

---

*running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`  
string or function handle

*Button-press callback routine.* A callback routine that executes when you press a mouse button while the pointer is in a 5-pixel wide border around the uipanel. This is useful for implementing actions to interactively modify control object properties, such as size and position, when they are clicked on (using the `selectmoveresize` function, for example).

If you define this routine as a string, the string can be a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

`Children`  
vector of handles

*Children of the uipanel.* A vector containing the handles of all children of the uipanel. A `uipanel` object's children are axes, uipanels, `uibuttongroups`, and `uicontrols`. You can use this property to reorder the children.

`Clipping`  
{on} | off

*Clipping mode.* By default, MATLAB clips a uipanel's child axes, uipanel, and uibuttongroups to the uipanel rectangle. If you set `Clipping` to `off`, the axis, uipanel, or uibuttongroup is displayed outside the panel rectangle. This property does not affect child uicontrols which, by default, can display outside the panel rectangle.

`CreateFcn`  
string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a uipanel object. MATLAB sets all property values for the uipanel before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the uipanel being created.

Setting this property on an existing uipanel object has no effect.

You can define a default `CreateFcn` callback for all new uipanel. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uipanel`. For example, the code

```
set(0, 'DefaultUipanelCreateFcn', 'set(gcbo, ...  
    ' 'FontName', 'arial', 'FontSize', 12)')
```

creates a default `CreateFcn` callback that runs whenever you create a new panel. It sets the default font name and font size of the uipanel title.

---

**Note** `Uibuttongroup` takes its default property values from `uipanel`. Defining a default property for all uipanel defines the same default property for all `uibuttongroups`.

---

# Uipanel Properties

---

To override this default and create a panel whose `FontName` and `FontSize` properties are set to different values, call `uipanel` with code similar to

```
hpt = uipanel(..., 'CreateFcn', 'set(gcbo,...  
'FontName','times','FontSize',14)')
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uipushtool` call. In the example above, if instead of redefining the `CreateFcn` property for this `uipanel`, you had explicitly set `FontSize` to 14, the default `CreateFcn` callback would have set `FontSize` back to the system dependent default.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## DeleteFcn

string or function handle

*Callback routine executed during object deletion.* A callback routine that executes when you delete the `uipanel` object (e.g., when you issue a `delete` command or `clear` the figure containing the `uipanel`). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine. The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

## FontAngle

{normal} | italic | oblique

*Character slant used in the Title.* MATLAB uses this property to select a font from those available on your particular system. Setting this property to *italic* or *oblique* selects a slanted version of the font, when it is available on your system.

## FontName

string

*Font family used in the Title.* The name of the font in which to display the Title. To display and print properly, this must be a font that your system supports. The default font is system dependent. To eliminate the need to hard code the name of a fixed-width font, which may not display text properly on systems that do not use ASCII character encoding (such as in Japan), set `FontName` to the string `FixedWidth` (this string value is case insensitive).

```
set(uicontrol_handle,'FontName','FixedWidth')
```

This then uses the value of the root `FixedWidthFontName` property which can be set to the appropriate value for a locale from `startup.m` in the end user's environment. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font

## FontSize

integer

*Title font size.* A number specifying the size of the font in which to display the Title, in units determined by the `FontUnits` property. The default size is system dependent.

## FontUnits

inches | centimeters | normalized | {points} | pixels

# Uipanel Properties

---

*Title font size units.* Normalized units interpret `FontSize` as a fraction of the height of the uipanel. When you resize the uipanel, MATLAB modifies the screen `FontSize` accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).

## FontWeight

`light` | `{normal}` | `demi` | `bold`

*Weight of characters in the title.* MATLAB uses this property to select a font from those available on your particular system. Setting this property to `bold` causes MATLAB to use a bold version of the font, when it is available on your system.

## ForegroundColor

`ColorSpec`

*Color used for title font and 2-D border line.* A three-element RGB vector or one of the MATLAB predefined names, specifying the font or line color. See the `ColorSpec` reference page for more information on specifying color.

## HandleVisibility

`{on}` | `callback` | `off`

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.

- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HighlightColor`  
`ColorSpec`

*3-D frame highlight color.* A three-element RGB vector or one of the MATLAB predefined names, specifying the highlight color. See the `ColorSpec` reference page for more information on specifying color.

`HitTest`  
{on} | off

*Selectable by mouse click.* `HitTest` determines if the uipanel can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the panel. If `HitTest` is `off`, clicking the panel sets the `CurrentObject` to the closest ancestor of the panel that registers `HitTest`. The uipanel property `HandleVisibility` must be `'on'` for it to become the `CurrentObject`. If the uipanel `HandleVisibility` is `'off'` or `'callback'`, or if the panel and all

# Uipanel Properties

---

its ancestors have `HitTest` set to 'off', the figure `CurrentObject` is the empty matrix.

`Interruptible`  
off | {on}

## *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:

- If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
- If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

# Uipanel Properties

---

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object's `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

## Parent

handle

*Uipanel parent.* The handle of the uipanel's parent figure, uipanel, or uibuttongroup. You can move a uipanel object to another figure, uipanel, or uibuttongroup by setting this property to the handle of the new parent.

## Position

position rectangle

*Size and location of uipanel relative to parent.* The rectangle defined by this property specifies the size and location of the panel within the parent figure window, uipanel, or uibuttongroup. Specify `Position` as

[left bottom width height]

`left` and `bottom` are the distance from the lower-left corner of the parent object to the lower-left corner of the uipanel object. `width` and `height` are the dimensions of the uipanel rectangle, including the title. All measurements are in units specified by the `Units` property.

## ResizeFcn

function handle or string

*Resize callback routine.* MATLAB executes this callback routine whenever a user manually or programmatically resizes the uipanel, or in GUIDE, the `Resize` behavior option is set to `other`. You can query the uipanel `Position` property to determine its new size and position. During execution of the callback routine, the handle to the uipanel being resized is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

All axes, uipanel, uitable and uicontrol objects that have their `Units` set to `normalized` automatically resize proportionally to the figure. You can define individual resize functions for any such object as needed. For example, you can use `ResizeFcn` to maintain a GUI layout that is not directly supported by the MATLAB `Position-and-Units` paradigm.

For example, consider a GUI layout that maintains an object attached to the top of the figure at a constant height in pixels, but always matches the width of the figure. The following `ResizeFcn` accomplishes this; it keeps the uicontrol whose `Tag` is `'StatusBar'` 20 pixels high, as wide as the figure, and attached to the top of the figure. Note the use of the `Tag` property to retrieve the uicontrol handle, and the `gcbo` function to retrieve the figure handle. The code also does “defensive programming” to save and restores figure `Units`. The callback requires `Units` in pixels in order to work correctly, but takes care not to permanently alter that property.

```
u = findobj('Tag','StatusBar');
fig = gcbo;
old_units = get(fig,'Units');
set(fig,'Units','pixels');
figpos = get(fig,'Position');
upos = [0, figpos(4) - 20, figpos(3), 20];
set(u,'Position',upos);
set(fig,'Units',old_units);
```

# Uipanel Properties

---

You can change the figure `Position` from within a `uipanel` `ResizeFcn` callback; however, the `ResizeFcn` is not called again as a result.

A figure's `uipanel`s resize before the figure itself does. Nested `uipanel`s resize from inner to outer, with child `ResizeFcns` being called before parent `ResizeFcns`.

The `print` command can cause the `ResizeFcn` to be called if the `PaperPositionMode` property is set to `manual` and you have defined a resize function. If you do not want your resize function called by `print`, set the `PaperPositionMode` to `auto`.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

See `Resize Behavior` for information on creating resize functions using `GUIDE`.

## Selected

on | off (read only)

*Is object selected?* This property indicates whether the panel is selected. When this property is on, MATLAB displays selection handles if the `SelectionHighlight` property is also on. You can, for example, define the `ButtonDownFcn` to set this property, allowing users to select the object with the mouse.

## SelectionHighlight

{on} | off

*Object highlighted when selected.* When the `Selected` property is on, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is off, MATLAB does not draw the handles.

## ShadowColor

ColorSpec

*3-D frame shadow color.* A three-element RGB vector or one of the MATLAB predefined names, specifying the shadow color. See the `ColorSpec` reference page for more information on specifying color.

## Tag

string

*User-specified object identifier.* The `Tag` property provides a means to identify graphics objects with a user-specified label. You can define `Tag` as any string.

With the `findobj` function, you can locate an object with a given `Tag` property value. This saves you from defining object handles as global variables. For example, this function call returns the handles of all children (of the specified figures) that have the `Tag` value `'FormatTb'`.

```
h = findobj(figurehandles,'Tag','FormatTb')
```

## Title

string

*Title string.* The text displayed in the panel title. Vertical slash (`'\'`) characters are not interpreted as line breaks and instead show up in the text displayed in the `uipanel` title. You can position the title using the `TitlePosition` property.

Setting a property value to `default`, `remove`, or `factory` produces the effect described in “Defining Default Values”. To set `Title` to one of these words, you must precede the word with the backslash character. For example,

```
hp = uipanel(...,'Title','\Default');
```

## TitlePosition

{lefttop} | centertop | righttop | leftbottom |  
centerbottom | rightbottom

# Uipanel Properties

---

*Location of the title.* This property determines the location of the title string, in relation to the uipanel.

Type

string (read-only)

*Object class.* This property identifies the kind of graphics object. For uipanel objects, Type is always the string 'uipanel'.

UIContextMenu

handle

*Associate a context menu with a uipanel.* Assign this property the handle of a Uicontextmenu object. MATLAB displays the context menu whenever you right-click the uipanel. Use the uicontextmenu function to create the context menu.

Units

inches | centimeters | {normalized} | points | pixels  
| characters

*Units of measurement.* MATLAB uses these units to interpret the Position property. For the panel itself, units are measured from the lower-left corner of the figure window. For children of the panel, they are measured from the lower-left corner of the panel.

- Normalized units map the lower-left corner of the panel or figure window to (0,0) and the upper-right corner to (1.0,1.0).
- pixels, inches, centimeters, and points are absolute units (1 point = 1/72 inch).
- Character units are characters using the default system font; the width of one character is the width of the letter x, the height of one character is the distance between the baselines of two lines of text.

If you change the value of Units, it is good practice to return it to its default value after completing your computation so as not

to affect other functions that assume `Units` is set to the default value.

## `UserData`

matrix

*User-specified data.* Any data you want to associate with the `uipanel` object. MATLAB does not use this data, but you can access it using `set` and `get`.

## `Visible`

{on} | off

*Uipanel visibility.* By default, a `uipanel` object is visible. When set to 'off', the `uipanel` is not visible, as are all child objects of the panel. When a panel is hidden in this manner, you can still query and set its properties.

---

**Note** The value of a `uipanel`'s `Visible` property determines whether its child components, such as axes, buttons, `uibuttongroups`, and other `uipanel`s, are visible. However, changing the `Visible` property of a panel does *not* change the settings of the `Visible` property of its child components even though hiding the panel causes them to be hidden.

---

# uipushtool

---

**Purpose** Create push button on toolbar

**Syntax**

```
hpt = uipushtool
hpt = uipushtool('PropertyName1',value1,'PropertyName2',
    value2,...)
hpt = uipushtool(ht,...)
```

**Description** `hpt = uipushtool` creates a push button on the `uitoolbar` at the top of the current figure window, sets all its properties to default values, and returns a handle to the tool. If no `uitoolbar` exists, one is created. The `uitoolbar` is the parent of the `uipushtool`. Use the returned handle `hpt` to set properties of the tool. The `ClickedCallback` passes the handle as its first argument. The button has no icon, but its border highlights when you hover over it with the mouse cursor. Add an icon by setting `CData` for the tool.

```
hpt =
uipushtool('PropertyName1',value1,'PropertyName2',value2,...)
, creates a uipushtool and returns a handle to it. uipushtool assigns
the specified property values, and assigns default values to the
remaining properties. You can change the property values at a later
time using the set function. You can specify properties as parameter
name/value pairs, cell arrays containing parameter names and values,
or structures with fields containing parameter names and values as
input arguments. For a complete list, see Uipushtool Properties. Type
get(hpt) to see a list of uipushtool object properties and their current
values. Type set(hpt) to see a list of uipushtool object properties that
you can set and their legal property values.
```

`hpt = uipushtool(ht,...)` creates a button with `ht` as a parent. `ht` must be a `uitoolbar` handle.

`Uipushtools` appear in figures whose `Window Style` is `'normal'` or `'docked'`. Push tools do not appear in figures with `'modal'` `WindowStyle`. If you change the `WindowStyle` of a figure containing a `uitoolbar` and its `uipushtool` children to `'modal'`, the `uipushtools` continue to exist as `Children` of the `uitoolbar`. However, they do

not display until you change the figure `WindowState` to `'normal'` or `'docked'`.

Unlike push buttons, uipushtools have no way to indicate that you have double-clicked them. That is, a double click does not set the figure `SelectionType` property to `'open'`. Double-clicking a uipushtool simply executes its `ClickedCallback` twice in succession. Also, uipushtools cannot have context menus.

## Examples

Create a `uitoolbar` object and places a `uipushtool` object on it. Generate an icon for the tool by reading a GIF file containing a MATLAB icon. Convert the indexed image to a truecolor image before specifying it as `CData`.

```
h = figure('ToolBar','none');
ht = uitoolbar(h);
% Use a MATLAB icon for the tool
[X map] = imread(fullfile(...
    matlabroot,'toolbox','matlab','icons','matlabicon.gif'));
% Convert indexed image and colormap to truecolor
icon = ind2rgb(X,map);
% Create a uipushtool in the toolbar
hpt = uipushtool(ht,'CData',icon,...
    'TooltipString','Toolbar push button',...
    'ClickedCallback',...
    'disp(''Thank you for clicking a uipushtool.'')')
```

**Alternatives**

You can also create toolbars with push tools using GUIDE.

Properties

**Tutorials**

- “GUI with Axes, Menu, and Toolbar”

**How To**

- “Create Toolbars for Programmatic GUIs”

## Purpose

Describe push tool properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default Uipushtool properties by typing:

```
set(h, 'DefaultUipushtoolPropertyName', PropertyValue...)
```

Where `h` can be the root handle (0), a figure handle, a uicontrol handle, or a uipushtool handle. *PropertyName* is the name of the Uipushtool property and *PropertyValue* is the value you specify as the default for that property.

For more information about changing the default value of a property see Setting Default Property Values.

## Uipushtool Properties

This section lists all properties useful to uipushtool objects along with valid values and a descriptions of their use. Curly braces { } enclose default values.

| Property        | Purpose                                           |
|-----------------|---------------------------------------------------|
| BeingDeleted    | This object is being deleted.                     |
| BusyAction      | Callback routine interruption.                    |
| CData           | Truecolor image displayed on the control.         |
| ClickedCallback | Control action.                                   |
| CreateFcn       | Callback routine executed during object creation. |
| DeleteFcn       | Delete uipushtool callback routine.               |

# Uipushtool Properties

---

| Property         | Purpose                                             |
|------------------|-----------------------------------------------------|
| Enable           | Enable or disable the uipushtool.                   |
| HandleVisibility | Control access to object's handle.                  |
| HitTest          | Whether selectable by mouse click                   |
| Interruptible    | Callback routine interruption mode.                 |
| Parent           | Handle of uipushtool's parent.                      |
| Separator        | Separator line mode                                 |
| Tag              | User-specified object label.                        |
| TooltipString    | Content of object's tooltip.                        |
| Type             | Object class.                                       |
| UicontextMenu    | Uicontextmenu object associated with the uipushtool |
| UserData         | User specified data.                                |
| Visible          | Uipushtool visibility.                              |

**BeingDeleted**  
on | {off} (read only)

*This object is being deleted.* The **BeingDeleted** property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB software sets the **BeingDeleted** property to on when the object's delete function callback is called (see the **DeleteFcn** property). It remains set to on while the delete function executes, after which the object no longer exists.

For example, some functions may not need to perform actions on objects that are being deleted, and therefore, can check the object's **BeingDeleted** property before acting.

**BusyAction**  
cancel | {queue}

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The **BusyAction** property of the *interrupting* callback determines how MATLAB handles its execution. When the **BusyAction** property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the **Interruptible** property of the callback controls whether other callbacks can interrupt the *running* callback, see the **Interruptible** property description.

**CData**  
3-dimensional array

*Truecolor image displayed on control.* An  $n$ -by- $m$ -by-3 array of RGB values that defines a truecolor image displayed on either a push button or toggle button. Each value must be between 0.0 and 1.0. If your **CData** array is larger than 16 in the first or second dimension, it may be clipped or cause other undesirable effects. If the array is clipped, only the center 16-by-16 part of the array is used.

**ClickedCallback**  
string or function handle

# Uipushtool Properties

---

*Control action.* A routine that executes when the uipushtool's Enable property is set to on, and you press a mouse button while the pointer is on the push tool itself or in a 5-pixel wide border around it.

CreateFcn  
string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a uipushtool object. MATLAB sets all property values for the uipushtool before executing the CreateFcn callback so these values are available to the callback. Within the function, use gcbo to get the handle of the push tool being created.

Setting this property on an existing uipushtool object has no effect.

You can define a default CreateFcn callback for all new uipushtools. This default applies unless you override it by specifying a different CreateFcn callback when you call uipushtool. For example, the code

```
imga(:,:,1) = rand(20);  
imga(:,:,2) = rand(20);  
imga(:,:,3) = rand(20);  
set(0,'DefaultUipushtoolCreateFcn','set(gcbo,''Cdata'',imga)')
```

creates a default CreateFcn callback that runs whenever you create a new push tool. It sets the default image imga on the push tool.

To override this default and create a push tool whose Cdata property is set to a different image, call uipushtool with code similar to

```
a = [.05:.05:0.95];  
imgb(:,:,1) = repmat(a,19,1)';  
imgb(:,:,2) = repmat(a,19,1);
```

```
imgb(:,:,3) = repmat(flipdim(a,2),19,1);  
hpt = uipushtool(...,'CreateFcn','set(gcbo,''CData'',imgb)',...)
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uipushtool` call. In the example above, if instead of redefining the `CreateFcn` property for this push tool, you had explicitly set `CData` to `imgb`, the default `CreateFcn` callback would have set `CData` back to `imga`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## DeleteFcn

string or function handle

*Callback routine executed during object deletion.* A callback routine that executes when you delete the `uipushtool` object (e.g., when you call the `delete` function or cause the figure containing the `uipushtool` to reset). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

# Uipushtool Properties

---

## Enable

{on} | off

*Enable or disable the uipushtool.* This property controls how uipushtools respond to mouse button clicks, including which callback routines execute.

- **on** – The uipushtool is operational (the default).
- **off** – The uipushtool is not operational and its image (set by the `Cdata` property) is grayed out.

When you left-click a uipushtool whose `Enable` property is `on`, MATLAB performs these actions in this order:

- 1** Executes the push tool's `ClickedCallback` routine.
- 2** Does *not* set the figure `CurrentPoint` property and does not execute the figure's `WindowButtonDownFcn` callback.
- 3** Does *not* set the figure `SelectionType` property.

When you left-click a uipushtool whose `Enable` property is `off`, or when you right-click a uipushtool whose `Enable` property has any value, no action is reported, no callback executes, and neither the `SelectionType` nor `CurrentPoint` figure properties are modified.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* This property has no effect on uipushtool objects.

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`

# Uipushtool Properties

---

- KeyReleaseFcn
- WindowButtonDownFcn
- WindowButtonMotionFcn
- WindowButtonUpFcn
- WindowKeyPressFcn
- WindowKeyReleaseFcn
- WindowScrollWheelFcn

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure’s `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object’s `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object’s `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

## Parent

handle

*Uipushtool parent.* The handle of the uipushtool’s parent toolbar. You can move a uipushtool object to another toolbar by setting this property to the handle of the new parent.

## Separator

on | {off}

*Separator line mode.* Setting this property to on draws a dividing line to the left of the uipushtool.

## Tag

string

# Uipushtool Properties

---

*User-specified object identifier.* The `Tag` property provides a means to identify graphics objects with a user-specified label. You can define `Tag` as any string.

With the `findobj` function, you can locate an object with a given `Tag` property value. This saves you from defining object handles as global variables. For example, this function call returns the handles of all children (of the specified toolbars) that have the `Tag` value 'Copy'.

```
h = findobj(uitoolbarhandles, 'Tag', 'Copy')
```

`TooltipString`  
string

*Content of tooltip for object.* The `TooltipString` property specifies the text of the tooltip associated with the `uipushtool`. When the user moves the mouse pointer over the control and leaves it there, the tooltip is displayed.

To create a tooltip that has more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the `TooltipString` to that value. For example:

```
h = uipushtool;  
s = sprintf('Pushtool tooltip line 1\nPushtool tooltip line 2');  
set(h, 'TooltipString', s)
```

`Type`  
string (read-only)

Object class. This property identifies the kind of graphics object. For `uipushtool` objects, `Type` is always the string 'uipushtool'.

`UIContextMenu`  
handle

*Associate a context menu with uicontrol.* This property has no effect on uipushtool objects.

**UserData**  
array

*User specified data.* You can specify **UserData** as any array you want to associate with the uipushtool object. The object does not use this data, but you can access it using the **set** and **get** functions.

**Visible**  
{on} | off

*Uipushtool visibility.* By default, all uipushtools are visible. When set to **off**, the uipushtool is not visible, but still exists and you can query and set its properties.

# uiputfile

---

**Purpose** Open standard dialog box for saving files

**Syntax**

```
FileName = uiputfile  
[FileName,PathName] = uiputfile  
[FileName,PathName,FilterIndex] = uiputfile(FilterSpec)  
[FileName,PathName,FilterIndex] = uiputfile(FilterSpec,  
    DialogTitle)  
[FileName,PathName,FilterIndex] = uiputfile(FilterSpec,  
    DialogTitle,DefaultName)
```

## Description

---

**Note** Successful execution of `uiputfile` does not create a file; it only returns the name of a new or existing file that you designate.

---

`FileName = uiputfile` displays a modal dialog box for selecting or specifying a file you want to create or save. The dialog box lists the files and folders in the current folder. If the selected or specified file name is valid, `uiputfile` returns it in `FileName`.

`[FileName,PathName] = uiputfile` also returns the path to `FileName` in `PathName`, or if you cancel the dialog, returns 0 for both arguments. If you do not provide any output arguments, the file name alone is returned in `ans`.

`[FileName,PathName,FilterIndex] = uiputfile(FilterSpec)` displays only those files with extensions that match `FilterSpec`. On some platforms `uiputfile` also displays in gray any files that do not match `FilterSpec`. The `uiputfile` function appends 'All Files' to the list of file types. `FilterSpec` can be a string or a cell array of strings, and can include the \* and ? wildcard characters. For example, '\*.m' lists all MATLAB program files in a folder.

`FilterSpec` can be a string that contains a file name. `uiputfile` displays the file name selected in the **File name** field and uses the file extension as the default filter. The `FilterSpec` string can include a path, or consist of a path only. To specify a folder only, make the

last character in `DefaultName` `'\'` or `'/'`. A path can contain special path characters, such as `'.'`, `'..'`, `'/'`, `'\'`, or `'~'`. For example, `'../*.m'` lists all program files in the folder above the current folder. If `FilterSpec` is a cell array of strings, the first column contains a list of file extensions. The optional second column contains a corresponding list of descriptions. These descriptions replace the default descriptions in the **Save as type** pop-up menu. A description cannot be an empty string. See the “Examples” on page 2-4863 for illustration of using cell arrays as `FilterSpec`. If you do not specify `FilterSpec`, `uiputfile` uses the default list of file types (all MATLAB files). `FilterIndex` is the index of the filter selected in the dialog box. Indexing starts at 1. If you click the **Cancel** button, close the dialog window, or if the file does not exist, `uiputfile` returns `FilterIndex` as 0.

```
[FileName,PathName,FilterIndex] =  
uiputfile(FilterSpec,DialogTitle) displays a dialog box that has  
the title DialogTitle. To use the default file types and to specify a  
dialog title, enter uiputfile(' ', 'DialogTitle')
```

```
[FileName,PathName,FilterIndex] =  
uiputfile(FilterSpec,DialogTitle,DefaultName) displays a dialog  
box in which the file name specified by DefaultName appears in the  
File name field. DefaultName can also be a path or a path+filename.  
To specify a folder only, make the last character in DefaultName '\' or  
'/'. In this case, uiputfile opens the dialog box in the folder specified  
by the path. If you specify a path in DefaultName that does not exist,  
uiputfile opens the dialog box in the current folder. You can use  
'.', '..', '\', '/', or ~ in the DefaultName argument.
```

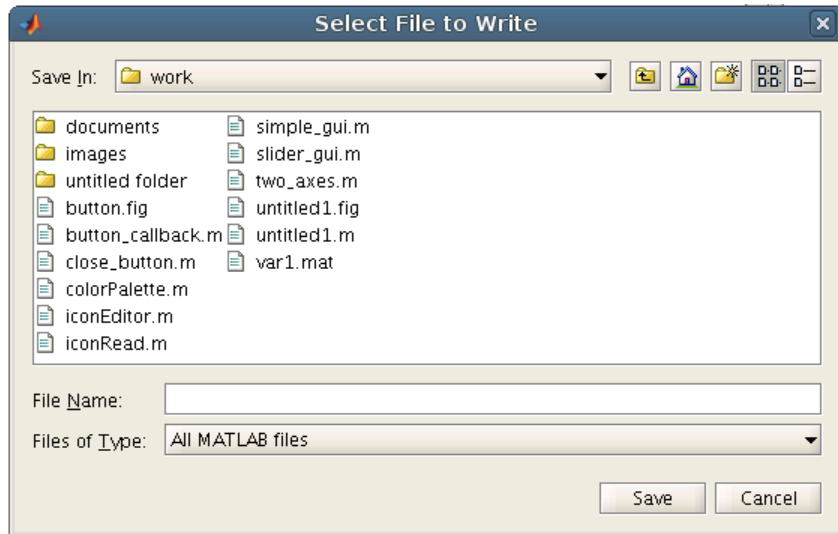

When typing into the dialog box, if you include either of the wildcard characters `'*'` or `'?'` in a file name, `uiputfile` does not respond to clicking **Save**. The dialog box remains open until you cancel it or remove the wildcard characters. This restriction applies to all platforms, even to file systems that permit these characters in file names.

If you select or specify an existing file name, a warning dialog box opens stating that the file already exists and asks if you want to replace it.

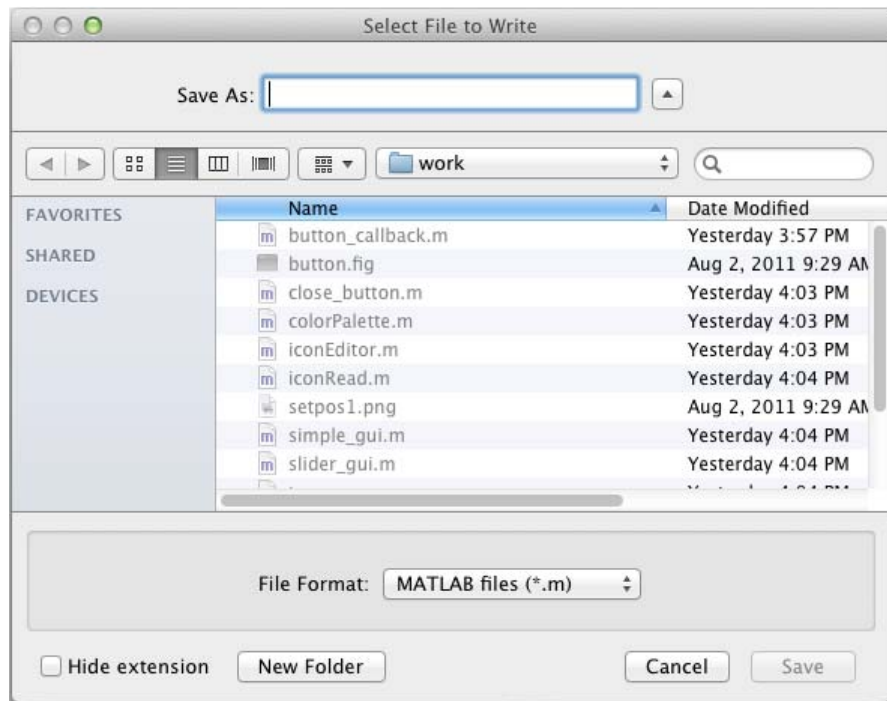

Select **Yes** to replace the existing file or **No** to return to the dialog to select another file name. Selecting **Yes** returns the name of the file. Selecting **No** returns 0.

For Microsoft Windows platforms, the dialog box is the Windows dialog box native to your platform, and thus can differ from what you see in the examples that follow.

For UNIX platforms, the dialog box is like the one shown in the following figure.

For Mac platforms, the dialog box is like the one shown in the following figure.

---

**Note** A modal dialog box prevents you from interacting with other MATLAB windows before responding. To block MATLAB program execution as well, use the `uiwait` function. For more information about modal dialog boxes, see `WindowState` in MATLAB Figure Properties.

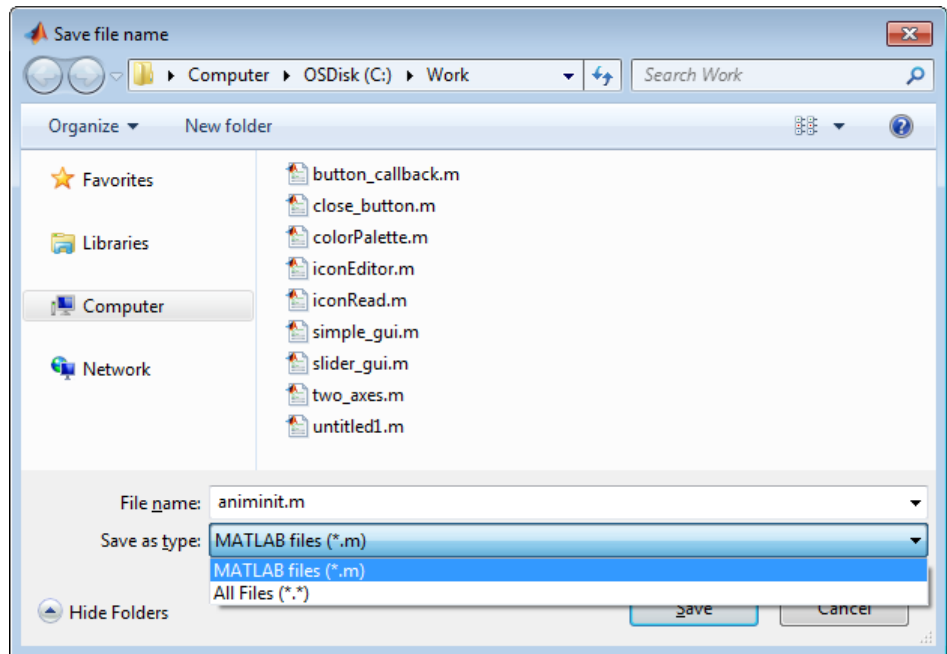

---

## Examples

The following statement displays a dialog box entitled 'Save file name', setting the **File name** field to `animinit.m` and the filter to program files (`*.m`). Because `FilterSpec` is a string, the filter also includes All Files (`*.*`)

```
[file,path] = uiputfile('animinit.m','Save file name');
```

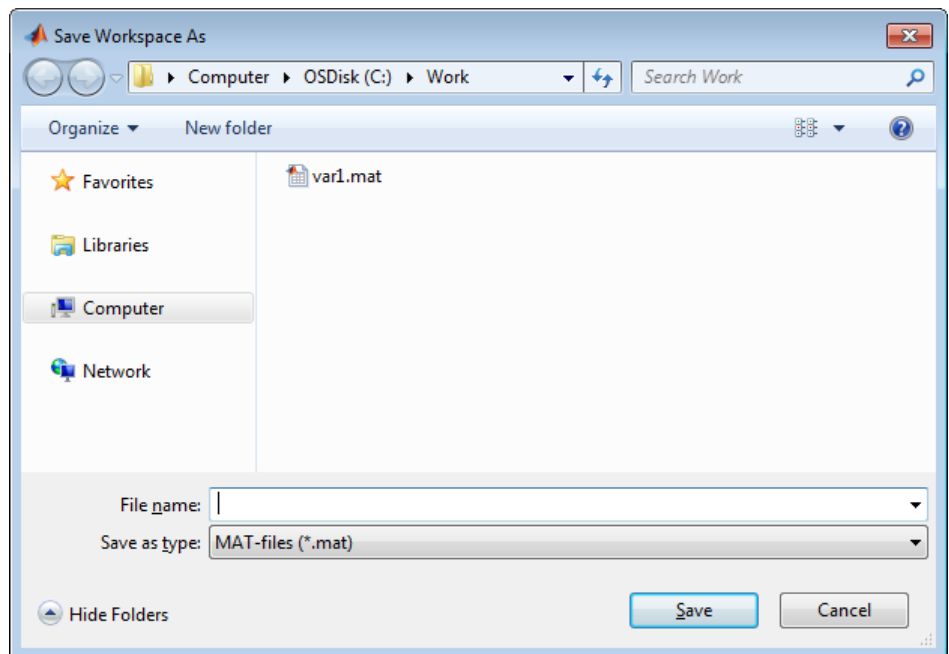

# uiputfile

The following statement displays a dialog box entitled 'Save Workspace As' with the filter set to MAT-files.

```
[file,path] = uiputfile('*.mat','Save Workspace As');
```

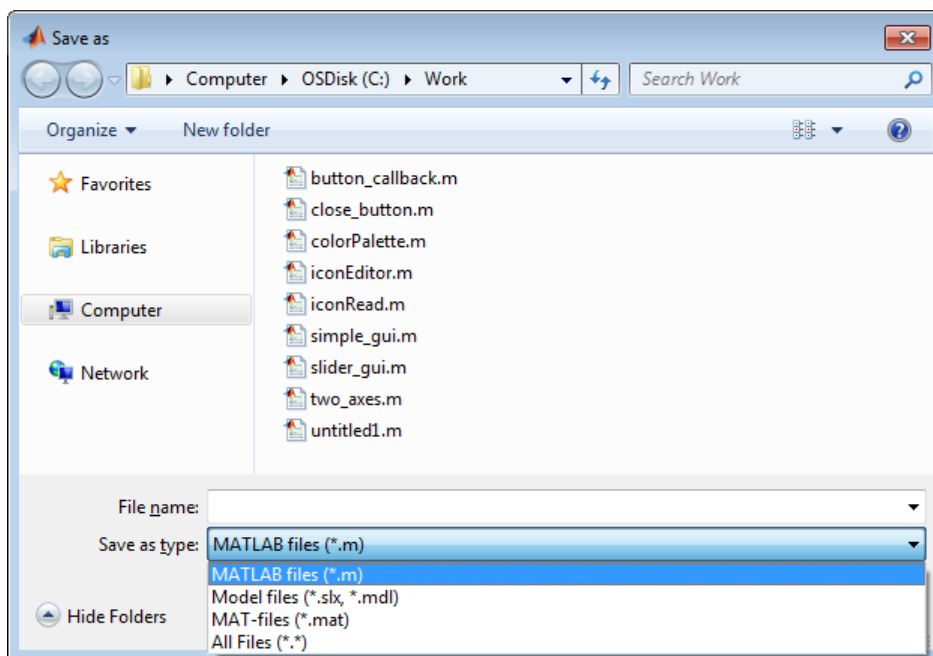

To display several file types in the **Save as type** list box, separate each file extension with a semicolon, as in the following code. `uiputfile` displays a default description for each known file type, such as "Model files" for Simulink `.mdl` and `.slx` files.

```
[filename, pathname] = uiputfile(...  
    {'*.m'; '*.slx'; '*.mat'; '*..*'},...  
    'Save as');
```

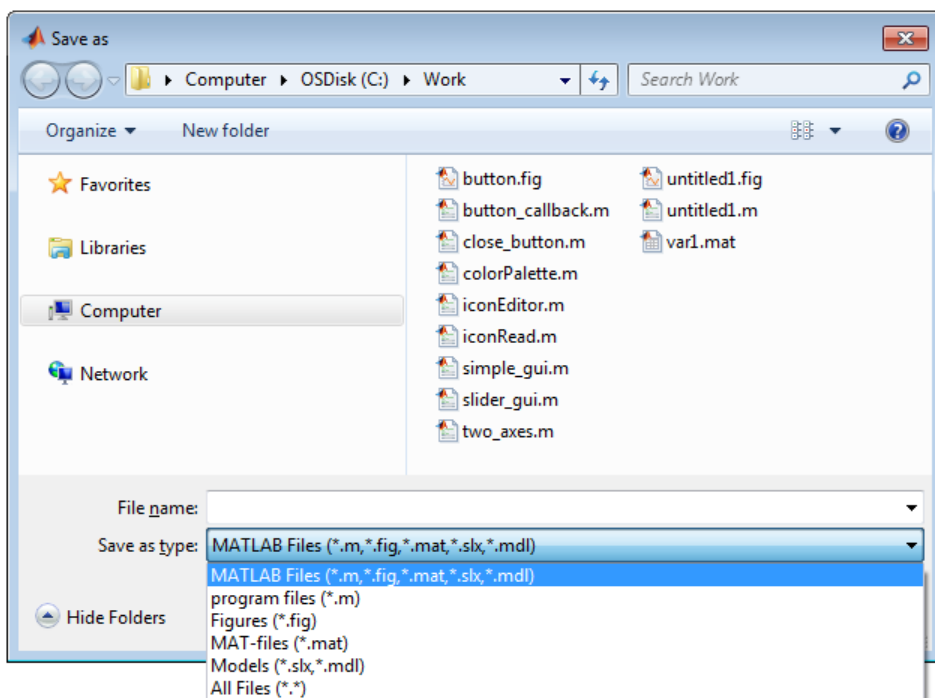

# uiputfile

To create a list of file types and give them descriptions that are different from the defaults, use a cell array. This example also associates multiple file types with the 'MATLAB Files' and 'Models' descriptions.

```
[filename, pathname, filterindex] = uiputfile( ...  
{ '*.m;*.fig;*.mat;*.slx;*.mdl', ...  
  'MATLAB Files (*.m,*.fig,*.mat,*.slx,*.mdl)';  
  '*.m', 'program files (*.m)'; ...  
  '*.fig', 'Figures (*.fig)'; ...  
  '*.mat', 'MAT-files (*.mat)'; ...  
  '*.slx;*.mdl', 'Models (*.slx,*.mdl)'; ...  
  '*.*', 'All Files (*.*)' }, ...  
'Save as');
```

The first column of the cell array contains the file extensions, while the second contains the descriptions you want to provide for the file types. The first entry of column one contains several extensions separated by semicolons. These file types all associate with the description 'MATLAB Files (\*.m;\*.fig;\*.mat;\*.slx;\*.mdl)'. The code produces the dialog box shown in the following figure.

The following code checks for the existence of the file and displays a message about the result of the file selection operation.

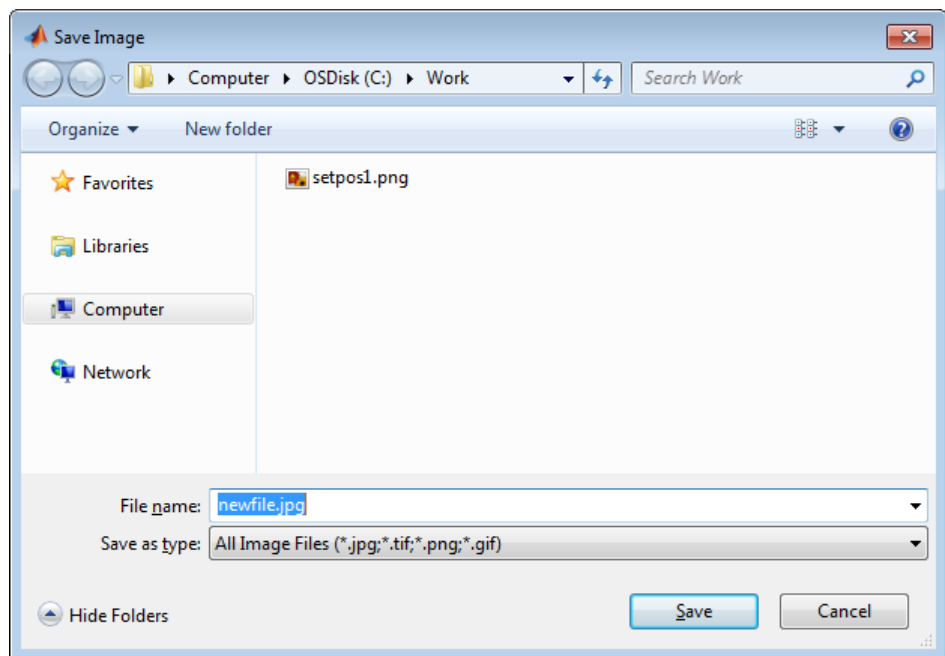

```
[filename, pathname] = uiputfile('*.m','Pick a MATLAB program file');
if isequal(filename,0) || isequal(pathname,0)
    disp('User selected Cancel')
else
```

# uiputfile

```
disp(['User selected ',fullfile(pathname,filename)])  
end
```

Select or enter a file name for saving a figure as an image in one of four formats, described in a cell array.

```
uiputfile({'*.jpg;*.tif;*.png;*.gif','All Image Files';...  
          '*.','All Files' },'Save Image',...  
          'C:\Work\newfile.jpg')
```

# uisave

---

## Purpose

Interactively save workspace variables to MAT-file

## Syntax

```
uisave  
uisave(variables)  
uisave(variables,filename)
```

## Description

`uisave`, with no arguments, prompts you for a file name, and then saves all variables from your workspace to that file.

`uisave(variables)` saves one or more workspace variables listed in `variables`.

`uisave(variables,filename)` uses the specified `filename` as the default **File name** in the Save Workspace Variables dialog box, instead of the default `matlab.mat`.

## Tips

- If you type a name in the **File name** field, such as `my_vars`, and click **Save**, the dialog saves all workspace variables to the file `my_vars.mat`. The default filename is `matlab.mat`.
- `uisave` calls `uiputfile` to choose a filename.
- If the filename you specify exists in that folder, `uisave` informs you and gives you a chance to cancel the operation.
- The `uisave` dialog box is modal.
- The `uisave` dialog is modal. A modal dialog box prevents you from interacting with other windows until you respond to it.

## Input Arguments

### **variable**

String containing the name of a variable in the current workspace or cell array of strings when specifying more than one variable.

**Default:** All variables in the current workspace are saved to a MAT-file.

### **filename**

String naming a file to appear in the dialog **File name** field when the dialog opens. You can omit a file extension, or specify the file extension as `.mat`.

**Default:** `matlab.mat`

## Definitions

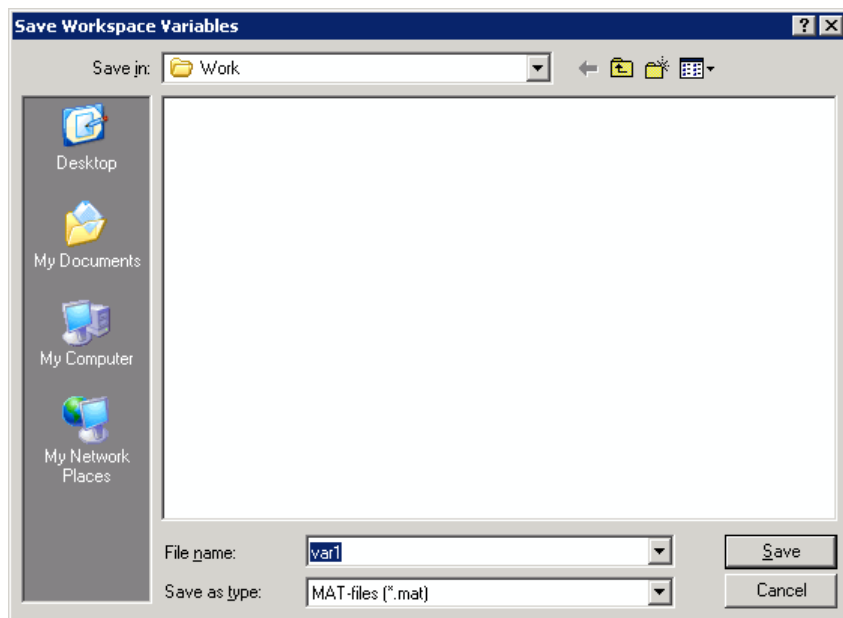

### Modal Dialog

A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

## Examples

Create workspace variables `h` and `g`, and then display the Save Workspace Variables dialog box in the current folder with the default **File name** set to `var1`.

```
h = 365;  
g = 52;  
uisave({'h', 'g'}, 'var1');
```

Clicking **Save** stores the workspace variables `h` and `g` in the file `var1.mat` in the displayed folder.

## Alternatives

Use any of the following GUI options to save workspace variables:

- Use **File > Save** to save workspace variables.
- Click the Save icon  in the Workspace Browser.
- Select one or more variables in the Workspace Browser, right-click, and choose **Save as** from the context menu.

`save` | `uigetfile` | `uiputfile` | `uiopen`

## Tutorials

- “Save, Load, and Delete Workspace Variables”

**Purpose** Open standard dialog box for setting object's ColorSpec

**Syntax**

```
c = uigetcolor
c = uigetcolor([r g b])
c = uigetcolor(h)
c = uigetcolor(...,'dialogTitle')
```

**Description**

`c = uigetcolor` displays a modal color selection dialog appropriate to the platform, and returns the color selected by the user. The dialog box is initialized to white.

`c = uigetcolor([r g b])` displays a dialog box initialized to the specified color, and returns the color selected by the user. `r`, `g`, and `b` must be values between 0 and 1.

`c = uigetcolor(h)` displays a dialog box initialized to the color of the object specified by handle `h`, returns the color selected by the user, and applies it to the object. `h` must be the handle to an object containing a color property.

`c = uigetcolor(...,'dialogTitle')` displays a dialog box with the specified title.

If the user presses **Cancel** from the dialog box, or if any error occurs, the output value is set to the input RGB triple, if provided; otherwise, it is set to 0.

