Above, we have used the form `{m,n}` to denote a range. Leaving out the `m` in front of the comma (which is still required) has the same effect as writing `{0,n}`, while leaving out the `n` after the comma effectively removes the upper bound. If that were legal in a regular expression, it would be the same as writing `{m,infinity}` – but that's not possible.

The following regular expression checks whether there is an `"a"` followed by at least three `"b"` followed by a `"c"` somewehere in the input string:
strmatch("abcd", "ab{3,}c"), strmatch("abbbcd", "ab{3,}c"), strmatch("abcdabbbc", "ab{3,}c")FALSE, TRUE, TRUE

FALSE, TRUE, TRUE

Just like the asterisk and plus sign discussed above, repetitions in general are by default "greedy" and can be switched to non-greedy with a following question mark:
strmatch("abcdabcdabcd", "a.{2,8}d", ReturnMatches), strmatch("abcdabcdabcd", "a.{2,8}?d", ReturnMatches)"abcdabcd", "abcd"

"abcdabcd", "abcd"

Example 9

Characters enclosed in brackets (`[ ]`) form a "character class", which matches any of the characters in the class (similar to an alternation between these characters):
strmatch("abc", "ab[cde]"), strmatch("abd", "ab[cde]"), strmatch("aba", "ab[cde]")TRUE, TRUE, FALSE

TRUE, TRUE, FALSE

Inside character classes, special characters are completely different: A dot, asterisk, plus, dollar, parentheses, or curly braces match

themselves, but a character class starting with a caret is “negated” and matches any character *not* listed:
strmatch("abcd", "[^ab]", All){"c", "d"}

{"c", "d"}

A caret not being the first character in a class represents itself:
strmatch("x^2", "[*^]2")TRUE

TRUE

A dash (-) not being the first character inside a class (apart from the caret) denotes a range of characters. Thus, we can check for a number with at least five digits in the following way:
strmatch("x = 123456...", "[0-9]{5,}", ReturnMatches)"123456"

"123456"

The exact meaning of a range depends on the language settings of your computer. (Technically, on the “collating”, which may be different for the same language on different versions of the same operating system.) For example, `"[a-z]"` may match only lowercase ASCII characters on one computer, while on the next one it also matches the uppercase characters from A through Y and on the third one includes the uppercase characters from B through Z. For this reason, it is usually a good idea to use the named character classes listed in the details above instead:
strmatch("some words", "[[:word:]]+", All){"some", "words"}

{"some", "words"}

Example 10

Some character classes are important enough to have received a short form. These short forms have the form `"\\x"` where `x` is `w`, `W`, `s`, `S`, `d`, or `D`. (The uppercase letters denote the negation of the lowercase letters.):
strmatch("abcd", "\\w"), strmatch("abcd", "\\W"), strmatch("abcd", "\\d"), strmatch("abcd", "\\D")TRUE, FALSE, FALSE, TRUE

TRUE, FALSE, FALSE, TRUE

"Negation" here means: A character not matching whatever is negated:
strmatch("abcd 1", "\\w"), strmatch("abcd 1", "\\W"), strmatch("abcd 1", "\\d"), strmatch("abcd 1", "\\D")TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE

In addition to these short forms, there are `"\\A"` and `"\\Z"`, which behave like `"^"` and `"$"` except they do not react to the `m` modifier. What is more interesting is the `"\\b"` (and its negated form, `"\\B"`) expression, which is a zero-width expression matching the place between a "word" and the spaces surrounding it (or the beginning and end of string etc.). We use this to look for words starting with an a:
strmatch("abc cbd cba (aa) b", "\\ba\\w*", All){"aa", "abc"}

{"aa", "abc"}

In the same way, `"\\b"` also matches the end of a word:
strmatch("abc cbd cba (aa) b", "\\w*a\\b", All){"aa", "cba"}

{"aa", "cba"}

Example 11

As we have seen in the first example, it is possible to change the behaviour of `strmatch` with some modifier flags. The most important example is the `i` modifier that switches on case-insensitive matching. (The precise effects of case-insensitive matching depend on your language settings, for example, most English computers won't regard the German umlauts "ä" and "Ä" as being the same up to case.) To switch case-insensitive matching on for the whole expression, simply prefix it with `"(?i)"`:
strmatch("ABC", "(?i)ab")TRUE