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

---

**See Also** ColorSpec

# uifont

---

**Purpose** Open standard dialog box for setting object's font characteristics

**Syntax**

```
uifont
uifont(h)
uifont(S)
uifont(..., 'DialogTitle')
S = uifont(...)
```

**Description** `uifont` enables you to change font properties (`FontName`, `FontUnits`, `FontSize`, `FontWeight`, and `FontAngle`) for a `text`, `axes`, or `uicontrol` object. The function returns a structure consisting of font properties and values. You can specify an alternate title for the dialog box.

`uifont` displays a modal dialog box and returns the selected font properties.

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

---

`uifont(h)` displays a modal dialog box, initializing the font property values with the values of those properties for the object whose handle is `h`. Selected font property values are applied to the current object. If a second argument is supplied, it specifies a name for the dialog box.

`uifont(S)` displays a modal dialog box, initializing the font property values with the values defined for the specified structure (`S`). `S` must define legal values for one or more of these properties: `FontName`, `FontUnits`, `FontSize`, `FontWeight`, and `FontAngle` and the field names must match the property names exactly. If other properties are defined, they are ignored. If a second argument is supplied, it specifies a name for the dialog box.

`uisetfont(..., 'DialogTitle')` displays a modal dialog box with the title `DialogTitle` and returns the values of the font properties selected in the dialog box.

`S = uisetfont(...)` returns the properties `FontName`, `FontUnits`, `FontSize`, `FontWeight`, and `FontAngle` as fields in a structure. If the user presses **Cancel** from the dialog box or if an error occurs, the output value is set to 0.

## Examples

These statements create a text object, then display a dialog box (labeled Update Font) that enables you to change the font characteristics:

```
h = text(.5,.5,'Figure Annotation');
uisetfont(h,'Update Font')
```

These statements create two push buttons, then set the font properties of one based on the values set for the other:

```
% Create push button with string ABC
c1 = uicontrol('Style', 'pushbutton', ...
    'Position', [10 10 100 20], 'String', 'ABC');
% Create push button with string XYZ
c2 = uicontrol('Style', 'pushbutton', ...
    'Position', [10 50 100 20], 'String', 'XYZ');
% Display set font dialog box for c1, make selections,
& and save to d
d = uisetfont(c1);
% Apply those settings to c2
set(c2, d)
```

## See Also

[axes](#) | [text](#) | [uicontrol](#)

# uisetpref

---

**Purpose** Manage preferences used in `uisetpref`

**Syntax** `uisetpref('clearall')`

**Description** `uisetpref('clearall')` resets the value of all preferences registered through `uisetpref` to 'ask'. This causes the dialog box to display when you call `uisetpref`.

---

**Note** Use `setpref` to set the value of a particular preference to 'ask'.

---

**See Also** `setpref` | `uisetpref`

**Purpose** Reorder visual stacking order of objects

**Syntax**

```
uistack(h)
uistack(h,stackopt)
uistack(h,stackopt,step)
```

**Description** `uistack(h)` raises the visual stacking order of the objects specified by the handles in `h` by one level (step of 1). All handles in `h` must have the same parent.

`uistack(h,stackopt)` moves the objects specified by `h` in the stacking order, where `stackopt` is one of the following:

- 'up' – moves `h` up one position in the stacking order
- 'down' – moves `h` down one position in the stacking order
- 'top' – moves `h` to the top of the current stack
- 'bottom' – moves `h` to the bottom of the current stack

`uistack(h,stackopt,step)` moves the objects specified by `h` up or down the number of levels specified by `step`.

---

**Note** In a GUI, axes objects are always at a lower level than `uicontrol` objects. You cannot stack an axes object on top of a `uicontrol` object.

---

See “Set Tab Order in a Programmatic GUI” in the MATLAB documentation for information about changing the tab order.

**Examples** The following code moves the child that is third in the stacking order of the figure handle `hObject` down two positions.

```
v = allchild(hObject)
uistack(v(3), 'down', 2)
```

# uitable

---

**Purpose** Create 2-D graphic table GUI component

**Syntax**

```
uitable  
uitable('PropertyName1', value1, 'PropertyName2', value2, ...)  
uitable(parent, ...)  
handle = uitable(...)
```

**Description** `uitable` creates an empty `uitable` object in the current figure window, using default property values. If no figure exists, a new figure window opens.

`uitable('PropertyName1', value1, 'PropertyName2', value2, ...)` creates a `uitable` object with specified property values. Properties that you do not specify assume the default property values. See the `Uitable Properties` reference page for information about the available properties.

`uitable(parent, ...)` creates a `uitable` object as a child of the specified parent handle `parent`. The parent can be a figure or `uipanel` handle. If you also specify a different value for the `Parent` property, the value of the `Parent` property takes precedence.

`handle = uitable(...)` creates a `uitable` object and returns its handle.

**Tips** After creating a `uitable` object, you can set and query its property values using the `set` and `get` functions.

If the `ColumnEditable` property is `true` for columns you edit, you can change values in a displayed table. By default, this property is `false` for all columns. If a noneditable column contains pop-up choices, only the current choice is visible (and not the pop-up menu control).

If you attempt to create a `uitable` object when running MATLAB on a UNIX<sup>10</sup> system without a Java virtual machine (`matlab -nojvm`) or without a display (`matlab nodisplay`), no table generates and you receive an error.

10. UNIX is a registered trademark of The Open Group in the United States and other countries.

The **CellEditCallback** executes after you edit a value and do any of the following:

- Type **Enter**.
- Click another table cell.
- Click anywhere else within the table.
- Click another control or area within the same figure window.
- Click another window, click again on the GUI containing the table (or use **Alt+Tab** to switch windows), and then perform any of the above four actions.

When the **CellEditCallback** callback executes, **uitable** updates the underlying data matrix (the table **Data** property) to contain the value that the cell now displays.

The **CellSelectionCallback** executes when you select a table cell or remove one from the current selection by **Ctrl**+clicking it. Clicking a cell without pressing any key selects it and deselects all currently selected cells. You can define a range of table cells by **Shift**+clicking an unselected cell after selecting one or more cells. The callback provides event data that identifies the rows and columns of all cells in the current selection.

You cannot select table cells programmatically. Directly clicking cells is the only method of selection.

## Examples

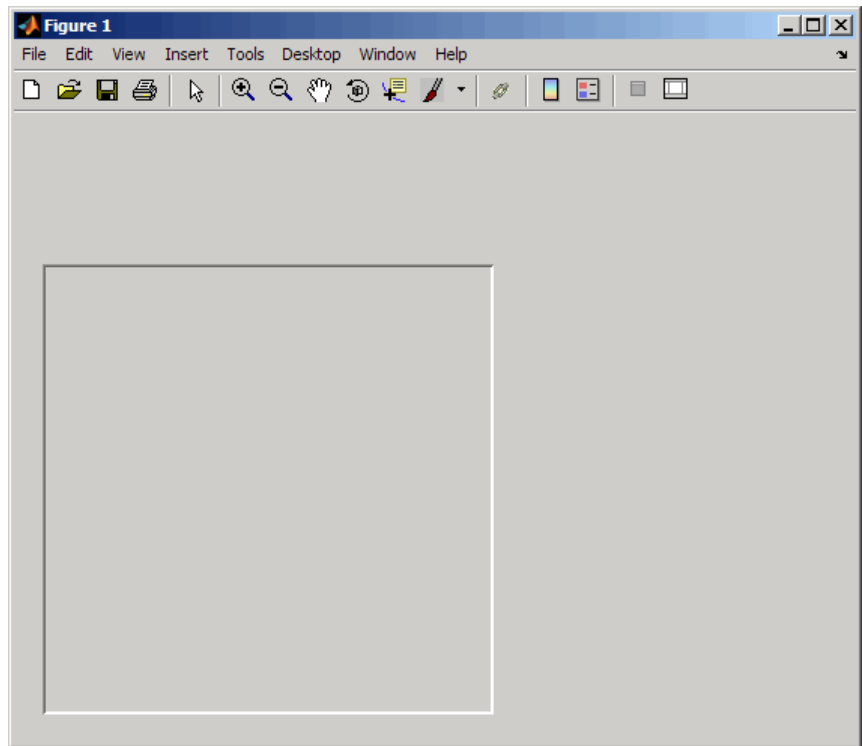

Create a table, provide magic-square data, set column widths uniformly, and specify the **uitable** **ColumnWidth** property as a cell array:

- 1 Create a table in the current figure. If no figure exists, one opens:

```
t = uitable;
```

# uitable

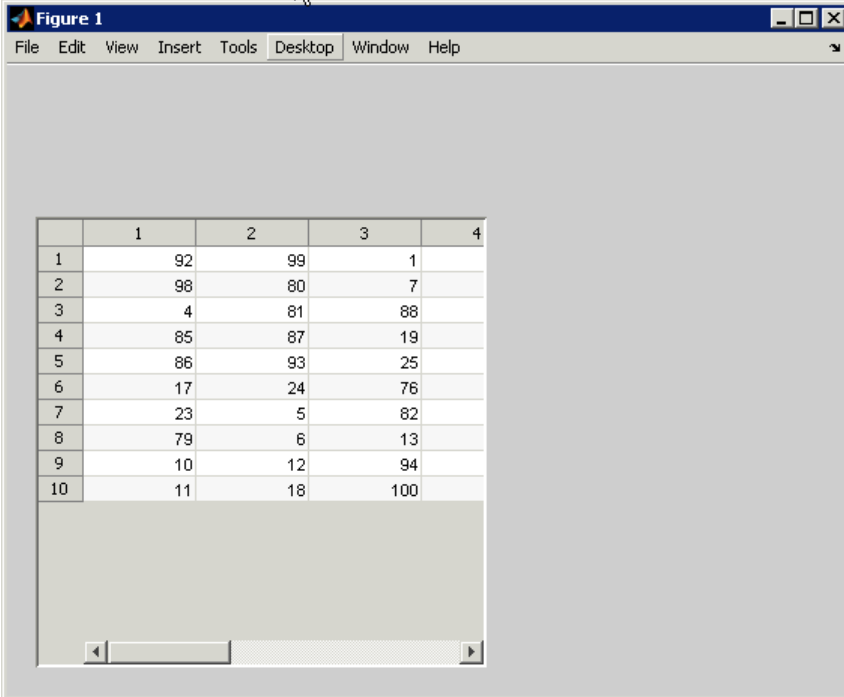

---

- 2** As the table has no content (its Data property is empty), it initially displays no rows or columns. Provide data (a magic square)

```
set(t,'Data',magic(10))
```

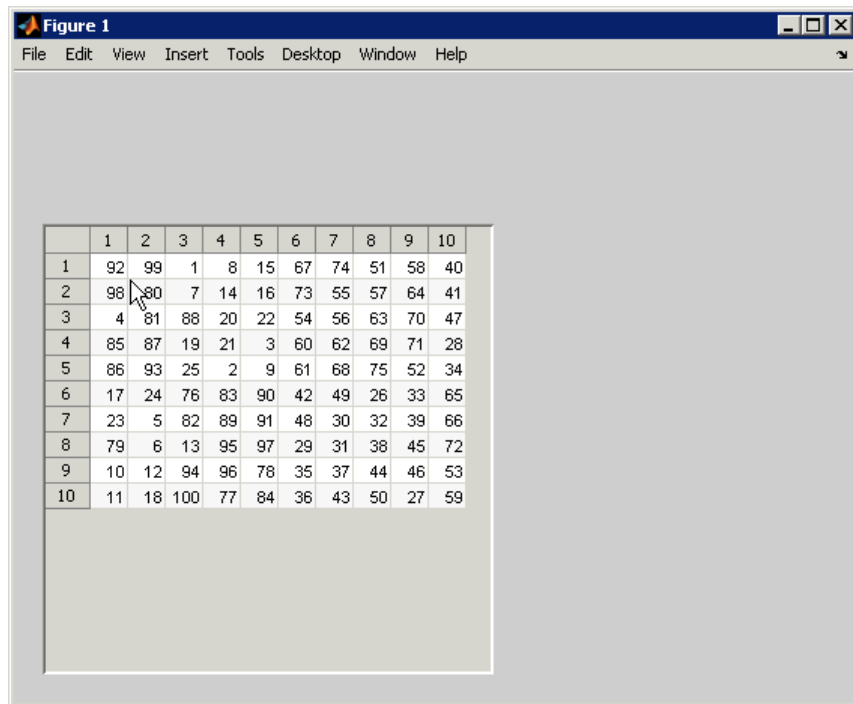

|    | 1  | 2  | 3   | 4 |
|----|----|----|-----|---|
| 1  | 92 | 99 | 1   |   |
| 2  | 98 | 80 | 7   |   |
| 3  | 4  | 81 | 88  |   |
| 4  | 85 | 87 | 19  |   |
| 5  | 86 | 93 | 25  |   |
| 6  | 17 | 24 | 76  |   |
| 7  | 23 | 5  | 82  |   |
| 8  | 79 | 6  | 13  |   |
| 9  | 10 | 12 | 94  |   |
| 10 | 11 | 18 | 100 |   |

- 3** Make the entire table contents visible. Set column widths to 25 pixels uniformly. Specify the `ColumnWidth` property of the table as a cell array.

```
set(t, 'ColumnWidth', {25})
```

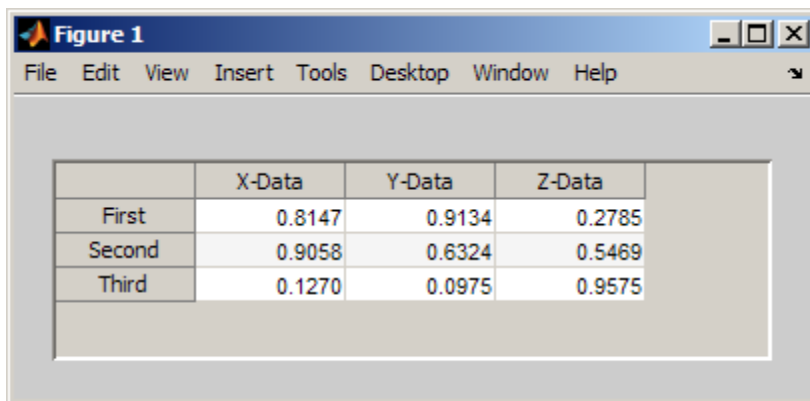

Cell arrays that specify `ColumnWidth` can contain:

- One number (a width measured in pixels, as shown here) or the string 'auto'.
- A cell array containing a list of pixel sizes having up to as many entries as the table has columns .

If a list of column widths has  $n$  entries, where  $n$  is smaller than the number of columns, it sets the first  $n$  column widths only. You can substitute 'auto' for any value in the cell array to have the width of that column calculated automatically.

Create a figure and add a table to contain a 3-by-3 data matrix. The code specifies the column names, row names, parent, and position of the table:

```
f = figure('Position',[200 200 400 150]);
dat = rand(3);
cnames = {'X-Data','Y-Data','Z-Data'};
rnames = {'First','Second','Third'};
t = uitable('Parent',f,'Data',dat,'ColumnName',cnames,...
           'RowName',rnames,'Position',[20 20 360 100]);
```

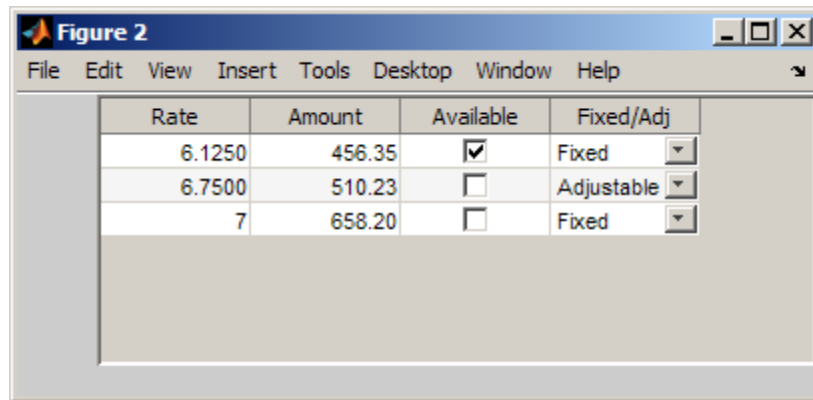

Create a table to contain a 3-by-4 array that contains numeric, logical, and string data, as follows:

- First column (**Rate**): Numeric, with three decimals (not editable)
- Second column (**Amount**): Currency (not editable)
- Third column (**Available**): Check box (editable)
- Fourth column (**Fixed/Adj**): Pop-up menu with two choices: Fixed and Adjustable (editable)
- Specify the RowName property as empty to remove row names from the table.

```
f = figure('Position',[100 100 400 150]);
```

# uitable

```
dat = {6.125, 456.3457, true, 'Fixed';...
       6.75, 510.2342, false, 'Adjustable';...
       7, 658.2, false, 'Fixed'}};
columnname = {'Rate', 'Amount', 'Available', 'Fixed/Adj'};
columnformat = {'numeric', 'bank', 'logical', {'Fixed' 'Adjustable'}};
columneditable = [false false true true];
t = uitable('Units','normalized','Position',...
           [0.1 0.1 0.9 0.9], 'Data', dat,...
           'ColumnName', columnname,...
           'ColumnFormat', columnformat,...
           'ColumnEditable', columneditable,...
           'RowName', []);
```

| Rate   | Amount | Available                           | Fixed/Adj  |
|--------|--------|-------------------------------------|------------|
| 6.1250 | 456.35 | <input checked="" type="checkbox"/> | Fixed      |
| 6.7500 | 510.23 | <input type="checkbox"/>            | Adjustable |
| 7      | 658.20 | <input type="checkbox"/>            | Fixed      |

## Alternatives

You can add tables to GUIs you create with “Table”.

# Uitable Properties

---

## Purpose

Describe table properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default uitable properties by typing:

```
set(h, 'DefaultUitablePropertyName', PropertyValue...)
```

Where `h` can be the root handle (0), a figure handle, or a uitable handle. *PropertyName* is the name of the uitable property and *PropertyValue* is the value you specify as the default for that property.

For more information about changing the default value of a property see “Setting Default Property Values”. For an example, see the `CreateFcn` property.

## Uitable Properties

This section lists all properties useful to uitable objects along with valid values and descriptions of their use. In the property descriptions, curly braces { } enclose default values.

| Property Name    | Description                              |
|------------------|------------------------------------------|
| BackgroundColor  | Background color of cells.               |
| BeingDeleted     | This object is being deleted.            |
| BusyAction       | Callback routine interruption            |
| ButtonDownFcn    | Button-press callback routine            |
| CellEditCallback | Callback when data in a cell is changed. |

# Uitable Properties

| Property Name         | Description                                   |
|-----------------------|-----------------------------------------------|
| CellSelectionCallback | Callback when cell is selected                |
| Children              | uitable objects have no children              |
| Clipping              | Does not apply to uitable objects             |
| ColumnEditable        | Determines data in a column as editable       |
| ColumnFormat          | Determines display and editability of columns |
| ColumnName            | Column header label                           |
| ColumnWidth           | Width of each column in pixels                |
| CreateFcn             | Callback routine during object creation       |
| Data                  | Table data                                    |
| DeleteFcn             | Callback routine during object deletion       |
| Enable                | Enable or disable the uitable                 |
| Extent                | Size of uitable rectangle                     |
| FontAngle             | Character slant of cell content               |
| FontName              | Font family for cell content                  |
| FontSize              | Font size of cell content                     |
| FontUnits             | Font size units for cell content              |
| FontWeight            | Weight of cell text characters                |
| ForegroundColor       | Color of text in cells                        |
| HandleVisibility      | Control access to object's handle             |
| HitTest               | Selectable by mouse click                     |
| Interruptible         | Callback routine interruption mode            |
| KeyPressFcn           | Key press callback function                   |
| Parent                | uitable parent                                |

# Uitable Properties

---

| Property Name        | Description                         |
|----------------------|-------------------------------------|
| Position             | Size and location of uitable        |
| RearrangeableColumns | Location of the column              |
| RowName              | Row header label names              |
| RowStriping          | Color striping of label rows        |
| Selected             | Is object selected?                 |
| SelectionHighlight   | Object highlight when selected      |
| Tag                  | Use-specified object label          |
| TooltipString        | Content of tooltip for object       |
| Type                 | Class of graphics object            |
| UIContextMenu        | Associate context menu with uitable |
| Units                | Units of measurement                |
| UserData             | User-specified data                 |
| Visible              | uitable visibility                  |

## BackgroundColor

1-by-3 or 2-by-3 matrix of RGB triples

*Cell background color.* Color used to fill the uitable cells.

Specify as an 1-by-3 or 2-by-3 matrix of RGB triples, such as [ .8 .9 .8] or [1 1 .9; .9 1 1]. Each row is an RGB triplet of real numbers between 0.0 and 1.0 that defines one color.

(Color names are not allowed.) The default is a 1-by-3 matrix of platform-dependent colors. See ColorSpec for information about RGB colors.

Row 2 of the matrix is used only if the `RowStriping` property is on. The table background is not striped unless both `RowStriping` is on and the `BackgroundColor` color matrix has two rows.

`BeingDeleted`  
on | {off} (read-only)

*This object is being deleted.* The `BeingDeleted` property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB software sets the `BeingDeleted` property to on when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to on while the delete function executes, after which the object no longer exists.

For example, some functions may not need to perform actions on objects that are being deleted, and therefore, can check the object's `BeingDeleted` property before acting.

`BusyAction`  
cancel | {queue}

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

# Uitable Properties

---

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

string or function handle (GUIDE sets this property)

*Button-press callback routine.* A callback routine that can execute when you press a mouse button while the pointer is on or near a `uitable`. Specifically:

- If the `uitable Enable` property is set to `on`, the `ButtonDownFcn` callback executes when you click the right or left mouse button in a 5-pixel border around the `uitable` or when you click the right mouse button on the control itself.
- If the `uitable Enable` property is set to `inactive` or `off`, the `ButtonDownFcn` executes when you click the right or left mouse button in the 5-pixel border or on the control itself.

This is useful for implementing actions to interactively modify control object properties, such as size and position, when they are clicked on.

Define this routine as a string that is a valid MATLAB expression or the name of a MATLAB function file. The expression executes in the MATLAB workspace.

To add a `ButtonDownFcn` callback in GUIDE, select **View Callbacks** from the Layout Editor **View** menu, then select `ButtonDownFcn`. GUIDE sets this property to the appropriate string and adds the callback to the program file the next time you save the GUI. Alternatively, you can set this property to the string `%automatic`. The next time you save the GUI, GUIDE sets this property to the appropriate string and adds the callback to the program file.

## CellEditCallback

function handle, cell array containing function handle and additional arguments, or string (not recommended)

*Callback to edit user-entered data*

Callback function executed when the user modifies a table cell. It can perform evaluations, validations, or other customizations. If this function is called as a function handle, `uitable` passes it two arguments. The first argument, `source`, is the handle of the `uitable`. The second argument, `eventdata`, is an event data structure that contains the fields shown in the following table. All fields in the event data structure are read only.

| Event Data Structure Field | Type                        | Description                                                                           |
|----------------------------|-----------------------------|---------------------------------------------------------------------------------------|
| Indices                    | 1-by-2 matrix               | Row index and column index of the cell the user edited.                               |
| PreviousData               | 1-by-1 matrix or cell array | Previous data for the changed cell. The default is an empty matrix, <code>[]</code> . |
| EditData                   | String                      | User-entered string.                                                                  |

# Uitable Properties

---

| <b>Event Data Structure Field</b> | <b>Type</b>                 | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------------|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NewData                           | 1-by-1 matrix or cell array | <p>Value that <code>uitable</code> wrote to <code>Data</code>. It is either the same as <code>EditData</code> or a converted value, for example, 2 where <code>EditData</code> is '2' and the cell is numeric.</p> <p>Empty if <code>uitable</code> detected an error in the user-entered data and did not write it to <code>Data</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Error                             | String                      | <p>Error that occurred when <code>uitable</code> tried to convert the <code>EditData</code> string into a value appropriate for <code>Data</code>. For example, <code>uitable</code> could not convert the <code>EditData</code> string consistent with the <code>Column Format</code> property, if any, or the data type for the changed cell.</p> <p>Empty if <code>uitable</code> wrote the value to <code>Data</code>.</p> <p>If <code>Error</code> is not empty, the <code>CellEditCallback</code> can pass the error string to the user or can attempt to manipulate the data. For example, the string 'pi' would raise an error in a numeric cell but the <code>CellEditCallback</code> could convert it to its numerical equivalent and store it in <code>Data</code> without passing the error to the user.</p> |

When a user edits a cell, `uitable` first attempts to store the user-entered value in `Data`, converting the value if necessary. It then calls the `CellEditCallback` and passes it the event data structure. If there is no `CellEditCallback` and the user-entered data results in an error, the contents of the cell reverts to its previous value and no error is displayed. The `CellEditCallback`

is issued when the user has modified a table cell and presses **Enter** or clicks anywhere outside the cell.

## CellSelectionCallback

function handle, cell array containing function handle and additional arguments, or string (not recommended)

*Callback that executes when cell is selected.* Callback function that executes when the user highlights a cell by navigating to it or clicking it. For multiple selection, this callback executes when new cells are added to the selection. The callback includes event data, a structure with one member

| Event Data Structure Field | Type          | Description                                                             |
|----------------------------|---------------|-------------------------------------------------------------------------|
| Indices                    | n-by-2 matrix | Row index and column index of the cells the user currently has selected |

Once a cell selection has been made, cells within it can be removed one at a time by **Ctrl**-clicking them.

## Children

matrix

The empty matrix; `uitable` objects have no children.

## Clipping

{on} | off

This property has no effect on `uitable` objects.

## ColumnEditable

logical 1-by-n matrix | scalar logical value | {} empty matrix ([ ])

*Determines if column is user-editable.*

# Editable Properties

---

Determines if the data can be edited by the end user. Each value in the cell array corresponds to a column. `false` is default because the developer needs to have control over changes users potentially might make to data.

Specify elements of a logical matrix as `true` if the data in a column is editable by the user or `false` if it is not. An empty matrix indicates that no columns are editable.

Columns that contain check boxes or pop-up menus must be editable for the user to manipulate these controls. If a column that contains pop-up menus is not editable, the currently selected choice appears without displaying the pop-up control. The elements of the `ColumnEditable` matrix must be in the same order as columns in the `Data` property. If you do not specify `ColumnEditable`, the default is an empty matrix (`[]`).

`ColumnFormat`  
cell array of strings

*Cell display formatting.* Determines how the data in each column displays and is edited. Elements of the cell array must be in the same order as table columns in the `Data` property. If you do not want to specify a display format for a particular column, enter `[]` as a placeholder. If no format is specified for a column, the default display is determined by the data type of the data in the cell. Default `ColumnFormat` is an empty cell array (`{}`). In most cases, the default is similar to the command window.

Elements of the cell array must be one of the strings described in the following table.

| Cell Format | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'char'      | <p>Displays a left-aligned string.</p> <p>To edit, the user types a string that replaces the existing string.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 'logical'   | <p>Displays a check box.</p> <p>To edit, the user checks or unchecks the check box. <code>uitable</code> sets the corresponding <code>Data</code> value to <code>true</code> or <code>false</code> accordingly.</p> <p>Initially, the check box is checked if the corresponding <code>Data</code> value would produce</p>                                                                                                                                                                                                                                                                                                                                                                               |
| 'numeric'   | <p>Displays a right-aligned string equivalent to the command window, for numeric data. If the cell <code>Data</code> value is boolean, then 1 or 0 is displayed. If the cell <code>Data</code> value is not numeric and not boolean, then NaN is displayed.</p> <p>To edit, the user can enter any string. This enables a user to enter a value such as 'pi' that can be converted to its numeric equivalent by a <code>CellEditCallback</code>. The <code>uitable</code> function first attempts to convert the user-entered string to a numeric value and store it in <code>Data</code>. It then calls the <code>CellEditCallback</code>. See <code>CellEditCallback</code> for more information.</p> |

# Uitable Properties

---

| Cell Format                                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1-by-n cell array of strings that define a pop-up menu, e.g., {'one' 'two' 'three'} | <p>Displays a pop-up menu.</p> <p>To edit, the user makes a selection from the pop-up menu. <code>uitable</code> sets the corresponding Data value to the selected menu item.</p> <p>The initial values for the pop-up menus in the column are the corresponding strings in Data. These initial values do not have to be items in the pop-up menu. See Example 3 on the <code>uitable</code> reference page.</p> |
| Valid string accepted by the format function, e.g., 'short' or 'bank'               | <p>Displays the Data value using the specified format. For example, for a two-column table, <code>set(htable, 'ColumnFormat', {'short', 'bank'})</code>.</p>                                                                                                                                                                                                                                                     |

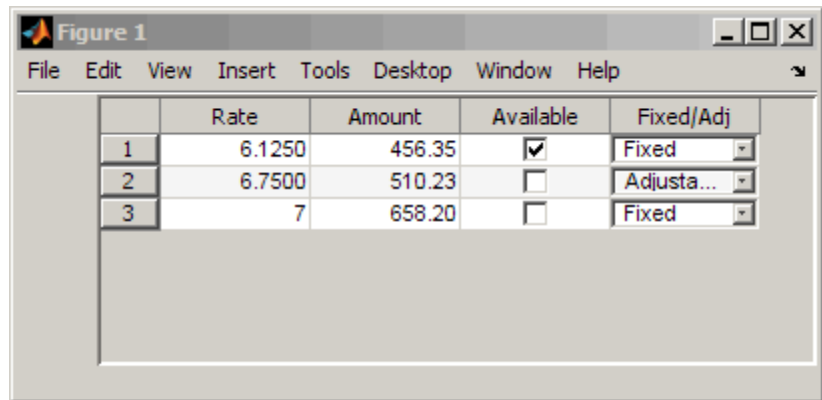

In some cases, you may need to insert an appropriate column in Data. If Data is a numerical or logical matrix, you must first convert it to a cell array using the `mat2cell` function.

## Data and ColumnFormat

When you create a table, you must specify value of Data. The Data property dictates what type of data can exist in any given cell. By default, the value of the Data also dictates the display of the cell to the end user, unless you specify a different format using the `ColumnFormat` property.

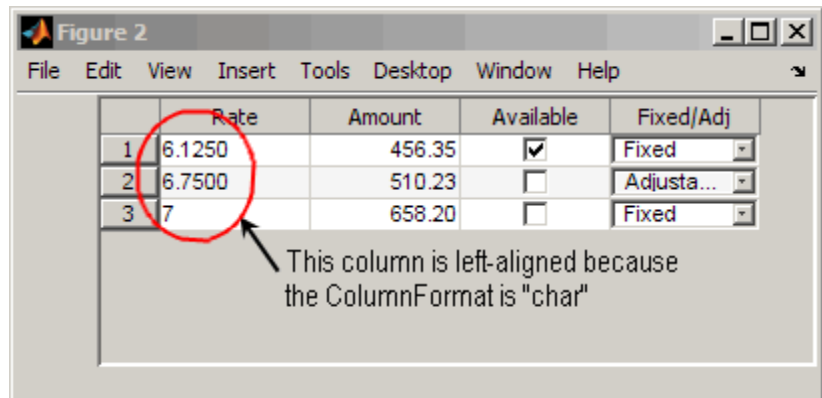

# Uitable Properties

|   | Rate   | Amount | Available                           | Fixed/Adj  |
|---|--------|--------|-------------------------------------|------------|
| 1 | 6.1250 | 456.35 | <input checked="" type="checkbox"/> | Fixed      |
| 2 | 6.7500 | 510.23 | <input type="checkbox"/>            | Adjusta... |
| 3 | 7      | 658.20 | <input type="checkbox"/>            | Fixed      |

ColumnFormat controls the presentation of the Data to the end user. Therefore, if you specify a ColumnFormat of char (or pick **Text** from the Table Property Editor), you are asking the table to display the Data associated with that column as a string. For example, if the Data for a particular column is numeric, and you specify the ColumnFormat as char, then the display of the numeric data will be left-aligned

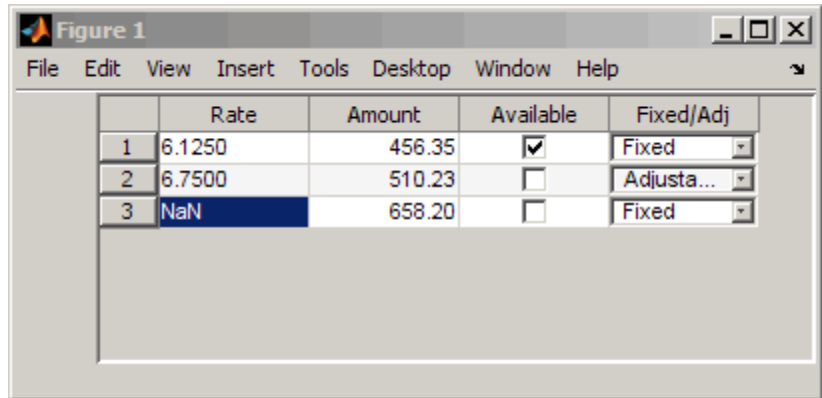

|   | Rate   | Amount | Available                           | Fixed/Adj  |
|---|--------|--------|-------------------------------------|------------|
| 1 | 6.1250 | 456.35 | <input checked="" type="checkbox"/> | Fixed      |
| 2 | 6.7500 | 510.23 | <input type="checkbox"/>            | Adjusta... |
| 3 | 7      | 658.20 | <input type="checkbox"/>            | Fixed      |

This column is left-aligned because the ColumnFormat is "char"

# Editable Properties

If your column is editable and the user enters a number, the number will be left-aligned. However, if the user enters a text string, the table displays a **NaN**.

|   | Rate   | Amount | Available                           | Fixed/Adj  |
|---|--------|--------|-------------------------------------|------------|
| 1 | 6.1250 | 456.35 | <input checked="" type="checkbox"/> | Fixed      |
| 2 | 6.7500 | 510.23 | <input type="checkbox"/>            | Adjusta... |
| 3 | NaN    | 658.20 | <input type="checkbox"/>            | Fixed      |

Another possible scenario is that the value Data is char and you set the ColumnFormat to be a pop-up menu. Here, if the value of the Data in the cell matches one of the pop-up menu choices you define in ColumnFormat, then the Data is shown in the cell. If it does not match, then the cell defaults to display the first option from the choices you specify in ColumnFormat. Similarly, if Data is numeric or logical with the ColumnFormat as pop-up menu, if the Data value in the cell does not match any of the choices you specify in ColumnFormat, the cell defaults to display the first option in the pop-menu choice.

This table describes how Data values correspond with your ColumnFormat when the columns are editable.

| ColumnFormat Selections |      |         |
|-------------------------|------|---------|
| numeric                 | char | logical |

## Uitable Properties

|                  |         |                                                                                                                                                  |                                                                                                                                                                                                     |                                                                                                                                                  |
|------------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Data Type</b> | numeric | Values match. MATLAB displays numbers as is.                                                                                                     | MATLAB converts the text string entered to a double. See <code>str2double</code> for more information. If string cannot be converted, <b>NaN</b> is displayed.                                      | Does not work: warning is thrown.<br><hr/> <b>Note</b> If you have defined <code>CellEditCallback</code> , this warning will not be thrown <hr/> |
|                  | char    | MATLAB converts the entered number to a text string.                                                                                             | Values match. MATLAB displays the string as is.                                                                                                                                                     | Does not work: warning is thrown.<br><hr/> <b>Note</b> If you have defined <code>CellEditCallback</code> , this warning will not be thrown <hr/> |
|                  | logical | Does not work: warning is thrown.<br><hr/> <b>Note</b> If you have defined <code>CellEditCallback</code> , this warning will not be thrown <hr/> | If text string entered is <code>true</code> or <code>false</code> , MATLAB converts string to the corresponding logical value and displays it. For all others, it Does not work: warning is thrown. | Values match. MATLAB displays logical value as a check box as is.                                                                                |

# Uitable Properties

---

|  |  |  |                                                                                                 |  |
|--|--|--|-------------------------------------------------------------------------------------------------|--|
|  |  |  | <b>Note</b> If you have defined <code>CellEditCallback</code> , this warning will not be thrown |  |
|--|--|--|-------------------------------------------------------------------------------------------------|--|

If you get a mismatch error, you have the following options:

- Change the `ColumnFormat` or value of `Data` to match.
- Implement the `CellEditCallback` to handle custom data conversion.

## `ColumnName`

1-by-*n* cell array of strings | {'numbered'} | empty matrix ([])

*Column heading names.* Each element of the cell array is the name of a column. Multiline column names can be expressed as a string vector separated by vertical slash (|) characters, e.g., 'Standard|Deviation'

For sequentially numbered column headings starting with 1, specify `ColumnName` as 'numbered'. This is the default.

To remove the column headings, specify `ColumnName` as the empty matrix ( []).

The number of columns in the table is the larger of `ColumnName` and the number of columns in the `Data` property matrix or cell array.

## `ColumnWidth`

1-by-*n* cell array or 'auto'

*Column widths.* The width of each column in units of pixels. Column widths are always specified in pixels; they do not obey the `Units` property. Each column in the cell array corresponds to a column in the uitable. By default, the width of the column name, as specified in `ColumnName`, along with some other factors, is used to determine the width of a column. If `ColumnWidth` is a cell array and the width of a column is set to 'auto' or if **auto** is selected for that column in the Property Inspector GUI for columns, the column width defaults to a size determined by the table. The table decides the default size using a number of factors, including the `ColumnName` and the minimum column size.

To default all column widths in an existing table, use

```
set(uitable_handle, 'ColumnWidth', 'auto')
```

To default some column widths but not others, use a cell array containing a mixture of pixel values and 'auto'. For example,

```
set(uitable_handle, 'ColumnWidth', {64 'auto' 40 40 'auto' 72})
```

## CreateFcn

string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a uitable object. MATLAB sets all property values for the uitable before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcb0` to get the handle of the uitable being created.

Setting this property on an existing uitable object has no effect.

You can define a default `CreateFcn` callback for all new uitables. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uitable`. For example, the code

```
set(0, 'DefaultUitableCreateFcn', 'set(gcb0, ...
```

# Uitable Properties

---

```
'BackgroundColor','blue')')
```

creates a default `CreateFcn` callback that runs whenever you create a new uitable. It sets the default background color of all new uitables.

To override this default and create a uitable whose `BackgroundColor` is set to a different value, call `uitable` with code similar to

```
hpt = uitable(...,'CreateFcn','set(gcbo,...  
'BackgroundColor','white'))')
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uitable` call. In the example above, if instead of redefining the `CreateFcn` property for this uitable, you had explicitly set `BackgroundColor` to `white`, the default `CreateFcn` callback would have set `BackgroundColor` back to the default, i.e., `blue`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## Data

matrix or cell array of numeric, logical, or character data

*Data content of uitable.* The matrix or cell array must be 2–dimensional. A cell array can mix data types.

Use `get` and `set` to modify `Data`. For example,

```
data = get(tablehandle, 'Data')
data(event.indices(1), event.indices(2)) = pi();
set(tablehandle, 'Data', data);
```

See `CellEditCallback` for information about the event data structure. See `ColumnFormat` for information about specifying the data display format.

The number of rows in the table is the larger of `RowName` and the number of rows in `Data`. The number of columns in the table is the larger of `ColumnName` and the number of columns in `Data`.

## DeleteFcn

string or function handle

*Delete uitable callback routine.* A callback routine that executes when you delete the `uitable` object (e.g., when you issue a `delete` command or `clear` the figure containing the `uitable`). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## Enable

{on} | inactive | off

*Enable or disable the uitable.* This property determines how uitables respond to mouse button clicks, including which callback routines execute.

- on – The uitable is operational (the default).

# Uitable Properties

---

- `inactive` – The uitable is not operational, but looks the same as when `Enable` is on.
- `off` – The uitable is not operational and its image is grayed out.

When you left-click on a uitable whose `Enable` property is on, MATLAB performs these actions in this order:

- 1** Sets the figure's `SelectionType` property.
- 2** Executes the uitable's `CellSelectionCallback` routine (but only for table cells, not header cells). Row and column indices of the cells the user selects continuously update the `Indices` field in the `eventdata` passed to the callback.
- 3** Does not set the figure's `CurrentPoint` property and does not execute either the table's `ButtonDownFcn` or the figure's `WindowButtonDownFcn` callback.

When you left-click on a uitable whose `Enable` property is `off`, or when you right-click a uitable whose `Enable` property has any value, MATLAB performs these actions in this order:

- 1** Sets the figure's `SelectionType` property.
- 2** Sets the figure's `CurrentPoint` property.
- 3** Executes the figure's `WindowButtonDownFcn` callback.

## Extent

position rectangle (read only)

*Size of uitable rectangle.* A four-element vector of the form `[0,0,width,height]` that contains the calculated values of the largest extent of the table based on the current `Data`, `RowName` and `ColumnName` property values. Calculation depends on column and row widths, when they are available. The calculated extent can be larger than the figure.

The first two elements are always zero. `width` and `height` are the dimensions of the rectangle. All measurements are in units specified by the `Units` property.

When the uitable's `Units` property is set to `'Normalized'`, its `Extent` is measured relative to the figure, regardless of whether the table is contained in (parented to) a `uipanel` or not.

You can use this property to determine proper sizing for the uitable with respect to its content. Do this by setting the `width` and `height` of the uitable `Position` property to the width and height of the `Extent` property. However, doing this can cause the table to extend beyond the right or top edge of the figure and/or its `uipanel` parent, if any, for tables with large extents.

## FontAngle

`{normal} | italic | oblique`

*Character slant of cell content.* MATLAB uses this property to select a font from those available on your particular system. Setting this property to `italic` or `oblique` selects a slanted version of the font, when it is available on your system.

## FontName

string

*Font family for cell content.* The name of the font in which to display cell content. To display and print properly, this must be a font that your system supports. The default font is system dependent.

To use a fixed-width font that looks good in any locale (and displays properly in Japan, where multibyte character sets are used), set `FontName` to the string `FixedWidth` (this string value is case sensitive):

```
set(uitable_handle, 'FontName', 'FixedWidth')
```

# Uitable Properties

---

This parameter value eliminates the need to hard code the name of a fixed-width font, which may not display text properly on systems that do not use ASCII character encoding (such as in Japan). A properly written MATLAB application that needs to use a fixed-width font should set `FontName` to `FixedWidth` and rely on the root `FixedWidthFontName` property to be set correctly in the end user's environment.

End users can adapt a MATLAB application to different locales or personal environments by setting the root `FixedWidthFontName` property to the appropriate value for that locale from `startup.m`. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

**FontSize**  
size in `FontUnits`

*Font size for cell contents.* A number specifying the size of the font in which to display cell contents, in units determined by the `FontUnits` property. The default point size is system dependent. If `FontUnits` is set to `normalized`, `FontSize` is a number between 0 and 1.

**FontUnits**  
{points} | normalized | inches |  
centimeters | pixels

*Font size units for cell contents.* This property determines the units used by the `FontSize` property. Normalized units interpret `FontSize` as a fraction of the height of the uitable. When you resize the uitable, MATLAB modifies the screen `FontSize` accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point =  $\frac{1}{72}$  inch).

**FontWeight**  
light | {normal} | demi | bold

*Weight of cell text characters.* MATLAB uses this property to select a font from those available on your particular system. Setting this property to **bold** causes MATLAB to use a bold version of the font, when it is available on your system.

## ForegroundColor

1-by-3 matrix of RGB triples or a color name

*Color of text in cells.* Determines the color of the text defined for cell contents. Text in all cells share the current color. Specify as a 1-by-3 matrix of RGB triples, such as [0 0 .8] or as a color name. The default is a 1-by-3 matrix of platform-dependent colors. See `ColorSpec` for information about specifying RGB colors.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine

# Uitable Properties

---

invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* When `HitTest` is `off`, the `ButtonDownFcn` callback does not execute.

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`

- WindowScrollWheelFcn

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted.

# Uitable Properties

---

For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure’s `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object’s `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object’s `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

## `KeyPressFcn`

string or function handle

*Key press callback function.* A callback routine invoked by a key press when the callback’s uitable object has focus. Focus is denoted by a border or a dotted border, respectively, in UNIX and Microsoft Windows. If no uitable has focus, the figure’s key press callback function, if any, is invoked. `KeyPressFcn` can be a function handle, the name of a MATLAB function file, or any legal MATLAB expression.

If the specified value is the name of a function code file, the callback routine can query the figure’s `CurrentCharacter` property to determine what particular key was pressed and thereby limit the callback execution to specific keys.

If the specified value is a function handle, the callback routine can retrieve information about the key that was pressed from its event data structure argument.

| Event Data Structure Field | Description                                                                         | Examples:  |            |           |           |
|----------------------------|-------------------------------------------------------------------------------------|------------|------------|-----------|-----------|
|                            |                                                                                     | a          | =          | Shift     | Shift/a   |
| Character                  | Character interpretation of the key that was pressed.                               | 'a'        | '='        | ' '       | 'A'       |
| Modifier                   | Current modifier, such as 'control', or an empty cell array if there is no modifier | {1x0 cell} | {1x0 cell} | {'shift'} | {'shift'} |
| Key                        | Name of the key that was pressed.                                                   | 'a'        | 'equal'    | 'shift'   | 'a'       |

The uitable `KeyPressFcn` callback executes for all keystrokes, including arrow keys or when a user edits cell content.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

**Parent**  
handle

*Uitable parent.* The handle of the uitable’s parent object. You can move a uitable object to another figure, uipanel, or uibuttongroup by setting this property to the handle of the new parent.

**Position**  
position rectangle

*Size and location of uitable.* The rectangle defined by this property specifies the size and location of the table within the parent figure window, ui, or uibuttongroup. Specify `Position` as a 4–element vector:

```
[left bottom width height]
```

`left` and `bottom` are the distance from the lower-left corner of the parent object to the lower-left corner of the uitable object.

# Uitable Properties

---

width and height are the dimensions of the uitable rectangle. All measurements are in units specified by the Units property.

---

**Note** If you are specifying both Units and Position in the same call to uitable, specify Units first if you want Position to be interpreted using those units.

---

RearrangeableColumns  
on | {off}

*This object can be rearranged.* The RearrangeableColumns property provides a mechanism that you can use to reorder the columns in the table. All columns are rearrangeable when this property is turned on. MATLAB software sets the RearrangeableColumns property to off by default.

When this property is on, the user of a table can move any column of data (but not the row labels) at a time left or right to reorder it by clicking and dragging its header. Rearranging columns does not affect the ordering of columns in the table's Data, only the user's view of it.

RowName  
1-by-n cell array of strings | {'numbered'} | empty matrix ([])

*Row heading names.* Each element of the cell array is the name of a row. Row names are restricted to one line of text.

For sequentially numbered row headings starting with 1, specify RowName as 'numbered'. This is the default.

To remove the row headings, specify RowName as the empty matrix ( []).

The number of rows in the table is the larger of RowName and the number of rows in the Data property matrix or cell array.

## RowStriping

{on} | off

*Color striping of table rows.* When RowStriping is on, the background of consecutive rows of the table display in the pair of colors that the BackgroundColor color matrix specifies. The first color matrix row applies to odd-numbered rows, and the second to even-numbered rows. If the BackgroundColor matrix has only one row, it is applied to all rows (that is, no striping occurs).

When RowStriping is off, the first color specified for BackgroundColor is applied to all rows.

## Selected

on | {off}

*Is object selected.* When this property is on, MATLAB displays selection handles if the SelectionHighlight property is also on. You can, for example, define the ButtonDownFcn to set this property, allowing users to select the object with the mouse.

## SelectionHighlight

{on} | off

*Object highlight when selected.* When the Selected property is on, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When SelectionHighlight is off, MATLAB does not draw the handles.

## Tag

string (GUIDE sets this property)

*User-specified object label.* The Tag property provides a means to identify graphics objects with a user-specified label. This is particularly useful when constructing interactive graphics programs that would otherwise need to define object handles as

# Uitable Properties

---

global variables or pass them as arguments between callback routines. You can define `Tag` as any string.

`TooltipString`  
string

*Content of tooltip for object.* The `TooltipString` property specifies the text of the tooltip associated with the uitable. When the user moves the mouse pointer over the table and leaves it there, the tooltip is displayed.

To create a tooltip that has more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the `TooltipString` to that value. For example:

```
h = uitable;  
s = sprintf('UITable tooltip line 1\nUITable tooltip line 2');  
set(h,'TooltipString',s)
```

`Type`  
string (read only)

*Class of graphics object.* For uitable objects, `Type` is always the string `'uitable'`.

`UIContextMenu`  
handle

*Associate a context menu with uitable.* Assign this property the handle of a `uicontextmenu` object. MATLAB displays the context menu whenever you right-click over the uitable. Use the `uicontextmenu` function to create the context menu.

`Units`  
{pixels} | normalized | inches | centimeters | points | characters (GUIDE default: normalized)

*Units of measurement.* MATLAB uses these units to interpret the `Extent` and `Position` properties. All units are measured from the lower-left corner of the parent object.

- Normalized units map the lower-left corner of the parent object to (0,0) and the upper-right corner to (1.0,1.0).
- `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).
- Character units are characters using the default system font; the width of one character is the width of the letter x, the height of one character is the distance between the baselines of two lines of text.

If you change the value of `Units`, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume `Units` is set to the default value.

## `UserData`

matrix

*User-specified data.* Any data you want to associate with the uitable object. MATLAB does not use this data, but you can access it using `set` and `get`.

## `Visible`

{on} | off

*Uitable visibility.* By default, all uitables are visible. When set to `off`, the uitable is not visible, but still exists and you can query and set its properties.

---

**Note** Setting `Visible` to `off` for uitables that are not displayed initially in the GUI, can result in faster startup time for the GUI.

---

# uitoggletool

---

**Purpose** Create toggle button on toolbar

**Syntax**

```
htt = uitoggletool
htt = uitoggletool('PropertyName1',value1,'PropertyName2',
    value2,...)
htt = uitoggletool(ht,...)
```

**Description** `htt = uitoggletool` creates a toggle button on the `uitoolbar` at the top of the current figure window, sets all its properties to default values, and returns a handle to the tool. If no `uitoolbar` exists, one is created. The `uitoolbar` is the parent of the `uitoggletool`. Use the returned handle `htt` to set properties of the `uitoggletool`. The `OnCallback`, `OffCallback` and `ClickedCallback` use the handle as their first argument. The button has no icon, but its border highlights when you hover over it with the mouse cursor. Add an icon by setting `CData` for the tool. Type `get(htt)` to see a list of `uitoggletool` object properties and their current values. Type `set(htt)` to see a list of `uitoggletool` object properties you can set and legal property values.