TRUE

To limit the effect of the modifier to some part of the expression, we wrap the expression inside "`(?i:...)`":
strmatch("ABC", "(?i:a)b"), strmatch("abc", "(?i:a)b"), strmatch("Abc", "(?i:a)b")FALSE, TRUE, TRUE

```
FALSE, TRUE, TRUE
```

Example 12

When using the results of `strmatch` with option `ReturnMatches` or `All`, it is often desirable to limit the matches beyond what is returned. Assume, for example, that we want to extract all the "words" used as function symbols (to keep things simple, we mean by this: followed by optional spaces and an opening parenthesis). Just for looking at the result, the following may be aufficient:
s := "f(sin (x) + abc + def(x))": strmatch(s, "\\b\\w+\\s*\\(", All){"def(", "f(", "sin ("}

```
{"def(", "f(", "sin ("}
```

To extract the function symbols themselves, we could use another match:
map(strmatch(s, "\\b\\w+\\s*\\(", All), strmatch, "\\w+", ReturnMatches){"def", "f", "sin"}

```
{"def", "f", "sin"}
```

However, there is a simpler way: Regular expressions can contain "zero-width assertions", which ensure that something does or does not follow, without actually including it or moving the conceptual pointer behind it. The syntax is to wrap the corresponding expression in "`(?=...)`":
strmatch(s, "\\b\\w+(?=\\s*\\()", All){"def", "f", "sin"}

```
{"def", "f", "sin"}
```

Example 13

In the same way as in “Example 12” on page 1-1813, regular expressions can also make zero-width assertions with respect to preceding text. (But thos must be of fixed width.) As an example, assume we want to extract the amount of money mentioned in the following text:
s := "In March 2005, we’ve spent $1192.23 on light.": strmatch(s, "(?<=\\$)\\d+(?:\\.\\d\\d)?", All){"1192.23"}

```
{"1192.23"}
```

Example 14

To detect where in the input string matches are found, include the option `Index` in the call:
strmatch("abc", "b", Index)[2, 2]

```
[2, 2]
```

The returned list contains two numbers, the beginning and end of the match. If no match is found, FALSE is returned:
strmatch("abc", "d", Index)FALSE

```
FALSE
```

When combined with `ReturnMatches`, the indices are followed by the match information in the list:
strmatch("abc", "b.", ReturnMatches, Index)[2, 3, "bc"]

```
[2, 3, "bc"]
```

Example 15

The option `All` causes the return value to be a set, each entry of which is of the same form as if option `All` had not been given:
strmatch("abc", ".", All), strmatch("abc", ".", Index, All), strmatch("abc", ".", ReturnMatches, All){"a", "b", "c"}, {[1, 1], [2, 2], [3, 3]}, {"a", "b", "c"}

```
{"a", "b", "c"}, {[1, 1], [2, 2], [3, 3]}, {"a", "b", "c"}
```

Parameters

text

pattern

character strings

Options

Index

Return the position of the match found. If the pattern is not found, FALSE is returned. Otherwise, the location of the match is returned as a list of two integers, `[i, j]` meaning that `text[i..j]` is the substring matched.

ReturnMatches

Return the substrings matched. If the regular expression contains groups (parenthesized subexpressions, see below), return lists containing the matched substring and the strings matched by the groups, in order of opening parnetheses.

All

By default, `strmatch` returns only the first match. With option `All`, further matches are sought and returned. If `Index` is not given, `All` implies `ReturnMatches`.

Return Values

Without options, either TRUE or FALSE is returned. With `Index`, a list of two nonnegative integers or FALSE is returned. With option `ReturnMatches`, a string or a list of strings is returned, depending on whether the pattern contains groups. With both `Index` and `ReturnMatches` given, a list starting with the indices of the match, followed by the string or strings of `ReturnMatches`, is returned. With option `All`, a set of elements of the types just described is returned.

See Also _concatlengthsubstringstringlib::containsstringlib::maskMetastringlib::pos

strprint

Purpose

Print into string

Syntax

`strprint(<All>, <Unquoted>, <NoNL>, <KeepOrder>, object1, object2, )`

Description

`strprint(objects)` returns the string `print(objects)` would display on the screen.

`strprint` returns a string that contains the output print would have sent to the screen for the same arguments. This string contains `` `\n' `` characters if the output would have consisted of multiple lines.

On Windows systems, each `\n` is preceded by `\r`, because that is the traditional end-of-line combination since that is the end-of-line combination inherited from CP/M. The examples in this documentation assume a system like UNIX. Also note that with Typesetting activated, `\r`, `\n`, `\t`, and `\b` will not be displayed in a string.

All options and dependencies on variables are interpreted as described in the documentation of print. Especially, this means PRETTYPRINT affects the output of `strprint`. Overloading of `print` is taken into account. See `?print` for details.

Environment Interactions

`strprint` is sensitive to the environment variables DIGITS, PRETTYPRINT, and TEXTWIDTH, and to the output preferences Pref::floatFormat, Pref::keepOrder, and Pref::trailingZeroes.

Examples

Example 1

The string returned by `strprint`, when printed with option `Unquoted`, yields the same output as the operands would have in the first place:
s := strprint(a*x^2-7): print(Unquoted, s) 2 a x - 7

This can be used to combine multiple outputs:
s1 := strprint(a*x^2-7): s2 := _concat("-" $ TEXTWIDTH)."\n": s3 := strprint(sin(1/x)): print(Unquoted, s1.s2.s3) 2 a x - 7

/ 1 \ sin| - | \ x /

In the example above, you can see that the output of `strprint` does not contain the spaces usually used for centering. The output in the first example was centered, because it used only a fraction of the text width, while the string `s1.s2.s3` in the second example spans the whole width of the line and is therefore printed flush left.

Example 2

`strprint` is useful for constructing pretty-print output of function environments and domains. For example, conjugate uses this method for non-typeset output:
expose(op(conjugate, 2)) proc(x) local pretty_arg; begin if PRETTYPRINT then pretty_arg := strprint(All, op(x)); if pretty_arg[2] <> pretty_arg[4] then FAIL else stdlib::Exposed(("_" $ pretty_arg[3])."\n".pretty_arg[1]) end_if else FAIL end_if end_proc

First of all, if PRETTYPRINT is FALSE, the procedure returns FAIL, indicating that it doesn't want to do the overloading. This causes standard output. The same result is given in the case of multiline output, which is detected by comparing the second and the fourth element of the return value of `strprint`. If the operand of the `conjugate` call, i.e., `op(x)`, renders into one line at the current setting of TEXTWIDTH, stdlib::Exposed is used to encapsulate the string composed of this rendering and a line of "_" above it. The net result:
conjugate(x), conjugate(f(1/x)),
conjugate(f(expand(sin(8*x))))conjugate(x), conjugate(f(1/x)),
conjugate(f(128*sin(x)*cos(x)^7 - 192*sin(x)*cos(x)^5 +
80*sin(x)*cos(x)^3 - 8*sin(x)*cos(x)))

$$\overline{x},\ \overline{f\left(\frac{1}{x}\right)},\ \overline{f\left(128\sin(x)\cos(x)^7 - 192\sin(x)\cos(x)^5 + 80\sin(x)\cos(x)^3 - 8\sin(x)\cos(x)\right)}$$

Note that the "baselines" of the expressions are intact, since the `` `\b' `` have not been touched.

Example 3

For demonstrative purposes, let us write a domain that puts an expression into a box. We make use of the fact that `strprint` returns

strings starting with a newline, of output::fence and of indexed assignment to strings:
domain box print := proc(e) local ex, str, w; save TEXTWIDTH; begin if TEXTWIDTH > 15 then TEXTWIDTH := TEXTWIDTH - 4; end_if; ex := extop(e, 1); str := strprint(All, ex); w := str[5]+4; str := output::fence("| ", " |", "\n".str[1]."\n", str[5], str[6]+1); str[1..w] := "+"._concat("-"$w-2)."+"; str[-w-1..-2] := "+"._concat("-"$w-2)."+"; str; end_proc; new := x -> new(dom, x); end_domainprint(Plain, box(a), box(sin(1/x))) +----------+ +---+ | / 1 \ | | a |, | sin| - | | +---+ | \ x / | +----------+ print(Plain, box(box(hold(E=m*c^2)))) +--------------+ | +----------+ | | | 2 | | | | E = m c | | | +----------+ | +--------------+