```
htt =
uitoggletool('PropertyName1',value1,'PropertyName2',value2,...)
assigns the specified property values, and assigns default values to the
remaining properties. You can change the property values at a later
time using the set function. You can specify properties as parameter
name/value pairs, cell arrays containing parameter names and values,
or structures with fields containing parameter names and values as
input arguments. For a complete list, see Uitoggletool Properties. Type
get(htt) to see a list of uipushtool object properties and their current
values. Type set(htt) to see a list of uipushtool object properties that
you can set and their legal property values.
```

`htt = uitoggletool(ht,...)` creates a button with `ht` as a parent. `ht` must be a `uitoolbar` handle.

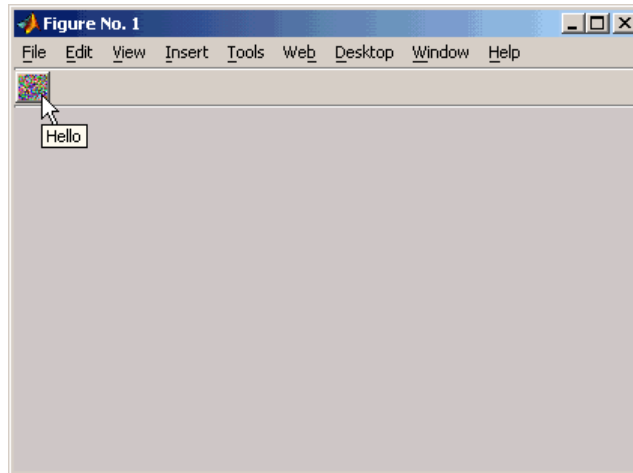

Toggle tools appear in figures whose `Window Style` is `normal` or `docked`. They do not appear in figures with a `'modal'` `WindowStyle`. If the `WindowStyle` property of a figure containing a tool bar and its toggle tool children changes to `modal`, the toggle tools continue to exist

as Children of the tool bar. The toggle tools do not display until you change the `WindowState` to normal or docked.

## Examples

Create a `uitoolbar` object and places a `uitoggletool` object on it by specifying the toolbar handle as the toggle tool parent. Generate a random set of colors for the tool icon and specify a tool tip.

```
h = figure('ToolBar','none');
ht = uitoolbar(h);
a = rand(16,16,3);
htt = uitoggletool(ht,'CData',a,'TooltipString','Hello');
```

## Alternatives

You can create toolbars with toggle tools using GUIDE.

# Uitoggletool Properties property

---

## Purpose

Describe toggle tool properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default Uitoggletool properties by typing:

```
set(h, 'DefaultUitoggletoolPropertyName', PropertyValue...)
```

Where `h` can be the root handle (0), a figure handle, a uitoolbar handle, or a uitoggletool handle. *PropertyName* is the name of the Uitoggletool property and *PropertyValue* is the value you specify as the default for that property.

For more information about changing the default value of a property see “Setting Default Property Values”.

## Properties

This section lists all properties useful to uitoggletool objects along with valid values and a descriptions of their use. Curly braces { } enclose default values.

| Property        | Purpose                                                 |
|-----------------|---------------------------------------------------------|
| BeingDeleted    | This object is being deleted.                           |
| BusyAction      | Callback routine interruption.                          |
| CData           | Truecolor image displayed on the toggle tool.           |
| ClickedCallback | Control action independent of the toggle tool position. |

# Uitoggletool Properties property

| Property         | Purpose                                                     |
|------------------|-------------------------------------------------------------|
| CreateFcn        | Callback routine executed during object creation.           |
| DeleteFcn        | Callback routine executed during object deletion.           |
| Enable           | Enable or disable the uitoggletool.                         |
| HandleVisibility | Control access to object's handle.                          |
| HitTest          | Whether selectable by mouse click                           |
| Interruptible    | Callback routine interruption mode.                         |
| OffCallback      | Control action when toggle tool is set to the off position. |
| OnCallback       | Control action when toggle tool is set to the on position.  |
| Parent           | Handle of uitoggletool's parent toolbar.                    |
| Separator        | Separator line mode.                                        |
| State            | Uitoggletool state.                                         |
| Tag              | User-specified object label.                                |
| TooltipString    | Content of object's tooltip.                                |
| Type             | Object class.                                               |
| UIContextMenu    | Uicontextmenu object associated with the uitoggletool       |
| UserData         | User specified data.                                        |
| Visible          | Uitoggletool visibility.                                    |

## BeingDeleted

on | {off} (read only)

*This object is being deleted.* The `BeingDeleted` property provides a mechanism that you can use to determine if objects are

# UIToggletool Properties property

---

in the process of being deleted. MATLAB software sets the `BeingDeleted` property to on when the object's delete function callback is called (see the `DeleteFcn` property) It remains set to on while the delete function executes, after which the object no longer exists.

For example, some functions may not need to perform actions on objects that are being deleted, and therefore, can check the object's `BeingDeleted` property before acting.

## BusyAction

cancel | {queue}

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## CData

3-dimensional array

*Truecolor image displayed on control as its icon.* An  $n$ -by- $m$ -by-3 array of RGB values that defines a truecolor image displayed

# Uitoggletool Properties property

---

on either a push button or toggle button. Each value must be between 0.0 and 1.0. If your CData array is larger than 16 in the first or second dimension, it can be clipped or result in other undesirable effects. If the array is clipped, only the center 16-by-16 part of the array is used.

## ClickedCallback

string or function handle

*Control action independent of the toggle tool position.* A routine that executes after either the OnCallback routine or OffCallback routine runs to completion. The uitoggletool Enable property must be set to on.

## CreateFcn

string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a uitoggletool object. MATLAB sets all property values for the uitoggletool before executing the CreateFcn callback so these values are available to the callback. Within the function, use gcbo to get the handle of the toggle tool being created.

Setting this property on an existing uitoggletool object has no effect.

You can define a default CreateFcn callback for all new uitoggletools. This default applies unless you override it by specifying a different CreateFcn callback when you call uitoggletool. For example, the statement,

```
set(0, 'DefaultUitoggletoolCreateFcn', ...  
    'set(gcbo, 'Enable', 'off')')
```

creates a default CreateFcn callback that runs whenever you create a new toggle tool. It sets the toggle tool Enable property to off.

## Uitoggletool Properties property

---

To override this default and create a toggle tool whose `Enable` property is set to `on`, you could call `uitoggletool` with code similar to

```
htt = uitoggletool(...,'CreateFcn',...  
                    'set(gcbo,'Enable','on')',...)
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uitoggletool` call. In the example above, if instead of redefining the `CreateFcn` property for this toggle tool, you had explicitly set `Enable` to `on`, the default `CreateFcn` callback would have set `CData` back to `off`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See [Function Handle Callbacks](#) for information on how to use function handles to define a callback function.

`DeleteFcn`  
string or function handle

*Callback routine executed during object deletion.* A callback routine that executes when you delete the `uitoggletool` object (e.g., when you call the `delete` function or cause the figure containing the `uitoggletool` to reset). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

# Uitoggletool Properties property

---

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define a callback function.

## Enable

{on} | off

*Enable or disable the uitoggletool.* This property controls how uitoggletools respond to mouse button clicks, including which callback routines execute.

- **on** – The uitoggletool is operational (the default).
- **off** – The uitoggletool is not operational and its icon (set by the `Cdata` property) is grayed out.

When you left-click on a uitoggletool whose `Enable` property is `on`, MATLAB performs these actions in this order:

- 1** Executes the toggle tool `OnCallback` or `OffCallback` routine, depending on its current state, and its `ClickedCallback` routine.
- 2** Does *not* set the figure `CurrentPoint` property and does *not* execute the figure's `WindowButtonDownFcn` callback.
- 3** Does *not* set the figure `SelectionType` property.

When you left-click a uitoggletool whose `Enable` property is `off`, or when you right-click a uitoggletool whose `Enable` property has any value, no action is reported, no callback executes, and neither the `SelectionType` nor `CurrentPoint` figure properties are modified.

## HandleVisibility

{on} | callback | off

# Uitoggletool Properties property

---

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is on.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* This property has no effect on `uitoggletool` objects.

`Interruptible`  
`off | {on}`

## *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.

# Uitoggletool Properties property

---

- If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure’s `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object’s `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object’s `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

`OffCallback`  
string or function handle

# Uitoggletool Properties property

---

*Control action.* A routine that executes if the uitoggletool's Enable property is set to on, and either

- The toggle tool State is set to off.
- The toggle tool is set to the off position by pressing a mouse button while the pointer is on the toggle tool itself or in a 5-pixel wide border around it.

The ClickedCallback routine, if there is one, runs after the OffCallback routine runs to completion.

## OnCallback

string or function handle

*Control action.* A routine that executes if the uitoggletool's Enable property is set to on, and either

- The toggle tool State is set to on.
- The toggle tool is set to the on position by pressing a mouse button while the pointer is on the toggle tool itself or in a 5-pixel wide border around it.

The ClickedCallback routine, if there is one, runs after the OffCallback routine runs to completion.

## Parent

handle

*Uitoggletool parent.* The handle of the uitoggletool's parent toolbar. You can move a uitoggletool object to another toolbar by setting this property to the handle of the new parent.

## Separator

on | {off}

*Separator line mode.* Setting this property to on draws a dividing line to left of the uitoggletool.

# Uitoggletool Properties property

---

## State

on | {off}

*Uitoggletool state.* When the state is on, the toggle tool appears in the down, or pressed, position. When the state is off, it appears in the up position. Changing the state causes the appropriate `OnCallback` or `OffCallback` routine to run.

## Tag

string

*User-specified object identifier.* The `Tag` property provides a means to identify graphics objects with a user-specified label. You can define `Tag` as any string.

With the `findobj` function, you can locate an object with a given `Tag` property value. This saves you from defining object handles as global variables. For example, this function call returns the handles of all children (of the specified toolbars) that have the `Tag` value 'Bold'.

```
h = findobj(uitoolbarhandles, 'Tag', 'Bold')
```

## TooltipString

string

*Content of tooltip for object.* The `TooltipString` property specifies the text of the tooltip associated with the `uitoggletool`. When the user moves the mouse pointer over the control and leaves it there, the tooltip is displayed.

To create a tooltip that has more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the `TooltipString` to that value. For example:

```
h = uitoggletool;  
s = sprintf('Toggletool tooltip line 1\nToggletool tooltip line 2');  
set(h, 'TooltipString', s)
```

# Uitoggletool Properties property

---

## Type

string (read-only)

Object class. This property identifies the kind of graphics object. For uitoggletool objects, Type is always the string 'uitoggletool'.

## UINavigationController

handle

*Associate a context menu with uicontrol.* This property has no effect on uitoggletool objects.

## UserData

array

*User specified data.* You can specify UserData as any array you want to associate with the uitoggletool object. The object does not use this data, but you can access it using the set and get functions.

## Visible

{on} | off

*Uitoggletool visibility.* By default, all uitoggletools are visible. When set to off, the uitoggletool is not visible, but still exists and you can query and set its properties.

# uitoolbar

---

**Purpose** Create toolbar on figure

**Syntax**

```
ht =  
uitoolbar('PropertyName1',value1,'PropertyName2',value2,  
    ...)  
ht = uitoolbar(h,...)
```

**Description**

ht = uitoolbar('PropertyName1',value1,'PropertyName2',value2,...) creates an empty toolbar at the top of the current figure window, and returns a handle to it. uitoolbar assigns the specified property values, and assigns default values to the remaining properties. You can change the property values at a later time using the set function.

Type get(ht) to see a list of uitoolbar object properties and their current values. Type set(ht) to see a list of uitoolbar object properties that you can set and legal property values. See the Uitoolbar Properties reference page for more information.

ht = uitoolbar(h,...) creates a toolbar with h as a parent. h must be a figure handle.

**Tips**

uitoolbar accepts property name/property value pairs, as well as structures and cell arrays of properties as input arguments.

Uitoolbars appear in figures whose Window Style is normal or docked. They do not appear in figures whose WindowStyle is modal. If the WindowStyle property of a figure containing a uitoolbar is changed to modal, the uitoolbar still exists and is contained in the Children list of the figure, but is not displayed until the WindowStyle is changed to normal or docked.

**Examples**

This example creates a figure with no toolbar, then adds a toolbar to it.

```
h = figure('ToolBar','none')  
ht = uitoolbar(h)
```

# Uitoolbar Properties

---

## Purpose

Describe toolbar properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default Uitoolbar properties by typing:

```
set(h, 'DefaultUitoolbarPropertyName', PropertyValue...)
```

Where `h` can be the root handle (0), a figure handle, or a uitoolbar handle. *PropertyName* is the name of the Uitoolbar property and *PropertyValue* is the value you specify as the default for that property.

For more information about changing the default value of a property see Setting Default Property Values.

## Uitoolbar Properties

This section lists all properties useful to uitoolbar objects along with valid values and a descriptions of their use. Curly braces { } enclose default values.

| Property         | Purpose                                           |
|------------------|---------------------------------------------------|
| BeingDeleted     | This object is being deleted.                     |
| BusyAction       | Callback routine interruption.                    |
| Children         | Handles of uitoolbar's children.                  |
| CreateFcn        | Callback routine executed during object creation. |
| DeleteFcn        | Callback routine executed during object deletion. |
| HandleVisibility | Control access to object's handle.                |

| Property      | Purpose                                            |
|---------------|----------------------------------------------------|
| HitTest       | Whether selectable by mouse click                  |
| Interruptible | Callback routine interruption mode.                |
| Parent        | Handle of uitoolbar's parent.                      |
| Tag           | User-specified object identifier.                  |
| Type          | Object class.                                      |
| UicontextMenu | Uicontextmenu object associated with the uitoolbar |
| UserData      | User specified data.                               |
| Visible       | Uitoolbar visibility.                              |

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* The `BeingDeleted` property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB software sets the `BeingDeleted` property to on when the object's delete function callback is called (see the `DeleteFcn` property) It remains set to on while the delete function executes, after which the object no longer exists.

For example, some functions may not need to perform actions on objects that are being deleted, and therefore, can check the object's `BeingDeleted` property before acting.

## BusyAction

cancel | {queue}

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

# Uitoolbar Properties

---

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## Children

vector of handles

*Handles of tools on the toolbar.* A vector containing the handles of all children of the `uitoolbar` object, in the order in which they appear on the toolbar. The children objects of `uitoolbars` are `uipushtools` and `uitoggletools`. You can use this property to reorder the children.

## CreateFcn

string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a `uitoolbar` object. MATLAB sets all property values for the `uitoolbar` before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcb0` to get the handle of the toolbar being created.

Setting this property on an existing `uitoolbar` object has no effect.

You can define a default `CreateFcn` callback for all new uitoolbars. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uitoolbar`. For example, the statement,

```
set(0, 'DefaultUitoolbarCreateFcn', ...  
    'set(gcbo, 'Visibility', 'off')')
```

creates a default `CreateFcn` callback that runs whenever you create a new toolbar. It sets the toolbar visibility to `off`.

To override this default and create a toolbar whose `Visibility` property is set to `on`, you could call `uitoolbar` with a call similar to

```
ht = uitoolbar(..., 'CreateFcn', ...  
    'set(gcbo, 'Visibility', 'on')', ...)
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uitoolbar` call. In the example above, if instead of redefining the `CreateFcn` property for this toolbar, you had explicitly set `Visibility` to `on`, the default `CreateFcn` callback would have set `Visibility` back to `off`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See [Function Handle Callbacks](#) for information on how to use function handles to define a callback function.

# Uitoolbar Properties

---

## DeleteFcn

string or function handle

*Callback routine executed during object deletion.* A callback function that executes when the uitoolbar object is deleted (e.g., when you call the `delete` function or cause the figure containing the uitoolbar to reset). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

Within the function, use `gcbo` to get the handle of the toolbar being deleted.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI

(such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* This property has no effect on uitoolbar objects.

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

# Uitoolbar Properties

---

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted.

For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure’s `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object’s `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object’s `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

Parent

handle

*Uitoolbar parent.* The handle of the uitoolbar’s parent figure. You can move a uitoolbar object to another figure by setting this property to the handle of the new parent.

Tag

string

*User-specified object identifier.* The Tag property provides a means to identify graphics objects with a user-specified label. You can define Tag as any string.

With the `findobj` function, you can locate an object with a given Tag property value. This saves you from defining object handles as global variables. For example, this function call returns the handles of all children (of the specified figures) that have the Tag value 'FormatTb'.

```
h = findobj(figurehandles,'Tag','FormatTb')
```

Type

string (read-only)

# Uitoolbar Properties

---

Object class. This property identifies the kind of graphics object. For uitoolbar objects, Type is always the string 'uitoolbar'.

UIContextMenu  
handle

*Associate a context menu with uicontrol.* This property has no effect on uitoolbar objects.

UserData  
array

*User specified data.* You can specify UserData as any array you want to associate with the uitoolbar object. The object does not use this data, but you can access it using the `set` and `get` functions.

Visible  
{on} | off

*Uitoolbar visibility.* By default, all uitoolbars are visible. When set to `off`, the uitoolbar is not visible, but still exists and you can query and set its properties.

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Block program execution and wait to resume                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Syntax</b>      | <pre>uiwait uiwait(h) uiwait(h,timeout)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | <p><code>uiwait</code> blocks execution until <code>uiresume</code> is called or the current figure is deleted. This syntax is the same as <code>uiwait(gcf)</code>.</p> <p><code>uiwait(h)</code> blocks execution until <code>uiresume</code> is called or the figure <code>h</code> is deleted.</p> <p><code>uiwait(h,timeout)</code> blocks execution until <code>uiresume</code> is called, the figure <code>h</code> is deleted, or <code>timeout</code> seconds elapse. The minimum value of <code>timeout</code> is 1. If <code>uiwait</code> receives a smaller value, it issues a warning and uses a 1 second <code>timeout</code>.</p>                                                                                                                |
| <b>Tips</b>        | <p>The <code>uiwait</code> and <code>uiresume</code> functions block and resume MATLAB and Simulink program execution. <code>uiwait</code> also blocks the execution of Simulink models. The functions <code>pause</code> (with no argument) and <code>waitfor</code> also block execution in this manner. <code>uiwait</code> is a convenient way to use the <code>waitfor</code> command. You typically use it in conjunction with a dialog box. It provides a way to block the execution of the MATLAB program that created the dialog, until the user responds to the dialog box. When used in conjunction with a modal dialog, <code>uiwait</code> can block the execution of the program file <i>and</i> restrict user interaction to the dialog only.</p> |
| <b>Examples</b>    | <p>This example creates a GUI with a <b>Continue</b> push button. The example calls <code>uiwait</code> to block MATLAB execution until <code>uiresume</code> is called. This happens when the user clicks the <b>Continue</b> push button because the push button's <code>Callback</code>, which responds to the click, calls <code>uiresume</code>.</p> <pre>f = figure; h = uicontrol('Position',[20 20 200 40],'String','Continue',...              'Callback','uiresume(gcf)'); disp('This will print immediately'); uiwait(gcf);</pre>                                                                                                                                                                                                                     |

# uiwait

---

```
disp('This will print after you click Continue');  
close(f);
```

gcbf is the handle of the figure that contains the object whose callback is executing.

**Purpose** Unary minus

**Syntax**  
`b = -a`  
`b = uminus(a)`

**Description** `b = -a` negates the elements of array `a` and returns the result in array `b`.  
`b = uminus(a)` is called for the syntax `-a` when `a` is an object.

**See Also** `uplus`

# undocheckout

---

**Purpose** Undo previous checkout from source control system (UNIX platforms)

**Syntax** `undocheckout('filename')`  
`undocheckout({'filename1', 'filename2', ..., 'filenamen'})`

**Description** `undocheckout('filename')` makes the file `filename` available for checkout, where `filename` does not reflect any of the changes you made after you last checked it out. Use the full path for `filename` and include the file extension.

`undocheckout({'filename1', 'filename2', ..., 'filenamen'})` makes `filename1` through `filenamen` available for checkout, where the files do not reflect any of the changes you made after you last checked them out. Use the full paths for the file names and include the file extensions.

**Examples** Undo the checkouts of `/myserver/myfiles/clock.m` and `/myserver/myfiles/calendar.m` from the source control system:

```
undocheckout({'/myserver/myfiles/clock.m', ...  
'/myserver/myfiles/calendar.m'})
```

**See Also** `checkin` | `checkout` | `verctrl`

**How To** • “Undo the Checkout (UNIX Platforms)”

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Purpose</b>     | Convert Unicode characters to numeric bytes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Syntax</b>      | <pre>bytes = unicode2native(unicodestr) bytes = unicode2native(unicodestr, encoding)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p><code>bytes = unicode2native(unicodestr)</code> takes a char vector of Unicode characters, <code>unicodestr</code>, converts it to the MATLAB default character encoding scheme, and returns the bytes as a <code>uint8</code> vector, <code>bytes</code>. Output vector <code>bytes</code> has the same general array shape as the <code>unicodestr</code> input. You can save the output of <code>unicode2native</code> to a file using the <code>fwrite</code> function.</p> <p><code>bytes = unicode2native(unicodestr, encoding)</code> converts the Unicode characters to the character encoding scheme specified by the string <code>encoding</code>. <code>encoding</code> must be the empty string (<code>''</code>) or a name or alias for an encoding scheme. Some examples are <code>'UTF-8'</code>, <code>'latin1'</code>, <code>'US-ASCII'</code>, and <code>'Shift_JIS'</code>. For common names and aliases, see the Web site <a href="http://www.iana.org/assignments/character-sets">http://www.iana.org/assignments/character-sets</a>. If <code>encoding</code> is unspecified or is the empty string (<code>''</code>), the MATLAB default encoding scheme is used.</p> |
| <b>Examples</b>    | <p>This example begins with two strings containing Unicode characters. It assumes that string <code>str1</code> contains text in a Western European language and string <code>str2</code> contains Japanese text. The example writes both strings into the same file, using the ISO-8859-1 character encoding scheme for the first string and the Shift-JIS encoding scheme for the second string. The example uses <code>unicode2native</code> to convert the two strings to the appropriate encoding schemes.</p> <pre>fid = fopen('mixed.txt', 'w'); bytes1 = unicode2native(str1, 'ISO-8859-1'); fwrite(fid, bytes1, 'uint8'); bytes2 = unicode2native(str2, 'Shift_JIS'); fwrite(fid, bytes2, 'uint8'); fclose(fid);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>See Also</b>    | <code>native2unicode</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

# union

---

**Purpose** Find set union of two arrays

**Compatibility** In a future release, the behavior of union will change. This change is introduced for adoption in R2012a. For a detailed demonstration that shows how you can preview the future behavior and preserve the current behavior of your existing code, see the example, “Assessing the Impact of the Forthcoming Changes to union” on page 2-4952. For a detailed explanation of all the forthcoming changes, see “Set Functions Changing Behavior in a Future Release”.

**Syntax**

```
C = union(A,B)
C = union(A,B, 'rows')
[C,ia,ib] = union(A,B)
[C,ia,ib] = union(A,B, 'rows')

[C,ia,ib] = union( __ , 'R2012a' )

[C,ia,ib] = union( __ , 'legacy' )

[C,ia,ib] = union(A,B,setOrder)

[C,ia,ib] = union(A,B, 'rows', setOrder)
```

**Description** `C = union(A,B)` returns the combined values from A and B with no repetitions. The values of C are in sorted order.

`C = union(A,B, 'rows')` returns the combined rows from A and B with no repetitions. The rows of the matrix C are in sorted order.

`[C,ia,ib] = union(A,B)` also returns index vectors `ia` and `ib`, such that the values in C are the combined values of `A(ia, :)` and `B(ib, :)`.

`[C,ia,ib] = union(A,B, 'rows')` also returns index vectors `ia` and `ib` such that the rows of C are the combined rows of `A(ia, :)` and `B(ib, :)`.

`[C,ia,ib] = union( __ , 'R2012a' )` adopts the future behavior of the `union` function. `[C,ia,ib] = union( __ , 'legacy' )` preserves the current behavior. You can specify either flag, 'R2012a' or 'legacy', as the final input argument in any previous syntax.

`[C,ia,ib] = union(A,B,setOrder)` and `[C,ia,ib] = union(A,B,'rows',setOrder)` returns C in a specific order. `setOrder='sorted'` returns the values (or rows) of C in sorted order. `setOrder='stable'` returns the values (or rows) of C in the same order as A then B.

## Input Arguments

### A,B - Input arrays

vectors | matrices | N-D arrays

Input arrays of which to find the union, specified as `logical`, `char`, a cell array of strings, or any numeric class. A and B also can be any object with the class methods: `sort` (or `sortrows` for the 'rows' option), and `ne`. This includes heterogeneous arrays derived from the same root class.

A and B must be of the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with double arrays.
- Cell arrays of strings can combine with `char` arrays.

If you specify the 'rows' option, A and B must have the same number of columns.

### Data Types

`double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

**Complex Number Support:** Yes

### 'rows' - Rows flag

Rows flag, specified as 'rows', identifies the rows of A and B as individual elements. When you specify this flag, `union` returns the combined rows of A and B. This option does not support cell arrays.

# union

## setOrder - Order flag

'sorted' | 'stable'

Order flag, specified as 'sorted' or 'stable', indicates the order of the values (or rows) in C.

| Order Flag | Meaning                                                                                                                                                          |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'sorted'   | The values (or rows) in C, are returned in sorted order. For example:<br>C = union([5 5 3],[1 2],'sorted') returns<br>C = [1 2 3 5].                             |
| 'stable'   | The values (or rows) in C, are returned in the same order as they appear in A and B. For example:<br>C = union([5 5 3],[1 2],'stable') returns<br>C = [5 3 1 2]. |

## 'legacy' - Legacy behavior flag

Legacy behavior flag, when specified, preserves the current behavior. If the new behavior adversely affects your existing code, you can preserve the current behavior by specifying 'legacy' as the final argument.

## 'R2012a' - Future behavior flag

Future behavior flag, when specified, adopts the future behavior change. Specify 'R2012a' as the final argument to see what impact the new behavior will have on your existing code.

## Output Arguments

### C - Combined values of A and B

vector | matrix

Combined values of A and B, returned as a vector or matrix. C is a vector unless you specify the 'rows' flag. If 'rows' is specified, C is a matrix containing the combined rows of A and B.

### ia - Index to A

vector

Index to A, returned a vector that indicates the values (or rows) in A that contribute to the union. If there is a repeated value (or row) appearing exclusively in A, then `ia` contains the index to the last occurrence of the value (or row).

If you call `union` with the `setOrder` or 'R2012a' argument, `ia` contains the index to the first occurrence of any repeated value (or row) in A.

### **ib - Index to B**

vector

Index to B, returned as a vector that indicates the values (or rows) in B that contribute to the union. If a value (or row) appears multiple times in B, then `ib` contains the index to the last occurrence of the value (or row). If a value (or row) appears in both A and B, then `ib` contains the index to the last occurrence in B.

If you call `union` with the `setOrder` or 'R2012a' argument, `ib` contains the index to the first occurrence of any repeated values (or rows).

## **Examples**

### **Union of Two Vectors**

```
A = [5 7 1]; B = [3 1 1];
C = union(A,B)
```

```
C =
```

```
     1     3     5     7
```

### **Find the Union of Two Vectors and Their Indices**

```
A = [5 7 1]; B = [3 1 1];
[C,ia,ib] = union(A,B)
```

```
C =
```

```
     1     3     5     7
```

# union

---

```
ia =
```

```
    1    2
```

```
ib =
```

```
    3    1
```

## Union of the Rows in Two Matrices

```
A = [2 2 2; 0 0 1];  
B = [1 2 3; 2 2 2; 2 2 2];  
[C,ia,ib] = union(A,B,'rows')
```

```
C =
```

```
    0    0    1  
    1    2    3  
    2    2    2
```

```
ia =
```

```
    2
```

```
ib =
```

```
    1  
    3
```

## Union of Two Vectors with Specified Output Order

Use the `setOrder` argument to specify the ordering of the values in C.

Specify 'stable' if you want the values in C to have the same order as in A and B.

```
A = [5 7 1]; B = [3 1 1];  
[C,ia,ib] = union(A,B,'stable')
```

```
C =
```

```
     5     7     1     3
```

```
ia =
```

```
     1  
     2  
     3
```

```
ib =
```

```
     1
```

Alternatively, you can specify 'sorted' order.

```
A = [5 7 1]; B = [3 1 1];  
[C,ia,ib] = union(A,B,'sorted')
```

```
C =
```

```
     1     3     5     7
```

```
ia =
```

```
     3  
     1  
     2
```

```
ib =
```

```
1
```

`union` adopts the forthcoming behavior when you specify the `setOrder` argument. If you omit the `setOrder` argument, the output is sorted, but the size and content of `C`, `ia`, and `ib` conforms to the current behavior. Compare the sorted output here to the output from the example, “Find the Union of Two Vectors and Their Indices” on page 2-4949.

## Assessing the Impact of the Forthcoming Changes to `union`

Use the `'R2012a'` flag to assess the impact of the forthcoming behavior changes. Use the `'legacy'` flag to preserve the current behavior of your existing code.

Find the union of `A` and `B` with the current default behavior.

```
A = [5 7 1]; B = [3 1 1];  
[C1,ia1,ib1] = union(A,B)
```

```
C1 =
```

```
1 3 5 7
```

```
ia1 =
```

```
1 2
```

```
ib1 =
```

```
3 1
```

Find the union of `A` and `B`, and opt into the forthcoming behavior. In the future, this behavior will be the default.

```
A = [5 7 1]; B = [3 1 1];  
[C2,ia2,ib2] = union(A,B, 'R2012a')
```

```
C2 =
```

```
    1    3    5    7
```

```
ia2 =
```

```
    3  
    1  
    2
```

```
ib2 =
```

```
    1
```

Notice that `ia1` and `ia2` have different shapes and content. The same is also true for `ib1` and `ib2`.

Find the union of `A` and `B`, and preserve the current behavior.

```
A = [5 7 1]; B = [3 1 1];  
[C3,ia3,ib3] = union(A,B, 'legacy')
```

```
C3 =
```

```
    1    3    5    7
```

```
ia3 =
```

```
    1    2
```

```
ib3 =
```

# union

---

```
3 1
```

C3, ia3, and ib3 match C1, ia1, and ib1, respectively.

## Union of Vectors Containing NaNs

```
A = [5 NaN 1]; B = [4 NaN NaN];  
C = union(A,B)
```

```
C =
```

```
1 4 5 NaN NaN NaN
```

union treats NaN values as distinct.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Find unique values in array                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Compatibility</b> | In a future release, the behavior of <code>unique</code> will change. This change is introduced for adoption in R2012a. For a detailed demonstration that shows how you can preview the future behavior and preserve the current behavior of your existing code, see the example, “Assessing the Impact of the Forthcoming Changes to <code>unique</code> ” on page 2-4963. For a detailed explanation of all the forthcoming changes, see “Set Functions Changing Behavior in a Future Release”.                                             |
| <b>Syntax</b>        | <pre>C = unique(A) C = unique(A, 'rows') [C,ia,ic] = unique(A) [C,ia,ic] = unique(A, 'rows') [C,ia,ic] = unique(A,occurrence) [C,ia,ic] = unique(A, 'rows',occurrence)  [C,ia,ic] = unique( __ , 'R2012a')  [C,ia,ic] = unique( __ , 'legacy')  [C,ia,ic] = unique(A,setOrder)  [C,ia,ic] = unique(A, 'rows',setOrder)</pre>                                                                                                                                                                                                                  |
| <b>Description</b>   | <p><code>C = unique(A)</code> for the array <code>A</code>, returns the same values as in <code>A</code> but with no repetitions. The values of <code>C</code> are in sorted order.</p> <p><code>C = unique(A, 'rows')</code> for the matrix <code>A</code>, returns the unique rows of <code>A</code>. The rows of the matrix <code>C</code> are in sorted order.</p> <p><code>[C,ia,ic] = unique(A)</code> also returns index vectors <code>ia</code> and <code>ic</code>, such that <code>C = A(ia)</code> and <code>A = C(ic)</code>.</p> |

# unique

---

`[C,ia,ic] = unique(A,'rows')` also returns index vectors `ia` and `ic` such that `C = A(ia,:)` and `A = C(ic,:)`.

`[C,ia,ic] = unique(A,occurrence)` and `[C,ia,ic] = unique(A,'rows',occurrence)` specify which index is returned in `ia` when there are repeated values (or rows) in `A`. The default value is `occurrence = 'last'`, and `unique` returns the index of the last occurrence of each unique value (or row) in `A`. If `occurrence = 'first'`, `unique` returns the index of the first occurrence of each unique value (or row).

`[C,ia,ic] = unique(___, 'R2012a')` adopts the future behavior of the `unique` function. `[C,ia,ic] = unique(___, 'legacy')` preserves the current behavior. You can specify either flag, `'R2012a'` or `'legacy'`, as the final input argument in any previous syntax.

`[C,ia,ic] = unique(A,setOrder)` and `[C,ia,ic] = unique(A,'rows',setOrder)` returns `C` in a specific order. `setOrder = 'sorted'` returns the values (or rows) of `C` in sorted order. `setOrder = 'stable'` returns the values (or rows) of `C` in the same order as `A`.

## Input Arguments

### **A - Input array**

vector | matrix | N-D array

Array in which to find unique values (or rows), specified as `logical`, `char`, a cell array of strings, or any numeric class. `A` also can be any object with the class methods: `sort` (or `sortrows` for the `'rows'` option), and `ne`. This includes heterogeneous arrays derived from the same root class.

### **Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

**'rows' - Rows flag**

Rows flag, specified as `'rows'`, identifies the rows of matrix A as individual elements. When you specify this flag, `unique` returns the unique rows of A. This option does not support cell arrays.

**occurrence - Occurrence flag**

`'last' | 'first'`

Occurrence flag, specified as `'first'` or `'last'`, indicates whether `ia` should contain the first or last indices to repeated values found in C. The default value is `'last'` in most cases. However, if you call `unique` with either the `setOrder` or `'R2012a'` argument, the default occurrence is `'first'`.

| Occurrence Flag      | Meaning                                                                                                                                                                                                                               |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>'last'</code>  | If there are repeated values (or rows) in A, then <code>ia</code> contains the index to the last occurrence of the repeated value. For example:<br><code>[C,ia,ic] = unique([9 9 9], 'last')</code> returns<br><code>ia = 3.</code>   |
| <code>'first'</code> | If there are repeated values (or rows) in A, then <code>ia</code> contains the index to the first occurrence of the repeated value. For example:<br><code>[C,ia,ic] = unique([9 9 9], 'first')</code> returns<br><code>ia = 1.</code> |

**setOrder - Order flag**

`'sorted' | 'stable'`

Order flag, specified as `'sorted'` or `'stable'`, indicates the order of the values (or rows) in C.

# unique

---

| Order Flag | Meaning                                                                                                                                    |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| 'sorted'   | The values (or rows) in C, are returned in sorted order. For example:<br>C = unique([5 5 3 4], 'sorted') returns<br>C = [3 4 5].           |
| 'stable'   | The values (or rows) in C, are returned in the same order as in A. For example:<br>C = unique([5 5 3 4], 'stable') returns<br>C = [5 3 4]. |

## 'legacy' - Legacy behavior flag

Legacy behavior flag, when specified, preserves the current behavior. If the new behavior adversely affects your existing code, you can preserve the current behavior by specifying 'legacy' as the final argument.

## 'R2012a' - Future behavior flag

Future behavior flag, when specified, adopts the future behavior change. Specify 'R2012a' as the final argument to see what impact the new behavior has on your existing code.

## Output Arguments

### C - Unique values of A

vector | matrix

Unique values of A, returned as a vector or matrix. C is a vector, unless you specify the 'rows' flag. If 'rows' is specified, C is a matrix containing the unique rows of A.

### ia - Index to A

vector

Index to A, returned as a vector that contains indices such that C = A(ia).

### ic - Index to C

vector

Index to C, returned as a vector that contains indices such that  $A = C(ic)$ .

## Examples

### Unique Values in a Vector

```
A = [9 2 9 5];
C = unique(A)
```

```
C =
```

```
     2     5     9
```

### Find Unique Values and Their Indices

```
A = [9 2 9 5];
[C, ia, ic] = unique(A)
```

```
C =
```

```
     2     5     9
```

```
ia =
```

```
     2     4     3
```

```
ic =
```

```
     3     1     3     2
```

### Unique Rows in a Matrix

```
A = [9 2 9 5; 9 2 9 0; 9 2 9 5];
[C, ia, ic] = unique(A, 'rows')
```

```
C =
```

```
     9     2     9     0
```

# unique

---

```
          9    2    9    5

ia =

     2
     3

ic =

     2
     1
     2
```

Notice that the second row in *A* is identified as unique even though 9, 2, and 9 are repeated in the other rows.

## Unique Values in a Vector with Specified Output Order

Use the `setOrder` argument to specify the ordering of the values in *C*.

Specify `'stable'` if you want the values in *C* to have the same order as in *A*.

```
A = [9 2 9 5];
[C, ia, ic] = unique(A, 'stable')
```

```
C =

     9     2     5

ia =

     1
     2
     4
```

```
ic =
```

```
1  
2  
1  
3
```

Alternatively, you can specify 'sorted' order.

```
[C, ia, ic] = unique(A, 'sorted')
```

```
C =
```

```
2    5    9
```

```
ia =
```

```
2  
4  
1
```

```
ic =
```

```
3  
1  
3  
2
```

`unique` adopts the forthcoming behavior when you specify the `setOrder` argument. If you omit the `setOrder` argument, the output is sorted, but the size and content of `C`, `ia`, and `ic` conforms to the current behavior. Compare the sorted output here to the output from the example, “Find Unique Values and Their Indices” on page 2-4959.

## Unique Values in a Vector with Repeated Items

Specify whether `ia` should contain the first or last index to repeated values.

Specify the first occurrence of 9 in A.

```
A = [9 2 9 5];  
[C1, ia1, ic1] = unique(A, 'first')
```

```
C1 =
```

```
     2     5     9
```

```
ia1 =
```

```
     2     4     1
```

```
ic1 =
```

```
     3     1     3     2
```

Alternatively, you can specify the last occurrence of 9 in A.

```
A = [9 2 9 5];  
[C2, ia2, ic2] = unique(A, 'last')
```

```
C2 =
```

```
     2     5     9
```

```
ia2 =
```

```
     2     4     3
```

```
ic2 =  
      3      1      3      2
```

### Assessing the Impact of the Forthcoming Changes to unique

Use the 'R2012a' flag to assess the impact of the forthcoming behavior changes. Use the 'legacy' flag to preserve the current behavior of your existing code.

Find the unique elements of A with the current default behavior.

```
A = [9 2 9 5];  
[C1, ia1, ic1] = unique(A)
```

```
C1 =  
      2      5      9
```

```
ia1 =  
      2      4      3
```

```
ic1 =  
      3      1      3      2
```

Find the unique elements of A, and opt into the forthcoming behavior. In the future, this behavior will be the default.

```
[C2, ia2, ic2] = unique(A, 'R2012a')
```

```
C2 =  
      2      5      9
```

# unique

---

```
ia2 =
```

```
2  
4  
1
```

```
ic2 =
```

```
3  
1  
3  
2
```

`ia1` and `ia2` have different shapes and content, while `ic1` and `ic2` differ only in shape.

Find the unique elements of `A`, and preserve the current behavior.

```
[C3, ia3, ic3] = unique(A, 'legacy')
```

```
C3 =
```

```
2    5    9
```

```
ia3 =
```

```
2    4    3
```

```
ic3 =
```

```
3    1    3    2
```

`C3`, `ia3`, and `ic3` match `C1`, `ia1`, and `ic1` respectively.

## Unique Values in Array Containing NaNs

```
A = [5 5 NaN NaN];  
C = unique(A)
```

```
C =  
  
     5     NaN     NaN
```

unique treats NaN values as distinct.

```

**Purpose** Execute UNIX command and return result

**Syntax**

```
unix command
status = unix('command')
[status, result] = unix('command')
[status,result] = unix('command','-echo')
```

**Description** `unix` command calls upon the UNIX operating system to execute the given command. The command executes in a UNIX shell, which might not be the shell from which you launched MATLAB.

`status = unix('command')` returns completion status to the `status` variable.

`[status, result] = unix('command')` returns the standard output to the `result` variable.

`[status,result] = unix('command','-echo')` displays the results in the Command Window as it executes, and assigns the results to `result`.

This function is interchangeable with the `system` and `dos` functions. They all have the same effect.

**Examples** List all users that are currently logged in.

```
[s,w] = unix('who');
```

MATLAB returns 0 (success) in `s` and a string containing the list of users in `w`.

---

Execute a string, `why`, that is not a UNIX command.

```
[s,w] = unix('why')
s =
    1
w =
why: Command not found.
```

MATLAB returns a nonzero value in `s` to indicate failure, and returns an error message in `w`.

**Algorithms**

The MATLAB software uses a shell program to execute the given command. It determines which shell program to use by checking environment variables on your system. MATLAB first checks the `MATLAB_SHELL` variable, and if either empty or not defined, then checks `SHELL`. If `SHELL` is also empty or not defined, MATLAB uses `/bin/sh`.

| <b>Description</b>      | <code>[L,XY] = unmesh(E)</code> returns the Laplacian matrix <code>L</code> and mesh vertex coordinate matrix <code>XY</code> for the <code>M</code> -by-4 edge matrix <code>E</code> . Each row of the edge matrix must contain the coordinates <code>[x1 y1 x2 y2]</code> of the edge endpoints. |                |                                                   |                 |                                |
| <b>Input Arguments</b>  | <table><tr><td><code>E</code></td><td><code>M</code>-by-4 edge matrix <code>E</code>.</td></tr></table>                                                                                                                                                                                            | <code>E</code> | <code>M</code> -by-4 edge matrix <code>E</code> . |                 |                                |
| <code>E</code>          | <code>M</code> -by-4 edge matrix <code>E</code> .                                                                                                                                                                                                                                                  |                |                                                   |                 |                                |
| <b>Output Arguments</b> | <table><tr><td><code>L</code></td><td>Laplacian matrix representation of the graph.</td></tr><tr><td><code>XY</code></td><td>Mesh vertex coordinate matrix.</td></tr></table>                                                                                                                      | <code>L</code> | Laplacian matrix representation of the graph.     | <code>XY</code> | Mesh vertex coordinate matrix. |
| <code>L</code>          | Laplacian matrix representation of the graph.                                                                                                                                                                                                                                                      |                |                                                   |                 |                                |
| <code>XY</code>         | Mesh vertex coordinate matrix.                                                                                                                                                                                                                                                                     |                |                                                   |                 |                                |
| <b>Examples</b>         | Take a simple example of a square with vertices at $(1,1)$ , $(1,-1)$ , $(-1,-1)$ , and $(-1,1)$ , where the connections between vertices are the four perpendicular edges of the square plus one diagonal connection between $(-1, -1)$ and $(1,1)$ .                                             |                |                                                   |                 |                                |

The edge matrix E for this graph is:

```
E=[1 1 1 -1; % edge from 1 to 2
1 -1 -1 -1; % edge from 2 to 3
-1 -1 -1 1; % edge from 3 to 4
-1 -1 1 1; % edge from 4 to 1
-1 1 1 1] % edge from 3 to 1
```

Use unmesh to create the output matrices,

```
[A,XY]=unmesh(E);
4 vertices:
4/4
```

The Laplacian matrix is defined as

$$L_{ij} = \begin{cases} \deg(v_i) & \text{if } i = j \\ -1 & \text{if } i \neq j \text{ and } v_i \text{ is adjacent to } v_j \\ 0 & \text{otherwise} \end{cases}$$

unmesh returns the Laplacian matrix L in sparse notation.

L

L =

|       |    |
|-------|----|
| (1,1) | 3  |
| (2,1) | -1 |
| (3,1) | -1 |
| (4,1) | -1 |
| (1,2) | -1 |
| (2,2) | 2  |
| (4,2) | -1 |
| (1,3) | -1 |
| (3,3) | 2  |
| (4,3) | -1 |
| (1,4) | -1 |
| (2,4) | -1 |
| (3,4) | -1 |

To see L in regular matrix notation, use the full command.

full(L)

ans =

|    |    |    |    |
|----|----|----|----|
| 3  | -1 | -1 | -1 |
| -1 | 2  | 0  | -1 |
| -1 | 0  | 2  | -1 |
| -1 | -1 | -1 | 3  |

The mesh coordinate matrix XY returns the coordinates of the corners of the square.

# unmesh

---

XY

XY =

```
-1  -1
-1   1
 1  -1
 1   1
```

[gplot](#) | [treepplot](#)

**Purpose** Piecewise polynomial details

**Syntax** `[breaks,coefs,l,k,d] = unmkpp(pp)`

**Description** `[breaks,coefs,l,k,d] = unmkpp(pp)` extracts, from the piecewise polynomial `pp`, its breaks `breaks`, coefficients `coefs`, number of pieces `l`, order `k`, and dimension `d` of its target. Create `pp` using `spline` or the spline utility `mkpp`.

**Examples** This example creates a description of the quadratic polynomial

$$\frac{-x^2}{4} + x$$

as a piecewise polynomial `pp`, then extracts the details of that description.

```
pp = mkpp([-8 -4],[-1/4 1 0]);
[breaks,coefs,l,k,d] = unmkpp(pp)
```

```
breaks =
    -8    -4
```

```
coefs =
   -0.2500    1.0000         0
```

```
l =
     1
```

```
k =
     3
```

```
d =
     1
```

**See Also** `mkpp` | `ppval` | `spline`

# unregisterallevents

---

**Purpose** Unregister all event handlers associated with COM object events at run time

**Syntax** `h.unregisterallevents`  
`unregisterallevents(h)`

**Description** `h.unregisterallevents` unregisters all events previously registered with COM object `h`. After calling `unregisterallevents`, the object no longer responds to any events until you register them again using the `registerevent` function.

`unregisterallevents(h)` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

**Examples** Register and unregister events for an instance of the `mwsamp` control, using the `eventlisteners` function to see the event handler associated with each event:

**1** Register three events and their respective handler routines.

```
f = figure ('position', [100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2', ...
    [0 0 200 200], f, ...
    {'Click' 'myclick'; 'Db1Click' 'my2click'; ...
    'MouseDown' 'mymoused'});
h.eventlisteners
```

MATLAB displays:

```
ans =
    'click'          'myclick'
    'dblclick'      'my2click'
    'mousedown'     'mymoused'
```

**2** Unregister all events simultaneously with `unregisterallevents`. `eventlisteners` returns an empty cell array, indicating that there are no longer any events registered with the control:

```
h.unregisterallevents;  
h.eventlisteners
```

MATLAB displays:

```
ans =  
    {}
```

## See Also

[events \(COM\)](#) | [eventlisteners](#) | [registerevent](#) | [unregisterevent](#)  
| [isevent](#)

# unregisterevent

---

**Purpose** Unregister event handler associated with COM object event at run time

**Syntax** `h.unregisterevent(eventhandler)`  
`unregisterevent(h, eventhandler)`

**Description** `h.unregisterevent(eventhandler)` unregisters specific event handler routines from their corresponding events. Once you unregister an event, the object no longer responds to the event.

`unregisterevent(h, eventhandler)` is an alternate syntax.

You can unregister events at any time after creating a control. The `eventhandler` argument, which is a cell array, specifies both events and event handlers.

```
h.unregisterevent({'event_name', @event_handler});
```

Specify events in the `eventhandler` argument using the names of the events. Strings used in the `eventhandler` argument are not case sensitive. `unregisterevent` does not accept numeric event identifiers.

COM functions are available on Microsoft Windows systems only.

**Examples** Unregister events for a control:

- 1 Create an `mwsamp` control and register all events with the same handler routine, `sampev`. Use `eventlisteners` to see the event handler used by each event. In this case, each event, when fired, calls `sampev.m`:

```
f = figure('position', [100 200 200 200]);  
h = actxcontrol('mwsamp.mwsampctrl.2', ...  
    [0 0 200 200], f, ...  
    'sampev');  
h.eventlisteners
```

MATLAB displays:

```
ans =  
    'Click'          'sampev'  
    'DbClick'       'sampev'  
    'MouseDown'     'sampev'  
    'Event_Args'    'sampev'
```

- 2 Unregister just the `dblclick` event. Now, when you list the registered events using `eventlisteners`, `dblclick` is no longer registered and the control does not respond when you double-click the mouse over it:

```
h.unregister(event({'dblclick' 'sampev'});  
h.eventlisteners
```

MATLAB displays:

```
ans =  
    'Click'          'sampev'  
    'MouseDown'     'sampev'  
    'Event_Args'    'sampev'
```

- 3 Now, register the `click` and `dblclick` events with a different event handler for `myclick` and `my2click`, respectively:

```
h.unregisterallevents;  
h.registerevent({'click' 'myclick'; ...  
    'dblclick' 'my2click'});  
h.eventlisteners
```

MATLAB displays:

```
ans =  
    'click'          'myclick'  
    'dblclick'      'my2click'
```

- 4 Unregister these same events by specifying event names and their handler routines in a cell array. `eventlisteners` now returns an

## unregisterevent

---

empty cell array, meaning that no events are registered for the `mwsamp` control:

```
h.unregisterevent({'click' 'myclick'; ...  
    'dblclick' 'my2click'});  
h.eventlisteners
```

MATLAB displays:

```
ans =  
    {}
```

---

Unregister Microsoft Excel workbook events:

- 1 Create a Workbook object and register two events with the event handler routines, `EvtActivateHndlr` and `EvtDeactivateHndlr`:

```
myApp = actxserver('Excel.Application');  
wbs = myApp.Workbooks;  
wb = wbs.Add;wb.registerevent({'Activate' 'EvtActivateHndlr'; ...  
    'Deactivate' 'EvtDeactivateHndlr'})  
wb.eventlisteners
```

MATLAB shows the events with the corresponding event handlers.

```
ans =  
    'Activate'      'EvtActivateHndlr'  
    'Deactivate'   'EvtDeactivateHndlr'
```

- 2 Next, unregister the `Deactivate` event handler:

```
wb.unregisterevent({'Deactivate' 'EvtDeactivateHndlr'})  
wb.eventlisteners
```

MATLAB shows the remaining registered event (`Activate`) with its corresponding event handler.

```
ans =  
    'Activate'      'EvtActivateHndlr'
```

## How To

- “Writing Event Handlers”

# untar

---

**Purpose** Extract contents of tar file

**Syntax**

```
untar(tarfilename)
untar(tarfilename,outputdir)
untar(url, ...)
filenames = untar(...)
```

**Description** `untar(tarfilename)` extracts the archived contents of `tarfilename` into the current directory and sets the files' attributes. It overwrites any existing files with the same names as those in the archive if the existing files' attributes and ownerships permit it. For example, if you rerun `untar` on the same `tarfilename`, MATLAB software does not overwrite files with a read-only attribute; instead, `untar` displays a warning for such files. On Microsoft Windows platforms, the hidden, system, and archive attributes are not set.

`tarfilename` is a string specifying the name of the tar file. `tarfilename` is gunzipped to a temporary directory and deleted if its extension ends in `.tgz` or `.gz`. If an extension is omitted, `untar` searches for `tarfilename` appended with `.tgz`, `.tar.gz`, or `.tar`. `tarfilename` can include the directory name; otherwise, the file must be in the current directory or in a directory on the MATLAB path.

`untar(tarfilename,outputdir)` uncompresses the archive `tarfilename` into the directory `outputdir`. If `outputdir` does not exist, MATLAB creates it.

`untar(url, ...)` extracts the tar archive from an Internet URL. The URL must include the protocol type (for example, `'http://'` or `'ftp://'`). MATLAB downloads the URL to a temporary directory, and then deletes it.

`filenames = untar(...)` extracts the tar archive and returns the names of the extracted files in the string cell array `filenames`. If `outputdir` specifies a relative path, `filenames` contains the relative path. If `outputdir` specifies an absolute path, `filenames` contains the absolute path.

**Examples****Using tar and untar to Copy Files**

Copy all .m files in the current directory to the directory backup.

```
tar('myfiles.tar.gz','*.m');  
untar('myfiles','backup');
```

**Using untar with URL**

Run untar to list Cleve Moler's "Numerical Computing with MATLAB" examples to the output directory ncm.

```
url = 'http://www.mathworks.com/moler/ncm.tar.gz';  
ncmFiles = untar(url,'ncm');
```

gzip | gunzip | tar | unzip | zip

# unwrap

---

**Purpose** Correct phase angles to produce smoother phase plots

**Syntax**

```
Q = unwrap(P)
Q = unwrap(P,tol)
Q = unwrap(P,[],dim)
Q = unwrap(P,tol,dim)
```

**Description** `Q = unwrap(P)` corrects the radian phase angles in a vector `P` by adding multiples of  $\pm 2\pi$  when absolute jumps between consecutive elements of `P` are greater than or equal to the default jump tolerance of  $\pi$  radians. If `P` is a matrix, `unwrap` operates columnwise. If `P` is a multidimensional array, `unwrap` operates on the first nonsingleton dimension.

`Q = unwrap(P,tol)` uses a jump tolerance `tol` instead of the default value,  $\pi$ .

`Q = unwrap(P,[],dim)` unwraps along `dim` using the default tolerance.

`Q = unwrap(P,tol,dim)` uses a jump tolerance of `tol`.

---

**Note** A jump tolerance less than  $\pi$  has the same effect as a tolerance of  $\pi$ . For a tolerance less than  $\pi$ , if a jump is greater than the tolerance but less than  $\pi$ , adding  $\pm 2\pi$  would result in a jump larger than the existing one, so `unwrap` chooses the current point. If you want to eliminate jumps that are less than  $\pi$ , try using a finer grid in the domain.

---

## Examples

### Example 1

The following phase data comes from the frequency response of a third-order transfer function. The phase curve jumps 3.5873 radians between  $w = 3.0$  and  $w = 3.5$ , from -1.8621 to 1.7252.

```
w = [0:.2:3,3.5:1:10];
p = [    0
     -1.5728
     -1.5747
     -1.5772
```

```
-1.5790  
-1.5816  
-1.5852  
-1.5877  
-1.5922  
-1.5976  
-1.6044  
-1.6129  
-1.6269  
-1.6512  
-1.6998  
-1.8621  
1.7252  
1.6124  
1.5930  
1.5916  
1.5708  
1.5708  
1.5708 ];  
semilogx(w,p,'b*-'), hold
```

# unwrap

Using `unwrap` to correct the phase angle, the resulting jump is 2.6959, which is less than the default jump tolerance  $\pi$ . This figure plots the new curve over the original curve.

```
semilogx(w,unwrap(p),'r*-')
```

### Example 2

Array P features smoothly increasing phase angles except for discontinuities at elements (3,1) and (1,2).

```
P = [
    0      7.0686   1.5708   2.3562
    0.1963  0.9817   1.7671   2.5525
    6.6759  1.1781   1.9635   2.7489
    0.5890  1.3744   2.1598   2.9452 ]
```

The function  $Q = \text{unwrap}(P)$  eliminates these discontinuities.

```
Q =
    0      7.0686   1.5708   2.3562
    0.1963  7.2649   1.7671   2.5525
    0.3927  7.4613   1.9635   2.7489
    0.5890  7.6576   2.1598   2.9452
```

# unwrap

| <b>Tips</b>            | <ul style="list-style-type: none"><li>• <code>unzip</code> does not support password-protected or encrypted zip archives.</li><li>• If any files in the target folder have the same name as files in the zip file, and you have write permission to the files, <code>unzip</code> overwrites the existing files with the archived versions. If you do not have write permission, <code>unzip</code> issues a warning.</li><li>• Extract files that contain non-7-bit ASCII characters on a machine that has the appropriate language/encoding settings.</li></ul>                                                                    |
| <b>Input Arguments</b> | <p><b>zipfilename</b></p> <p>String that specifies the name of the zip file.</p> <p>If <code>zipfilename</code> does not include the full path, <code>unzip</code> searches for the file in the current folder and along the MATLAB path. If you do not specify the file extension, <code>unzip</code> appends <code>.zip</code>.</p> <p>If you are downloading a URL, <code>zipfilename</code> must include the protocol type (for example, <code>http://</code>). The <code>unzip</code> function downloads the URL to the temporary folder on your system, and deletes the URL on cleanup.</p>                                    |

# unzip

---

## **outputdir**

String that specifies the target folder for the extracted files.

**Default:** current folder ('.')

## **Output Arguments**

### **entrynames**

Cell array of strings that contain the paths of the extracted files.

If `outputdir` specifies a relative path, `entrynames` contains the relative path. If `outputdir` specifies an absolute path, `entrynames` contains the absolute path.

## **Examples**

Copy the example MAT-files to the folder archive:

```
% Zip the example MAT-files to examples.zip
zip('examples.zip','*.mat',...
    fullfile(matlabroot,'toolbox','matlab','demos'))
```

```
% Unzip examples.zip to the folder 'archive'
unzip('examples','archive')
```

---

Download Cleve Moler's "Numerical Computing with MATLAB" examples to the output folder `ncm`:

```
url = 'http://www.mathworks.com/moler/ncm.zip';
ncmFiles = unzip(url,'ncm')
```

## **Alternatives**

To extract files from a zip file using the Current Folder browser, select the zip file, right-click to open the context menu, and then select **Extract**.

## **See Also**

`fileattrib` | `gzip` | `gunzip` | `tar` | `untar` | `zip`

**Purpose**           Unary plus

**Syntax**           **b = +a**  
**b = uplus(a)**

**Description**      **b = +a** for numeric arrays is **a**.  
**b = uplus(a)** is called for the syntax **+a** when **a** is an object.

**See Also**          **uminus**

# upper

---

**Purpose** Convert string to uppercase

**Syntax** `t = upper('str')`  
`B = upper(A)`

**Description** `t = upper('str')` converts any lowercase characters in the string `str` to the corresponding uppercase characters and leaves all other characters unchanged.

`B = upper(A)` when `A` is a cell array of strings, returns a cell array the same size as `A` containing the result of applying `upper` to each string within `A`.

**Examples** `upper('attention!')` is ATTENTION!.

**Tips** Character sets supported:

- PC: Windows Latin-1
- Other: ISO Latin-1 (ISO 8859-1)

**See Also** `lower`

**Purpose** Download URL content to MATLAB string

**Syntax**

```
str = urlread(URL)
str = urlread(URL,Name,Value)
[str,status] = urlread( ___ )
```

**Description** `str = urlread(URL)` downloads the HTML Web content from the specified URL into the string `str`. `urlread` does not retrieve hyperlink targets and images.

`str = urlread(URL,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[str,status] = urlread( ___ )` suppresses the display of error messages, using any of the input arguments in the previous syntaxes. When the operation is successful, `status` is 1. Otherwise, `status` is 0

## Input Arguments

### URL - Content location

string

Content location, specified as a string. Include the transfer protocol, such as `http`, `ftp`, or `file`.

**Example:** `'http://www.mathworks.com/matlabcentral'`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Timeout',10,'Charset','UTF-8'` specifies that `urlread` should time out after 10 seconds, and the character encoding of the file is UTF-8.

### Get - Data to send to the Web form using the GET method

cell array

Parameters of the data to send to the Web form using the GET method, specified as the comma-separated pair consisting of 'get' and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

'Get' includes the data in the URL, separated by ? and & characters.

**Example:** 'Get', {'term', 'urlread'}

## **Post - Data to send to the Web form using the POST method**

cell array

Parameters of the data to send to the Web form using the POST method, specified as the comma-separated pair consisting of 'post' and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

'Post' submits the data as part of the request headers, not explicitly in the URL.

## **Timeout - Timeout duration**

number

Timeout duration in seconds, specified as the comma-separated pair consisting of 'Timeout' and a number. The timeout duration determines when the function errors rather than continues to wait for the server to respond or send data.

**Example:** 'Timeout', 10

## **UserAgent - Client user agent identification**

string

Client user agent identification, specified as the comma-separated pair consisting of 'UserAgent' and a string.

**Example:** 'UserAgent', 'MATLAB R2012b'

## **Charset - Character encoding**

string

Character encoding, specified as the comma-separated pair consisting of 'Charset' and a string. If you do not specify Charset, the function attempts to determine the character encoding from the headers of the file. If the character encoding cannot be determined, Charset defaults to the native encoding for the file protocol, and UTF-8 for all other protocols.

**Example:** 'Charset', 'ISO-8859-1'

## Output Arguments

### **str - Contents of the file at the specified URL**

string

Contents of the file at the specified URL, returned as a string. For example, if the URL corresponds to an HTML page, str contains the text and markup in the HTML file. If the URL corresponds to a binary file, str is not readable.

### **status - Download status**

1 | 0

Download status, returned as either 1 or 0. When the download is successful, status is 1. Otherwise, status is 0.

## Examples

### **Download Web Content by Specifying Complete URL**

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to urldread.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...
           '?term=urldread'];
str = urldread(fullURL);
```

urldread reads from the specified URL and downloads the HTML content to the string str.

## Download Web Content Related to a Term

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to `urlread`.

```
URL = 'http://www.mathworks.com/matlabcentral/fileexchange';  
str = urlread(URL, 'Get', {'term', 'urlread'});
```

`urlread` reads from `http://www.mathworks.com/matlabcentral/fileexchange/?term=urlread` and downloads the HTML content to the string `str`.

## Specify Timeout Duration

Download content from a page on the MATLAB Central File Exchange as in the first example, and specify a timeout duration of 5 seconds.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...  
          '?term=urlread'];  
str = urlread(fullURL, 'Timeout', 5);
```

## Tips

- `urlread` saves Web content to a string. To save content to a file, use `urlwrite`.
- `urlread` and `urlwrite` can download content from FTP sites. Alternatively, use the `ftp` function to connect to an FTP server and the `mget` function to download a file.

## See Also

`urlwriteftp` | `webmget` |

## Concepts

- “Specify Proxy Server Settings for Connecting to the Internet”

**Purpose** Download URL content and save to file

**Syntax** `urlwrite(URL,filename)`  
`urlwrite(URL,filename,Name,Value)`  
  
`[filestr,status] = urlwrite( __ )`

**Description** `urlwrite(URL,filename)` reads Web content at the specified URL and saves it to the file specified by `filename`.

`urlwrite(URL,filename,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[filestr,status] = urlwrite( __ )` stores the file path in variable `filestr`, and suppresses the display of error messages, using any of the input arguments in the previous syntaxes. When the operation is successful, `status` is 1. Otherwise, `status` is 0.

## Input Arguments

### **URL - Content location**

string

Content location, specified as a string. Include the transfer protocol, such as `http`, `ftp`, or `file`.

**Example:** `'http://www.mathworks.com/matlabcentral'`

### **filename - Name of file to store Web content**

string

Name of the file to store the Web content, specified as a string. If you do not specify the path for `filename`, `urlwrite` saves the file in the current folder.

**Example:** `'myfile.html'`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Timeout',10,'Charset','UTF-8'` specifies that `urlread` should time out after 10 seconds, and the character encoding of the file is UTF-8.

## **Get - Data to send to the Web form using the GET method**

cell array

Parameters of the data to send to the Web form using the GET method, specified as the comma-separated pair consisting of `'get'` and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

`'Get'` includes the data in the URL, separated by `?` and `&` characters.

**Example:** `'Get',{'term','urlread'}`

## **Post - Data to send to the Web form using the POST method**

cell array

Parameters of the data to send to the Web form using the POST method, specified as the comma-separated pair consisting of `'post'` and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

`'Post'` submits the data as part of the request headers, not explicitly in the URL.

## **Timeout - Timeout duration**

number

Timeout duration in seconds, specified as the comma-separated pair consisting of `'Timeout'` and a number. The timeout duration

determines when the function errors rather than continues to wait for the server to respond or send data.

**Example:** 'Timeout',10

### **UserAgent - Client user agent identification**

string

Client user agent identification, specified as the comma-separated pair consisting of 'UserAgent' and a string.

**Example:** 'UserAgent', 'MATLAB R2012b'

### **Charset - Character encoding**

string

Character encoding, specified as the comma-separated pair consisting of 'Charset' and a string. If you do not specify Charset, the function attempts to determine the character encoding from the headers of the file. If the character encoding cannot be determined, Charset defaults to the native encoding for the file protocol, and UTF-8 for all other protocols.

**Example:** 'Charset', 'ISO-8859-1'

## **Output Arguments**

### **filestr - Path of the file**

string

Path of the file specified by filename, returned as a string.

### **status - Download status**

1 | 0

Download status, returned as either 1 or 0. When the download is successful, status is 1. Otherwise, status is 0.

## **Examples**

### **Download Web Content by Specifying Complete URL**

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to urlwrite. Save the results to samples.html in the current directory.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...  
          '?term=urlwrite'];  
filename = 'samples.html';  
urlwrite(fullURL,filename);
```

View the file.

```
web(filename)
```

## Download Web Content Related to a Term

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to `urlwrite`. Save the results to `samples.html` in the current directory.

```
URL = 'http://www.mathworks.com/matlabcentral/fileexchange';  
filename = 'samples.html';  
urlwrite(URL,filename,'get',{'term','urlwrite'});
```

`urlwrite` downloads the HTML content from `http://www.mathworks.com/matlabcentral/fileexchange/?term=urlwrite` and writes it to `samples.html`.

## Specify Timeout Duration

Download content from a page on the MATLAB Central File Exchange as in the first example, and specify a timeout duration of 5 seconds.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...  
          '?term=urlwrite'];  
filename = 'samples.html';  
urlwrite(fullURL,filename,'Timeout',5);
```

## Tips

- `urlread` and `urlwrite` can download content from FTP sites. Alternatively, use the `ftp` function to connect to an FTP server and the `mget` function to download a file.

# usejava

---

**Purpose** Determine whether Java feature is supported in MATLAB software

**Syntax** `usejava(feature)`

**Description** `usejava(feature)` returns 1 if the specified feature is supported and 0 otherwise.

The following table shows the valid feature arguments.

| Feature   | Description                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------|
| 'awt'     | Java GUI components in the Abstract Window Toolkit components are available.                     |
| 'desktop' | The MATLAB interactive desktop is running.                                                       |
| 'jvm'     | The Java Virtual Machine software (JVM) is running.                                              |
| 'swing'   | Swing components (Java lightweight GUI components in the Java Foundation Classes) are available. |

## Examples

The following conditional code ensures that the AWT GUI components are available before the script attempts to display a Java Frame.

```
if usejava('awt')
    myFrame = java.awt.Frame;
else
    disp('Unable to open a Java Frame');
end
```

The next example is part of a script that includes Java code. It fails gracefully when run in a MATLAB session that does not have access to JVM software.

```
if ~usejava('jvm')
    error([mfilename ' requires Java to run.']);
end
```

javachk

# userpath

---

**Purpose** View or change user portion of search path

**Syntax**

```
userpath  
userpath('newpath')  
userpath('reset')  
userpath('clear')
```

**Description** `userpath` returns a string specifying the user portion of the search path. The user portion of the search path is the first folder on the search path, above the folders supplied by MathWorks. The default folder is Documents/MATLAB on all platforms except Windows platforms released before Windows Vista™—for those Windows platforms, the default is My Documents/MATLAB. By default, the *userpath* folder is the current folder when you start up MATLAB — that is, it is the default startup folder. For information on specifying a different folder for the startup folder, see “Startup Folder for the MATLAB Program”. On Macintosh and UNIX platforms, you can automatically add additional subfolders to the top of the search path upon startup by specifying the path for the subfolders via the MATLABPATH environment variable.

`userpath('newpath')` sets the *userpath* value to `newpath`. The `newpath` folder appears at the top of the search path immediately and at startup in future sessions. MATLAB removes the folder previously specified by *userpath* from the search path. `newpath` must be an absolute path.

`userpath('reset')` sets the *userpath* value to the default for that platform, creating the Documents/MATLAB (or My Documents/MATLAB) folder, if it does not exist. MATLAB immediately adds the default folder to the top of the search path, and also adds it to the search path at startup in future sessions.

`userpath('clear')` clears the value for *userpath*. MATLAB removes the folder previously specified by *userpath* from the search path.

## Examples

- “Viewing `userpath`” on page 2-5003
- “Setting a New Value for `userpath`” on page 2-5004

- “Clearing the Value for userpath, and Specifying a New Startup Folder on Windows Platforms” on page 2-5004
- “Removing userpath from the Search Path Resets the Startup Folder” on page 2-5006
- “Assigning userpath as the Startup Folder on a UNIX or Macintosh Platform” on page 2-5008
- “Adding Folders to the Search Path Upon Startup on a UNIX or Macintosh Platform” on page 2-5009

## Viewing userpath

This example assumes `userpath` is set to the default value on the Windows XP platform, `My Documents\MATLAB`. Start MATLAB and display the current folder:

```
cd
```

MATLAB returns:

```
H:\My Documents\MATLAB
```

where H is the drive at which `My Documents` is located for this example. Confirm the current folder is the *userpath*:

```
userpath
```

MATLAB returns:

```
H:\My Documents\MATLAB;
```

Display the search path:

```
path
```

MATLAB returns the search path. The *userpath* portion is at the top:

```
MATLABPATH
```

```
H:\My Documents\MATLAB
```

```
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general  
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops
```

## Setting a New Value for userpath

This example assumes `userpath` is set to the default value on the Windows XP platform, `My Documents\MATLAB`. Change the value from the default for `userpath` to `C:\Research_Project`:

```
userpath('C:\Research_Project')
```

View the effect of the change on the search path:

```
path
```

MATLAB displays the search path, with the new value for `userpath` portion at the top:

```
MATLABPATH
```

```
C:\Research_Project  
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general  
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops  
...
```

Note that MATLAB automatically removed the previous value of `userpath`, `H:\My Documents\MATLAB`, from the search path when you assigned a new value to `userpath`. The next time you start MATLAB, the current folder will be `C:\Research_Project` on Windows platforms.

## Clearing the Value for userpath, and Specifying a New Startup Folder on Windows Platforms

Assume `userpath` is set to the default value and you do not want any folders to be added to the search path upon startup. Confirm the default is currently set:

```
userpath
```

MATLAB returns:

```
H:\My Documents\MATLAB;
```

Verify that the *userpath* folder is at the top of the search path:

```
path
```

MATLAB returns:

```
MATLABPATH
```

```
H:\My Documents\MATLAB  
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general  
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops  
...
```

Clear the value:

```
userpath('clear')
```

Verify the result:

```
userpath
```

MATLAB returns:

```
ans =  
    ''
```

Confirm the *userpath* folder was removed from the search path:

```
path
```

MATLAB returns

```
MATLABPATH
```

```
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general  
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops  
...
```

Clearing the *userpath* value might affect the startup folder. Unless you otherwise specify the startup folder, the startup folder on Windows platforms will be the folder from which you invoke MATLAB. If you specify a startup folder, such as described in “Changing the Startup Folder”, that startup folder will *not* be on the search path. Note that you do not have to clear *userpath* to specify a different startup folder; when you otherwise specify a startup folder, the *userpath* folder is added to the search path upon startup, but is not the startup folder.

## **Removing *userpath* from the Search Path Resets the Startup Folder**

In this example, *userpath* is set to the default value and you remove the *userpath* folder from the search path, then save the changes. This has the same effect as clearing the value for *userpath*. Confirm the default is currently set:

```
userpath
```

```
MATLAB returns:
```

```
H:\My Documents\MATLAB;
```

View the *userpath* folder at the top of the search path:

```
path
```

```
MATLAB returns:
```

```
MATLABPATH
```

```
H:\My Documents\MATLAB  
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general  
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops  
...
```

Remove H:\My Documents\MATLAB from the search path and confirm the result:

```
rmpath('H:\My Documents\MATLAB')
```

path

MATLAB returns:

MATLABPATH

```
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops
...
```

Verify the value:

userpath

MATLAB returns:

```
H:\My Documents\MATLAB;
```

Save changes to the search path:

savepath

View the value:

userpath

MATLAB returns:

```
ans =
     ''
```

The value is now cleared. Removing the folder from the search path *and* saving the changes to the path has the same effect as clearing the value for `userpath`. At the next startup, the startup folder will *not* be `H:\My Documents\MATLAB`, and `H:\My Documents\MATLAB` will *not* be on the search path.

## Assigning userpath as the Startup Folder on a UNIX or Macintosh Platform

Assume `userpath` is set to the default value on a Macintosh platform and you start MATLAB using a bash shell, where `smith` is the home folder. Set the `MATLAB_USE_USERPATH` environment variable so that `userpath` will be used as the startup folder:

```
export MATLAB_USE_USERPATH=1
```

From that shell, start MATLAB. After MATLAB starts, verify the current folder in MATLAB:

```
pwd
```

MATLAB returns:

```
/Users/smith/Documents/MATLAB
```

That is the folder defined for `userpath`, which you can confirm:

```
userpath
```

MATLAB returns:

```
/Users/smith/Documents/MATLAB;
```

The *userpath* is at the top of the search path, which you can confirm:

```
path
```

MATLAB returns:

```
/Users/smith/Documents/MATLAB  
/Users/smith/Applications/MATLAB/R2009a/toolbox/matlab/general  
/Users/smith/Applications/MATLAB/R2009a/toolbox/matlab/ops
```

```
...
```

## Adding Folders to the Search Path Upon Startup on a UNIX or Macintosh Platform

Assume userpath is set to the default value on a UNIX platform with a csh shell, where *j* is your home folder.

To add additional folders to the search path upon startup, for example, `/home/j/Documents/MATLAB/mine` and `/home/j/Documents/MATLAB/mine/research`, run the following in a terminal:

```
setenv MATLABPATH '/home/j/Documents/MATLAB/mine': '/home/j/Documents/MATLAB/mine/research'
```

Separate multiple folders using a colon (:).

MATLAB displays

```
MATLABPATH
```

```
home/j/Documents/MATLAB
home/j/Documents/MATLAB/mine
home/j/Documents/MATLAB/mine/research
home/j/Applications/MATLAB/R2009a/toolbox/matlab/general
home/j/Applications/MATLAB/R2009a/toolbox/matlab/ops
...
```

### How To

- “Using the MATLAB Search Path”
- “Startup Folder for the MATLAB Program”

# validateattributes

---

**Purpose** Check validity of array

**Syntax**

```
validateattributes(A,classes,attributes)
validateattributes(A,classes,attributes,argIndex)
validateattributes(A,classes,attributes,funcName)
validateattributes(A,classes,attributes,funcName,varName)
validateattributes(A,classes,attributes,funcName,varName,
    argIndex)
```

**Description**

`validateattributes(A,classes,attributes)` validates that array `A` belongs to at least one of the specified classes (or its subclass) and has all of the specified attributes. If `A` does not meet the criteria, MATLAB throws an error and displays a formatted error message. Otherwise, `validateattributes` completes without displaying any output.

`validateattributes(A,classes,attributes,argIndex)` includes the position of the input in your function argument list as part of any generated error messages.

`validateattributes(A,classes,attributes,funcName)` includes the specified function name in generated error identifiers.

`validateattributes(A,classes,attributes,funcName,varName)` includes the specified variable name in generated error messages.

`validateattributes(A,classes,attributes,funcName,varName,argIndex)` includes the specified information in generated error messages or identifiers.

**Input Arguments**

**A**  
Any type of array.

**classes**

Cell array of strings that specify valid data types for array `A`. Each string can be the name of any MATLAB built-in or custom class, including:

|                   |                                                                                                                                                                                                                                                                                                          |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'numeric'         | Any value for which the <code>isnumeric</code> function returns true, including <code>int8</code> , <code>int16</code> , <code>int32</code> , <code>int64</code> , <code>uint8</code> , <code>uint16</code> , <code>uint32</code> , <code>uint64</code> , <code>single</code> , or <code>double</code> . |
| 'single'          | Single-precision number.                                                                                                                                                                                                                                                                                 |
| 'double'          | Double-precision number.                                                                                                                                                                                                                                                                                 |
| 'int8'            | Signed 8-bit integer.                                                                                                                                                                                                                                                                                    |
| 'int16'           | Signed 16-bit integer.                                                                                                                                                                                                                                                                                   |
| 'int32'           | Signed 32-bit integer.                                                                                                                                                                                                                                                                                   |
| 'int64'           | Signed 64-bit integer.                                                                                                                                                                                                                                                                                   |
| 'uint8'           | Unsigned 8-bit integer.                                                                                                                                                                                                                                                                                  |
| 'uint16'          | Unsigned 16-bit integer.                                                                                                                                                                                                                                                                                 |
| 'uint32'          | Unsigned 32-bit integer.                                                                                                                                                                                                                                                                                 |
| 'uint64'          | Unsigned 64-bit integer.                                                                                                                                                                                                                                                                                 |
| 'logical'         | Logical true or false.                                                                                                                                                                                                                                                                                   |
| 'char'            | Character or string.                                                                                                                                                                                                                                                                                     |
| 'struct'          | Structure array.                                                                                                                                                                                                                                                                                         |
| 'cell'            | Cell array.                                                                                                                                                                                                                                                                                              |
| 'function_handle' | Scalar function handle.                                                                                                                                                                                                                                                                                  |

## attributes

Cell array that contains descriptions of valid attributes for array A. All attribute names are strings.

Some attributes also require numeric values, such as attributes that specify the size or number of elements of A. For these attributes, the numeric value or vector must immediately follow the attribute name string in the cell array.

Attributes that describe the size and shape of array A:

# validateattributes

---

|                        |                                                                                                                                                 |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| '2d'                   | Two-dimensional array, including scalars, vectors, matrices, and empty arrays.                                                                  |
| 'column'               | Column vector, N-by-1.                                                                                                                          |
| 'row'                  | Row vector, 1-by-N.                                                                                                                             |
| 'scalar'               | Scalar value, 1-by-1.                                                                                                                           |
| 'vector'               | Row or column vector, or a scalar value.                                                                                                        |
| 'size',<br>[d1,...,dN] | Array with dimensions d1-by-...-by-dN. If you do not want to check a particular dimension, specify NaN for that dimension, such as [3,4,NaN,2]. |
| 'numel', N             | Array with N elements.                                                                                                                          |
| 'ncols', N             | Array with N columns.                                                                                                                           |
| 'nrows', N             | Array with N rows.                                                                                                                              |
| 'nonempty'             | No dimensions equal zero.                                                                                                                       |
| 'nonsparse'            | Array that is not sparse.                                                                                                                       |

Attributes that specify valid ranges for values in A:

|         |                                            |
|---------|--------------------------------------------|
| '>', N  | All values are greater than N.             |
| '>=', N | All values are greater than or equal to N. |
| '<', N  | All values are less than N.                |
| '<=', N | All values are less than or equal to N.    |

Attributes that check types of values in A, where A is a numeric or logical array:

|          |                                                 |
|----------|-------------------------------------------------|
| 'binary' | Array of ones and zeros.                        |
| 'even'   | All elements are even integers (includes zero). |
| 'odd'    | All elements are odd integers.                  |

|               |                                             |
|---------------|---------------------------------------------|
| 'integer'     | All elements are integer-valued.            |
| 'real'        | All elements are real.                      |
| 'finite'      | All elements are finite.                    |
| 'nonnan'      | No elements equal to NaN (Not a Number).    |
| 'nonnegative' | No elements are less than zero.             |
| 'nonzero'     | No elements are equal to zero.              |
| 'positive'    | No elements are less than or equal to zero. |

## **funcName**

String that specifies the name of the function whose input you are validating. If you specify an empty string, '', the validateattribute function ignores the funcName input.

## **varName**

String that specifies the name of the input variable. If you specify an empty string, '', the validateattribute function ignores the varName input.

## **argIndex**

Positive integer that specifies the position of the input argument.

## **Examples**

Check the size of an array.

```
classes = {'numeric'};
attributes = {'size',[4,6,2]};

A = rand(3,5,2);
validateattributes(A,classes,attributes)
```

Because A is not of the expected size, validateattributes throws an error and displays this message:

# validateattributes

---

Expected input to be of size 4x6x2 when it is actually size 3x5x2.

---

Check that the values in an array are 8-bit integers within a specific range.

```
classes = {'uint8','int8'};
attributes = {'>',0,'<',70};
```

```
A = randi(100,4,6,2,'uint8');
validateattributes(A,classes,attributes)
```

If some of the values are outside the range, MATLAB displays this error message:

Expected input to be an array with all of the values < 70.

---

Check the attributes of a complex number.

```
a = complex(1,1);
validateattributes(a,{'numeric'},{'nonnegative'});
```

MATLAB displays this error message:

Expected input to be nonnegative.

Because complex numbers lack a well-defined ordering in the complex plane, `validateattributes` does not recognize them as positive or negative.

---

Check inputs to a custom function, and include information about the input name and position in generated errors.

```
function v = findVolume(shape,ht,wd,ln)

    validateattributes(shape,{'char'},{'nonempty'},mfilename,'Shape',1)
```

```
validateattributes(ht,{'numeric'},{'nonempty'},mfilename,'Height',2  
validateattributes(wd,{'numeric'},{'nonempty'},mfilename,'Width',3  
validateattributes(ln,{'numeric'},{'nonempty'},mfilename,'Length',4
```

When you call the function without the shape input string,

```
vol = findVolume(10,7,4)
```

MATLAB displays

```
Error using findVolume
```

```
Expected input number 1, Shape, to be one of these types:
```

```
char
```

Instead its type was double.

The function name is part of the error identifier, so

```
MException.last.identifier
```

returns

```
ans =  
    MATLAB:findVolume:invalidType
```

---

Create a custom function that checks input parameters with `inputParser`, and use `validateattributes` as the validating function for the `addRequired` and `addOptional` methods.

```
function a = findArea(shape,dim1,varargin)  
    p = inputParser;  
    charchk = {'char'};  
    numchk = {'numeric'};  
    nempty = {'nonempty'};  
  
    addRequired(p,'shape',@(x)validateattributes(x,charchk,nempty));  
    addRequired(p,'dim1',@(x)validateattributes(x,numchk,nempty));
```

# validateattributes

---

```
addOptional(p,'dim2',1,@(x)validateattributes(x,numchk,nempty));  
parse(p,shape,dim1,varargin{:});  
  
switch shape  
    case 'circle'  
        a = pi * dim1.^2;  
    case 'rectangle'  
        a = dim1 .* p.Results.dim2;  
end
```

If you call the function with a nonnumeric third input,

```
myarea = findArea('rectangle',3,'x')
```

MATLAB displays

```
Error using findArea  
Argument 'dim2' failed validation with error:  
Expected input to be one of these types:
```

```
    numeric
```

Instead its type was char.

## Purpose

Check validity of text string

## Syntax

```
validStr = validatestring(str,validStrings)
validStr = validatestring(str,validStrings,argIndex)
validStr = validatestring(str,validStrings,funcName)
validStr =
validatestring(str,validStrings,funcName,varName)
validStr =
validatestring(str,validStrings,funcName,varName,
    argIndex)
```

## Description

`validStr = validatestring(str,validStrings)` checks the validity of text string `str`. If `str` is an unambiguous, case-insensitive match to a string in cell array `validStrings`, the `validatestring` function returns the matching string in `validStr`. Otherwise, MATLAB throws an error and issues a formatted error message.

`validStr = validatestring(str,validStrings,argIndex)` includes the position of the input in your function argument list as part of any generated error messages.

`validStr = validatestring(str,validStrings,funcName)` includes the specified function name in generated error identifiers.

`validStr = validatestring(str,validStrings,funcName,varName)` includes the specified variable name in generated error messages.

`validStr = validatestring(str,validStrings,funcName,varName,argIndex)` includes the specified information in generated error messages or identifiers.

## Input Arguments

### **str**

String to validate, of type `char`.

### **validStrings**

# validatestring

---

Cell array of allowed strings.

## **funcName**

String that specifies the name of the function whose input you are validating. If you specify an empty string, '', the validatestring function ignores the funcname input.

## **varName**

String that specifies the name of the input variable. If you specify an empty string, '', the validatestring function ignores the varName input.

## **argIndex**

Positive integer that specifies the position of the input argument.

## **Output Arguments**

## **validStr**

String that contains the element of validStrings that is an unambiguous, case-insensitive match to str.

| <b>Example – Match 'ball' with . . .</b> | <b>Return Value</b>       | <b>Type of Match</b>                                              |
|------------------------------------------|---------------------------|-------------------------------------------------------------------|
| ball, barn, bell                         | ball                      | Exact match                                                       |
| balloon, barn                            | balloon                   | Partial match (leading characters)                                |
| ballo, balloo, balloon                   | ballo<br>(shortest match) | Multiple partial matches where each string is a subset of another |
| balloon, ballet                          | Error                     | Multiple partial matches to unique strings                        |
| barn, bell                               | Error                     | No match                                                          |

## Examples

Check whether a string is in a set of valid values.

```
str = 'won';
validStrings = {'wind','wonder','when'};

validStr = validatestring(str,validStrings)
```

Because `str` is a partial match to a unique string, this code returns

```
validStr =
    wonder
```

However, if `str` is a partial match to multiple strings, and the strings are not subsets of each other, `validatestring` throws an error and displays a formatted message.

```
str = 'won';
validStrings = {'wonder','wondrous','wonderful'};

validStr = validatestring(str,validStrings)
```

The error message is

Expected argument to match one of these strings:

```
wonder, wondrous, wonderful
```

The input, 'won', matched more than one valid string.

---

Check inputs to a custom function, and include information about the input name and position in generated errors.

```
function a = findArea(shape,ht,wd,units)
    a = 0;
    expectedShapes = {'square','rectangle','triangle'};
    expectedUnits = {'cm','m','in','ft','yds'};
```

# validatestring

---

```
shapeName = validatestring(shape,expectedShapes,mfilename,'Shape',1)
unitAbbrev = validatestring(units,expectedUnits,mfilename,'Units',4)
```

When you call the function with valid input strings,

```
myarea = findArea('rect',10,3,'cm')
```

the function stores the inputs in local variables `shapeName` and `unitAbbrev`:

```
shapeName =
    rectangle
```

```
unitAbbrev =
    cm
```

However, if the inputs are not valid, such as

```
myarea = findArea('circle',10,3,'cm')
```

MATLAB displays

```
Error using findArea
Expected argument 1, Shape, to match one of these strings:
```

```
    square, rectangle, triangle
```

The input, 'circle', did not match any of the valid strings.