Example 4

As a last example, we implement a print-method for matrices over $_5$:
M5 :=
Dom::Matrix(Dom::IntegerMod(5))Dom::Matrix(Dom::IntegerMod(5))

Dom::Matrix(Dom::IntegerMod(5))

The standard output function simply puts “mod 5” behind every entry, inherited from the output method of `Dom::IntegerMod(5)`:
A :=
M5([[1,2,3,4],[5,6,7,8],[-2,-3,0,1]])Dom::Matrix(Dom::IntegerMod(5))([[1, 2, -2, -1], [0, 1, 2, -2], [-2, 2, 0, 1]])

$$\begin{pmatrix} 1 \bmod 5 & 2 \bmod 5 & 3 \bmod 5 & 4 \bmod 5 \\ 0 \bmod 5 & 1 \bmod 5 & 2 \bmod 5 & 3 \bmod 5 \\ 3 \bmod 5 & 2 \bmod 5 & 0 \bmod 5 & 1 \bmod 5 \end{pmatrix}$$

We now replace this method:
M5::print := proc(A) local str, h1, w1, h, w, b; begin [str, h1, w1, h, w, b] := strprint(All, expr(A)); _concat(str, " " $ w, "[mod 5]"); end_proc:print(A): +- -+ | 1, 2, 3, 4 | | | | 0, 1, 2, 3 | | | | 3, 2, 0, 1 | +- -+ [mod 5]

Alternatively, we can set the `[mod 5]` right beneath the brackets:

M5::print := proc(A) local str; begin str := strprint(expr(A)); str[-1..-1] := " [mod 5]"; str end_proc:print(A): +- -+ | 1, 2, 3, 4 | | | | 0, 1, 2, 3 | | | | 3, 2, 0, 1 | +- -+ [mod 5]

Parameters

$object_1$, $object_2$, ...

Any MuPAD objects

Options

All

When the option `All` is given, `strprint` returns additional information on the string generated by printing. More specifically, it returns a list consisting of

1 the formatted string,

2 the height (in characters) of the first line,

3 the width of the first line,

4 the height of the complete string,

5 the width of the complete string,

6 the baseline, counted from top to bottom.

Examples “Example 2” on page 1-1818 and “Example 3” on page 1-1818 contain sample code that makes use of this information.

Unquoted

Display character strings without quotation marks and with expanded control characters `'\n'`, `'\t'`, and `'\b'`.

NoNL

Like `Unquoted`, but no newline is put at the end. PRETTYPRINT is implicitly set to FALSE.

KeepOrder

Display operands of sums (of type "_plus") always in the internal order.

Return Values

DOM_STRING or a list of a `DOM_STRING` and five integers.

subs

Purpose

Substitute into an object

Syntax

```
subs(f, old = new, <Unsimplified>)
subs(f, old1 = new1, old2 = new2,  , options)
subs(f, [old1 = new1, old2 = new2,  ], options)
subs(f, {old1 = new1, old2 = new2,  }, options)
subs(f, table(old1 = new1, old2 = new2,  ), options)
subs(f, s1, s2,  , options)
```

Description

`subs(f, old = new)` searches `f` for operands matching `old`, and replaces `old` with `new`. See "Example 1" on page 1-1823.

The `subs` function returns a modified copy of the object. The function does not change the object itself.

By default, the `subs` function does not evaluate the result of a substitution. To enforce evaluation of all modified subexpressions, use the `EvalChanges` option. Also, you can reevaluate the whole returned result by using the eval function. Evaluation of the returned result is slower and less efficient than evaluation of the modified subexpressions. See "Example 3" on page 1-1824 and "Example 4" on page 1-1825.

The call `subs(f, old1 = new1, old2 = new2, ...)` applies the specified substitutions in a sequence from left to right (sequential substituton). This call applies each substitution (except for the first substitution) to the result of the previous substitution. See "Example 5" on page 1-1825.