The function name is part of the error identifier, so

```
MException.last.identifier
```

returns

```
MATLAB:findArea:unrecognizedStringChoice
```

```

**Purpose** Identify values in containers.Map object

**Syntax**  
`valueSet = values(mapObj)`  
`valueSet = values(mapObj, keySet)`

**Description**  
`valueSet = values(mapObj)` returns all of the values in `mapObj`.  
`valueSet = values(mapObj, keySet)` returns values that correspond to the specified keys.

**Input Arguments**  
**mapObj**  
Object of class `containers.Map`.

**keySet**  
Cell array that specifies keys in `mapObj`.

**Output Arguments**  
**valueSet**  
Cell array containing values from `mapObj`. If you specify `keySet`, the `valueSet` array has the same size and dimensions as `keySet`.

## Examples

### Get All Values in a Map

Create a map, and view all values in the map:

```
myKeys = {'a', 'b', 'c'};  
myValues = [1,2,3];  
mapObj = containers.Map(myKeys,myValues);
```

```
valueSet = values(mapObj)
```

This code returns 1-by-3 cell array `valueSet`:

```
valueSet =  
    [1]    [2]    [3]
```

# containers.Map.values

---

## Get Selected Values in a Map

View the values corresponding to keys a and c in `mapObj`, created in the previous example:

```
keySet = {'a', 'c'};  
valueSet = values(mapObj, keySet)
```

This code returns 1-by-2 cell array `valueSet`:

```
valueSet =  
    [1]    [3]
```

## See Also

**Purpose** Vandermonde matrix

**Syntax** `A = vander(v)`

**Description** `A = vander(v)` returns the Vandermonde matrix whose columns are powers of the vector `v`, that is,  $A(i, j) = v(i)^{(n-j)}$ , where  $n = \text{length}(v)$ .

**Examples** `vander(1:.5:3)`

`ans =`

|         |         |        |        |        |
|---------|---------|--------|--------|--------|
| 1.0000  | 1.0000  | 1.0000 | 1.0000 | 1.0000 |
| 5.0625  | 3.3750  | 2.2500 | 1.5000 | 1.0000 |
| 16.0000 | 8.0000  | 4.0000 | 2.0000 | 1.0000 |
| 39.0625 | 15.6250 | 6.2500 | 2.5000 | 1.0000 |

# var

---

**Purpose** Variance

**Syntax**  
`V = var(X)`  
`V = var(X,1)`  
`V = var(X,w)`  
`V = var(X,w,dim)`

**Description** `V = var(X)` returns the variance of `X` for vectors. For matrices, `var(X)` is a row vector containing the variance of each column of `X`. For `N`-dimensional arrays, `var` operates along the first nonsingleton dimension of `X`. The result `V` is an unbiased estimator of the variance of the population from which `X` is drawn, as long as `X` consists of independent, identically distributed samples.

`var` normalizes `V` by  $N - 1$  if  $N > 1$ , where  $N$  is the sample size. This is an unbiased estimator of the variance of the population from which `X` is drawn, as long as `X` consists of independent, identically distributed samples. For  $N = 1$ , `V` is normalized by 1.

`V = var(X,1)` normalizes by  $N$  and produces the second moment of the sample about its mean. `var(X,0)` is equivalent to `var(X)`.

`V = var(X,w)` computes the variance using the weight vector `w`. The length of `w` must equal the length of the dimension over which `var` operates, and its elements must be nonnegative. If `X(i)` is assumed to have variance proportional to  $1/w(i)$ , then  $V * \text{mean}(w)/w(i)$  is an estimate of the variance of `X(i)`. In other words,  $V * \text{mean}(w)$  is an estimate of variance for an observation given weight 1.

`V = var(X,w,dim)` takes the variance along the dimension `dim` of `X`. Pass in 0 for `w` to use the default normalization by  $N - 1$ , or 1 to use  $N$ .

The variance is the square of the standard deviation (STD).

**Examples** Create a matrix and find the variance along the dimensions.

```
X = [4 -2 1; 9 5 7]
var(X,0,1)
ans =
```

```
12.5000  24.5000  18.0000
```

```
var(X,0,2)
ans =
     9
     4
```

**See Also**

```
corrcoef | cov | mean | median | std
```

# varargin

---

**Purpose** Variable-length input argument list

**Syntax** varargin

**Description** varargin is an input variable in a function definition statement that allows the function to accept any number of input arguments. Specify varargin using lowercase characters, and include it as the last input argument after any explicitly declared inputs. When the function executes, varargin is a 1-by- $N$  cell array, where  $N$  is the number of inputs that the function receives after the explicitly declared inputs.

## Examples **Variable Number of Function Inputs**

Define a function in a file named `varlist.m` that accepts a variable number of inputs and displays the values of each input.

```
function varlist(varargin)
    fprintf('Number of arguments: %d\n',nargin);
    celldisp(varargin)
```

Call `varlist` with several inputs.

```
varlist(ones(3),'some text',pi)
```

```
Number of arguments: 3
```

```
varargin{1} =
     1     1     1
     1     1     1
     1     1     1
```

```
varargin{2} =
some text
```

```
varargin{3} =
3.1416
```

## varargin and Declared Inputs

Define a function in a file named `varlist2.m` that expects inputs `X` and `Y`, and accepts a variable number of additional inputs.

```
function varlist2(X,Y,varargin)
    fprintf('Total number of inputs = %d\n',nargin);

    nVarargs = length(varargin);
    fprintf('Inputs in varargin(%d):\n',nVarargs)
    for k = 1:nVarargs
        fprintf('    %d\n', varargin{k})
    end
```

Call `varlist2` with more than two inputs.

```
varlist2(10,20,30,40,50)
```

```
Total number of inputs = 5
Inputs in varargin(3):
    30
    40
    50
```

# varargout

---

**Purpose** Variable-length output argument list

**Syntax** varargout

**Description** varargout is an output variable in a function definition statement that allows the function to return any number of output arguments. Specify varargout using lowercase characters, and include it as the last output argument after any explicitly declared outputs. When the function executes, varargout is a 1-by- $N$  cell array, where  $N$  is the number of outputs requested after the explicitly declared outputs.

## Examples

### Variable Number of Function Outputs

Define a function in a file named `sizeout.m` that returns an output size vector `s` and a variable number of additional scalar values.

```
function [s,varargout] = sizeout(x)
nout = max(nargout,1) - 1;
s = size(x);
for k=1:nout
    varargout{k} = s(k);
end
```

Output `s` contains the dimensions of the input array `x`. Additional outputs correspond to the individual dimensions within `s`.

Call `sizeout` on a three-dimensional array and request three outputs.

```
[s,rows,cols] = sizeout(rand(4,5,2))
```

```
s =
    4     5     2
```

```
rows =
    4
```

```
cols =
    5
```

# vectorize

---

**Purpose** Vectorize expression

**Syntax** `vectorize(s)`  
`vectorize(f)`

**Description** `vectorize(s)` where `s` is a string expression, inserts a `.` before any `^`, `*` or `/` in `s`. The result is a character string.

`vectorize(f)` where `f` is an inline function object, vectorizes the formula for `f`. The result is the vectorized version of the function.

**See Also** `inline` | `cd` | `dbtype` | `delete` | `dir` | `path` | `what` | `who`

**Purpose**

Version information for MathWorks products

**Syntax**

```
ver
ver product

product_info = ver(product)
```

**Description**

`ver` displays:

- A header containing the current MATLAB product family version number, license number, operating system, and version of Java software for the MATLAB product.
- The version numbers for MATLAB and all other installed MathWorks products.

`ver product` displays, in addition to the header information:

- The current version number for `product`, where `product` is the name of the folder that contains the `Contents.m` file for the product you are inquiring about.

`product_info = ver(product)` returns product information to the structure array, `product_info`.

**Input Arguments****product - product-specific information**

The product or toolbox for which you want to view version information, specified as a string.

To determine the string to use, run the following code, substituting the name of a product function for *toolboxfcn*:

```
n = 'toolboxfcn';
pat = '(?<=^[\\/]toolbox[\\/])(^\\/[\\/]*)';
regexp(which(n), pat, 'match', 'once')
```

## Output Arguments

### **product\_info - product name, version, release, and date**

Product name, version, release, and date, returned as a structure array with these fields: Name, Version, Release, and Date. If a license is a trial version, the value in the Version field is preceded by the letter T

## Examples

### **Version for All Installed Products**

Display version information for all installed products. The output shown here is representative. Your results may differ.

```
ver
```

```
-----  
MATLAB Version 7.14.0.39041 (R2012a)  
MATLAB License Number: 234567  
Operating System: Microsoft Windows 7 Version 6.1 (Build 7600)  
Java Version: Java 1.6.0_17-b04 with Sun Microsystems Inc. Java HotSpot(T
```

```
-----  
MATLAB                               Version 7.14  
Simulink                             Version 8.0  
Control System Toolbox               Version 9.3
```

### **Version for a Particular Product**

Display version information for MATLAB and the Control System Toolbox product. The output shown here is representative. Your results may differ.

1. Determine the product name for Control System Toolbox by setting `n` to the name of a function unique to Control System Toolbox, such as `dss`:

```
n = 'dss';  
pat = '(?<=^[\\/]toolbox[\\/])[^\\/]+';  
regexp(which(n), pat, 'match', 'once')
```

```
ans=  
control
```

2. Specify the value returned in the previous step as an argument to `ver`:

```
ver control
```

```
-----  
MATLAB Version 7.14.0.39041 (R2012a)  
MATLAB License Number: 234567  
Operating System: Microsoft Windows 7 Version 6.1 (Build 7600)  
Java Version: Java 1.6.0_17-b04 with Sun Microsystems Inc. Java HotSpot  
-----  
Control System Toolbox                               Version 9.3
```

### **Structure Containing Version for the MATLAB family of products**

Create a structure containing version information, and then display the structure values. The output shown here is representative. Your results may differ.

```
v=ver;  
for k = 1:length(v)  
    fprintf('%s\n', v(k).Name);  
    fprintf('  Version: %s\n', v(k).Version);  
end
```

```
MATLAB  
  Version: 7.14
```

```
MATLAB Builder JA  
  Version: 2.2.4
```

```
MATLAB Builder NE  
  Version: 4.2
```

```
MATLAB Compiler  
  Version: 4.17
```

```
My Custom Toolbox
Version: 1.0
```

## Structure Containing Version for a Particular Product

Create a structure containing version information for just the Symbolic Math Toolbox™ product. The output shown here is representative. Your results may differ.

1. Determine the product name for Symbolic Math Toolbox by setting `n` to the name of a function unique to Symbolic Math Toolbox, such as `sym`:

```
n = 'sym';
pat = '(?<=^[\\/]toolbox[\\/])[^\\/]+';
regexp(which(n), pat, 'match', 'once')
```

```
ans =
```

```
symbolic
```

2. Specify the value returned in the previous step as an argument to `ver`:

```
v = ver('symbolic')
```

```
v =
```

```
    Name: 'Symbolic Math Toolbox'
  Version: '5.8'
  Release: '(R2012a)'
    Date: '14-Sep-2011'
```

## Concepts

- “Information About your Installation”
- “Create Help Summary Files (Contents.m)”

**Purpose** Source control actions (Windows platforms)

**Syntax**

```
verctrl('action',{filename1,'filename2',...},0)
result=verctrl('action',{filename1,'filename2',...},0)
verctrl('action','filename',0)
result=verctrl('isdiff','filename',0)
list = verctrl('all_systems')
```

**Description** `verctrl('action',{filename1,'filename2',...},0)` performs the source control operation specified by `'action'` for a single file or multiple files. Enter one file as a string; specify multiple files using a cell array of strings. Use the full paths for each file name and include the extensions. Specify `0` as the last argument. Complete the resulting dialog box to execute the operation. Available values for `'action'` are as follows:

| <b>action Argument</b> | <b>Purpose</b>                                                                                                                 |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| 'add'                  | Adds files to the source control system. Files can be open in the Editor or closed when added.                                 |
| 'checkin'              | Checks files into the source control system, storing the changes and creating a new version.                                   |
| 'checkout'             | Retrieves files for editing.                                                                                                   |
| 'get'                  | Retrieves files for viewing and compiling, but not editing. When you open the files, they are labeled as read-only.            |
| 'history'              | Displays the history of files.                                                                                                 |
| 'remove'               | Removes files from the source control system. It does not delete the files from disk, but only from the source control system. |

# verctrl

---

| <b>action Argument</b> | <b>Purpose</b>                                                                                                                                                               |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'runsc'                | Starts the source control system. The file name can be an empty string.                                                                                                      |
| 'uncheckout'           | Cancels a previous checkout operation and restores the contents of the selected files to the precheckout version. All changes made to the files since the checkout are lost. |

`result=verctrl('action',{'filename1','filename2',...},0)` performs the source control operation specified by '*action*' on a single file or multiple files. The action can be any one of: 'add', 'checkin', 'checkout', 'get', 'history', or 'undocheckout'. `result` is a logical 1 (true) when you complete the operation by clicking **OK** in the resulting dialog box, and is a logical 0 (false) when you abort the operation by clicking **Cancel** in the resulting dialog box.

`verctrl('action','filename',0)` performs the source control operation specified by '*action*' for a single file. Use the absolute path for '*filename*'. Specify 0 as the last argument. Complete any resulting dialog boxes to execute the operation. Available values for '*action*' are as follows:

| <b>action Argument</b> | <b>Purpose</b>                                                                                                      |
|------------------------|---------------------------------------------------------------------------------------------------------------------|
| 'showdiff'             | Displays the differences between a file and the latest checked in version of the file in the source control system. |
| 'properties'           | Displays the properties of a file.                                                                                  |

`result=verctrl('isdiff','filename',0)` compares `filename` with the latest checked in version of the file in the source control system. `result` is a logical 1 (true) when the files are different, and is a logical 0

(false) when the files are identical. Use the full path for 'filename'. Specify 0 as the last argument.

`list = verctrl('all_systems')` displays in the Command Window a list of all source control systems installed on your computer.

## Examples

### Check In a File

Check in D:\file1.ext to the source control system:

```
result = verctrl('checkin','D:\file1.ext', 0)
```

This opens the Check in file(s) dialog box. Click **OK** to complete the check in. MATLAB displays

```
result = 1
```

indicating the checkin was successful.

### Add Files to the Source Control System

Add D:\file1.ext and D:\file2.ext to the source control system.

```
verctrl('add',{ 'D:\file1.ext', 'D:\file2.ext' }, 0)
```

This opens the Add to source control dialog box. Click **OK** to complete the operation.

### Display the Properties of a File

Display the properties of D:\file1.ext.

```
verctrl('properties','D:\file1.ext', 0)
```

This opens the source control properties dialog box for your source control system. The function is complete when you close the properties dialog box.

### Show Differences for a File

To show the differences between the version of file1.ext that you just edited and saved, with the last version in source control, run

```
verctrl('showdiff','D:\file1.ext',0)
```

MATLAB displays differences dialog boxes and results specific to your source control system. After checking in the file, if you run this statement again, MATLAB displays

```
??? The file is identical to latest version under source control.
```

## List All Installed Source Control Systems

To view all of the source control systems installed on your computer, type

```
list = verctrl ('all_systems')
```

MATLAB displays all the source control systems currently installed on your computer. For example:

```
list =  
'Microsoft Visual SourceSafe'  
'ComponentSoftware RCS'
```

## See Also

`checkin` | `checkout` | `undoccheckout` | `cmopts`

## How To

- “Source Control Interface on Microsoft Windows”

**Purpose** Compare toolbox version to specified version string

**Syntax** `verLessThan(toolbox, version)`

**Description** `verLessThan(toolbox, version)` returns logical 1 (true) if the version of the toolbox specified by the string `toolbox` is older than the version specified by the string `version`, and logical 0 (false) otherwise. Use this function when you want to write code that can run across multiple versions of the MATLAB software, when there are differences in the behavior of the code in the different versions.

The `toolbox` argument is a string enclosed within single quotation marks that contains the name of a MATLAB toolbox folder. The `version` argument is a string enclosed within single quotation marks that contains the version to compare against. This argument must be in the form `major[.minor[.revision]]`, such as 7, 7.1, or 7.0.1. If `toolbox` does not exist, MATLAB generates an error.

To specify `toolbox`, find the folder that holds the `Contents.m` file for the toolbox and use that folder name. To see a list of all toolbox folder names, enter the following statement in the MATLAB Command Window:

```
dir([matlabroot '/toolbox'])
```

**Tips** The `verLessThan` function is available with MATLAB Version 7.4 and subsequent versions. If you are running a version of MATLAB prior to 7.4, you can download the `verLessThan` function from the following MathWorks Technical Support solution. You must be running MATLAB Version 6.0 or higher to use this function:

<http://www.mathworks.com/support/solutions/data/1-38LI61.html?solution>

**Examples** These examples illustrate usage of the `verLessThan` function.

### **Example 1 – Checking For the Minimum Required Version**

```
if verLessThan('simulink', '4.0')
    error('Simulink 4.0 or higher is required.');
```

# verLessThan

---

```
end
```

## Example 2 – Choosing Which Code to Run

```
if verLessThan('matlab', '7.0.1')
% -- Put code to run under MATLAB 7.0.0 and earlier here --
else
% -- Put code to run under MATLAB 7.0.1 and later here --
end
```

## Example 3 – Looking Up the Folder Name

Find the name of the Data Acquisition Toolbox folder:

```
dir([matlabroot '/toolbox/d*'])

      daq      database      des      distcomp      dotnetbuilder
dastudio  datafeed    dials      dml      dspblks
```

Use the toolbox folder name, daq, to compare the Data Acquisition Toolbox software version that MATLAB is currently running against version number 3:

```
verLessThan('daq', '3')
ans =
     1
```

| <b>Purpose</b>     | Version number for MATLAB and libraries                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Syntax</b>      | <pre>version version -date version -description version -release version -java v = version('-versionOption') [v d] = version</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b> | <p>version returns in ans the version and release number for the MATLAB software currently running.</p> <p>version -date returns in ans the release date for the MATLAB software.</p> <p>version -description returns in ans a description of the version. Usually, the description is for special versions, such as beta versions.</p> <p>version -release returns in ans the release number for the MATLAB software currently running.</p> <p>version -java returns in ans the version of the Sun Microsystems™ JVM software that MATLAB is using.</p> <p>v = version('-versionOption'), where <i>versionOption</i> is one of the above option strings, is an alternate form of the syntax.</p> <p>[v d] = version returns the version and release number in string v and the release date in string d. No input arguments are allowed in this syntax.</p> |
| <b>Examples</b>    | <p>Display the version:</p> <pre>version</pre> <p>MATLAB returns:</p> <pre>7.9.0.2601 (R2009b)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

# version

---

---

Display the release, prefaced by a descriptor:

```
['Release R' version('-release')]
```

MATLAB returns:

```
Release R2009b
```

---

Return release version and release date as separate strings:

```
[v d] = version
```

returns:

```
v =  
7.12.0.39132 (R2011a)
```

```
d =  
December 1, 2010
```

---

View the Java version:

```
version -java
```

MATLAB returns:

```
Java 1.6.0_17-b04 with Sun Microsystems Inc. Java HotSpot(TM) 64-Bit Serv
```

## How To

computer | ver | verlessthan

- “Check for Software Updates”

**Purpose** Concatenate arrays vertically

**Syntax** `C = vertcat(A1, A2, ...)`

**Description** `C = vertcat(A1, A2, ...)` vertically concatenates matrices `A1`, `A2`, and so on. All matrices in the argument list must have the same number of columns.

`vertcat` concatenates N-dimensional arrays along the first dimension. The remaining dimensions must match.

`vertcat` also concatenates character strings. Each string being concatenated must have the same number of characters.

MATLAB calls `C = vertcat(A1, A2, ...)` for the syntax `C = [A1; A2; ...]` when any of `A1`, `A2`, etc. is an object.

**Tips** For information on combining unlike integer types, integers with nonintegers, cell arrays with non-cell arrays, or empty matrices with other elements, see “Valid Combinations of Unlike Classes”.

**Examples** Create a 5-by-3 matrix, `A`, and a 3-by-3 matrix, `B`. Then vertically concatenate `A` and `B`.

```
A = magic(5);           % Create 5-by-3 matrix, A
A(:, 4:5) = []
```

```
A =
```

```
    17    24     1
    23     5     7
     4     6    13
    10    12    19
    11    18    25
```

```
B = magic(3)*100       % Create 3-by-3 matrix, B
```

## vertcat

---

```
B =  
  
    800    100    600  
    300    500    700  
    400    900    200  
  
C = vertcat(A,B)           % Vertically concatenate A and B  
  
C =  
  
    17     24     1  
    23     5     7  
     4     6    13  
    10    12    19  
    11    18    25  
    800    100    600  
    300    500    700  
    400    900    200
```

### See Also

horzcat | cat

### How To

- “Redefining Concatenation for Your Class”

**Purpose** Vertical concatenation for tscollection objects

**Syntax** `tsc = vertcat(tsc1,tsc2,...)`

**Description** `tsc = vertcat(tsc1,tsc2,...)` performs  
`tsc = [tsc1;tsc2;...]`

This operation appends tscollection objects. The time vectors must not overlap. The last time in tsc1 must be earlier than the first time in tsc2. All tscollection objects to be concatenated must have the same timeseries members.

**See Also** `horzcat (tscollection) | tscollection`

# TriRep.vertexAttachments

---

**Purpose** Return simplices attached to specified vertices

**Syntax** `SI = vertexAttachments(TR, VI)`

**Description** `SI = vertexAttachments(TR, VI)` returns the vertex-to-simplex information for the specified vertices `VI`. For 2-D triangulations in MATLAB, the triangles `SI` are arranged in counter-clockwise order around the attached vertex `VI`.

**Input Arguments**

|    |                                                                                                                                                                                                                                                                                                                                         |
|----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TR | Triangulation representation                                                                                                                                                                                                                                                                                                            |
| VI | VI is a column vector of indices into the array of points representing the vertex coordinates, <code>TR.X</code> . The simplices associated with vertex <code>i</code> are the <code>i</code> 'th entry in the cell array. If <code>VI</code> is not specified the vertex-simplex information for the entire triangulation is returned. |

**Output Arguments**

|    |                                                                                                                                                                                                                                                                                                              |
|----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SI | Cell array of indices of the simplices attached to a vertex. A cell array is used to store the information because the number of simplices associated with each vertex can vary. The simplices associated with vertex <code>i</code> are in the <code>i</code> 'th entry in the cell array <code>SI</code> . |
|----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Definitions** A simplex is a triangle/tetrahedron or higher dimensional equivalent.

## **Examples** **Example 1**

Load a 2-D triangulation and use `TriRep` to compute the vertex-to-triangle relations.

```
load trimesh2d
trep = TriRep(tri, x, y);
```

Find the indices of the tetrahedra attached to the first vertex:

```
Tv = vertexAttachments(trep, 1)
Tv{:}
```

## Example 2

Perform a direct query of a 2-D triangulation created using DelaunayTri.

```
x = rand(20,1);
y = rand(20,1);
dt = DelaunayTri(x,y);
```

Find the triangles attached to vertex 5:

```
t = vertexAttachments(dt,5);
```

Plot the triangulation:

```
triplot(dt);
hold on;
```

Plot the triangles attached to vertex 5 (in red):

```
triplot(dt(t{:},:),x,y,'Color','r');
hold off;
```

# TriRep.vertexAttachments

For more information, see “Supported Video File Formats” in the MATLAB Data Import and Export documentation.

**Construction** `obj = VideoReader(filename)` constructs `obj` to read video data from the file named `filename`. If it cannot construct the object for any reason, `VideoReader` generates an error.

`obj = VideoReader(filename,Name,Value)` constructs the object with additional options specified by one or more `Name,Value` pair

# VideoReader

---

arguments. Name is 'Tag' or 'UserData' and Value is the corresponding value. You can specify two name and value pair arguments in any order as Name1,Value1,Name2,Value2.

## Input Arguments

### filename

String in single quotation marks that specifies the video file to read. The VideoReader constructor searches for the file on the MATLAB path.

### Name-Value Pair Arguments

Optional comma-separated pairs of Name,Value arguments, where Name is 'Tag' or 'UserData' and Value is the corresponding value. You can specify two name and value pair arguments in any order as Name1,Value1,Name2,Value2.

### Tag

String that identifies the object.

**Default:** ''

### UserData

Generic field for data of any class that you want to add to the object.

**Default:** []

## Properties

All properties are read only except Tag and UserData.

### BitsPerPixel

Bits per pixel of the video data.

### Duration

Total length of the file in seconds.

**FrameRate**

Frame rate of the video in frames per second.

**Height**

Height of the video frame in pixels.

**Name**

Name of the file associated with the object.

**NumberOfFrames**

Total number of frames in the video stream.

Some files store video at a variable frame rate, including many Windows Media Video files. For these files, `VideoReader` cannot determine the number of frames until you read the last frame. When you construct the object, `VideoReader` returns a warning and does not set the `NumberOfFrames` property.

To count the number of frames in a variable frame rate file, use the `read` method to read the last frame of the file. For example:

```
vidObj = VideoReader('varFrameRateFile.wmv');  
lastFrame = read(vidObj, inf);  
numFrames = vidObj.NumberOfFrames;
```

For more information, see “Reading Variable Frame Rate Video” in the MATLAB Data Import and Export documentation..

**Path**

String containing the full path to the file associated with the reader.

**Tag**

String that identifies the object.

**Default:** ''

# VideoReader

---

## Type

Class name of the object: 'VideoReader'.

## UserData

Generic field for data of any class that you want to add to the object.

**Default:** []

## VideoFormat

String indicating the MATLAB representation of the video format, such as 'RGB24'.

## Width

Width of the video frame in pixels.

## Methods

|                |                                               |
|----------------|-----------------------------------------------|
| get            | Query property values for video reader object |
| getFileFormats | File formats that VideoReader supports        |
| read           | Read video frame data from file               |
| set            | Set property values for video reader object   |

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB Programming Fundamentals documentation.

## Examples

Construct a VideoReader object for the example movie file xylophone.mpg and view its properties:

```
xyloObj = VideoReader('xylophone.mpg', 'Tag', 'My reader object');  
get(xyloObj)
```

Read and play back the movie file `xylophone.mpg`:

```
xyloObj = VideoReader('xylophone.mpg');

nFrames = xyloObj.NumberOfFrames;
vidHeight = xyloObj.Height;
vidWidth = xyloObj.Width;

% Preallocate movie structure.
mov(1:nFrames) = ...
    struct('cdata', zeros(vidHeight, vidWidth, 3, 'uint8'),...
          'colormap', []);

% Read one frame at a time.
for k = 1 : nFrames
    mov(k).cdata = read(xyloObj, k);
end

% Size a figure based on the video's width and height.
hf = figure;
set(hf, 'position', [150 150 vidWidth vidHeight])

% Play back the movie once at the video's frame rate.
movie(hf, mov, 1, xyloObj.FrameRate);
```

## How To

- “Read Video Files”

# VideoWriter

---

## Purpose

Write video files

## Description

Use the `VideoWriter` function with the `open`, `writeVideo`, and `close` methods to create video files from figures, still images, or MATLAB movies. `VideoWriter` can create AVI and Motion JPEG 2000 files on all platforms, and MPEG-4 files on Windows 7 platforms. `VideoWriter` supports files larger than 2 GB, which is the limit for `avifile`.

To set video properties, `VideoWriter` includes predefined *profiles* such as 'Uncompressed AVI' or 'MPEG-4'.

## Construction

`writerObj = VideoWriter(filename)` constructs a `VideoWriter` object to write video data to a compressed AVI file.

`writerObj = VideoWriter(filename,profile)` applies a set of properties tailored to a specific file format (such as 'MPEG-4' or 'Uncompressed AVI') to a `VideoWriter` object.

## Input Arguments

### filename

String enclosed in single quotation marks that specifies the name of the file to create.

`VideoWriter` supports these file extensions:

|                                        |                                      |
|----------------------------------------|--------------------------------------|
| <code>.avi</code>                      | AVI file                             |
| <code>.mj2</code>                      | Motion JPEG 2000 file                |
| <code>.mp4</code> or <code>.m4v</code> | MPEG-4 file (Windows 7 systems only) |

If you do not specify the file extension, `VideoWriter` appends the extension `.avi`, `.mj2` or `.mp4`, depending on the `profile`. If you do not specify a value for `profile`, then `VideoWriter` creates an AVI file with the extension `.avi`.

### profile

String enclosed in single quotation marks that describes the type of file to create. Specifying a profile sets default values for video properties such as `VideoCompressionMethod`. Possible values:

|                    |                                                                     |
|--------------------|---------------------------------------------------------------------|
| 'Archival'         | Motion JPEG 2000 file with lossless compression                     |
| 'Motion JPEG AVI'  | Compressed AVI file using Motion JPEG codec                         |
| 'Motion JPEG 2000' | Compressed Motion JPEG 2000 file                                    |
| 'MPEG-4'           | Compressed MPEG-4 file with H.264 encoding (Windows 7 systems only) |
| 'Uncompressed AVI' | Uncompressed AVI file with RGB24 video                              |

**Default:** 'Motion JPEG AVI'

## Properties

### ColorChannels

Number of color channels in each output video frame. (Read-only)

AVI and MPEG-4 files have three color channels (RGB). The number of channels for Motion JPEG 2000 files depends on the input data to the `writeVideo` method: one for monochrome image data, three for color data.

### CompressionRatio

Number greater than 1 that specifies the target ratio between the number of bytes in the input image and the number of bytes in the compressed image. The data is compressed as much as possible, up to the specified target.

Only available for objects associated with Motion JPEG 2000 files. After you call `open`, you cannot change the `CompressionRatio` value. If you previously set `LosslessCompression` to `true`, setting `CompressionRatio` generates an error.

# VideoWriter

---

**Default:** 10

## **Duration**

Scalar value specifying the duration of the file in seconds.  
(Read-only)

## **FileFormat**

String specifying the type of file to write: 'avi', 'mp4', or 'mj2'.  
(Read-only)

## **Filename**

String specifying the name of the file. (Read-only)

## **FrameCount**

Number of frames written to the video file. (Read-only)

## **FrameRate**

Rate of playback for the video in frames per second. After you call `open`, you cannot change the `FrameRate` value.

**Default:** 30

## **Height**

Height of each video frame in pixels. The `writeVideo` method sets values for `Height` and `Width` based on the dimensions of the first frame. (Read-only)

MPEG-4 files require frame dimensions that are divisible by two. If the input frame height for an MPEG-4 file is not an even number, `VideoWriter` pads the frame with a row of black pixels at the bottom.

## **LosslessCompression**

Boolean value (logical `true` or `false`) only available for objects associated with Motion JPEG 2000 files. If `true`:

- The `writeVideo` method uses reversible mode so that the decompressed data is identical to the input data.
- `VideoWriter` ignores any specified value for `CompressionRatio`.

After you call `open`, you cannot change the `LosslessCompression` value.

**Default:** `false` for the 'Motion JPEG 2000' profile, `true` for the 'Archival' profile

## **MJ2BitDepth**

Number of least significant bits in the input image data, from 1 to 16.

Only available for objects associated with Motion JPEG 2000 files. If you do not specify a value before calling the `open` method, `VideoWriter` sets the bit depth based on the input data type. For example, if the input data to `writeVideo` is an array of `uint8` or `int8` values, `MJ2BitDepth` is 8.

## **Path**

String specifying the fully qualified path. (Read-only)

## **Quality**

Number from 0 through 100. Higher quality numbers result in higher video quality and larger file sizes. Lower quality numbers result in lower video quality and smaller file sizes.

Only available for objects associated with the MPEG-4 or Motion JPEG AVI profile. After you call `open`, you cannot change the `Quality` value.

**Default:** 75

## **VideoBitsPerPixel**

Number of bits per pixel in each output video frame. (Read-only)

AVI and MPEG-4 files have 24 bits per pixel (8 bits for each of three color bands).

For Motion JPEG 2000 files, the number of bits per pixel depends on the value of `MJ2BitDepth` and the number of bands of image data. For example, if the input data to `writeVideo` is a three-dimensional array of `uint16` or `int16` values, the default value of `MJ2BitDepth` is 16, and `VideoBitsPerPixel` is 48 (three times the bit depth).

## VideoCompressionMethod

String indicating the type of video compression: 'None', 'H.264', 'Motion JPEG', or 'Motion JPEG 2000'. (Read-only)

## VideoFormat

String indicating the MATLAB representation of the video format. (Read-only)

For AVI or MPEG-4 files, `VideoFormat` is 'RGB24'.

For Motion JPEG 2000 files, `VideoFormat` depends on the value of `MJ2BitDepth` and the format of the input image data to the `writeVideo` method. For example, if you do not specify the `MJ2BitDepth` property, `VideoWriter` sets the format as shown in this table.

| Image Data                       | VideoFormat     |
|----------------------------------|-----------------|
| Single-band <code>uint8</code>   | 'Mono8'         |
| Single-band <code>int8</code>    | 'Mono8 Signed'  |
| Single-band <code>uint16</code>  | 'Mono16'        |
| Single-band <code>int16</code>   | 'Mono16 Signed' |
| Three-banded <code>uint8</code>  | 'RGB24'         |
| Three-banded <code>int8</code>   | 'RGB24 Signed'  |
| Three-banded <code>uint16</code> | 'RGB48'         |
| Three-banded <code>int16</code>  | 'RGB48 Signed'  |

## Width

Width of each video frame in pixels. The `writeVideo` method sets values for `Height` and `Width` based on the dimensions of the first frame. (Read-only)

MPEG-4 files require frame dimensions that are divisible by two. If the input frame width for an MPEG-4 file is not an even number, `VideoWriter` pads the frame with a column of black pixels along the right side.

## Methods

|                          |                                                                      |
|--------------------------|----------------------------------------------------------------------|
| <code>close</code>       | Close file after writing video data                                  |
| <code>getProfiles</code> | List profiles and file formats supported by <code>VideoWriter</code> |
| <code>open</code>        | Open file for writing video data                                     |
| <code>writeVideo</code>  | Write video data to file                                             |

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB Programming Fundamentals documentation](#).

## Examples

### Object Properties

Construct a `VideoWriter` object and view its properties.

```
writerObj = VideoWriter('newfile.avi')
```

Set the frame rate to 60 frames per second.

```
writerObj.FrameRate = 60;
```

### AVI File from Animation

Write a sequence of frames to a compressed AVI file, `peaks.avi`.

Prepare the new file.

```
writerObj = VideoWriter('peaks.avi');
```

# VideoWriter

---

```
open(writerObj);
```

Generate initial data and set axes and figure properties.

```
Z = peaks; surf(Z);  
axis tight  
set(gca, 'nextplot', 'replacechildren');  
set(gcf, 'Renderer', 'zbuffer');
```

Setting the `Renderer` property to `zbuffer` or `Painters` works around limitations of `getframe` with the OpenGL renderer on some Windows systems.

Create a set of frames and write each frame to the file.

```
for k = 1:20  
    surf(sin(2*pi*k/20)*Z,Z)  
    frame = getframe;  
    writeVideo(writerObj,frame);  
end  
  
close(writerObj);
```

## See Also

[VideoReader](#) | [mmfileinfo](#)

**Purpose**

Viewpoint specification

**Syntax**

```
view(az,e1)
view([az,e1])
view([x,y,z])
view(2)
view(3)
view(ax,...)
[az,e1] = view
```

**Description**

The position of the viewer (the viewpoint) determines the orientation of the axes. You specify the viewpoint in terms of azimuth and elevation, or by a point in three-dimensional space.

`view(az,e1)` and `view([az,e1])` set the viewing angle for a three-dimensional plot. The azimuth, `az`, is the horizontal rotation about the  $z$ -axis as measured in degrees from the negative  $y$ -axis. Positive values indicate counterclockwise rotation of the viewpoint. `e1` is the vertical elevation of the viewpoint in degrees. Positive values of elevation correspond to moving above the object; negative values correspond to moving below the object.

`view([x,y,z])` sets the viewpoint to the Cartesian coordinates  $x$ ,  $y$ , and  $z$ . The magnitude of  $(x,y,z)$  is ignored.

`view(2)` sets the default two-dimensional view, `az = 0`, `e1 = 90`.

`view(3)` sets the default three-dimensional view, `az = 37.5`, `e1 = 30`.

`view(ax,...)` uses axes `ax` instead of the current axes.

`[az,e1] = view` returns the current azimuth and elevation.

**Tips**

Azimuth is a polar angle in the  $x$ - $y$  plane, with positive angles indicating counterclockwise rotation of the viewpoint. Elevation is the angle above (positive angle) or below (negative angle) the  $x$ - $y$  plane.

This diagram illustrates the coordinate system. The arrows indicate positive directions.

# view

---

## Examples

View the object from directly overhead.

```
az = 0;  
el = 90;  
view(az, el);
```

Set the view along the  $y$ -axis, with the  $x$ -axis extending horizontally and the  $z$ -axis extending vertically in the figure.

```
view([0 0]);
```

Rotate the view about the  $z$ -axis by  $180^\circ$ .

```
az = 180;  
el = 90;  
view(az, el);
```

**See Also**

[hgtransform](#) | [rotate3d](#) | [CameraPosition](#) | [CameraTarget](#) | [CameraViewAngle](#) | [Projection](#)

**How To**

- “View Overview”
-

# viewmtx

---

**Purpose** View transformation matrices

**Syntax**

```
viewmtx  
T = viewmtx(az,e1)  
T = viewmtx(az,e1,phi)  
T = viewmtx(az,e1,phi,xc)
```

**Description** viewmtx computes a 4-by-4 orthographic or perspective transformation matrix that projects four-dimensional homogeneous vectors onto a two-dimensional view surface (e.g., your computer screen).

T = viewmtx(az,e1) returns an *orthographic* transformation matrix corresponding to azimuth az and elevation e1. az is the azimuth (i.e., horizontal rotation) of the viewpoint in degrees. e1 is the elevation of the viewpoint in degrees. This returns the same matrix as the commands

```
view(az,e1)  
T = view
```

but does not change the current view.

T = viewmtx(az,e1,phi) returns a *perspective* transformation matrix. phi is the perspective viewing angle in degrees. phi is the subtended view angle of the normalized plot cube (in degrees) and controls the amount of perspective distortion.

| Phi        | Description                |
|------------|----------------------------|
| 0 degrees  | Orthographic projection    |
| 10 degrees | Similar to telephoto lens  |
| 25 degrees | Similar to normal lens     |
| 60 degrees | Similar to wide-angle lens |

T = viewmtx(az,e1,phi,xc) returns the perspective transformation matrix using xc as the target point within the normalized plot cube (i.e., the camera is looking at the point xc). xc is the target point that is the

center of the view. You specify the point as a three-element vector,  $xc = [xc, yc, zc]$ , in the interval  $[0,1]$ . The default value is  $xc = [0,0,0]$ .

A four-dimensional homogenous vector is formed by appending a 1 to the corresponding three-dimensional vector. For example,  $[x, y, z, 1]$  is the four-dimensional vector corresponding to the three-dimensional point  $[x, y, z]$ .

## Examples

Determine the projected two-dimensional vector corresponding to the three-dimensional point  $(0.5,0.0,-3.0)$  using the default view direction. Note that the point is a column vector.

```
A = viewmtx(-37.5,30);
x4d = [.5 0 -3 1]';
x2d = A*x4d;
x2d = x2d(1:2)
x2d =
    0.3967
   -2.4459
```

These vectors trace the edges of a unit cube:

```
x = [0 1 1 0 0 0 1 1 0 0 1 1 1 1 0 0];
y = [0 0 1 1 0 0 0 1 1 0 0 0 1 1 1 1];
z = [0 0 0 0 0 1 1 1 1 1 1 1 0 0 1 1];
```

Transform the points in these vectors to the screen, then plot the object.

```
A = viewmtx(-37.5,30);
[m,n] = size(x);
x4d = [x(:),y(:),z(:),ones(m*n,1)]';
x2d = A*x4d;
x2 = zeros(m,n); y2 = zeros(m,n);
x2(:) = x2d(1,:);
y2(:) = x2d(2,:);
figure
plot(x2,y2)
```

# viewmtx

Use a perspective transformation with a 25 degree viewing angle:

```
A = viewmtx(-37.5,30,25);  
x4d = [.5 0 -3 1]';  
x2d = A*x4d;  
x2d = x2d(1:2)/x2d(4) % Normalize  
x2d =  
    0.1777  
   -1.8858
```

Transform the cube vectors to the screen and plot the object:

```
figure  
A = viewmtx(-37.5,30,25);
```

```
[m,n] = size(x);  
x4d = [x(:),y(:),z(:),ones(m*n,1)]';  
x2d = A*x4d;  
x2 = zeros(m,n); y2 = zeros(m,n);  
x2(:) = x2d(1,:)./x2d(4,:);  
y2(:) = x2d(2,:)./x2d(4,:);  
plot(x2,y2)
```

## Tutorials

- “Defining Scenes with Cameras”

# visdiff

---

**Purpose** Compare two text files, MAT-Files, binary files, Zip files, or folders

**Syntax** `visdiff('fname1', 'fname2')`  
`visdiff('filename1', 'filename2', 'type')`

**Description** `visdiff('fname1', 'fname2')` opens the Comparison Tool and presents the differences between the two files or folders. Either ensure that the two files or folders appear on the MATLAB path, or provide the full path for each file or folder. You can compare files or any combination of folders, zip files, or Simulink manifests.

If you have Simulink Report Generator™ software, you can select a pair of Simulink models (.mdl files) to compare XML text files generated from them.

`visdiff('filename1', 'filename2', 'type')` opens the Comparison Tool and presents the differences between the two files using the specified comparison type. *type* can be 'text' or 'binary'. If you do not specify *type*, `visdiff` creates the default comparison type for your selected files. The *type* option does not apply when comparing folders.

If there are multiple comparison types available for your selections (e.g., text, binary, file list, or XML comparison), you can create a new comparison and choose a different comparison type.

**1** In the Comparison Tool, click the New comparison button.

The dialog box Select Files or Folders for Comparison opens and shows your previous comparison selections in the drop-down lists.

**2** Change the comparison type and click **Compare**.

## Examples

### Specifying Files or Folders to Compare

The `visdiff` function accepts fully qualified file names, relative file names, or names of files on the MATLAB path.

If the files you want to compare appear on the MATLAB path or in the current folder, you can specify the file names without the full path, for example:

```
visdiff('lengthofline.m', 'lengthofline2.m')
```

or

```
visdiff('lengthofline', 'lengthofline2')
```

If the files you want to compare are not on the path, either specify the full path to each file, or add the folders to the path.

For example, to specify the fully qualified file names to compare two example files:

```
visdiff(fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'gatlin.mat'), ...  
fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'gatlin2.mat'))
```

Specify the full path to files as follows:

```
visdiff('C:\Work\comp\lengthofline.m', 'C:\Work\comp\lengthofline2.m')
```

You can specify paths to files relative to the current folder. For the preceding example, if the current folder is `Work`, then the relative paths are:

```
visdiff('comp\lengthofline.m', 'comp\lengthofline2.m')
```

### Compare Two Text Files

To view a comparison of the two example files, `lengthofline.m` and `lengthofline2.m`:

```
visdiff(fullfile(matlabroot, 'help', 'techdoc', 'matlab_env', ...  
'examples', 'lengthofline.m'), fullfile(matlabroot, 'help', ...
```

```
'techdoc','matlab_env','examples','lengthofline2.m'))
```

For information about using the report features, see “Comparing Text Files”.

---

**Note** If the text files you compare are XML files, you see different results if you have MATLAB Report Generator installed. For details, see “Comparing Files and Folders”.

---

## Compare Two MAT-Files

To compare two example files:

```
visdiff(fullfile(matlabroot,'toolbox','matlab','demos','gatlin.mat'), ...  
fullfile(matlabroot,'toolbox','matlab','demos','gatlin2.mat'))
```

For information about the report features, see “Comparing MAT-Files”.

## Compare Two Binary Files

The following example code adds a folder containing two MEX-files to the MATLAB path, and then compares the files:

```
addpath([matlabroot '\extern\examples\shrlib'])  
visdiff('shrlibsample.mexw32', 'yprime.mexw32')
```

The Comparison Tool opens and indicates that the files are different, but does not provide details about the differences.

For more information on binary comparisons, see “Comparing Binary Files”.

## Compare Two Folders or Zip Files

You can perform file list comparisons for any combinations of folders and zip files. To view an example folder comparison and instructions for using the report features, see “Comparing Folders and Zip Files”.

## Compare Files and Specify Type

To compare two example text files and specify comparison type as binary:

```
visdiff(fullfile(matlabroot,'help','techdoc','matlab_env',...  
'examples','lengthofline.m'), fullfile(matlabroot,'help',...  
'techdoc','matlab_env','examples','lengthofline2.m'), 'binary')
```

If you do not specify type, `visdiff` creates the default comparison type for your selected files, in this case, text comparison. By changing to the binary comparison type you could examine differences such as end-of-line characters.

Similarly, when you compare XML files without specifying type, you get a hierarchical XML comparison report. If instead you want a text or binary comparison, you can specify "text" or "binary" comparison types to see more details. When you compare zip files, the default comparison type is a file list comparison, and you might want to specify a binary comparison instead.

## Alternatives

As an alternative to the `visdiff` function, compare files and folders using any of these GUI methods:

- From the Current Folder browser:
  - Select a file or folder. Right-click the file or folder, and select **Compare Against**.
  - For two files or subfolders in the same folder, select the files or folders. Then, right-click, and select **Compare Selected Files/Folders**.
- From the MATLAB desktop, select **Desktop > Comparison Tool**, and then select the files or folders to compare.
- If you have a file open in the Editor, select **Tools > Compare Against**. You can use the Editor options browse, **Autosave Version**, or **Compare Against Version on Disk**.

## How To

- “Comparing Files and Folders”

## Purpose

Coordinate and color limits for volume data

## Syntax

```
lims = volumebounds(X,Y,Z,V)
lims = volumebounds(X,Y,Z,U,V,W)
lims = volumebounds(V), lims = volumebounds(U,V,W)
```

## Description

`lims = volumebounds(X,Y,Z,V)` returns the x, y, z, and color limits of the current axes for scalar data. `lims` is returned as a vector:

```
[xmin xmax ymin ymax zmin zmax cmin cmax]
```

You can pass this vector to the `axis` command.

`lims = volumebounds(X,Y,Z,U,V,W)` returns the x, y, and z limits of the current axes for vector data. `lims` is returned as a vector:

```
[xmin xmax ymin ymax zmin zmax]
```

`lims = volumebounds(V)`, `lims = volumebounds(U,V,W)` assumes X, Y, and Z are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p] = size(V)`.

## Examples

This example uses `volumebounds` to set the axis and color limits for an isosurface generated by the flow function.

```
[x y z v] = flow;
p = patch(isosurface(x,y,z,v,-3));
isonormals(x,y,z,v,p)
daspect([1 1 1])
isocolors(x,y,z,flipdim(v,2),p)
shading interp
axis(volumebounds(x,y,z,v))
view(3)
camlight
lighting phong
```

# volumebounds

---

## See Also

`isosurface` | `streamslice`

**Purpose** Voronoi diagram

---

**Note** Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `voronoi`.

---

**Syntax**

```
voronoi(x,y)
voronoi(x,y,TRI)
voronoi(dt)
voronoi(AX,...)
voronoi(...,'LineStyle')
h = voronoi(...)
[vx,vy] = voronoi(...)
```

**Description**

`voronoi(x,y)` plots the bounded cells of the Voronoi diagram for the points `x,y`. Lines-to-infinity are approximated with an arbitrarily distant endpoint.

`voronoi(x,y,TRI)` uses the triangulation `TRI` instead of computing internally.

`voronoi(dt)` uses the Delaunay triangulation `dt` instead of computing it.

`voronoi(AX,...)` plots into `AX` instead of `gca`.

`voronoi(...,'LineStyle')` plots the diagram with color and line style specified.

`h = voronoi(...)` returns, in `h`, handles to the line objects created.

`[vx,vy] = voronoi(...)` returns the finite vertices of the Voronoi edges in `vx` and `vy`.

---

**Note** For the topology of the Voronoi diagram, i.e., the vertices for each Voronoi cell, use `voronoin`.

```
[v,c] = voronoin([x(:) y(:)])
```

---

## Definitions

Consider a set of coplanar points  $P$ . For each point  $P_x$  in the set  $P$ , you can draw a boundary enclosing all the intermediate points lying closer to  $P_x$  than to other points in the set  $P$ . Such a boundary is called a *Voronoi polygon*, and the set of all Voronoi polygons for a given point set is called a *Voronoi diagram*.

## Visualization

Use one of these methods to plot a Voronoi diagram:

- If you provide no output argument, `voronoi` plots the diagram.
- To gain more control over color, line style, and other figure properties, use the syntax `[vx,vy] = voronoi(...)`. This syntax returns the vertices of the finite Voronoi edges, which you can then plot with the `plot` function.
- To fill the cells with color, use `voronoin` with `n = 2` to get the indices of each cell, and then use `patch` and other plot functions to generate the figure. Note that `patch` does not fill unbounded cells with color.

## Examples

### Example 1

This code uses the `voronoi` function to plot the Voronoi diagram for 10 randomly generated points.

```
x = gallery('uniformdata',[1 10],0);  
y = gallery('uniformdata',[1 10],1);  
voronoi(x,y)
```

### Example 2

This code uses the vertices of the finite Voronoi edges to plot the Voronoi diagram for the same 10 points.

```
x = gallery('uniformdata',[1 10],0);  
y = gallery('uniformdata',[1 10],1);  
[vx, vy] = voronoi(x,y);  
plot(x,y,'r+',vx,vy,'b-'); axis equal
```

# voronoi

Note that you can add this code to get the figure shown in Example 1.

```
xlim([min(x) max(x)])  
ylim([min(y) max(y)])
```

### Example 3

This code uses `voronoin` and `patch` to fill the bounded cells of the same Voronoi diagram with color.

```
x = gallery('uniformdata',[10 2],5);  
[v,c]=voronoin(x);  
for i = 1:length(c)  
if all(c{i}~=1) % If at least one of the indices is 1,  
                % then it is an open region and we can't  
                % patch that.  
patch(v(c{i},1),v(c{i},2),i); % use color i.  
end
```

end

# DelaunayTri.voronoiDiagram

---

**Purpose** Voronoi diagram

**Syntax** `[V, R] = voronoiDiagram(DT)`

**Description** `[V, R] = voronoiDiagram(DT)` returns the vertices  $V$  and regions  $R$  of the Voronoi diagram of the points  $DT.X$ . The region  $R\{i\}$  is a cell array of indices into  $V$  that represents the Voronoi vertices bounding the region. The Voronoi region associated with the  $i$ 'th point,  $DT.X(i)$  is  $R\{i\}$ . For 2-D, vertices in  $R\{i\}$  are listed in adjacent order, i.e. connecting them will generate a closed polygon (Voronoi diagram). For 3-D the vertices in  $R\{i\}$  are listed in ascending order.

The Voronoi regions associated with points that lie on the convex hull of  $DT.X$  are unbounded. Bounding edges of these regions radiate to infinity. The vertex at infinity is represented by the first vertex in  $V$ .

**Input Arguments**

|    |                         |
|----|-------------------------|
| DT | Delaunay triangulation. |
|----|-------------------------|

**Output Arguments**

|   |                                                                                                                                                                                |
|---|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| V | numv-by-ndim matrix representing the coordinates of the Voronoi vertices, where numv is the number of vertices and ndim is the dimension of the space where the points reside. |
| R | Vector cell array of length(DR.X), representing the Voronoi cell associated with each point.                                                                                   |

**Definitions** The *Voronoi diagram* of a discrete set of points  $X$  decomposes the space around each point  $X(i)$  into a region of influence  $R\{i\}$ . Locations within the region are closer to point  $i$  than any other point. The region of influence is called the Voronoi region. The collection of all the Voronoi regions is the Voronoi diagram.

The *convex hull* of a set of points  $X$  is the smallest convex polygon (or polyhedron in higher dimensions) containing all of the points of  $X$ .

## Examples

Compute the Voronoi Diagram of a set of points:

```
X = [ 0.5    0
      0      0.5
      -0.5  -0.5
      -0.2  -0.1
      -0.1   0.1
      0.1   -0.1
      0.1   0.1 ]
dt = DelaunayTri(X)
[V,R] = voronoiDiagram(dt)
```

## See Also

[voronoi](#) | [voronoin](#)

# voronoin

---

**Purpose** N-D Voronoi diagram

**Syntax** `[V,C] = voronoin(X)`  
`[V,C] = voronoin(X,options)`

**Description** `[V,C] = voronoin(X)` returns Voronoi vertices `V` and the Voronoi cells `C` of the Voronoi diagram of `X`. `V` is a `numv`-by-`n` array of the `numv` Voronoi vertices in `n`-dimensional space, each row corresponds to a Voronoi vertex. `C` is a vector cell array where each element contains the indices into `V` of the vertices of the corresponding Voronoi cell. `X` is an `m`-by-`n` array, representing `m` `n`-dimensional points, where `n > 1` and `m >= n+1`. The first row of `V` is a point at infinity. If any index in a cell of the cell array is 1, then the corresponding Voronoi cell contains the first point in `V`, a point at infinity. This means the Voronoi cell is unbounded.

`voronoin` uses `Qhull`.

`[V,C] = voronoin(X,options)` specifies a cell array of strings `options` to be used in `Qhull`. The default options are

- `'Qbb'` for 2- and 3-dimensional input
- `'Qbb','Qx'` for 4 and higher-dimensional input

If `options` is `[]`, the default options are used. If `code` is `{''}`, no options are used, not even the default. For more information on `Qhull` and its options, see <http://www.qhull.org>.

**Visualization** You can plot individual bounded cells of an `n`-dimensional Voronoi diagram. To do this, use `convhulln` to compute the vertices of the facets that make up the Voronoi cell. Then use `patch` and other plot functions to generate the figure.

**Examples** **Example 1**

Let

```
x = [ 0.5  0
      0    0.5
```

```
-0.5  -0.5
-0.2  -0.1
-0.1   0.1
 0.1  -0.1
 0.1   0.1 ]
```

then

```
[V,C] = voronoin(x)
```

V =

```
      Inf      Inf
    0.3833    0.3833
    0.7000   -1.6500
    0.2875    0.0000
   -0.0000    0.2875
   -0.0000   -0.0000
   -0.0500   -0.5250
   -0.0500   -0.0500
   -1.7500    0.7500
   -1.4500    0.6500
```

C =

```
[1x4 double]
[1x5 double]
[1x4 double]
[1x4 double]
[1x4 double]
[1x5 double]
[1x4 double]
```

Use a for loop to see the contents of the cell array C.

```
for i=1:length(C), disp(C{i}), end
```

```
 4   2   1   3
10   5   2   1   9
 9   1   3   7
```

# voronoin

---

```
10   8   7   9
10   5   6   8
 8   6   4   3   7
 6   4   2   5
```

In particular, the fifth Voronoi cell consists of 4 points:  $V(10, :)$ ,  $V(5, :)$ ,  $V(6, :)$ ,  $V(8, :)$ .

## Example 2

The following example illustrates the options input to `voronoin`. The commands

```
X = [-1 -1; 1 -1; 1 1; -1 1];
[V,C] = voronoin(X)
```

return an error message.

```
? qhull input error: can not scale last coordinate. Input is
cocircular
  or cospherical. Use option 'Qz' to add a point at infinity.
```

The error message indicates that you should add the option `'Qz'`. The following command passes the option `'Qz'`, along with the default `'Qbb'`, to `voronoin`.

```
[V,C] = voronoin(X,{'Qbb','Qz'})
V =
```

```
Inf   Inf
 0     0
```

```
C =
```

```
[1x2 double]
[1x2 double]
[1x2 double]
[1x2 double]
```

**Algorithms**

voronoin is based on Qhull [1]. For information about Qhull, see <http://www.qhull.org/>. For copyright information, see <http://www.qhull.org/COPYING.txt>.

# wait

---

**Purpose** Wait until timer stops running

**Syntax** `wait(obj)`

**Description** `wait(obj)` blocks the MATLAB command line and waits until the timer, represented by the timer object `obj`, stops running. When a timer stops running, the value of the timer object's `Running` property changes from 'on' to 'off'.

If `obj` is an array of timer objects, `wait` blocks the MATLAB command line until all the timers have stopped running.

If the timer is not running, `wait` returns immediately.

**See Also** `timer` | `start` | `stop`

**Purpose**

Open or update wait bar dialog box

**Syntax**

```
h = waitbar(x,'message')
waitbar(x,'message','CreateCancelBtn','button_callback')
waitbar(x,'message',property_name,property_value,...)
waitbar(x)
waitbar(x,h)
waitbar(x,h,'updated message')
```

**Description**

A wait bar is a figure that displays what percentage of a calculation is complete as the calculation proceeds by progressively filling a bar with red from left to right.

`h = waitbar(x,'message')` displays a wait bar of fractional length `x`. The wait bar figure displays until the code that controls it closes it or the user clicks its Close Window button. Its (figure) handle is returned in `h`. The argument `x` must be between 0 and 1.

---

**Note** Wait bars are not modal figures (their `WindowState` is 'normal'). They often appear to be modal because the computational loops within which they are called prevent interaction with the Command Window until they terminate. For more information, see `WindowState` in the MATLAB Figure Properties documentation.

---

`waitbar(x,'message','CreateCancelBtn','button_callback')` specifying `CreateCancelBtn` adds a **Cancel** button to the figure that executes the MATLAB commands specified in `button_callback` when the user clicks the **Cancel** button or the **Close Figure** button. `waitbar` sets both the **Cancel** button callback and the figure `CloseRequestFcn` to the string specified in `button_callback`.

`waitbar(x,'message',property_name,property_value,...)` optional arguments `property_name` and `property_value` enable you to set figure properties for the waitbar.

# waitbar

---

`waitbar(x)` subsequent calls to `waitbar(x)` extend the length of the bar to the new position `x`. Successive values of `x` normally increase. If they decrease, the wait bar runs in reverse.

`waitbar(x,h)` extends the length of the bar in the wait bar `h` to the new position `x`.

`waitbar(x,h,'updated message')` updates the message text in the waitbar figure, in addition to setting the fractional length to `x`.

## Examples

### Example 1 – Basic Wait Bar

Typically, you call `waitbar` repeatedly inside a `for` loop that performs a lengthy computation. For example:

```
h = waitbar(0,'Please wait...');
steps = 1000;
for step = 1:steps
    % computations take place here
    waitbar(step / steps)
end
close(h)
```

### Example 2 – Wait Bar with Dynamic Text and Cancel Button

Adding a **Cancel** button allows user to abort the computation. Clicking it sets a logical flag in the figure's application data (`appdata`). The function tests for that value within the main loop and exits the loop as soon as the flag has been set. The example iteratively approximates the value of  $\pi$ . At each step, the current value is encoded as a string and displayed in the wait bar's message field. When the function finishes,

it destroys the wait bar and returns the current estimate of  $\pi$  and the number of steps it ran.

Copy the following function to a code file and save it as `approxpi.m`. Execute it as follows, allowing it to run for 10,000 iterations.

```
[estimated_pi steps] = approxpi(10000)
```

You can click **Cancel** or close the window to abort the computation and return the current estimate of  $\pi$ .

```
function [valueofpi step] = approxpi(steps)
% Converge on pi in steps iterations, displaying waitbar.
% User can click Cancel or close button to exit the loop.
% Ten thousand steps yields error of about 0.001 percent.

h = waitbar(0,'1','Name','Approximating pi...',...
           'CreateCancelBtn',...
           'setappdata(gcf,'canceling',1)');
setappdata(h,'canceling',0)
% Approximate as pi^2/8 = 1 + 1/9 + 1/25 + 1/49 + ...
pisqover8 = 1;
denom = 3;
valueofpi = sqrt(8 * pisqover8);
for step = 1:steps
    % Check for Cancel button press
    if getappdata(h,'canceling')
        break
    end
    % Report current estimate in the waitbar's message field
    waitbar(step/steps,h,sprintf('%12.9f',valueofpi))
    % Update the estimate
    pisqover8 = pisqover8 + 1 / (denom * denom);
    denom = denom + 2;
    valueofpi = sqrt(8 * pisqover8);
end
delete(h)      % DELETE the waitbar; don't try to CLOSE it.
```

# waitbar

---

The function sets the figure Name property to describe what is being computed. In the for loop, calling waitbar sets the fractional progress indicator and displays intermediate results. the code `waitbar(i/steps,h,sprintf('%12.9f',valueofpi))` sets the wait bar's message variable to a string representation of the current estimate of  $\pi$ . Naturally, the extra computation involved makes iterations last longer than they need to, but such feedback can be helpful to users.

---

**Note** You should call `delete` to remove a wait bar when you give it a `CloseRequestFcn`, as in the preceding code; calling `close` does not close it, and makes its `Cancel` and `Close Window` buttons unresponsive. This happens because the figure's `CloseRequestFcn` recursively calls itself. In such a situation you must forcibly remove the wait bar, for example like this:

```
set(0,'ShowHiddenHandles','on')
delete(get(0,'Children'))
```

However, as issuing these commands will delete all open figures—not just the wait bar—it is best never to use `close` in a `CloseRequestFcn` to close a window.

---

**Purpose**

Block execution and wait for event or condition

**Syntax**

```
waitfor(h)
waitfor(h, 'PropertyName')
waitfor(h, 'PropertyName', PropertyValue)
```

**Description**

`waitfor(h)` blocks the caller from executing statements until the graphics object identified by handle `h` closes (is deleted). `h` must be scalar. When object `h` no longer exists, `waitfor` returns, enabling execution to resume. If the object does not exist, `waitfor` returns immediately without processing any events.

`waitfor(h, 'PropertyName')` blocks the caller from executing until the value of `'PropertyName'` (any property of the graphics object `h`) changes or `h` closes (is deleted). If `'PropertyName'` is not a valid property for the object, `waitfor` returns immediately without processing any events.

`waitfor(h, 'PropertyName', PropertyValue)` blocks the caller from executing until the value of `'PropertyName'` for the graphics object `h` changes to the specific value `PropertyValue` or `h` closes (is deleted). If the value of `'PropertyName'` is already `PropertyValue`, `waitfor` returns immediately without processing any events.

**Definitions**

- `waitfor` blocks execution so that command-line expressions and subsequent statements in the blocked file do not execute until a specified condition occurs.
- While `waitfor` prevents its caller from continuing, callbacks that respond to various events (for example, pressing a mouse button) can still run, unaffected by `waitfor`.
- `waitfor` also blocks Simulink models from executing, but callbacks do still execute.
- `waitfor` can block nested function calls. For example, a callback invoked while `waitfor` is active can invoke `waitfor`.
- If you type **Ctrl+C** in the Command Window while `waitfor` is blocking execution, the executing program terminates. To avoid

terminating, the program can call `waitfor` within a `try/catch` block that handles the exception that typing **Ctrl+C** generates. To learn more, see the third following example.

## Examples

Create a plot and pause execution of the rest of the statements until you close the figure window:

```
f = warndlg('This is a warning.', 'A Warning Dialog');
disp('This prints immediately');
drawnow % Necessary to print the message
waitfor(f);
disp('This prints after you close the warning dialog');
```

---

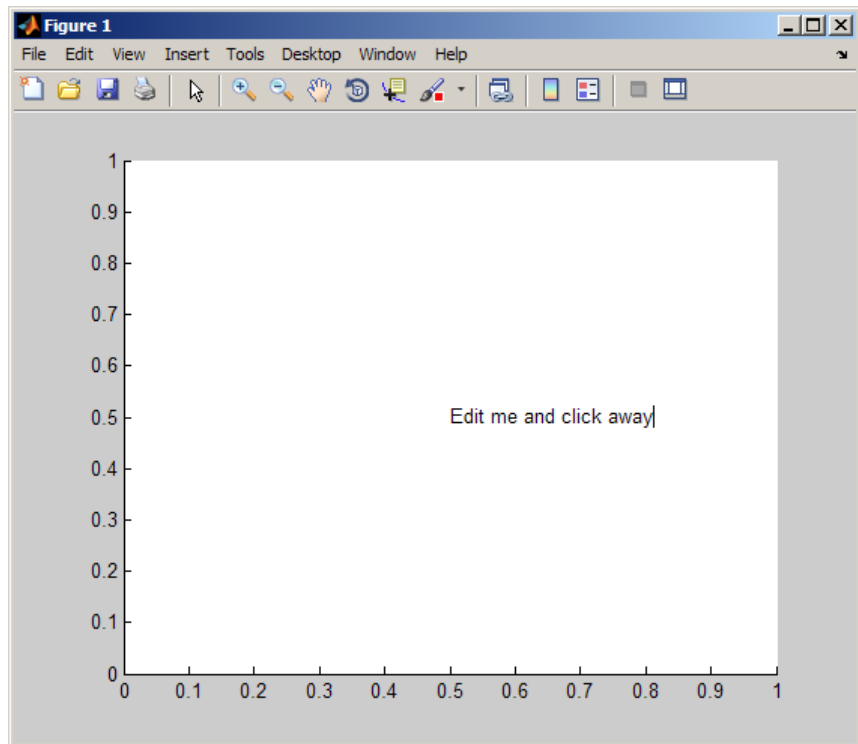

Suspend execution until name of figure changes:

```
f = figure('Name', datestr(now));
h = uicontrol('String', 'Change Name', 'Position', [20 20 100 30], ...
'Callback', 'set(gcf, 'Name', datestr(now))');
disp('This prints immediately');
drawnow % Necessary to print the message
waitfor(f, 'Name');
disp('This prints after button click that changes the figure''s name');
```

---

Display text object and wait for user to edit it:

```
figure;
textH = text(.5, .5, 'Edit me and click away');
set(textH, 'Editing', 'on', 'BackgroundColor', [1 1 1]);
disp('This prints immediately. ');
drawnow
waitfor(textH, 'Editing', 'off');
set(textH, 'BackgroundColor', [1 1 0]);
disp('This prints after text editing is complete.');
```

If you close the figure while `waitfor` is executing, an error occurs because the code attempts to access handles of objects that no longer exist. You can handle the error by enclosing code starting with the call to `waitfor` in a `try/catch` block, as follows:

```
figure;
textH = text(.5, .5, 'Edit me and click away');
set(textH,'Editing','on', 'BackgroundColor',[1 1 1]);
disp('This prints immediately.');
```

`drawnow`

```
% Use try/catch block to handle errors, such as deleting figure
try
    waitfor(textH,'Editing','off');
    set(textH,'BackgroundColor',[1 1 0]);
```

# waitfor

---

```
        disp('This prints after text editing is complete.');
```

```
catch ME
```

```
    disp('This prints if figure is deleted:')
```

```
    disp(ME.message)
```

```
    % You can place other code to respond to the error here
```

```
end
```

The ME variable is a MATLAB Exception object that you can use to determine the type of error that occurred. For more information, see “Respond to an Exception”.

## How To

- “Control Callback Execution and Interruption”

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Wait for key press or mouse-button click                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Syntax</b>      | <code>k = waitforbuttonpress</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p><code>k = waitforbuttonpress</code> blocks the caller's execution stream until the function detects that the user has clicked a mouse button or pressed a key while the figure window is active. The function returns</p> <ul style="list-style-type: none"><li>• 0 if it detects a mouse button click</li><li>• 1 if it detects a key press</li></ul> <p>If a <code>WindowButtonDownFcn</code> is defined for the figure, its callback is executed before <code>waitforbuttonpress</code> returns a value.</p> <p>Only keys that generate characters cause the function to return. Pressing any of the following keys by itself does nothing: <b>Ctrl</b>, <b>Shift</b>, <b>Alt</b>, <b>Caps_lock</b>, <b>Num_lock</b>, <b>Scroll_lock</b>.</p> <p>Additional information about the event that causes execution to resume is available through the figure <code>CurrentCharacter</code>, <code>SelectionType</code>, and <code>CurrentPoint</code> properties.</p> <p>You can interrupt <code>waitforbuttonpress</code> by typing <b>Ctrl+C</b>, but an error results unless the function is called from within a <code>try/catch</code> block. You also receive an error from <code>waitforbuttonpress</code> if you close the figure by clicking the <b>X</b> close box unless you call <code>waitforbuttonpress</code> within a <code>try/catch</code> block.</p> |

**Examples** These statements display text in the Command Window when the user either clicks a mouse button or types a key in the figure window:

```
w = waitforbuttonpress;  
if w == 0  
    disp('Button click')  
else  
    disp('Key press')  
end
```

# waitforbuttonpress

---

## See Also

`dragrect` | `ginput` | `rbbox` | `waitfor`

**Purpose**

Open warning dialog box

**Syntax**

```
h = warndlg
h = warndlg(warningstring)
h = warndlg(warningstring,dlgname)
h = warndlg(warningstring,dlgname,createmode)
```

**Description**

`h = warndlg` displays a dialog box named Warning Dialog containing the string `This is the default warning string`. The `warndlg` function returns the handle of the dialog box in `h`. The warning dialog box disappears after the user clicks **OK**.

`h = warndlg(warningstring)` displays a dialog box with the title Warning Dialog containing the string specified by `warningstring`. The `warningstring` argument can be any valid string format – cell arrays are preferred.

To use multiple lines in your warning, define `warningstring` using either of the following:

- `sprintf` with newline characters separating the lines

```
warndlg(sprintf('Message line 1 \n Message line 2'))
```

- Cell arrays of strings

```
warndlg({'Message line 1';'Message line 2'})
```

`h = warndlg(warningstring,dlgname)` displays a dialog box with title `dlgname`.

`h = warndlg(warningstring,dlgname,createmode)` specifies whether the warning dialog box is modal or nonmodal. Optionally, it can also specify an interpreter for `warningstring` and `dlgname`. The `createmode` argument can be a string or a structure.

If `createmode` is a string, it must be one of the values shown in the following table.

| createmode Value    | Description                                                                                                                                                                                                                                                                         |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| modal               | Replaces the warning dialog box having the specified Title, that was last created or clicked on, with a modal warning dialog box as specified. All other warning dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal.    |
| non-modal (default) | Creates a new nonmodal warning dialog box with the specified parameters. Existing warning dialog boxes with the same title are not deleted.                                                                                                                                         |
| replace             | Replaces the warning dialog box having the specified Title, that was last created or clicked on, with a nonmodal warning dialog box as specified. All other warning dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal. |

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. To block MATLAB program execution as well, use the `uiwait` function.

If you open a dialog with `errordlg`, `msgbox`, or `warndlg` using 'CreateMode', 'modal' and a non-modal dialog created with any of these functions is already present and *has the same name as the modal dialog*, the non-modal dialog closes when the modal one opens.

For more information about modal dialog boxes, see `WindowState` in the Figure Properties.

---

If `CreateMode` is a structure, it can have fields `WindowStyle` and `Interpreter`. `WindowStyle` must be one of the options shown in the table above. `Interpreter` is one of the strings 'tex' or 'none'. The default value for `Interpreter` is 'none'.

## Examples

The statement

```
warndlg('Pressing OK will clear memory','!! Warning !!')
```

displays this dialog box:

# warning

---

**Purpose** Warning message

**Syntax**

```
warning('message')
warning('message', a1, a2,...)
warning('message_id', 'message')
warning('message_id', 'message', a1, a2, ..., an)
s = warning(state, 'message_id')
s = warning(state, mode)
```

**Description**

`warning('message')` displays descriptive text message and sets the warning state that `lastwarn` returns. If `message` is an empty string (' '), `warning` resets the warning state but does not display any text.

`warning('message', a1, a2,...)` displays a message string that contains formatting conversion characters, such as those used with the MATLAB `sprintf` function. Each conversion character in `message` is converted to one of the values `a1, a2, ...` in the argument list.

---

**Note** MATLAB converts special characters (like `\n` and `%d`) in the warning message string only when you specify more than one input argument with `warning`. See Example 3 below.

---

`warning('message_id', 'message')` attaches a unique identifier, or `message_id`, to the warning message. The identifier enables you to single out certain warnings during the execution of your program, controlling what happens when the warnings are encountered.

`warning('message_id', 'message', a1, a2, ..., an)` includes formatting conversion characters in `message`, and the character translations in arguments `a1, a2, ..., an`.

`s = warning(state, 'message_id')` is a warning control statement that enables you to indicate how you want MATLAB to act on certain warnings. The `state` argument can be 'on', 'off', or 'query'. The `message_id` argument can be a message identifier string, 'all', or 'last'.

Output `s` is a structure array that indicates the previous state of the selected warnings. The structure has the fields `identifier` and `state`.

`s = warning(state, mode)` is a warning control statement that enables you to display a stack trace or display more information with each warning. The `state` argument can be `'on'`, `'off'`, or `'query'`. The `mode` argument can be `'backtrace'` or `'verbose'`.

## Examples

### Example 1

Generate a warning that displays a simple string:

```
if ~ischar(p1)
    warning('Input must be a string')
end
```

### Example 2

Generate a warning string that is defined at run-time. The first argument defines a message identifier for this warning:

```
warning('MATLAB:paramAmbiguous', ...
        'Ambiguous parameter name, "%s".', param)
```

### Example 3

MATLAB converts special characters (like `\n` and `%d`) in the warning message string only when you specify more than one input argument with `warning`. In the single argument case shown below, `\n` is taken to mean `backslash-n`. It is not converted to a newline character:

```
warning('In this case, the newline \n is not converted.')
Warning: In this case, the newline \n is not converted.
```

But, when more than one argument is specified, MATLAB does convert special characters. This is true regardless of whether the additional argument supplies conversion values or is a message identifier:

```
warning('WarnTests:convertTest', ...
        'In this case, the newline \n is converted.')
Warning: In this case, the newline
```

# warning

---

is converted.

## Example 4

Turn on one particular warning, saving the previous state of this one warning in `s`. Remember that this nonquery syntax performs an implicit query prior to setting the new state:

```
s = warning('on', 'Control:parameterNotSymmetric');
```

After doing some work that includes making changes to the state of some warnings, restore the original state of all warnings:

```
warning(s)
```

**Purpose** Waterfall plot

**Syntax**

```
waterfall(Z)
waterfall(X,Y,Z)
waterfall(...,C)
waterfall(axes_handles,...)
h = waterfall(...)
```

**Description** The `waterfall` function draws a mesh similar to the `meshz` function, but it does not generate lines from the columns of the matrices. This produces a “waterfall” effect.

`waterfall(Z)` creates a waterfall plot using  $x = 1:\text{size}(Z,2)$  and  $y = 1:\text{size}(Z,1)$ .  $Z$  determines the color, so color is proportional to surface height.

`waterfall(X,Y,Z)` creates a waterfall plot using the values specified in  $X$ ,  $Y$ , and  $Z$ .  $Z$  also determines the color, so color is proportional to the surface height. If  $X$  and  $Y$  are vectors,  $X$  corresponds to the columns of  $Z$ , and  $Y$  corresponds to the rows, where  $\text{length}(x) = n$ ,  $\text{length}(y) = m$ , and  $[m,n] = \text{size}(Z)$ .  $X$  and  $Y$  are vectors or matrices that define the  $x$ - and  $y$ -coordinates of the plot.  $Z$  is a matrix that defines the  $z$ -coordinates of the plot (i.e., height above a plane). If  $C$  is omitted, color is proportional to  $Z$ .

`waterfall(...,C)` uses scaled color values to obtain colors from the current colormap. Color scaling is determined by the range of  $C$ , which must be the same size as  $Z$ . MATLAB performs a linear transformation on  $C$  to obtain colors from the current colormap.

`waterfall(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = waterfall(...)` returns the handle of the patch graphics object used to draw the plot.

# waterfall

---

## Tips

For column-oriented data analysis, use `waterfall(Z')` or `waterfall(X',Y',Z')`.

## Examples

Produce a waterfall plot of the peaks function.

```
figure  
[X,Y,Z] = peaks(30);  
waterfall(X,Y,Z)
```

## Algorithms

The range of X, Y, and Z, or the current setting of the axes `Xlim`, `Ylim`, and `Zlim` properties, determines the range of the axes (also set by `axis`). The range of C, or the current setting of the axes `CLim` property, determines the color scaling (also set by `caxis`).

The `CData` property for the patch graphics objects specifies the color at every point along the edge of the patch, which determines the color of the lines.

The `waterfall` plot looks like a mesh surface; however, it is a patch graphics object. To create a surface plot similar to `waterfall`, use the `meshz` function and set the `MeshStyle` property of the surface to 'Row'. For a discussion of parametric surfaces and related color properties, see `surf`.

# wavinfo

---

**Purpose** Information about WAVE (.wav) sound file

**Syntax** `[m d] = wavinfo(filename)`

**Description** `[m d] = wavinfo(filename)` returns information about the contents of the WAVE sound file specified by the string *filename*. Enclose the *filename* input in single quotes.

*m* is the string 'Sound (WAV) file', if *filename* is a WAVE file. Otherwise, it contains an empty string ('').

*d* is a string that reports the number of samples in the file and the number of channels of audio data. If *filename* is not a WAVE file, it contains the string 'Not a WAVE file'.

**See Also** audioplayer | audiorecorder | audioread | audiowrite

**Purpose** Play recorded sound on PC-based audio output device

---

**Note** wavplay will be removed in a future release. Use audioplayer instead.

---

**Syntax**

```
wavplay(y,Fs)
wavplay(y,Fs,mode)
```

**Description** wavplay(y,Fs) plays the audio signal stored in the vector y on a PC-based audio output device. Fs is the integer sample rate in Hz (samples per second). The default value for Fs is 11025 Hz. wavplay supports only 1- or 2-channel (mono or stereo) audio signals. To play in stereo, y must be a two-column matrix.

wavplay(y,Fs,mode) specifies how wavplay interacts with the command line. The string mode is one of the following:

- 'sync' (default): You do not have access to the command line until the sound has finished playing (a blocking device call).
- 'async': You have immediate access to the command line as soon as the sound begins to play on the audio output device (a nonblocking device call). If you call wavplay again in async mode while the audio is playing, wavplay blocks access to the command line until the original playback completes.

The audio signal y can be one of four data types. The number of bits used to quantize and play back each sample depends on the data type.

#### Data Types for wavplay

| Data Type                        | Quantization   |
|----------------------------------|----------------|
| Double-precision (default value) | 16 bits/sample |
| Single-precision                 | 16 bits/sample |

## Data Types for wavplay (Continued)

| Data Type              | Quantization   |
|------------------------|----------------|
| 16-bit signed integer  | 16 bits/sample |
| 8-bit unsigned integer | 8 bits/sample  |

### Tips

The `wavplay` function is for use only with 32-bit Microsoft Windows operating systems. To play audio data on other platforms, use `audioplayer`.

### Examples

The MAT-files `gong.mat` and `chirp.mat` both contain an audio signal `y` and a sampling frequency `Fs`. Load and play the `gong` and the `chirp` audio signals. Change the names of these signals in between load commands and play them sequentially using the `'sync'` option for `wavplay`.

```
load chirp;
y1 = y; Fs1 = Fs;
load gong;
wavplay(y1,Fs1,'sync') % The chirp signal finishes before the
wavplay(y,Fs)          % gong signal begins playing.
```

### See Also

`audioplayer` | `audioinfo` | `audioread` | `audiowrite`

**Purpose** Read WAVE (.wav) sound file

**Syntax**

```
y = wavread(filename)
[y, Fs] = wavread(filename)
[y, Fs, nbits] = wavread(filename)
[y, Fs, nbits, opts] = wavread(filename)
[ ___ ] = wavread(filename, N)
[ ___ ] = wavread(filename, [N1 N2])
[ ___ ] = wavread( ___, fmt)
siz = wavread(filename, 'size')
```

**Description** `y = wavread(filename)` loads a WAVE file specified by the string `filename`, returning the sampled data in `y`. If `filename` does not include an extension, `wavread` appends `.wav`.

`[y, Fs] = wavread(filename)` returns the sample rate (`Fs`) in Hertz used to encode the data in the file.

`[y, Fs, nbits] = wavread(filename)` returns the number of bits per sample (`nbits`).

`[y, Fs, nbits, opts] = wavread(filename)` returns a structure `opts` of additional information contained in the WAV file. The content of this structure differs from file to file. Typical structure fields include `opts.fmt` (audio format information) and `opts.info` (text that describes the title, author, etc.).

`[ ___ ] = wavread(filename, N)` returns only the first `N` samples from each channel in the file.

`[ ___ ] = wavread(filename, [N1 N2])` returns only samples `N1` through `N2` from each channel in the file.

`[ ___ ] = wavread( ___, fmt)` specifies the data format of `y` used to represent samples read from the file. `fmt` can be either of the following values, or a partial match (case-insensitive):

'double' Double-precision normalized samples (default).

'native' Samples in the native data type found in the file.

# wavread

`siz = wavread(filename, 'size')` returns the size of the audio data contained in `filename` instead of the actual audio data, returning the vector `siz = [samples channels]`.

## Output Scaling

The range of values in `y` depends on the data format `fmt` specified. Some examples of output scaling based on typical bit-widths found in a WAV file are given below for both 'double' and 'native' formats.

### Native Formats

| Number of Bits | MATLAB Data Type         | Data Range                     |
|----------------|--------------------------|--------------------------------|
| 8              | uint8 (unsigned integer) | $0 \leq y \leq 255$            |
| 16             | int16 (signed integer)   | $-32768 \leq y \leq +32767$    |
| 24             | int32 (signed integer)   | $-2^{23} \leq y \leq 2^{23}-1$ |
| 32             | single (floating point)  | $-1.0 \leq y < +1.0$           |

### Double Formats

| Number of Bits | MATLAB Data Type | Data Range                                                                                                                                        |
|----------------|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| N<32           | double           | $-1.0 \leq y < +1.0$                                                                                                                              |
| N=32           | double           | $-1.0 \leq y \leq +1.0$<br>Note: Values in <code>y</code> might exceed -1.0 or +1.0 for the case of N=32 bit data samples stored in the WAV file. |

`wavread` supports multi-channel data, with up to 32 bits per sample.

`wavread` supports Pulse-code Modulation (PCM) data format only.

## Examples

Create a WAV file from the example file `handel.mat`, and read portions of the file back into MATLAB.

```
% Create WAV file in current folder.
load handel.mat

hfile = 'handel.wav';
wavwrite(y, Fs, hfile)
clear y Fs

% Read the data back into MATLAB, and listen to audio.
[y, Fs, nbits, readinfo] = wavread(hfile);
sound(y, Fs);

% Pause before next read and playback operation.
duration = numel(y) / Fs;
pause(duration + 2)

% Read and play only the first 2 seconds.
nsamples = 2 * Fs;
[y2, Fs] = wavread(hfile, nsamples);
sound(y2, Fs);
pause(4)

% Read and play the middle third of the file.
sizeinfo = wavread(hfile, 'size');

tot_samples = sizeinfo(1);
startpos = tot_samples / 3;
endpos = 2 * startpos;

[y3, Fs] = wavread(hfile, [startpos endpos]);
sound(y3, Fs);
```

`mmfileinfo` | `audioinfo` | `audiowrite` | `audioread` | `audioplayer`  
| `audiorecorder` | `sound`

# wavrecord

---

**Purpose** Record sound using PC-based audio input device

---

**Note** wavrecord will be removed in a future release. Use audiorecorder instead.

---

**Syntax**

```
y = wavrecord(n,Fs)
y = wavrecord( __ ,ch)
y = wavrecord( __ , 'dtype' )
```

**Description** `y = wavrecord(n,Fs)` records `n` samples of an audio signal, sampled at a rate of `Fs` Hz (samples per second). The default value for `Fs` is 11025 Hz.

`y = wavrecord( __ ,ch)` uses `ch` number of input channels from the audio device. `ch` can be either 1 or 2, for mono or stereo, respectively. The default value for `ch` is 1.

`y = wavrecord( __ , 'dtype' )` uses the data type specified by the string `'dtype'` to record the sound. The following table lists the string values for `'dtype'` along with the corresponding bits per sample and acceptable data range for `y`.

| <b>dtype</b> | <b>Bits/sample</b> | <b>y Data Range</b>         |
|--------------|--------------------|-----------------------------|
| 'double'     | 16                 | $-1.0 \leq y < +1.0$        |
| 'single'     | 16                 | $-1.0 \leq y < +1.0$        |
| 'int16'      | 16                 | $-32768 \leq y \leq +32767$ |
| 'uint8'      | 8                  | $0 \leq y \leq 255$         |

**Tips** Standard sampling rates for PC-based audio hardware are 8000, 11025, 22050, and 44100 samples per second. Stereo signals are returned as two-column matrices. The first column of a stereo audio matrix corresponds to the left input channel, while the second column corresponds to the right input channel.

The `wavrecord` function is for use only with 32-bit Microsoft Windows operating systems. To record audio data from audio input devices on other platforms, use `audiorecorder`.

**Examples**

Record 5 seconds of 16-bit audio sampled at 11025 Hz. Play back the recorded sound using `wavplay`. Speak into your audio device (or produce your audio signal) while the `wavrecord` command runs.

```
Fs = 11025;  
y = wavrecord(5*Fs,Fs,'int16');  
wavplay(y,Fs);
```

**See Also**

`audiorecorder` | `audioinfo` | `audioread` | `audiowrite`

# wavwrite

---

**Purpose** Write WAVE (.wav) sound file

**Syntax**  
`wavwrite(y, filename)`  
`wavwrite(y, Fs, filename)`  
`wavwrite(y, Fs, N, filename)`

**Description** `wavwrite(y, filename)` writes the data stored in the variable `y` to a WAVE file called `filename`. The `filename` input is a string enclosed in single quotes. The data has a sample rate of 8000 Hz and is assumed to be 16-bit. Each column of the data represents a separate channel. Therefore, stereo data should be specified as a matrix with two columns.

`wavwrite(y, Fs, filename)` writes the data stored in the variable `y` to a WAVE file called `filename`. The data has a sample rate of `Fs` Hz and is assumed to be 16-bit.

`wavwrite(y, Fs, N, filename)` writes the data stored in the variable `y` to a WAVE file called `filename`. The data has a sample rate of `Fs` Hz and is `N`-bit, where `N` is 8, 16, 24, or 32.

## Input Data Ranges

The range of values in `y` depends on the number of bits specified by `N` and the data type of `y`. The following tables list the valid input ranges based on the value of `N` and the data type of `y`.

If `y` contains integer data:

| N Bits | y Data Type | y Data Range                     | Output Format |
|--------|-------------|----------------------------------|---------------|
| 8      | uint8       | $0 \leq y \leq 255$              | uint8         |
| 16     | int16       | $-32768 \leq y \leq +32767$      | int16         |
| 24     | int32       | $-2^{23} \leq y \leq 2^{23} - 1$ | int32         |

If  $y$  contains floating-point data:

| N Bits | y Data Type      | y Data Range            | Output Format |
|--------|------------------|-------------------------|---------------|
| 8      | single or double | $-1.0 \leq y < +1.0$    | uint8         |
| 16     | single or double | $-1.0 \leq y < +1.0$    | int16         |
| 24     | single or double | $-1.0 \leq y < +1.0$    | int32         |
| 32     | single or double | $-1.0 \leq y \leq +1.0$ | single        |

For floating point data where  $N < 32$ , amplitude values are clipped to the range  $-1.0 \leq y < +1.0$ .

---

**Note** 8-, 16-, and 24-bit files are type 1 integer pulse code modulation (PCM). 32-bit files are written as type 3 normalized floating point.

---

## See Also

`mmfileinfo` | `audioinfo` | `audioread` | `audiowrite` | `audioplayer`  
| `audiorecorder` | `sound`

**Purpose** Open Web page or file in browser

**Syntax**

```
web
web(url)
web(url,opt)
web(url,opt1,...,optN)

stat = web( ___ )
[stat,h] = web( ___ )
[stat,h,url] = web( ___ )
```

**Description** web opens an empty MATLAB Web browser.

`web(url)` opens the page specified by `url` in the MATLAB Web browser. If multiple browsers are open, the page displays in the one that was most recently used.

`web(url,opt)` opens the page using the specified browser option, such as `'-new'` to create a new browser instance or `'-browser'` to use the system browser.

`web(url,opt1,...,optN)` opens the page using one or more browser options.

`stat = web( ___ )` returns the status of the operation: 0 if successful, 1 or 2 if unsuccessful. You can include any of the input arguments in previous syntaxes.

`[stat,h] = web( ___ )` returns a handle to a MATLAB Web browser that allows you to close it using the command `close(h)`. If you do not specify any inputs to the `web` function, such as `[stat,h] = web`, then the handle corresponds to the most recently used MATLAB Web browser.

[stat,h,url] = web( \_\_\_ ) returns the URL of the current page in the MATLAB Web browser.

## Input Arguments

### url - Web page address or file location

string

Web page address or file location, specified as a string. File locations can include an absolute or relative path.

If url corresponds to a file in the installed product documentation, then the page displays in the MATLAB Help browser instead of the Web browser.

**Example:** 'http:\\www.mathworks.com'

**Example:** 'myfolder/myfile.html'

### opt - Browser option

'-browser' | '-new' | '-noaddressbox' | '-notoolbar'

Browser option, specified as one of the following strings. Options can appear in any order.

- |            |                                                                                                                                                                                                                                                                                                                       |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| '-browser' | Opens the page in a system browser window instead of the MATLAB Web browser. On Microsoft Windows and Apple Macintosh platforms, the operating system determines the system Web browser. On other systems, the default is the Mozilla® Firefox® browser, but you can change the default using MATLAB Web preferences. |
| '-new'     | Opens the page in a new MATLAB Web browser window. Does not apply to the system browser.                                                                                                                                                                                                                              |

'-noaddressbox' Opens the page in a browser that does not display the address box. Only applies to new instances of the MATLAB Web browser.

'-notoolbar' Opens the page in a browser that does not display a toolbar or address box. Only applies to new instances of the MATLAB Web browser.

**Example:** '-new', '-noaddressbox'

## Output Arguments

### **stat - Browser status**

0 | 1 | 2

Browser status, returned as an integer with one of these values:

- 0 Found and launched system browser.
- 1 Could not find system browser.
- 2 Found, but could not launch system browser.

### **h - Handle to most recent MATLAB Web browser**

scalar

Handle to the most recent MATLAB Web browser, returned as a scalar instance of the associated Java class.

If you do not request the handle when you open the page, be aware that this handle might not correspond to your most recent use of the `web` function. Other MATLAB functionality also uses the `web` function, such as links to external sites from the Help browser.

### **url - Current page address**

string

Current page address in the most recent MATLAB Web browser, returned as a string.

## Examples

### Web Page in MATLAB Web Browser

Open the MathWorks Web site home page.

```
url = 'http://www.mathworks.com';  
web(url)
```

Open the page in a new instance of the browser that does not include a toolbar.

```
web(url, '-new', '-notoolbar')
```

### File in MATLAB Web Browser

View an HTML file that resides on your system.

Create an HTML file by publishing an example program file. Copy the program file to the current folder so that the code can run during the publishing process.

```
program = fullfile(matlabroot, 'help', 'techdoc', 'matlab_env', 'examples', 'copyfile(program);  
htmlFile = publish('fourier_demo2.m');
```

View a file by specifying the file name.

```
web(htmlFile)
```

Alternatively, you can use the `file:///` URL scheme, as long as you include the full path. The `publish` function returns the path in the `htmlFile` output.

```
url = ['file:///', htmlFile];  
web(url)
```

### Web Page in System Browser

Open the MathWorks Web site home page in the system browser.

```
url = 'http://www.mathworks.com';  
web(url, '-browser')
```

## Email from System Browser

Send email from your system browser's default mail application using the `mailto:` URL scheme.

To run this example, replace the value for `email` with a valid email address.

```
email = 'myaddress@provider.ext';  
url = ['mailto:',email];  
web(url)
```

## Handle to MATLAB Web Browser

Open the MathWorks Web site home page, and then close the browser using its handle.

```
url = 'http://www.mathworks.com';  
[stat,h] = web(url);
```

Close the browser window.

```
close(h)
```

## Text Displayed in MATLAB Web Browser

View formatted text using the `text://` URL scheme.