The call `subs(f, [old1 = new1, old2 = new2, ...])` applies all specified substitutions to the operands of the original input object `f` (parallel substitution). This call does not use the results of any previous substitutions. If you specify multiple substitutions of the same operand, this call computes only the first substitution. Specifying substitutions by lists, sets, or tables invokes parallel substitution. See "Example 6" on page 1-1826.

The call `subs(f, s1, s2, ...)` is a general form of substitution that can combine sequential and parallel substitutions. This call is

equivalent to `subs(... subs(subs(f, s1), s2), ...)`. MuPAD treats each substitution step as a sequential or a parallel substitution depending on the form of the parameters `s1`, `s2`, ... See "Example 7" on page 1-1827.

`subs` replaces only those operands that you can access via the function op ("syntactical substitution"). To apply a more "semantical" substitution, use the subsex function. The subsex function also identifies and replaces partial sums and products. See "Example 8" on page 1-1827.

You can use `subs` to replace operands of expression sequences. The `subs` function does not flatten such objects. See "Example 9" on page 1-1828.

If you do not specify substitutions, `subs` returns the original expression without modifications. For example, `subs(f)` returns `f`.

Examples

Example 1

Use the `subs` function to substitute the operands in the following expressions:
subs(a + b*a, a = 4)4*b + 4

$$4\,b + 4$$

subs([a * (b + c), sin(b +c)], b + c = a)[a^2, sin(a)]

$$[a^2, \sin(a)]$$

Example 2

When replacing the sine function in an expression, use the hold command to prevent the evaluation of the identifier `sin`:
subs(sin(x), hold(sin) = cos); domtype(hold(sin))cos(x)

$$\cos(x)$$

DOM_IDENT

DOM_IDENT

Otherwise, MuPAD replaces `sin` by its value. The function environment (see funcenv) defines the value of `sin`:
subs(sin(x), sin = cos); domtype(sin)sin(x)

$\sin(x)$
DOM_FUNC_ENV

DOM_FUNC_ENV

Inside the expression `sin(x)`, the 0-th operand `sin` is the identifier, not the function environment:
domtype(op(sin(x), 0))DOM_IDENT

DOM_IDENT

Example 3

The `subs` function evaluates the original expression, performs a substitution, but does not evaluate the modified expression:
subs(y^2 + sin(x), x = PI)y^2 + sin(PI)

$y^2 + \sin(\pi)$

To evaluate the modified subexpression, use the `EvalChanges` option:
subs(y^2 + sin(x), x = PI, EvalChanges)y^2

y^2

Alternatively, use the eval function to evaluate the result returned by `subs`:
S := subs(y^2 + sin(x), x = PI): eval(S)y^2

y^2

Example 4

The `subs` function with the `EvalChanges` option returns the same results as the evaluation of the whole expression:
eval(subs(sin(x + 3 - PI)*numeric::int(_plus(sin(k/y) $ k = 1..5), y = 0..1), x=-3)); subs(sin(x + 3 - PI)*numeric::int(_plus(sin(k/y) $ k = 1..5), y = 0..1), x = -3, EvalChanges)0

```
0
```

0

```
0
```

The evaluation of the returned result is slower and less efficient than the evaluation of the modified subexpressions:
time(eval(subs(sin(x + 3 - PI)*numeric::int(_plus(sin(k/y) $ k = 1..5), y = 0..1), x = -3))); time(subs(sin(x + 3 - PI)*numeric::int(_plus(sin(k/y) $ k = 1..5), y = 0..1), x = -3, EvalChanges))12218.75

```
12218.75
```

6265.625

```
6265.625
```

Example 5

The following call results in the sequential substitution _outputSequence(x, Symbol::rightarrow, y, Symbol::rightarrow, z)$x \to y \to z$:
subs(x^3 + y*z, x = y, y = z)z^3 + z^2

$$z^3 + z^2$$

Example 6

The `subs` function lets you use sequential and parallel substitutions. For example, substitute the operand in the following expressions sequentiallly:
subs(a^2 + b^3, a = b, b = a)a^3 + a^2

$$a^3 + a^2$$

subs(a^2 + b^3, b = a, a = b)b^3 + b^2

$$b^3 + b^2$$

For the same expression, parallel substitution swaps the identifiers:
subs(a^2 + b^3, [a = b, b = a])a^3 + b^2