```
web('text://<html><h1>Hello World</h1></html>')
```

## Tips

- If you plan to deploy an application that calls the `web` function using the MATLAB Compiler product, then use the `'-browser'` option.
- If you are displaying Japanese streaming text in the MATLAB Web browser, specify a header that includes the `charset` attribute. For example:

```
web(['text://<html><head><meta http-equiv="content-type" ' ...  
' content="text/html;charset=utf-8"></head><body>TEXT</body></html>'])
```

# weekday

---

**Purpose** Day of week

**Syntax**  
[N, S] = weekday(D)  
[N, S] = weekday(D, form)  
[N, S] = weekday(D, locale)  
[N, S] = weekday(D, form, locale)

**Description** [N, S] = weekday(D) returns the day of the week in numeric (N) and string (S) form for a given serial date number or date string D. Input argument D can represent more than one date in an array of serial date numbers or a cell array of date strings.

[N, S] = weekday(D, form) returns the day of the week in numeric (N) and string (S) form, where the content of S depends on the form argument. If form is **'long'**, then S contains the full name of the weekday (e.g., Tuesday). If form is **'short'**, then S contains an abbreviated name (e.g., Tues) from this table.

The days of the week are assigned these numbers and abbreviations.

| <b>N</b> | <b>S (short)</b> | <b>S (long)</b> |
|----------|------------------|-----------------|
| 1        | Sun              | Sunday          |
| 2        | Mon              | Monday          |
| 3        | Tue              | Tuesday         |
| 4        | Wed              | Wednesday       |
| 5        | Thu              | Thursday        |
| 6        | Fri              | Friday          |
| 7        | Sat              | Saturday        |

[N, S] = weekday(D, locale) returns the day of the week in numeric (N) and string (S) form, where the format of the output depends on the locale argument. If locale is **'local'**, then weekday uses local format for its output. If locale is **'en\_US'**, then weekday uses US English.

`[N, S] = weekday(D, form, locale)` returns the day of the week using the formats described above for `form` and `locale`.

## Examples

Either

```
[n, s] = weekday(728647)
```

or

```
[n, s] = weekday('19-Dec-1994')
```

returns `n = 2` and `s = Mon`.

# what

---

**Purpose** List MATLAB files in folder

**Syntax**

```
what  
what folderName  
what className  
what packageName  
s = what(' folderName')
```

**Description**

`what` lists the path for the current folder, and lists all files and folders relevant to MATLAB found in the current folder. Files listed are M, MAT, MEX, MDL, and P-files. Folders listed are all class and package folders.

`what folderName` lists path, file, and folder information for *folderName*.

`what className` lists path, file, and folder information for method folder *@className*. For example, `what cfit` lists the MATLAB files and folders in `toolbox/curvefit/curvefit/@cfit`.

`what packageName` lists path, file, and folder information for package folder *+packageName*. For example, `what commsrc` lists the MATLAB files and folders in `toolbox/comm/comm/+commsrc`.

`s = what(' folderName')` returns the results in a structure array with the fields shown in the following table.

| Field | Description                             |
|-------|-----------------------------------------|
| path  | Path to folder                          |
| m     | Cell array of MATLAB program file names |
| mat   | Cell array of MAT-file names            |
| mex   | Cell array of MEX-file names            |
| mdl   | Cell array of MDL-file names            |
| slx   | Cell array of SLX-file names            |
| p     | Cell array of P-file names              |

| Field    | Description                   |
|----------|-------------------------------|
| classes  | Cell array of class folders   |
| packages | Cell array of package folders |

## Examples

List the MATLAB files and folders in C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo\+audiovideo, where *Rnnnn* represents the folder for the MATLAB release, for example, R2012b:

```
what audiovideo
```

```
MATLAB Code files in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo\+audiovideo
```

```
FileFormatInfo
```

```
Packages in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo\+audiovideo
```

```
internal writer
```

```
MATLAB Code files in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo
```

```
Contents      auinfo      mmcompinfo  wavplay
audiodevinfo  aread      mmfileinfo  wavread
audioinfo     auwrite    movie2avi   wavrecord
audioplayerreg  avgate    mu2lin      wavwrite
audioread     avifinfo  prefspanel
audiorecorderreg  aviinfo  sound
audiouniquename  aviread  soundsc
audiowrite    lin2mu    wavfinfo
```

```
MAT-files in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo
```

```
chirp      handel      splat
gong       laughter    train
```

# what

---

```
Classes in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo
```

```
VideoReader    audioplayer    avifile
VideoWriter    audiorecorder  mmreader
```

```
Packages in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo
```

```
audiovideo
```

---

Obtain a structure array containing the file and folder names in `toolbox/matlab/codetools` that are relevant to MATLAB, where *Rnnnn* represents the folder for the MATLAB release, for example, R2012a:

```
s = what('codetools')
```

```
s =
```

```
    path: 'C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\codetools'
         m: {76x1 cell}
         mat: {0x1 cell}
         mex: {0x1 cell}
         mdl: {0x1 cell}
         p: {0x1 cell}
    classes: {2x1 cell}
    packages: {3x1 cell}
```

---

Find the supporting files for one of the packages in the Communications System Toolbox product:

```
p1 = what('comm');
p1.packages
ans =
```

```
'gpu'  
'internal'  
  
ans =  
  
    'internal'.

# whatsnew

---

**Purpose** Release Notes

---

**Note** `whatsnew` will be removed in a future release.

---

**Syntax** `whatsnew`

**Description** `whatsnew` displays the MATLAB Release Notes in the Help browser, presenting information about new features, problems from previous releases that have been fixed in the current release, and compatibility issues.

**See Also** `help` | `version`

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Purpose</b>      | Locate functions and files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Alternatives</b> | As an alternative to the <code>which</code> function, you can use the Current Folder Browser to find files. You can find functions using the Function Browser in the Command Window or Editor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Syntax</b>       | <pre>which fun which classname/fun which <b>private</b>/fun which classname/<b>private</b>/fun which fun1 <b>in</b> fun2 which fun(a,b,c,...) which file.ext which fun <b>-all</b> s = which('fun',...)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b>  | <p><code>which fun</code> displays the full pathname for the argument <code>fun</code>. If <code>fun</code> is a</p> <ul style="list-style-type: none"><li>• MATLAB function or Simulink model in an M, P, or MDL file on the MATLAB path, then <code>which</code> displays the full pathname for the corresponding file</li><li>• Workspace variable, then <code>which</code> displays a message identifying <code>fun</code> as a variable</li><li>• Method in a loaded Java class, then <code>which</code> displays the package, class, and method name for that method</li></ul> <p>If <code>fun</code> is an overloaded function or method, then <code>which fun</code> returns only the pathname of the first function or method found.</p> <p><code>which classname/fun</code> displays the full pathname for the file that defines the <code>fun</code> method in MATLAB class, <code>classname</code>. For example, <code>which serial/fopen</code> displays the path for <code>fopen.m</code> in the MATLAB class folder, <code>@serial</code>.</p> <p><code>which <b>private</b>/fun</code> limits the search to private functions. For example, <code>which private/orthog</code> displays the path for <code>orthog.m</code> in the <code>/private</code> subfolder of <code>toolbox/matlab/elmat</code>.</p> |

# which

---

`which classname/private/fun` limits the search to private methods defined by the MATLAB class, `classname`. For example, `which dfilt/private/todtf` displays the path for `todtf.m` in the private folder of the `dfilt` class.

`which fun1 in fun2` displays the pathname to function `fun1` in the context of file `fun2`. Use this form to determine whether a local function is being called instead of a function on the path. For example, `which parseargs in area` tells you which `parseargs` function is called by `area.m`.

`which fun(a,b,c,...)` displays the path to the specified function with the given input arguments. For example, `which feval(g)`, when `g=inline('sin(x)')`, indicates that `inline/feval.m` would be invoked. `which toLowerCase(s)`, when `s=java.lang.String('my Java string')`, indicates that the `toLowerCase` method in class `java.lang.String` would be invoked.

`which file.ext` displays the full pathname of the specified file if that file is in the current working folder or on the MATLAB path. To display the path for a file that has no file extension, type “`which file.`” (the period following the filename is required). Use `exist` to check for the existence of files anywhere else.

`which fun -all` displays the paths to all items on the MATLAB path with the name `fun`. Such items include methods of instantiated classes. You may use the `-all` qualifier with any of the above formats of the `which` function.

`s = which('fun',...)` returns the results of `which` in the string `s`. For workspace variables, `s` is the string `'variable'`. You may specify an output variable in any of the above formats of the `which` function.

If `-all` is used with this form, the output `s` is always a cell array of strings, even if only one string is returned.

## Tips

For more information about how MATLAB uses scope and precedence when calling a function, see “Function Precedence Order”.

**Examples**

The statement below indicates that `pinv` is in the `matfun` folder of MATLAB.

```
which pinv
matlabroot\toolbox\matlab\matfun\pinv.m
```

To find the `fopen` function used on MATLAB serial class objects

```
which serial/fopen
matlabroot\toolbox\matlab\iofun\@serial\fopen.m % serial method
```

To find the `setMonth` method used on objects of the Java `Date` class, the class must first be loaded into MATLAB. The class is loaded when you create an instance of the class:

```
myDate = java.util.Date;
which setMonth
```

MATLAB displays:

```
setMonth is a Java method % java.util.Date method
```

When you specify an output variable, `which` returns a cell array of strings to the variable. You must use the *function* form of `which`, enclosing all arguments in parentheses and single quotes:

```
s = which('private/stradd', '-all');
whos s
  Name      Size      Bytes  Class
  s         3x1         562   cell array
Grand total is 146 elements using 562 bytes
```

# while

---

**Purpose** Repeatedly execute statements while condition is true

**Syntax** `while expression`  
`statements`  
`end`

**Description** `while expression, statements, end` repeatedly executes one or more MATLAB program *statements* in a loop as long as an expression remains true.

An evaluated expression is true when the result is nonempty and contains all nonzero elements (logical or real numeric). Otherwise, the expression is false.

Expressions can include relational operators (such as `<` or `==`) and logical operators (such as `&&`, `||`, or `~`). MATLAB evaluates compound expressions from left to right, adhering to operator precedence rules.

## Tips

- If you inadvertently create an infinite loop (that is, a loop that never ends on its own), stop execution of the loop by pressing **Ctrl+C**.
- To programmatically exit the loop, use a `break` statement. To skip the rest of the instructions in the loop and begin the next iteration, use a `continue` statement.
- You can nest any number of `while` statements. Each `while` statement requires an `end` keyword.
- Within an `if` or `while` expression, all logical operators, including `|` and `&`, short-circuit. That is, if the first part of the expression determines a true or false result, MATLAB does not evaluate the second part of the expression.

## Examples

Find the first integer `n` for which `factorial(n)` is a 100-digit number:

```
n = 1;  
nFactorial = 1;  
while nFactorial < 1e100  
    n = n + 1;
```

```
        nFactorial = nFactorial * n;
end
```

---

Count the number of lines of code in the file `magic.m`, skipping all blank lines and comments:

```
fid = fopen('magic.m','r');
count = 0;
while ~feof(fid)
    line = fgetl(fid);
    if isempty(line) || strncmp(line,'% ',1) || ~ischar(line)
        continue
    end
    count = count + 1;
end
fprintf('%d lines\n',count);
fclose(fid);
```

---

Find the root of the polynomial  $x^3 - 2x - 5$  using interval bisection:

```
a = 0; fa = -Inf;
b = 3; fb = Inf;
while b-a > eps*b
    x = (a+b)/2;
    fx = x^3-2*x-5;
    if fx == 0
        break
    elseif sign(fx) == sign(fa)
        a = x; fa = fx;
    else
        b = x; fb = fx;
    end
end
disp(x)
```

# while

---

---

Take advantage of short-circuiting to avoid error or warning messages:

```
x = 42;
while exist('myfunction.m') && (myfunction(x) >= pi)
    disp('Condition is true')
    break
end
```

| <b>Purpose</b>     | Change axes background color                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Syntax</b>      | <pre>whitebg whitebg(fig) whitebg(ColorSpec) whitebg(fig, ColorSpec) whitebg(fig, ColorSpec) whitebg(fig)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | <p><code>whitebg</code> complements the colors in the current figure.</p> <p><code>whitebg(fig)</code> complements colors in all figures specified in the vector <code>fig</code>.</p> <p><code>whitebg(ColorSpec)</code> and <code>whitebg(fig, ColorSpec)</code> change the color of the axes, which are children of the figure, to the color specified by <code>ColorSpec</code>. Without a figure specification, <code>whitebg</code> or <code>whitebg(ColorSpec)</code> affects the current figure and the root's default properties so subsequent plots and new figures use the new colors.</p> <p><code>whitebg(fig, ColorSpec)</code> sets the default axes background color of the figures in the vector <code>fig</code> to the color specified by <code>ColorSpec</code>. Other axes properties and the figure background color can change as well so that graphs maintain adequate contrast. <code>ColorSpec</code> can be a 1-by-3 RGB color or a color string such as 'white' or 'w'.</p> <p><code>whitebg(fig)</code> complements the colors of the objects in the specified figures. This syntax is typically used to toggle between black and white axes background colors, and is where <code>whitebg</code> gets its name. Include the root window handle (0) in <code>fig</code> to affect the default properties for new windows or for <code>clf reset</code>.</p> |
| <b>Tips</b>        | <p><code>whitebg</code> works best in cases where all the axes in the figure have the same background color.</p> <p><code>whitebg</code> changes the colors of the figure's children, with the exception of shaded surfaces. This ensures that all objects are visible against the new background color. <code>whitebg</code> sets the default properties on the root such that all subsequent figures use the new background color.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

# whitebg

---

## Examples

Set the background color to blue-gray.

```
whitebg([0 .5 .6])
```

Set the background color to blue.

```
whitebg('blue')
```

|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>         | List variables in workspace                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Syntax</b>          | <pre>who who(variables) who(location) who(variables,location) c = who(variables,location)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b>     | <p><code>who</code> lists in alphabetical order all variables in the currently active workspace.</p> <p><code>who(variables)</code> lists only the specified variables.</p> <p><code>who(location)</code> lists variables in the specified location: 'global' for the global workspace, or '-file' for a MAT-file. For MAT-files, you must also include the file name as an input.</p> <p><code>who(variables,location)</code> lists the specified variables in the specified location. The <code>location</code> input can appear before or after <code>variables</code>.</p> <p><code>c = who(variables,location)</code> stores the names of the variables in cell array <code>c</code>. Specifying <code>variables</code> and <code>location</code> is optional.</p> |
| <b>Tips</b>            | <ul style="list-style-type: none"><li>• The <code>who</code> function displays the variable list unless you specify an output argument.</li><li>• When used within a nested function, the <code>who</code> function lists the variables in the workspaces of that function and all functions containing that function, grouped by workspace. This applies whether you call <code>who</code> from your function code or from the MATLAB debugger.</li></ul>                                                                                                                                                                                                                                                                                                              |
| <b>Input Arguments</b> | <p><b>variables</b></p> <p>Strings that specify the variables to list. Use one of these forms:</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

# who

---

*var1, var2, ...*

List the specified variables. Use the '\*' wildcard to match patterns. For example, `who('A*')` lists all variables that start with A.

'-regexp', *expressions*

List variables whose names match the specified regular expressions.

**Default:** '\*' (all variables)

## location

String that indicates whether to list variables from the global workspace or from a file:

'global'

Global workspace.

'-file', *filename*

MAT-file. The *filename* input can include the full, relative, or partial path.

**Default:** '' (current workspace)

## Output Arguments

**c**

Cell array of strings that correspond to each variable name.

## Examples

Display information about variables in the current workspace whose names start with the letter a:

```
who a*
```

---

Show variables stored in MAT-file `durer.mat`:

```
who -file durer
```

This code returns:

Your variables are:

```
X          caption  map
```

---

Store the variable names from `durer.mat` in cell array `durerInfo`:

```
durerInfo = who('-file', 'durer');
```

Display the contents of cell array `durerInfo`:

```
for k=1:length(durerInfo)
    disp(durerInfo{k})
end
```

This code returns:

```
X
  caption
  map
```

---

Suppose that a file `mydata.mat` contains variables with names that start with `java` and end with `Array`. Display information about those variables:

```
whos -file mydata -regexp \<java.*Array\>
```

---

Call `who` within a nested function (`get_date`):

```
function who_demo
date_time = datestr(now);

[str pos] = textscan(date_time, '%S%S%S', ...
                    1, 'delimiter', '- :');
```

# who

---

```
get_date(str);

function get_date(d)
    day = d{1};
    mon = d{2};
    year = d{3};
    who
end

end
```

When you run `who_demo`, the `who` function displays the variables by function workspace (although the name of the function does not appear in the output):

Your variables are:

```
d          mon          ans          pos
day        year        date_time  str
```

## Alternatives

To view the variables in the workspace, use the Workspace browser. To view the contents of MAT-files, use the Details Panel of the Current Folder Browser.

**Purpose**

List variables in workspace, with sizes and types

**Syntax**

```
whos
whos(variables)
whos(location)
whos(variables,location)
s = whos(variables,location)
```

**Description**

`whos` lists in alphabetical order all variables in the currently active workspace, including their sizes and types.

`whos(variables)` lists only the specified variables.

`whos(location)` lists variables in the specified location: 'global' for the global workspace, or '-file' for a MAT-file. For MAT-files, you must also include the file name as an input.

`whos(variables,location)` lists the specified variables in the specified location. The `location` input can appear before or after `variables`.

`s = whos(variables,location)` stores information about the variables in structure `s`. Specifying `variables` and `location` is optional.

**Tips**

- The `whos` function displays the variable list unless you specify an output argument.
- `whos` returns the number of bytes each variable occupies in the workspace, not in a MAT-file. Version 7 and later MAT-files (the default starting with R2006b) are compressed, so the number of bytes in the file is typically less than the number of bytes required in the workspace.
- `whos -file filename` does not return the sizes of any MATLAB objects in file `filename`.
- When used within a nested function, `whos` lists the variables in the workspaces of that function and all functions containing that function, grouped by workspace. This applies whether you call `whos` from your function code or from the MATLAB debugger.

# whos

---

## Input Arguments

### variables

Strings that specify the variables to list. Use one of these forms:

*var1, var2, ...*

List the specified variables. Use the '\*' wildcard to match patterns. For example, `whos('A*')` lists all variables that start with A.

'-regexp', *expressions*

List variables whose names match the specified regular expressions.

**Default:** '\*' (all variables)

### location

String that indicates whether to list variables from the global workspace or from a file:

'global'

Global workspace.

'-file', *filename*

MAT-file. The *filename* input can include the full, relative, or partial path.

**Default:** '' (current workspace)

## Output Arguments

### s

Nested structure array that contains a scalar struct for each variable. Each scalar struct contains these fields:

|       |                                                   |
|-------|---------------------------------------------------|
| name  | Name of the variable.                             |
| size  | Dimensions of the variable array.                 |
| bytes | Number of bytes allocated for the variable array. |

|                         |                                                                                                                                                                                                                                          |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>class</code>      | Class of the variable. If the variable has no value, class is '(unassigned)'.                                                                                                                                                            |
| <code>global</code>     | True if the variable is global; otherwise, false.                                                                                                                                                                                        |
| <code>sparse</code>     | True if the variable is sparse; otherwise, false.                                                                                                                                                                                        |
| <code>complex</code>    | True if the variable is complex; otherwise, false.                                                                                                                                                                                       |
| <code>nesting</code>    | Structure with these fields: <ul style="list-style-type: none"> <li>• <code>function</code> — Name of the nested or outer function that defines the variable.</li> <li>• <code>level</code> — Nesting level of that function.</li> </ul> |
| <code>persistent</code> | True if the variable is persistent; otherwise, false.                                                                                                                                                                                    |

## Examples

Display information about variables in the current workspace whose names start with the letter a:

```
whos a*
```

---

Show variables stored in MAT-file `durer.mat`:

```
whos -file durer
```

This code returns:

| Name    | Size    | Bytes   | Class  | Attributes |
|---------|---------|---------|--------|------------|
| X       | 648x509 | 2638656 | double |            |
| caption | 2x28    | 112     | char   |            |
| map     | 128x3   | 3072    | double |            |

---

Store information about the variables from `durer.mat` in structure array `durerInfo`:

```
durerInfo = whos('-file', 'durer');
```

Display the contents of structure durerInfo:

```
for k=1:length(durerInfo)
    disp([' ' durerInfo(k).name ...
         ' ' mat2str(durerInfo(k).size) ...
         ' ' durerInfo(k).class]);
end
```

This code returns:

```
X [648 509] double
caption [2 28] char
map [128 3] double
```

---

Suppose that a file `mydata.mat` contains variables with names that start with `java` and end with `Array`. Display information about those variables:

```
whos -file mydata -regexp \<java.*Array\>
```

---

Create a function that displays information about variables with persistent, global, sparse, and complex attributes:

```
function show_attributes
persistent p;
global g;
p = 1;
g = 2;
s = sparse(eye(5));
c = [4+5i 9-3i 7+6i];
whos
```

When you call the function, `show_attributes` displays the attributes:

| Name | Size | Bytes | Class  | Attributes |
|------|------|-------|--------|------------|
| c    | 1x3  | 48    | double | complex    |
| g    | 1x1  | 8     | double | global     |
| p    | 1x1  | 8     | double | persistent |
| s    | 5x5  | 128   | double | sparse     |

---

Call whos within a nested function (get\_date):

```
function whos_demo
date_time = datestr(now);

[str pos] = textscan(date_time, '%s%s%s', ...
                    1, 'delimiter', '- :');
get_date(str);

    function get_date(d)
        day = d{1};
        mon = d{2};
        year = d{3};
        whos
    end

end
```

When you run whos\_demo, the whos function displays the variables by function workspace:

| Name                | Size | Bytes | Class | Attributes |
|---------------------|------|-------|-------|------------|
| ---- get_date ----- |      |       |       |            |
| d                   | 1x3  | 690   | cell  |            |
| day                 | 1x1  | 116   | cell  |            |
| mon                 | 1x1  | 118   | cell  |            |
| year                | 1x1  | 120   | cell  |            |

# whos

---

```
---- whos_demo -----  
ans          0x0          0 (unassigned)  
date_time    1x20         40 char  
pos          1x1          8 double  
str          1x3         690 cell
```

## Alternatives

To view the variables in the workspace, use the Workspace browser. To view the contents of MAT-files, use the Details Panel of the Current Folder Browser.

Optionally, match patterns with the '*' wildcard, such as <code>whos(matobj, 'A*')</code> . | <code>'-regex',expressions</code> | Regular expression strings that describe variable names. |
| <code>var1,...,varN</code>        | Comma-separated list of variable name strings. Optionally, match patterns with the '*' wildcard, such as <code>whos(matobj, 'A*')</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                            |                                                                                                                                            |                                   |                                                          |
| <code>'-regex',expressions</code> | Regular expression strings that describe variable names.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                            |                                                                                                                                            |                                   |                                                          |
| <b>Output Arguments</b>           | <p><b>details</b><br/>Structure array with these fields (identical to the structure returned by the <code>whos</code> function):</p> <table border="0" style="margin-left: 40px;"> <tr> <td style="padding-right: 40px;"><code>name</code></td> <td>Variable name</td> </tr> <tr> <td style="padding-right: 40px;"><code>size</code></td> <td>Dimensions of the variable</td> </tr> </table>                                                                                                                                                                                                                                                          | <code>name</code>          | Variable name                                                                                                                              | <code>size</code>                 | Dimensions of the variable                               |
| <code>name</code>                 | Variable name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                            |                                                                                                                                            |                                   |                                                          |
| <code>size</code>                 | Dimensions of the variable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                            |                                                                                                                                            |                                   |                                                          |

|            |                                                                                                                                                                                                                    |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bytes      | Number of bytes allocated for the array when you load the entire variable                                                                                                                                          |
| class      | Class (data type) of the variable                                                                                                                                                                                  |
| global     | Whether the variable is global (true or false)                                                                                                                                                                     |
| sparse     | Whether the variable is sparse                                                                                                                                                                                     |
| complex    | Whether the variable is complex                                                                                                                                                                                    |
| nesting    | Structure with these fields: <ul style="list-style-type: none"><li>• <code>function</code> — Name of the nested or outer function that defines the variable</li><li>• <code>level</code> — Nesting level</li></ul> |
| persistent | Whether the variable is persistent                                                                                                                                                                                 |

## Examples

Display a list of variables in the example file `topography.mat`:

```
matObj = matfile('topography.mat');  
whos(matObj)
```

This code returns:

| Name       | Size    | Bytes  | Class  | Attributes |
|------------|---------|--------|--------|------------|
| topo       | 180x360 | 518400 | double |            |
| topolegend | 1x3     | 24     | double |            |
| topomap1   | 64x3    | 1536   | double |            |
| topomap2   | 128x3   | 3072   | double |            |

---

Without loading any data, find the size and number of dimensions of the variable `topo` in `topography.mat`:

```
matObj = matfile('topography.mat');  
info = whos(matObj, 'topo');
```

```
sizeX = info.size  
nDimsX = length(sizeX)
```

This code returns:

```
sizeX =  
    180    360  
  
nDimsX =  
        2
```

# wilkinson

---

**Purpose** Wilkinson's eigenvalue test matrix

**Syntax** `W = wilkinson(n)`

**Description** `W = wilkinson(n)` returns one of J. H. Wilkinson's eigenvalue test matrices. It is a symmetric, tridiagonal matrix with pairs of nearly, but not exactly, equal eigenvalues.

**Examples** `wilkinson(7)`

```
ans =
```

```
    3    1    0    0    0    0    0
    1    2    1    0    0    0    0
    0    1    1    1    0    0    0
    0    0    1    0    1    0    0
    0    0    0    1    1    1    0
    0    0    0    0    1    2    1
    0    0    0    0    0    1    3
```

The most frequently used case is `wilkinson(21)`. Its two largest eigenvalues are both about 10.746; they agree to 14, but not to 15, decimal places.

**Purpose** Open file in appropriate application (Windows)

**Syntax** `winopen(fileName)`

**Description** `winopen(fileName)` opens `fileName` in the associated Microsoft Windows application. The application is associated with the extension in `fileName` in the Windows operating system. `filename` is a string enclosed in single quotes. `winopen` uses a Windows shell command, and performs the same action as double-clicking the file in the Windows Explorer program. That is, `winopen` calls the application associated with the file extension to open the file. Use an absolute or relative path for `fileName`.

**Examples** Open the file `thesis.doc`, located in the current folder, in the Microsoft Word program:

```
winopen('thesis.doc')
```

---

Open `myresults.html` in the system Web browser:

```
winopen('D:/myfiles/myresults.html')
```

---

On Microsoft Windows platforms, open the current folder in the Windows Explorer tool:

```
winopen(cd)
```

---

To open a file on the MATLAB path, use `winopen` with `which`. For example, to open the `meshgrid` function in the Editor, use:

```
winopen(which('meshgrid'))
```

**See Also** `dos` | `open` | `web`

## How To

- “Opening and Running Files”

**Purpose**

Item from Windows registry

**Syntax**

```
valnames = winqueryreg('name', 'rootkey', 'subkey')  
value = winqueryreg('rootkey', 'subkey', 'valname')  
value = winqueryreg('rootkey', 'subkey')
```

**Description**

`valnames = winqueryreg('name', 'rootkey', 'subkey')` returns all value names in `rootkey\subkey` of Microsoft Windows operating system registry to a cell array of strings. The first argument is the literal quoted string, 'name'.

`value = winqueryreg('rootkey', 'subkey', 'valname')` returns the value for value name `valname` in `rootkey\subkey`.

If the value retrieved from the registry is a string, `winqueryreg` returns a string. If the value is a 32-bit integer, `winqueryreg` returns the value as an integer of the MATLAB software type `int32`.

`value = winqueryreg('rootkey', 'subkey')` returns a value in `rootkey\subkey` that has no value name property.

---

**Note** The literal **name** argument and the `rootkey` argument are case-sensitive. The `subkey` and `valname` arguments are not.

---

**Tips**

This function works only for the following registry value types:

- strings (REG\_SZ)
- expanded strings (REG\_EXPAND\_SZ)
- 32-bit integer (REG\_DWORD)

**Examples****Example 1**

Get the value of CLSID for the MATLAB sample Microsoft COM control `mwsampctrl.2`:

```
winqueryreg 'HKEY_CLASSES_ROOT' 'mwsamp.mwsampctrl.2\clsid'
```

```
ans =  
    {5771A80A-2294-4CAC-A75B-157DCDDD3653}
```

## Example 2

Get a list in variable `mousechar` for registry subkey `Mouse`, which is under subkey `Control Panel`, which is under root key `HKEY_CURRENT_USER`.

```
mousechar = winqueryreg('name', 'HKEY_CURRENT_USER', ...  
    'control panel\mouse');
```

For each name in the `mousechar` list, get its value from the registry and then display the name and its value:

```
for k=1:length(mousechar)  
    setting = winqueryreg('HKEY_CURRENT_USER', ...  
        'control panel\mouse', mousechar{k});  
    str = sprintf('%s = %s', mousechar{k}, num2str(setting));  
    disp(str)  
end
```

```
ActiveWindowTracking = 0  
DoubleClickHeight = 4  
DoubleClickSpeed = 830  
DoubleClickWidth = 4  
MouseSpeed = 1  
MouseThreshold1 = 6  
MouseThreshold2 = 10  
SnapToDefaultButton = 0  
SwapMouseButtons = 0
```

**Purpose** Determine whether file contains 1-2-3 WK1 worksheet

---

**Note** wk1info has been removed.

---

**Syntax** [extens, typ] = wk1info(filename)

**Description** [extens, typ] = wk1info(filename) returns the string 'WK1' in extens, and ' 1-2-3 Spreadsheet' in typ if the file filename contains a readable worksheet. The filename input is a string enclosed in single quotes.

**Examples** This example returns information on spreadsheet file matA.wk1:

```
[extens, typ] = wk1info('matA.wk1')  
  
extens =  
    WK1  
typ =  
    123 Spreadsheet
```

**See Also** xlsread | xlswrite | dlmread | dlmwrite

# wk1read

## Purpose

Read Lotus 1-2-3 WK1 spreadsheet file into matrix

---

**Note** wk1read has been removed.

---

## Syntax

```
M = wk1read(filename)
M = wk1read(filename,r,c)
M = wk1read(filename,r,c,range)
```

## Description

`M = wk1read(filename)` reads a Lotus1-2-3 WK1 spreadsheet file into the matrix `M`. The `filename` input is a string enclosed in single quotes.

`M = wk1read(filename,r,c)` starts reading at the row-column cell offset specified by `(r,c)`. `r` and `c` are zero based so that `r=0`, `c=0` specifies the first value in the file.

`M = wk1read(filename,r,c,range)` reads the range of values specified by the parameter `range`, where `range` can be

- A four-element vector specifying the cell range in the format

```
[upper_left_row upper_left_col lower_right_row lower_right_col]
```

- A cell range specified as a string, for example, 'A1...C5'
- A named range specified as a string, for example, 'Sales'

**Examples**

Create a 8-by-8 matrix A and export it to Lotus spreadsheet matA.wk1:

```
A = [1:8; 11:18; 21:28; 31:38; 41:48; 51:58; 61:68; 71:78]
```

```
A =
```

| 1  | 2  | 3  | 4  | 5  | 6  | 7  | 8  |
| 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 |
| 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 |
| 31 | 32 | 33 | 34 | 35 | 36 | 37 | 38 |
| 41 | 42 | 43 | 44 | 45 | 46 | 47 | 48 |
| 51 | 52 | 53 | 54 | 55 | 56 | 57 | 58 |
| 61 | 62 | 63 | 64 | 65 | 66 | 67 | 68 |
| 71 | 72 | 73 | 74 | 75 | 76 | 77 | 78 |

```
wk1write('matA.wk1', A);
```

To read in a limited block of the spreadsheet data, specify the upper left row and column of the block using zero-based indexing:

```
M = wk1read('matA.wk1', 3, 2)
```

```
M =
```

|    |    |    |    |    |    |
|----|----|----|----|----|----|
| 33 | 34 | 35 | 36 | 37 | 38 |
| 43 | 44 | 45 | 46 | 47 | 48 |
| 53 | 54 | 55 | 56 | 57 | 58 |
| 63 | 64 | 65 | 66 | 67 | 68 |
| 73 | 74 | 75 | 76 | 77 | 78 |

To select a more restricted block of data, you can specify both the upper left and lower right corners of the block you want imported. Read in a range of values from row 4, column 3 (defining the upper left corner) to row 6, column 6 (defining the lower right corner). Note that, unlike the second and third arguments, the range argument [4 3 6 6] is one-based:

```
M = wk1read('matA.wk1', 3, 2, [4 3 6 6])
```

```
M =
```

|    |    |    |    |

# wk1read

---

## **See Also**

xlsread

**Purpose** Write matrix to Lotus 1-2-3 WK1 spreadsheet file

---

**Note** wk1write has been removed.

---

**Syntax**

```
wk1write(filename,M)
wk1write(filename,M,r,c)
```

**Description**

wk1write(filename,M) writes the matrix M into a Lotus1-2-3 WK1 spreadsheet file named filename. The filename input is a string enclosed in single quotes.

wk1write(filename,M,r,c) writes the matrix starting at the spreadsheet location (r,c). r and c are zero based so that r=0, c=0 specifies the first cell in the spreadsheet.

**Examples** Write a 4-by-5 matrix A to spreadsheet file matA.wk1. Place the matrix with its upper left corner at row 2, column 3 using zero-based indexing:

```
A = [1:5; 11:15; 21:25; 31:35]
A =
     1     2     3     4     5
    11    12    13    14    15
    21    22    23    24    25
    31    32    33    34    35
```

# wk1write

---

```
wk1write('matA.wk1', A, 2, 3)
```

```
M = wk1read('matA.wk1')
```

```
M =
```

```
    0    0    0    0    0    0    0    0
    0    0    0    0    0    0    0    0
    0    0    0    1    2    3    4    5
    0    0    0   11   12   13   14   15
    0    0    0   21   22   23   24   25
    0    0    0   31   32   33   34   35
```

## See Also

[dlmwrite](#) | [dlmread](#) | [xlswrite](#) | [xlsread](#)

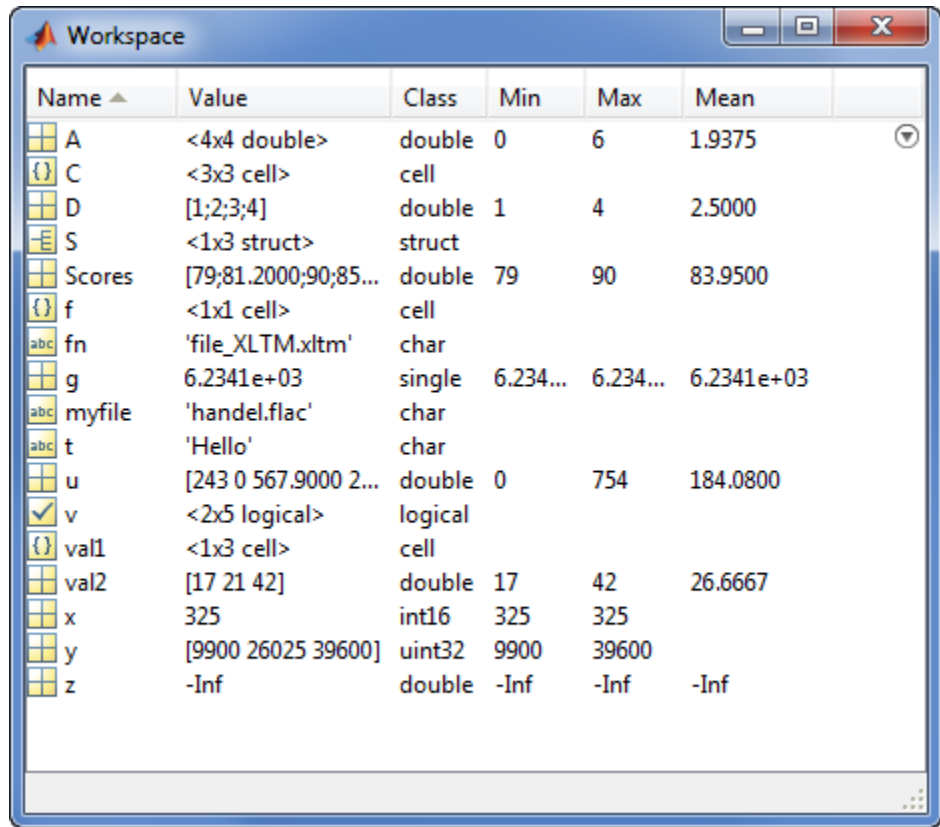

**Purpose** Open Workspace browser to manage workspace

**Syntax** workspace

**Description** workspace displays the Workspace browser, a graphical user interface that allows you to view and manage the contents of the workspace in MATLAB. It provides a graphical representation of the whos display, and allows you to perform the equivalent of the clear, load, open, and save functions.

The Workspace browser also displays and automatically updates statistical calculations for each variable, which you can choose to show or hide.

# workspace

You can edit a value directly in the Workspace browser for small numeric and character arrays. To see and edit a graphical representation of larger variables and for other classes, double-click the variable in the Workspace browser. The variable displays in the Variables editor, where you can view the full contents and make changes.

## How To

- “What Is the MATLAB Workspace?”

**Purpose**

Write entire image

**Syntax**

```
tiffobj.write(imageData)  
tiffobj.write(Y,Cb,Cr)
```

**Description**

`tiffobj.write(imageData)` writes `imageData` to TIFF file associated with the Tiff object, `tiffobj`. The `write` method breaks the data into strips or tiles, depending on the value of the `RowsPerStrip` tag, or the `TileLength` and `TileWidth` tags.

`tiffobj.write(Y,Cb,Cr)` writes the YCbCr component data to the TIFF file.

**See Also**

`Tiff.writeDirectory`

**Tutorials**

- “Exporting Image Data and Metadata to TIFF Files”

# Tiff.writeDirectory

---

**Purpose** Create new IFD and make it current IFD

**Syntax** `tiffobj.writeDirectory()`

**Description** `tiffobj.writeDirectory()` create a new image file directory (IFD) and makes it the current IFD. Tiff object methods operate on the current IFD. If you are creating a TIFF file that only contains one image, you do not need to use this method. With single-image TIFF files, just close the Tiff object to write data to the file.

**Examples** Open a TIFF file for modification and create a new IFD in the file. `writeDirectory` makes the newly created IFD the current IFD. Replace the name `myfile.tif` with the name of a TIFF file on your MATLAB path.

```
t = Tiff('myfile.tif', 'r+');
dnum = t.currentDirectory();
t.writeDirectory();
dnum = t.currentDirectory();
```

**References** This method corresponds to the `TIFFWriteDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**See Also** `Tiff.write` | `Tiff.close`

**Tutorials**

## Purpose

Write data to specified strip

## Syntax

```
tiffobj.writeEncodedStrip(stripNumber,imageData)  
tiffobj.writeEncodedStrip(stripNumber,Y,Cb,Cr)
```

## Description

`tiffobj.writeEncodedStrip(stripNumber,imageData)` writes the data in `imageData` to the strip specified by `stripNumber`. Strip identification numbers are one-based. If `imageData` has fewer bytes than fit into a strip, `writeEncodedStrip` silently pads the strip. If `imageData` has more bytes than fit into a strip, `writeEncodedStrip` issues a warning and truncates the data. To determine the size of a strip, view the value of the `RowsPerStrip` tag.

`tiffobj.writeEncodedStrip(stripNumber,Y,Cb,Cr)` writes the YCbCr component data to the specified tile. You must set the `YCbCrSubSampling` tag.

## Examples

Open a Tiff object for modification. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path. The folder in which you run the example must be writable.

```
t = Tiff('myfile.tif', 'r+');  
  
if ~t.isTiled()  
    width = t.getTag('ImageWidth');  
    height = t.getTag('RowsPerStrip');  
    numSamples = t.getTag('SamplesPerPixel');  
    imageData = zeros(height,width,numSamples,'uint8');  
    t.writeEncodedStrip(1,imageData);  
end
```

## References

This method corresponds to the `TIFFWriteEncodedStrip` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

## See Also

# Tiff.writeEncodedStrip

---

## **Tutorials**

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

## Purpose

Write data to specified tile

## Syntax

```
tiffobj.writeEncodedTile(tileNumber,imageData)  
tiffobj.writeEncodedTile(tileNumber,Y,Cb,Cr)
```

## Description

`tiffobj.writeEncodedTile(tileNumber,imageData)` writes the data in `imageData` to the tile specified by `tileNumber`. Tile identification numbers are one-based. If `imageData` has fewer bytes than fit into a tile, `writeEncodedTile` silently pads the tile. If `imageData` has more bytes than fit into a tile, `writeEncodedTile` issues a warning and truncates the data. To determine the size of a tile, view the value of the `tileLength` and `tileWidth` tags.

`tiffobj.writeEncodedTile(tileNumber,Y,Cb,Cr)` writes the YCbCr component data to the specified tile. You must set the `YCbCrSubSampling` tags.

## Examples

Open a TIFF file for modification. Replace `myfile.tif` with the name of a TIFF file on your MATLAB path.

```
t = Tiff('myfile.tif', 'r+');  
  
if t.isTiled()  
    width = t.getTag('tileWidth');  
    height = t.getTag('tileLength');  
    numSamples = t.getTag('SamplesPerPixel');  
    imageData = zeros(height,width,numSamples,'uint8');  
    t.writeEncodedTile(1,imageData);  
end
```

## **Tutorials**

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

**Purpose**

Write video data to file

**Syntax**

```
writeVideo(writerObj,frame)
writeVideo(writerObj,mov)
writeVideo(writerObj,img)
writeVideo(writerObj,images)
```

**Description**

`writeVideo(writerObj,frame)` writes a frame to the video file associated with `writerObj`.

`writeVideo(writerObj,mov)` writes a MATLAB movie to a video file. `MOV` is an array of frame structures.

`writeVideo(writerObj,img)` writes data from an image to a video file.

`writeVideo(writerObj,images)` writes a sequence of color images to a video file.

**Input Arguments****writerObj**

VideoWriter object created by the VideoWriter function.

**frame**

Structure typically returned by the `getframe` function that contains two fields: `cdata` and `colormap`. If the `colormap` is not empty, `writeVideo` expects a two-dimensional (height-by-width) array `cdata`, and constructs RGB image frames. The height and width must be consistent for all frames within a file.

**mov**

Array of frame structures, each of which contains fields `cdata` and `colormap`.

**img**

When creating AVI or MPEG-4 files, `img` is an array of `single`, `double`, or `uint8` values representing a grayscale or RGB color

# VideoWriter.writeVideo

---

image, which `writeVideo` writes as an RGB video frame. Data of type `single` or `double` must be in the range `[0,1]`.

When creating Motion JPEG 2000 files, `img` is an array of `uint8`, `int8`, `uint16`, or `int16` values representing a monochrome or RGB color image.

For grayscale or monochrome data, `img` is two-dimensional: height-by-width. For color data, `img` is three-dimensional: height-by-width-by-3. The height and width must be consistent for all frames within a file. For more information, see “Image Types”.

## images

Four-dimensional array of grayscale (height-by-width-by-1-by-frames) or RGB (height-by-width-by-3-by-frames) images.

## Examples

### AVI File from Animation

Write a sequence of frames to a compressed AVI file, `peaks.avi`.

Prepare the new file.

```
writerObj = VideoWriter('peaks.avi');  
open(writerObj);
```

Generate initial data and set axes and figure properties.

```
Z = peaks; surf(Z);  
axis tight  
set(gca, 'nextplot', 'replacechildren');  
set(gcf, 'Renderer', 'zbuffer');
```

Setting the `Renderer` property to `zbuffer` or `Painters` works around limitations of `getframe` with the OpenGL renderer on some Windows systems.

Create a set of frames and write each frame to the file.

```
for k = 1:20
    surf(sin(2*pi*k/20)*Z,Z)
    frame = getframe;
    writeVideo(writerObj,frame);
end

close(writerObj);
```

## MPG to AVI Conversion

Convert an example file, xylophone.mpg, to an uncompressed AVI file:

Create objects to read and write the video, and open the AVI file for writing.

```
readerObj = VideoReader('xylophone.mpg');
writerObj = VideoWriter('transcoded_xylophone.avi', ...
                        'Uncompressed AVI');

open(writerObj);
```

Read and write each frame.

```
for k = 1:readerObj.NumberOfFrames
    img = read(readerObj,k);
    writeVideo(writerObj,img);
end

close(writerObj);
```

# xlabel

---

## Purpose

Label *x*-axis

## Syntax

```
xlabel('string')
xlabel(fname)
xlabel(..., 'PropertyName', PropertyValue, ...)
xlabel(axes_handle, ...)
h = xlabel(...)
```

## Description

Every axes graphics object can have one label for the *x*-axis. The label appears beneath its respective axis in a two-dimensional plot and to the side or beneath the axis in a three-dimensional plot.

`xlabel('string')` labels the *x*-axis of the current axes.

`xlabel(fname)` evaluates the function `fname`, which must return a string. Then it displays the string beside the *x*-axis.

`xlabel(..., 'PropertyName', PropertyValue, ...)` specifies property name-value pairs for the text graphics object created by `xlabel`.

`xlabel(axes_handle, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = xlabel(...)` returns the handle to the text object used as the label.

## Tips

Reissuing `xlabel` command causes the new label to replace the old label.

For three-dimensional graphics, MATLAB puts the label in the front or on the side, so the plot does not hide it.

## Examples

This example shows how to give a string as input to `xlabel`.

```
xlabel('Population');
```

---

Passing a numeric input as input to the function.

```
xlabel(123);
```

---

---

Passing a handle as input to `xlabel`.

```
h = figure;  
xlabel(h);
```

---

This example displays the label in multiple lines.

```
xlabel({2010;'Population';'in Years'});
```

---

This example shows you how to use name-value pairs in `xlabel`.

```
xlabel('Population','fontsize',12,'fontweight','b','color','r');
```

When resizing the figure window, you may want to display graph to the scale or be able to see the text in title and labels completely. For more information about this, see “Properties Controlling Axes Size”.

## Alternatives

To control the presence and appearance of axis labels on a graph, use the Property Editor plotting tool . For details, see The Property Editor.

# ylabel

---

## Purpose

Label *y*-axis

## Syntax

```
ylabel('string')
ylabel(fname)
ylabel(..., 'PropertyName', PropertyValue, ...)
ylabel(axes_handle, ...)
h = ylabel(...)
```

## Description

Every axes graphics object can have one label for the *y*-axis. The label appears beneath its respective axis in a two-dimensional plot and to the side or beneath the axis in a three-dimensional plot.

`ylabel('string')` labels the *y*-axis of the current axes.

`ylabel(fname)` evaluates the function `fname`, which must return a string. Then it displays the string beside the *y*-axis.

`ylabel(..., 'PropertyName', PropertyValue, ...)` specifies property name-value pairs for the text graphics object created by `ylabel`.

`ylabel(axes_handle, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ylabel(...)` returns the handle to the text object used as the label.

## Tips

Reissuing `ylabel` command causes the new label to replace the old label.

For three-dimensional graphics, MATLAB puts the label in the front or on the side, so that the plot does not hide it.

## Examples

This example shows how to give a string as input to `ylabel`.

```
ylabel('Population');
```

---

Passing a numeric input as input to the function.

```
ylabel(123);
```

---

---

Passing a handle as input to ylabel.

```
h = figure;  
ylabel(h);
```

---

This example displays the label in multiple lines.

```
ylabel({2010;'Population';'in Years'});
```

---

This example shows you how to use name-value pairs in ylabel.

```
ylabel('Population','fontsize',12,'fontweight','b','color','r');
```

When resizing the figure window, you may want to display graph to the scale or be able to see the text in title and labels completely. For more information about this, see “Properties Controlling Axes Size”.

---

## Purpose

Label *z*-axis

## Syntax

```
zlabel('string')  
zlabel(fname)  
zlabel(..., 'PropertyName', PropertyValue, ...)  
zlabel(axes_handle, ...)  
h = zlabel(...)
```

## Description

Every axes graphics object can have one label for the *z*-axis. The label appears beneath its respective axis in a two-dimensional plot and to the side or beneath the axis in a three-dimensional plot.

`zlabel('string')` labels the *z*-axis of the current axes.

`zlabel(fname)` evaluates the function `fname`, which must return a string. Then display the string beside the *z*-axis.

`zlabel(..., 'PropertyName', PropertyValue, ...)` specifies property name-value pairs for the text graphics object created by `zlabel`.

`zlabel(axes_handle, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = zlabel(...)` returns the handle to the text object used as the label.

## Tips

Reissuing `zlabel` command causes the new label to replace the old label.

For three-dimensional graphics, MATLAB puts the label in the front or on the side, so the plot does not hide it.

## Examples

This example shows how to give a string as input to `zlabel`.

```
zlabel('Population');
```

---

Passing a numeric input as input to the function.

## How To

- “Adding Axis Labels to Graphs”

**Purpose** Set or query  $x$ -axis limits

**Syntax**

```
xlim  
xlim([xmin xmax])  
xlim('mode')  
xlim('auto')  
xlim('manual')  
xlim(axes_handle,...)
```

**Description**

`xlim` with no arguments returns the limits of the current axes.

`xlim([xmin xmax])` sets the axis limits in the current axes to the specified values.

`xlim('mode')` returns the current value of the axis limits mode, which can be either `auto` (the default) or `manual`.

`xlim('auto')` sets the axis limit mode to `auto`.

`xlim('manual')` sets the axis limit mode to `manual`.

`xlim(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, it operates on the current axes.

**Tips**

`xlim` sets or queries values of the axes object `XLim`, and `XLimMode` property.

When the axis limit mode is set to `auto` (the default), MATLAB uses limits, which are round numbers, to span the range of the data being displayed. Setting a value for any of the limits also sets the corresponding mode to `manual`. If you set the limits on an existing graph and want to maintain these limits while adding more graphs, use the `hold` command.

---

**Note** High-level plotting functions like `plot` and `surf` reset both the modes and the limits.

---

## Examples

This example illustrates how to set the  $x$ - and  $y$ -axis limits to match the actual range of the data, rather than the rounded values of  $[-2\ 3]$  for the  $x$ -axis,  $[-2\ 4]$  for the  $y$ -axis and  $[-0.5\ 0.5]$  for  $z$ -axis originally selected by MATLAB.

```
[x,y] = meshgrid([-1.75:.2:3.25]);  
z = x.*exp(-x.^2-y.^2);  
surf(x,y,z)  
xlim([-1.75 3.25])  
ylim([-1.75 3.25])  
zlim([-0.45 0.45])
```

## Alternatives

To control the upper and lower axis limits on a graph, use the Property Editor, one of the plotting tools . For details, see The Property Editor.

## See Also

- `YLim`

- ZLim
- Understanding Axes Aspect Ratio

**Purpose** Set or query *y*-axis limits

**Syntax**

```
ylim  
ylim([ymin ymax])  
ylim('mode')  
ylim('auto')  
ylim('manual')  
ylim(axes_handle,...)
```

**Description**

`ylim` with no arguments returns the limits of the current axes.

`ylim([ymin ymax])` sets the axis limits in the current axes to the specified values.

`ylim('mode')` returns the current value of the axis limits mode, which can be either `auto` (the default) or `manual`.

`ylim('auto')` sets the axis limit mode to `auto`.

`ylim('manual')` sets the axis limit mode to `manual`.

`ylim(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, it operates on the current axes.

**Tips** `ylim` sets or queries values of the axes object `YLim` and `YLimMode` property.

When the axis limit mode is set to `auto` (the default), MATLAB uses limits, which are round numbers, to span the range of the data being displayed. Setting a value for any of the limits also sets the corresponding mode to `manual`. If you set the limits on an existing graph and want to maintain these limits while adding more graphs, use the `hold` command.

---

**Note** High-level plotting functions like `plot` and `surf` reset both the modes and the limits.

---

**Examples**

This example illustrates how to set the  $x$ - and  $y$ -axis limits to match the actual range of the data, rather than the rounded values of  $[-2 \ 3]$  for the  $x$ -axis and  $[-2 \ 4]$  for the  $y$ -axis and  $[-0.5 \ 0.5]$  for  $z$ -axis originally selected by MATLAB.

```
[x,y] = meshgrid([-1.75:.2:3.25]);  
z = x.*exp(-x.^2-y.^2);  
surf(x,y,z)  
xlim([-1.75 3.25])  
ylim([-1.75 3.25])  
zlim([-0.45 0.45])
```

## Alternatives

To control the upper and lower axis limits on a graph, use the Property Editor, one of the plotting tools . For details, see The Property Editor.

# zlim

---

**Purpose** Set or query z-axis limits

**Syntax**

```
zlim
zlim([zmin zmax])
zlim('mode')
zlim('auto')
zlim('manual')
zlim(axes_handle,...)
```

**Description**

`zlim` with no arguments returns the limits of the current axes.

`zlim([zmin zmax])` sets the axis limits in the current axes to the specified values.

`zlim('mode')` returns the current value of the axis limits mode, which can be either `auto` (the default) or `manual`.

`zlim('auto')` sets the axis limit mode to `auto`.

`zlim('manual')` sets the axis limit mode to `manual`.

`zlim(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, it operates on the current axes.

**Tips**

`zlim` sets or queries values of the axes object `ZLim` and `ZLimMode` property.

When the axis limit mode is set to `auto` (the default), MATLAB uses limits, which are round numbers, to span the range of the data being displayed. Setting a value for any of the limits also sets the corresponding mode to `manual`. status = xlsfinfo(filename)
[status,sheets] = xlsfinfo(filename)
[status,sheets,format] = xlsfinfo(filename)
```

**Description** `status = xlsfinfo(filename)` returns a nonempty string when the specified file is in an Excel format that `xlsread` can read (for example, 'Microsoft Excel Spreadsheet'). Otherwise, `status` is an empty string, ''.

`[status,sheets] = xlsfinfo(filename)` returns a cell array of strings containing the names of each spreadsheet in the file.

`[status,sheets,format] = xlsfinfo(filename)` returns a string containing the format description that Excel returns for the file. On systems without Excel for Windows, `format` is an empty string, ''.

**Input Arguments**

**filename**  
String enclosed in single quotation marks that specifies the name of the file.

**Output Arguments**

**status**  
If the file is in an Excel format that `xlsread` can read, `status` is a nonempty string. Otherwise, `status` is an empty string, ''.

**sheets**  
If the file is in an Excel format that `xlsread` can read, `sheets` is a 1-by-`n` cell array of strings, where `n` is the number of worksheets. Each cell contains the name of a worksheet. If MATLAB cannot read a particular worksheet, the corresponding cell contains an error message.  
If the file is not in a readable Excel format, `sheets` is a string containing an error message.

**format**

On Windows systems with Excel software, `format` is a string that contains the description that Excel returns for the file. For example:

|                                                            |                                                            |
|------------------------------------------------------------|------------------------------------------------------------|
| <code>'xlOpenXMLWorkbook'</code>                           | Spreadsheet in XLSX format (Excel 2007 or later).          |
| <code>'xlWorkbookNormal'</code> or <code>'xlExcel8'</code> | Spreadsheet in XLS format (compatible with Excel 97-2003). |
| <code>'xlCSV'</code>                                       | File in comma-separated value (CSV) format.                |
| <code>'xlHtml'</code> or <code>'xlWebArchive'</code>       | Spreadsheet exported to HTML format.                       |

On all other systems, `format` is an empty string, `''`.

## Examples

Consider a hypothetical file with worksheets named `Sheet1`, `Income`, and `Expenses`. Get information about the file:

```
[typ, desc, fmt] = xlsfinfo('myaccount.xlsx')
```

This code returns:

```
typ =
    Microsoft Excel Spreadsheet

desc =
    'Sheet1'    'Income'    'Expenses'

fmt =
    xlOpenXMLWorkbook
```

## Limitations

- `xlsfinfo` supports only 7-bit ASCII characters.

## See Also

`xlsread` | `xlswrite`

# xlsread

---

**Purpose** Read Microsoft Excel spreadsheet file

**Syntax**

```
num = xlsread(filename)
num = xlsread(filename, sheet)
num = xlsread(filename, xlRange)
num = xlsread(filename, sheet, xlRange)
num = xlsread(filename, sheet, xlRange, 'basic')
[num, txt, raw] = xlsread( ___ )

___ = xlsread(filename, -1)
```

```
[num, txt, raw, custom] = xlsread(filename, sheet, xlRange, '',
    functionHandle)
```

**Description** `num = xlsread(filename)` reads data from the first worksheet in the Microsoft Excel spreadsheet file named `filename` and returns the numeric data in array `num`.

On Windows systems with Microsoft Excel software, `xlsread` reads any file format recognized by your version of Excel.

If your system does not have Excel for Windows, `xlsread` operates in basic import mode, and reads only XLS, XLSX, XLSM, XLTX, and XLTM files.

`num = xlsread(filename, sheet)` reads the specified worksheet.

`num = xlsread(filename, xlRange)` reads data from the specified range, `xlRange`, of the first worksheet in the file.

`num = xlsread(filename, sheet, xlRange)` reads from the specified sheet and range, `xlRange`.

`num = xlsread(filename, sheet, xlRange, 'basic')` reads data from the spreadsheet in basic mode, the default on systems without Excel for Windows.

`[num,txt,row] = xlsread( ___ )` additionally returns the text fields in cell array `txt`, and the unprocessed data (numbers and text) in cell array `row` using any of the input arguments in the previous syntaxes. If `xlRange` is specified, leading blank rows and columns in the worksheet that precede rows and columns with data are returned in `row`.

`___ = xlsread(filename, -1)` opens an Excel window to interactively select data. Select the worksheet, drag and drop the mouse over the range you want, and click **OK**. This syntax is supported only on Windows systems with Excel software.

`[num,txt,row,custom] = xlsread(filename, sheet, xlRange, '', functionHandle)` reads from the spreadsheet, executes the function associated with `functionHandle` on the data, and returns the final results as numeric data in array `num`. The `xlsread` function optionally returns the text fields in cell array `txt`, the unprocessed data (numbers and text) in cell array `row`, and the second output from the function associated with `functionHandle` in array `custom`. The `xlsread` function does not change the data stored in the spreadsheet. This syntax is supported only on Windows systems with Excel software.

## Input Arguments

### **filename - Name of file to read**

string

Name of the file to read, specified as a string. If you do not include an extension, `xlsread` searches for a file with the specified name and a supported Excel extension. `xlsread` can read data saved in files that are currently open in Excel for Windows.

**Example:** `'myFile.xlsx'`

### **sheet - Worksheet to read**

string | positive integer

Worksheet to read, specified as one of the following:

- String that contains the worksheet name. Cannot contain a colon (:). To determine the names of the sheets in a spreadsheet file, use `xlsfinfo`. For XLS files in `basic` mode, `sheet` is case sensitive.
- Positive integer that indicates the worksheet index. Not supported for XLS files in `basic` mode.

## **xlRange - Rectangular portion of the worksheet to read**

string

Rectangular portion of the worksheet to read, specified as a string.

Specify `xlRange` using the syntax '`C1:C2`', where `C1` and `C2` are two opposing corners that define the region to read. For example, '`D2:H4`' represents the 3-by-5 rectangular region between the two corners `D2` and `H4` on the worksheet. The `xlRange` input is not case sensitive, and uses Excel A1 reference style (see Excel help).

Not supported for XLS files in `basic` mode.

If you do not specify `sheet`, then `xlRange` must include both corners and a colon character, even for a single cell (such as '`D2:D2`'). Otherwise, `xlsread` interprets the input as a worksheet name (such as '`sales`' or '`D2`').

If you specify `sheet`, then `xlRange`:

- Does not need to include a colon and opposite corner to describe a single cell.
- Can refer to a named range that you defined in the Excel file (see the Excel help).

## **'basic' - Flag to request reading in basic mode**

Flag to request reading in `basic` mode, which is the default for systems without Excel for Windows. In `basic` mode, `xlsread`:

- Reads XLS, XLSX, XLSM, XLTX, and XLTM files only.
- Does not support function handle inputs.

- Imports all dates as Excel serial date numbers. Excel serial date numbers use a different reference date than MATLAB date numbers.

### **functionHandle - Handle to a custom function**

function handle

Handle to a custom function, starting with the symbol @. Supported only on Windows systems with Excel software. `xlsread` reads from the spreadsheet, executes your function on a copy of the data, and returns the final results. `xlsread` does not change the data stored in the spreadsheet.

When `xlsread` calls the custom function, it passes a range interface from the Excel application to provide access to the data. The custom function must include this interface both as an input and output argument. (See the Examples.)

**Example:** `@myFunctionHandle`

## **Output Arguments**

### **num - Numeric data**

matrix

Numeric data, returned as a two-dimensional array of `double` values. The array does not contain any information from header lines, or from outer rows or columns that contain nonnumeric data. `xlsread` converts text in inner rows and columns to `NaN`.

### **txt - Text data**

cell array

Text data, returned as a cell array. `xlsread` converts numeric values to an empty string, `''`.

Except for XLS files in basic mode, undefined values (such as `'#N/A'`) appear in the `txt` output as `'#N/A'`.

### **raw - Unprocessed data**

cell array

Unprocessed data from the worksheet, returned as a cell array.  
Contains both numeric and text data.

On systems with Excel for Windows, undefined values (such as '#N/A') appear in the raw output as 'ActiveX\_VT\_ERROR:'. For XLSX, XLSM, XLTX, and XLTM files on other systems, undefined values appear as '#N/A'.

**custom** - Second output of the function corresponding to **functionHandle**.

Second output of the function corresponding to **functionHandle**. The value and data type of **custom** are determined by the function.

## Examples

### Read Data from First Worksheet Into Numeric Array

Create an Excel file named `myExample.xlsx`.

```
values = {1, 2, 3 ; 4, 5, 'x' ; 7, 8, 9};  
headers = {'First', 'Second', 'Third'};  
xlswrite('myExample.xlsx', [headers; values]);
```

Sheet1 of `myExample.xlsx` contains:

| First | Second | Third |
|-------|--------|-------|
| 1     | 2      | 3     |
| 4     | 5      | x     |
| 7     | 8      | 9     |

Read data from the first worksheet.

```
filename = 'myExample.xlsx';  
A = xlsread(filename)
```

```
A =  
    1     2     3  
    4     5  NaN  
    7     8     9
```

xlsread returns the numeric data in array A.

### Read a Specific Range of Data

Read a specific range of data from the Excel file in the previous example.

```
filename = 'myExample.xlsx';
sheet = 1;
xlRange = 'B2:C3';

subsetA = xlsread(filename, sheet, xlRange)

subsetA =
     2     3
     5    NaN
```

### Read a Column of Data

Read the second column of data from the Excel file in the first example.

```
filename = 'myExample.xlsx';

columnB = xlsread(filename, 'B:B')

columnB =
     2
     5
     8
```

For better performance, specify the row numbers in the range, as shown in the previous example.

### Request Numeric, Text, and Unprocessed Data

Request the numeric data, text, and a copy of the unprocessed (raw) data from the Excel file in the first example.

```
[ndata, text, alldata] = xlsread('myExample.xlsx')

ndata =
     1     2     3
```

# xlsread

---

```
    4     5   NaN
    7     8     9
```

```
text =
    'First'   'Second'   'Third'
    ''        ''         ''
    ''        ''         'x'
```

```
alldata =
    'First'   'Second'   'Third'
    [ 1]      [ 2]      [ 3]
    [ 4]      [ 5]      'x'
    [ 7]      [ 8]      [ 9]
```

`xlsread` returns numeric data in array `ndata`, text data in cell array `text`, and unprocessed data in cell array `alldata`.

## Execute a Function on a Worksheet and Return Numeric Data

In the Editor, create a function to process data from a worksheet. In this case, set values outside the range `[-3, 3]` to `-3` or `3`.

```
function [Data] = setMinMax(Data)

    minval = -3; maxval = 3;

    for k = 1:Data.Count
        v = Data.Value{k};
        if v > maxval || v < minval
            if v > maxval
                Data.Value{k} = maxval;
            else
                Data.Value{k} = minval;
            end
        end
    end
end
```

In the Command Window, add data to `myExample.xlsx`.

```
misc = pi*gallery('normaldata',[10,3],1);
xlswrite('myExample.xlsx', misc, 'MyData');
```

Worksheet MyData contains the following values, which range from -6.6493 to 3.4845:

|         |         |         |
|---------|---------|---------|
| 2.7156  | -6.1744 | 1.8064  |
| 0.2959  | -2.3383 | -2.7210 |
| -2.6764 | -1.7351 | -6.6493 |
| 2.7442  | -2.5752 | -3.0300 |
| -1.3761 | 3.4845  | 0.6683  |
| -1.3498 | -1.9319 | 1.5014  |
| -3.4643 | -0.8000 | 0.3162  |
| 1.2448  | -0.8477 | 0.9344  |
| -3.0314 | -5.2527 | 1.7912  |
| 0.5292  | -5.8938 | -5.1035 |

Read the data from the worksheet, and reset any values outside the range [-3, 3]. Specify the sheet name, but use '' as placeholders for the xlRange and 'basic' inputs.

```
trim = xlsread('myExample.xlsx','MyData','','',@setMinMax)
```

```
trim =
    2.7156    -3.0000     1.8064
    0.2959    -2.3383    -2.7210
   -2.6764    -1.7351    -3.0000
    2.7442    -2.5752    -3.0000
   -1.3761     3.0000     0.6683
   -1.3498    -1.9319     1.5014
   -3.0000    -0.8000     0.3162
    1.2448    -0.8477     0.9344
   -3.0000    -3.0000     1.7912
    0.5292    -3.0000    -3.0000
```

### Request Custom Output

Execute a function on a worksheet and display the custom index output.

In the Editor, modify the function `setMinMax` from the previous example to return the indices of the changed elements (custom output).

```
function [Data, indices] = setMinMax(Data)

    minval = -3; maxval = 3;
    indices = [];

    for k = 1:Data.Count
        v = Data.Value{k};
        if v > maxval || v < minval
            if v > maxval
                Data.Value{k} = maxval;
            else
                Data.Value{k} = minval;
            end
            indices = [indices k];
        end
    end
```

Read the data from the worksheet `MyData`, and request the custom index output, `idx`.

```
[trim,txt,row,idx] = xlsread('myExample.xlsx','MyData', '', '', @setMinMax);
disp(idx)
```

```
7      9      11      15      19      20      23      24      30
```

## Algorithms

- If you do not specify `x1Range`, then `xlsread` ignores leading blank rows and columns in the worksheet that precede your data.
- If you specify `x1Range`, then leading blank rows and columns in the worksheet that precede your data are returned in `row`, but not in `num` or `txt`.
- When the specified `x1Range` overlaps merged cells:
  - On Windows systems with Excel, `xlsread` expands the range to include all merged cells.

- On systems without Excel for Windows, `xlsread` returns data for the specified range only, with empty or NaN values for merged cells.
- `xlsread` imports formatted dates as strings (such as '10/31/96'), except in basic mode and on systems without Excel for Windows.

## Limitations

- `xlsread` reads only 7-bit ASCII characters.
- `xlsread` does not support non-contiguous ranges.

## See Also

`xlswrite` | `xlsfinfo` | `importdata` | `uiimport` | `function_handle`

## Concepts

- “When to Convert Dates from Excel Files”

# xlswrite

---

## Purpose

Write Microsoft Excel spreadsheet file

## Syntax

```
xlswrite(filename,A)
xlswrite(filename,A,sheet)
xlswrite(filename,A,xlRange)
xlswrite(filename,A,sheet,xlRange)
```

```
status = xlswrite( ___ )
[status,message] = xlswrite( ___ )
```

## Description

`xlswrite(filename,A)` writes array `A` to the first worksheet in Excel file, `filename`, starting at cell `A1`.

`xlswrite(filename,A,sheet)` writes to the specified worksheet.

`xlswrite(filename,A,xlRange)` writes to the rectangular region specified by `xlRange` in the first worksheet of the file.

`xlswrite(filename,A,sheet,xlRange)` writes to the specified sheet and range, `xlRange`.

`status = xlswrite( ___ )` returns the status of the write operation, and can include any of the input arguments in previous syntaxes. When the operation is successful, `status` is 1. Otherwise, `status` is 0.

`[status,message] = xlswrite( ___ )` additionally returns any warning or error message generated by the write operation in structure `message`.

## Input Arguments

**filename - Name of file to write**

string

Name of file to write, specified as a string.

If `filename` does not exist, `xlswrite` creates a file, determining the format based on the specified extension. To create a file compatible with Excel 97-2003 software, specify an extension of `.xls`. To create files in Excel 2007 formats, specify an extension of `.xlsx`, `.xlsb`, or `.xlsm`. If you do not specify an extension, `xlswrite` uses the default, `.xls`.

**Example:** `'myFile.xlsx'`

## **A - Data to write**

`matrix` | `cell array`

Data to write, specified as a two-dimensional numeric or character array, or, if each cell contains a single element, a cell array.

If `A` is a cell array containing something other than a scalar numeric or a string, then `xlswrite` silently leaves the corresponding cell in the spreadsheet empty.

The maximum size of array `A` depends on the associated Excel version. For more information on Excel specifications and limits, see the Excel help.

**Example:** `[10,2,45;-32,478,50]`

**Example:** `{92.0,'Yes',45.9,'No'}`

## **Data Types**

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `cell`

## **sheet - Worksheet name**

`string` | `positive integer`

Worksheet name, specified as one of the following:

- String that contains the worksheet name. Cannot contain a colon (:). To determine the names of the sheets in a spreadsheet file, use `xlsfinfo`.
- Positive integer that indicates the worksheet index.

# xlswrite

---

If `sheet` does not exist, `xlswrite` adds a new sheet at the end of the worksheet collection. If `sheet` is an index larger than the number of worksheets, `xlswrite` appends empty sheets until the number of worksheets in the workbook equals `sheet`. In either case, `xlswrite` generates a warning indicating that it has added a new worksheet.

## **xlRange - Rectangular portion of the worksheet to write**

string

Rectangular portion of the worksheet to write, specified as a string.

Specify `xlRange` using the syntax '`C1:C2`', where `C1` and `C2` are two opposing corners that define the region to read. For example, '`D2:H4`' represents the 3-by-5 rectangular region between the two corners `D2` and `H4` on the worksheet. The `xlRange` input is not case sensitive, and uses Excel A1 reference style (see Excel help). `xlswrite` does not recognize named ranges.

- If you do not specify `sheet`, then `xlRange` must include both corners and a colon character, even for a single cell (such as '`D2:D2`'). Otherwise, `xlswrite` interprets the input as a worksheet name (such as '`D2`').
- If you specify `sheet`, then `xlRange` can specify only the first cell (such as '`D2`'). `xlswrite` writes input array `A` beginning at this cell.
- If `xlRange` is larger than the size of input array `A`, Excel software fills the remainder of the region with `#N/A`. If `xlRange` is smaller than the size of `A`, then `xlswrite` writes only the subset that fits into `xlRange` to the file.

## **Output Arguments**

### **status - Status of the write operation**

1 | 0

Status of the write operation, returned as either 1 (true) or 0 (false). When the write operation is successful, `status` is 1. Otherwise, `status` is 0.

### **message - Error or warning generated during the write operation**

structure array

Error or warning generated during the write operation, returned as a structure array containing two fields:

|            |                                                             |
|------------|-------------------------------------------------------------|
| message    | Text of the warning or error message, returned as a string. |
| identifier | Message identifier, returned as a string.                   |

## Examples

### Write Data to a Spreadsheet

Write a 7-element vector to an Excel file, testdata.xlsx.

```
filename = 'testdata.xlsx';  
A = [12.7, 5.02, -98, 63.9, 0, -.2, 56];  
xlswrite(filename,A)
```

### Write Data to a Specific Sheet and Range in a Spreadsheet

Write mixed text and numeric data to an Excel file, testdata.xlsx, starting at cell E1 of Sheet2.

```
filename = 'testdata.xlsx';  
A = {'Time', 'Temperature'; 12,98; 13,99; 14,97};  
sheet = 2;  
xlRange = 'E1';  
xlswrite(filename,A,sheet,xlRange)
```

## Tips

- If your system has Microsoft Office 2003 software, but you want to create a file in an Excel 2007 format, install the Office 2007 Compatibility Pack.
- Excel and MATLAB can store dates as strings (such as '10/31/96') or serial date numbers (such as 729329). If your array A includes serial date numbers, convert the dates to strings using `datestr` before calling `xlswrite`. Alternatively, see [Converting Dates](#).

# xlswrite

---

- To write data to Excel files with custom formats (such as fonts or colors), access the Windows COM server directly using `actxserver` rather than `xlswrite`. For example, Technical Solution 1-QLD4K uses `actxserver` to establish a connection between MATLAB and Excel, writes data to a worksheet, and specifies the colors of the cells.

## Algorithms

Excel converts `Inf` values to 65535. MATLAB converts `NaN` values to empty cells.

If your system does not have Excel for Windows, or if the COM server (part of the typical installation of Excel) is unavailable, then the `xlswrite` function:

- Writes array `A` to a text file in comma-separated value (CSV) format.
- Ignores the `sheet` and `xlRange` arguments.
- Generates an error when input array `A` is a cell array.

`xlsread` | `xlsfinfo`

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Read XML document and return Document Object Model node                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Syntax</b>           | <code>DOMnode = xmlread(filename)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b>      | <code>DOMnode = xmlread(filename)</code> reads the specified XML file and returns a Document Object Model node representing the document.                                                                                                                                                                                                                                                                                                                                                       |
| <b>Tips</b>             | <p>The display for a properly parsed document is <code>[#document: null]</code>. For example,</p> <pre>xDoc = xmlread('info.xml')</pre> <p>returns</p> <pre>xDoc =<br/>[#document: null]</pre>                                                                                                                                                                                                                                                                                                  |
| <b>Input Arguments</b>  | <p><b>filename</b></p> <p>String enclosed in single quotation marks that specifies the name of the local file or URL.</p>                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Output Arguments</b> | <p><b>DOMnode</b></p> <p>Document Object Model node, as defined by the World Wide Web consortium. For more information, see “What Is an XML Document Object Model (DOM)?”.</p>                                                                                                                                                                                                                                                                                                                  |
| <b>Examples</b>         | <p>The root element in an XML file sometimes includes an <code>xsi:noNamespaceSchemaLocation</code> attribute. The value of this attribute is the name of the preferred schema file. Call the <code>getAttribute</code> method to get this value:</p> <pre>xDoc = xmlread(fullfile(matlabroot,'toolbox',...<br/>                        'matlab','general','info.xml'));<br/><br/>xRoot = xDoc.getDocumentElement;<br/>schema = char(xRoot.getAttribute('xsi:noNamespaceSchemaLocation'))</pre> |

This code returns:

```
schema =  
http://www.mathworks.com/namespace/info/v1/info.xsd
```

---

Create functions that parse data from an XML file into a MATLAB structure array with fields Name, Attributes, Data, and Children:

```
function theStruct = parseXML(filename)  
% PARSEXML Convert XML file to a MATLAB structure.  
try  
    tree = xmlread(filename);  
catch  
    error('Failed to read XML file %s.',filename);  
end  
  
% Recurse over child nodes. This could run into problems  
% with very deeply nested trees.  
try  
    theStruct = parseChildNodes(tree);  
catch  
    error('Unable to parse XML file %s.',filename);  
end  
  
% ----- Local function PARSECHILDNODES -----  
function children = parseChildNodes(theNode)  
% Recurse over node children.  
children = [];  
if theNode.hasChildNodes  
    childNodes = theNode.getChildNodes;  
    numChildNodes = childNodes.getLength;  
    allocCell = cell(1, numChildNodes);  
  
    children = struct(  
        'Name', allocCell, 'Attributes', allocCell, ...
```

```
        'Data', allocCell, 'Children', allocCell);

    for count = 1:numChildNodes
        theChild = childNodes.item(count-1);
        children(count) = makeStructFromNode(theChild);
    end
end

% ----- Local function MAKESTRUCTFROMNODE -----
function nodeStruct = makeStructFromNode(theNode)
% Create structure of node info.

nodeStruct = struct(
    'Name', char(theNode.getNodeName), ...
    'Attributes', parseAttributes(theNode), ...
    'Data', '', ...
    'Children', parseChildNodes(theNode));

if any(strcmp(methods(theNode), 'getData'))
    nodeStruct.Data = char(theNode.getData);
else
    nodeStruct.Data = '';
end

% ----- Local function PARSEATTRIBUTES -----
function attributes = parseAttributes(theNode)
% Create attributes structure.

attributes = [];
if theNode.hasAttributes
    theAttributes = theNode.getAttributes;
    numAttributes = theAttributes.getLength;
    allocCell = cell(1, numAttributes);
    attributes = struct('Name', allocCell, 'Value', ...
        allocCell);

    for count = 1:numAttributes
```

# xmlread

---

```
        attrib = theAttributes.item(count-1);
        attributes(count).Name = char(attrib.getName);
        attributes(count).Value = char(attrib.getValue);
    end
end
```

## How To

- “What Is an XML Document Object Model (DOM)?”
- “Creating an XML File”

## Related Links

- [DOM Package Summary \(methods and properties for nodes\)](#)

**Purpose** Logical exclusive-OR

**Syntax** `C = xor(A, B)`

**Description** `C = xor(A, B)` performs an exclusive OR operation on the corresponding elements of arrays A and B. The resulting element `C(i, j, ...)` is logical true (1) if `A(i, j, ...)` or `B(i, j, ...)`, but not both, is nonzero.

| <b>A</b> | <b>B</b> | <b>C</b> |
|----------|----------|----------|
| Zero     | Zero     | 0        |
| Zero     | Nonzero  | 1        |
| Nonzero  | Zero     | 1        |
| Nonzero  | Nonzero  | 0        |

**Examples** Given `A = [0 0 pi eps]` and `B = [0 -2.4 0 1]`, then

```
C = xor(A,B)
C =
    0     1     1     0
```

To see where either A or B has a nonzero element and the other matrix does not,

```
spy(xor(A,B))
```

**See Also** `all` | `any` | `find` | Elementwise Logical Operators | Short-Circuit Logical Operators

# xslt

---

**Purpose** Transform XML document using XSLT engine

**Syntax**

```
result = xslt(source, style, dest)
[result,style] = xslt( ___ )
xslt( ___ , '-web')
```

**Description** `result = xslt(source, style, dest)` transforms an XML document using a stylesheet and returns the resulting document's URL. The function uses these inputs, the first of which is required:

- `source` is the filename or URL of the source XML file. `source` can also specify a DOM node.
- `style` is the filename or URL of an XSL stylesheet.
- `dest` is the filename or URL of the desired output document. If `dest` is absent or empty, the function uses a temporary filename. If `dest` is `'-tostring'`, the function returns the output document as a MATLAB string.

`[result,style] = xslt( ___ )` returns a processed stylesheet appropriate for passing to subsequent XSLT calls as `style`. This prevents costly repeated processing of the stylesheet.

`xslt( ___ , '-web')` displays the resulting document in the Help Browser.

**Tips** MATLAB uses the Saxon XSLT processor, version 6.5.5, which supports XSLT 1.0 expressions. For more information, see <http://saxon.sourceforge.net/saxon6.5.5/>

For additional information on writing XSL stylesheets, see the World Wide Web Consortium (W3C®) web site, <http://www.w3.org/Style/XSL/>.

**Examples** This example converts the file `info.xml` using the stylesheet `info.xsl`, writing the output to the file `info.html`. It launches the resulting HTML file in the MATLAB Web Browser.

```
xslt('info.xml', 'info.xsl', 'info.html', '-web')
```

`xmlread` | `xmlwrite`

# zeros

---

**Purpose** Create array of all zeros

**Syntax**

```
B = zeros(n)
B = zeros(m,n)
B = zeros([m n])
B = zeros(m,n,p,...)
B = zeros([m n p ...])
B = zeros(size(A))
Y = zeros
zeros(m, n,...,classname)
zeros([m,n,...],classname)
```

**Description** `B = zeros(n)` returns an  $n$ -by- $n$  matrix of zeros. An error message appears if  $n$  is not a scalar.

`B = zeros(m,n)` or `B = zeros([m n])` returns an  $m$ -by- $n$  matrix of zeros.

`B = zeros(m,n,p,...)` or `B = zeros([m n p ...])` returns an  $m$ -by- $n$ -by- $p$ -by-... array of zeros.

---

**Note** The size inputs  $m$ ,  $n$ ,  $p$ , ... should be nonnegative integers. Negative integers are treated as 0. If any trailing dimensions are 0, output  $B$  does not include those dimensions.

---

`B = zeros(size(A))` returns an array the same size as  $A$  consisting of all zeros.

`Y = zeros` with no arguments is the scalar 0.

`zeros(m, n,...,classname)` or `zeros([m,n,...],classname)` is an  $m$ -by- $n$ -by-... array of zeros of data type `classname`. `classname` is a string specifying the data type of the output. `classname` can have the following values: 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', or 'uint64'.

**Examples**

```
x = zeros(2,3,'int8');
```

**Tips**

The MATLAB language does not have a dimension statement; MATLAB automatically allocates storage for matrices. Nevertheless, for large matrices, MATLAB programs may execute faster if the `zeros` function is used to set aside storage for a matrix whose elements are to be generated one at a time, or a row or column at a time. For example

```
x = zeros(1,n);  
for i = 1:n, x(i) = i; end
```

`eye` | `ones` | `rand` | `randn` | `complex` | `false`

# zip

---

**Purpose** Compress files into zip file

**Syntax**

```
zip(zipfile,files)
zip(zipfile,files,rootfolder)
entrynames = zip(zipfile,files,rootfolder)
```

**Description** `zip(zipfile,files)` creates a zip file with the name `zipfile` from the list of files and folders specified in `files`. Folders recursively include all of their content.

`zip(zipfile,files,rootfolder)` specifies the path for files relative to `rootfolder` instead of the current folder.

`entrynames = zip(zipfile,files,rootfolder)` returns a string cell array of the names of the files contained in `zipfile`. Specifying `rootfolder` is optional.

## Input Arguments

### **zipfile**

String that specifies the name of the zip file. If `zipfile` has no extension, MATLAB appends the `.zip` extension.

If `files` includes relative paths, the zip file also contains relative paths. The zip file does not include absolute paths.

### **files**

String or cell array of strings containing the list of files or folders to include in `zipfile`.

Individual files that are on the MATLAB path can be specified as partial path names. Otherwise an individual file can be specified relative to the current folder or with an absolute path.

Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with `~/` or `~username/`, which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character `*` can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.

**rootfolder**

String that specifies the root of the paths for the files to zip.

Relative paths in the zip file reflect the relative paths in files, and do not include path information from rootfolder.

**Default:** current folder ('.')

**Output Arguments****entrynames**

Cell array of strings that contain the paths to the files in zipfile. If files includes relative paths, entrynames also contains relative paths.

**Examples****Zip a File**

Create a zip file of the file membrane.m, which is in the MATLAB general folder. Save the zip file tmwlogo.zip in the current folder:

```
file = fullfile(matlabroot,'toolbox','matlab','general','membrane.m');  
zip('tmwlogo',file);
```

**Zip Selected Files**

Suppose that your system has a folder named d:/myfiles. Zip the files membrane.m and logo.m, which are on the MATLAB search path, into a file named tmwlogo.zip:

```
myfile = fullfile('d:','myfiles','tmwlogo.zip');  
zip(myfile,{'membrane.m','logo.m'});
```

Zip all .m and .mat files in the current folder to the file backup.zip:

```
zip('backup',{'*.m','*.mat'});
```

**Zip a Folder**

Suppose that your current folder contains a subfolder named mywork. Zip the contents of all subfolders of mywork, and store the relative paths in the zip file:

# zip

---

```
zip('myfiles.zip','mywork');
```

## Zip Between Folders

Suppose that you have files `thesis.doc` and `defense.ppt` in `d:/PhD`. Zip these files into `thesis.zip`, one level up from the current folder:

```
zip('../thesis.zip',{'thesis.doc','defense.ppt'],'d:/PhD');
```

## Alternatives

To zip files in the Current Folder browser, select the files, right-click to open the context menu, and then select **Create Zip File**.

## See Also

`gzip` | `gunzip` | `tar` | `untar` | `unzip`

**Purpose** Turn zooming on or off or magnify by factor

**Syntax**

```
zoom on
zoom off
zoom out
zoom reset
zoom
zoom xon
zoom yon
zoom(factor)
zoom(fig, option)
h = zoom(figure_handle)
```

**Description** `zoom on` turns on interactive zooming. When interactive zooming is enabled in a figure, pressing a mouse button while your cursor is within an axes zooms into the point or out from the point beneath the mouse. Zooming changes the axes limits. When using zoom mode, you

- Zoom in by positioning the mouse cursor where you want the center of the plot to be and either
  - Press the mouse button or
  - Rotate the mouse scroll wheel away from you (upward).
- Zoom out by positioning the mouse cursor where you want the center of the plot to be and either
  - Simultaneously press **Shift** and the mouse button, or
  - Rotate the mouse scroll wheel toward you (downward).

Each mouse click or scroll wheel click zooms in or out by a factor of 2.

Clicking and dragging over an axes when zooming in is enabled draws a rubberband box. When you release the mouse button, the axes zoom in to the region enclosed by the rubberband box.

Double-clicking over an axes returns the axes to its initial zoom setting in both zoom-in and zoom-out modes.

`zoom off` turns interactive zooming off.

`zoom out` returns the plot to its initial zoom setting.

`zoom reset` remembers the current zoom setting as the initial zoom setting. Later calls to `zoom out`, or double-clicks when interactive zoom mode is enabled, will return to this zoom level.

`zoom` toggles the interactive zoom status between off and on (restoring the most recently used zoom tool).

`zoom xon` and `zoom yon` set `zoom on` for the  $x$ - and  $y$ -axis, respectively.

`zoom(factor)` zooms in or out by the specified zoom factor, without affecting the interactive zoom mode. Values greater than 1 zoom in by that amount, while numbers greater than 0 and less than 1 zoom out by  $1/\text{factor}$ .

`zoom(fig, option)` Any of the preceding options can be specified on a figure other than the current figure using this syntax.

`h = zoom(figure_handle)` returns a *zoom mode object* for the figure `figure_handle` for you to customize the mode's behavior.

## Using Zoom Mode Objects

Access the following properties of zoom mode objects via `get` and modify some of them using `set`.

- *Enable* 'on' | 'off' — Specifies whether this figure mode is currently enabled on the figure
- *FigureHandle* <handle> — The associated figure handle, a read-only property that cannot be set
- *Motion* 'horizontal' | 'vertical' | 'both' — The type of zooming enabled for the figure
- *Direction* 'in' | 'out' — The direction of the zoom operation
- *RightClickAction* 'InverseZoom' | 'PostContextMenu' — The behavior of a right-click action

A value of 'InverseZoom' causes a right-click to zoom out. A value of 'PostContextMenu' displays a context menu. This setting persists between MATLAB sessions.

- `UIContextMenu <handle>` — Specifies a custom context menu to be displayed during a right-click action

This property is ignored if the `RightClickAction` property has been set to `'on'`.

## Zoom Mode Callbacks

You can program the following callbacks for zoom mode operations.

- `ButtonDownFilter <function_handle>` — Function to intercept `ButtonDown` events

The application can inhibit the zoom operation under circumstances the programmer defines, depending on what the callback returns. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks), as follows:

```
function [res] = myfunction(obj,event_obj)
% obj          handle to the object that has been clicked on
% event_obj    struct for event data (empty in this release)
% res [output] a logical flag determines whether the zoom
%              operation should take place(for 'res' set to 'false'
%              or the 'ButtonDownFcn' property of the object should
%              take precedence (when 'res' is 'true'))
```

- `ActionPreCallback <function_handle>` — Function to execute before zooming

Set this callback if you want to execute code when a zoom operation starts. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks), as follows:

```
function myfunction(obj,event_obj)
% obj          handle to the figure that has been clicked on.
% event_obj    object containing struct of event data
```

The event data has the following field.

|      |                                             |
|------|---------------------------------------------|
| Axes | The handle of the axes that is being zoomed |
|------|---------------------------------------------|

- **ActionPostCallback** <function\_handle> — Function to execute after zooming

Set this callback if you want to execute code when a zoom operation finishes. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks), as follows:

```
function myfunction(obj,event_obj)
% obj          handle to the figure that has been clicked on
% event_obj    object containing struct of event data (same as the
%              event data of the 'ActionPreCallback' callback)
```

## Zoom Mode Utility Functions

The following functions in zoom mode query and set certain of its properties.

- **flags = isAllowAxesZoom(h,axes)** — Function querying permission to zoom axes

Calling the function `isAllowAxesZoom` on the zoom object, `h`, with a vector of axes handles, `axes`, as input returns a logical array of the same dimension as the axes handle vector, which indicates whether a zoom operation is permitted on the axes objects.

- **setAllowAxesZoom(h,axes,flag)** — Function to set permission to zoom axes

Calling the function `setAllowAxesZoom` on the zoom object, `h`, with a vector of axes handles, `axes`, and a logical scalar, `flag`, either allows or disallows a zoom operation on the axes objects.

- **info = getAxesZoomMotion(h,axes)** — Function to get style of zoom operations

Calling the function `getAxesZoomMotion` on the zoom object, `H`, with a vector of axes handles, `axes`, as input returns a character cell array of the same dimension as the axes handle vector, which indicates the type of zoom operation for each axes. Possible values for the type of operation are 'horizontal', 'vertical', or 'both'.

- `setAxesZoomMotion(h,axes,style)` — Function to set style of zoom operations

Calling the function `setAxesZoomMotion` on the zoom object, `h`, with a vector of axes handles, `axes`, and a character array, `style`, sets the style of zooming on each axes.

## Examples

### Example 1 — Entering Zoom Mode

Plot a graph and turn on Zoom mode:

```
plot(1:10);  
zoom on  
% zoom in on the plot
```

### Example 2 — Constrained Zoom

Create zoom mode object and constrain to *x*-axis zooming:

```
plot(1:10);  
h = zoom;  
set(h,'Motion','horizontal','Enable','on');  
% zoom in on the plot in the horizontal direction.
```

### Example 3 — Constrained Zoom in Subplots

Create four axes as subplots and set zoom style differently for each by setting a different property for each axes handle:

```
ax1 = subplot(2,2,1);  
plot(1:10);  
h = zoom;  
ax2 = subplot(2,2,2);  
plot(rand(3));
```

```
setAllowAxesZoom(h,ax2,false);
ax3 = subplot(2,2,3);
plot(peaks);
setAxesZoomMotion(h,ax3,'horizontal');
ax4 = subplot(2,2,4);
contour(peaks);
setAxesZoomMotion(h,ax4,'vertical');
% Zoom in on the plots.
```

### Example 4 – Coding a ButtonDown Callback

Create a `ButtonDown` callback for zoom mode objects to trigger. Copy the following code to a new file, execute it, and observe zooming behavior:

```
function demo
% Allow a line to have its own 'ButtonDownFcn' callback.
hLine = plot(rand(1,10));
set(hLine,'ButtonDownFcn','disp(''This executes'')');
set(hLine,'Tag','DoNotIgnore');
h = zoom;
set(h,'ButtonDownFilter',@mycallback);
set(h,'Enable','on');
% mouse click on the line
%
function [flag] = mycallback(obj,event_obj)
% If the tag of the object is 'DoNotIgnore', then return true.
objTag = get(obj,'Tag');
if strcmpi(objTag,'DoNotIgnore')
    flag = true;
else
    flag = false;
end
```

### Example 5 – Coding Pre- and Post-Callback Behavior

Create callbacks for pre- and post-buttonDown events for zoom mode objects to trigger. Copy the following code to a new file, execute it, and observe zoom behavior:

```
function demo
% Listen to zoom events
plot(1:10);
h = zoom;
set(h,'ActionPreCallback',@myprecallback);
set(h,'ActionPostCallback',@mypostcallback);
set(h,'Enable','on');
%
function myprecallback(obj,evd)
disp('A zoom is about to occur.');
```

```
%
function mypostcallback(obj,evd)
newLim = get(evd.Axes,'XLim');
msgbox(sprintf('The new X-Limits are [%f %f].',newLim));
```

### Example 6 – Creating a Context Menu for Zoom Mode

Coding a context menu that lets the user to switch to Pan mode by right-clicking:

```
figure;plot(magic(10))
hCMZ = uicontextmenu;
hZMenu = uimenu('Parent',hCMZ,'Label','Switch to pan','Callback','pan');
hZoom = zoom(gcf);
set(hZoom,'UIContextMenu',hCMZ);
zoom('on')
```

You cannot add items to the built-in zoom context menu, but you can replace it with your own.

### Tips

zoom changes the axes limits by a factor of 2 (in or out) each time you press the mouse button while the cursor is within an axes. You can

also click and drag the mouse to define a zoom area, or double-click to return to the initial zoom level.

You can create a zoom mode object once and use it to customize the behavior of different axes, as Example 3 illustrates. You can also change its callback functions on the fly.

---

**Note Do not change figure callbacks within an interactive mode.** While a mode is active (when panning, zooming, etc.), you will receive a warning if you attempt to change any of the figure's callbacks and the operation will not succeed. The one exception to this rule is the figure `WindowButtonMotionFcn` callback, which can be changed from within a mode. Therefore, if you are creating a GUI that updates a figure's callbacks, the GUI should somehow keep track of which interactive mode is active, if any, before attempting to do this.

---

When you assign different zoom behaviors to different subplot axes via a mode object and then link them using the `linkaxes` function, the behavior of the axes you manipulate with the mouse carries over to the linked axes, regardless of the behavior you previously set for the other axes.

### Alternatives

Use the **Zoom** tools  on the figure toolbar to zoom in or zoom out on a plot, or select **Zoom In** or **Zoom Out** from the figure's **Tools** menu. For details, see “Zooming in Graphs”.