$$a^3 + b^2$$

In the following call, the substitution of `y + x` for `a` yields the intermediate result `y + 2*x`. From there, the substitution of `z` for `x` results in `y + 2 z`:
subs(a + x, a = x + y, x = z)y + 2*z

$$y + 2\,z$$

Parallel substitution produces a different result. The following call substitues `a` with `x + y`. Simultaneously, this call substitutes the operand `x` *of the original expression* `a + x` with `z`:
subs(a + x, [a = x + y, x = z])x + y + z

$$x + y + z$$

If you specify the substitutions using a set of a table of equations, the `subs` function also performs a parallel substitution:
subs(a + x, {a = x + y, x = z})x + y + z

$x + y + z$

T := table(): T[a] := x + y: T[x] := z: Ttable(x = z, a = x + y)

a	x + y
x	z

subs(a + x, T)x + y + z

$x + y + z$

delete T:

Example 7

You can combine sequential and parallel substitutions:
subs(a + x, {a = x + y, x = z}, x = y)2*y + z

$2\,y + z$

Example 8

The `subs` function replaces only those operands that the op function can return. The following expression contains the subexpression `x + y` as the operand `op(f, [1, 2])`:
f := sin(z*(x + y)): op(f, [1, 2]);x + y

$x + y$

Consequently, the `subs` function replaces this subexpression:
subs(f, x + y = z)sin(z^2)

$\sin\left(z^2\right)$

Syntactically, the following sum does not contain the subexpression `x + y`. Therefore, the `subs` function does not replace it:
subs(x + y + z, x + y = z)x + y + z

$x + y + z$

In contrast to `subs`, the subsex function finds and replaces partial sums and products:
subsex(x + y + z, x + y = z)2*z

$2\,z$

subs(a*b*c, a*c = 5), subsex(a*b*c, a*c = 5)a*b*c, 5*b

$a\,b\,c,\ 5\,b$

delete f:

Example 9

You can substitute operands of expression sequences. Enclose sequences in parentheses:
subs((a, b, a*b), a = x)x, b, b*x

$x,\ b,\ b\,x$

Example 10

The `Unsimplified` option suppresses simplification:
subs(a + b + 2, a = 1, b = 0, Unsimplified)1 + 0 + 2

$1 + 0 + 2$

Example 11

If you try to substitute something in a domain, MuPAD ignores the substitution. For example, define a new domain with the methods `"foo"` and `"bar"`:
mydomain := newDomain("Test"): mydomain::foo := x -> 4*x:
mydomain::bar := x -> 4*x^2:

Now try to replace every number 4 inside the domain with the number 3:
mydomain := subs(mydomain, 4 = 3):

That substitution does not have any effect:
mydomain::foo(x), mydomain::bar(x)4*x, 4*x^2

$$4\,x,\ 4\,x^2$$

To substitute objects in a domain method, you must substitute in the individual methods:
mydomain::foo := subs(mydomain::foo, 4 = 3): mydomain::bar := subs(mydomain::bar, 4 = 3): mydomain::foo(x), mydomain::bar(x)3*x, 3*x^2

$$3\,x,\ 3\,x^2$$

delete mydomain:

Parameters

f

An arbitrary MuPAD object

old, $\mathbf{old_1}$, $\mathbf{old_2}$, ...

Arbitrary MuPAD objects

new, $\mathbf{new_1}$, $\mathbf{new_2}$, ...

Arbitrary MuPAD objects

$\mathbf{s_1}$, $\mathbf{s_2}$, ...

Either equations `old = new`, or lists or sets of such equations, or tables whose entries are interpreted as such equations.

Options

EvalChanges

After substitution, evaluate all modified subexpressions.

By default, the `subs` function does not evaluate the modified object. The `EvalChanges` option enforces the evaluation of all modified subexpressions. See “Example 3” on page 1-1824 and “Example 4” on page 1-1825.

Unsimplified

Do not simplify the result of a substitution.

As the last step of a substitution, MuPAD automatically simplifies (but does not evaluate) the modified object. The `Unsimplified` option suppresses the final simplification. See “Example 10” on page 1-1828.

Return Values

Copy of the input object with replaced operands.

Overloaded By

`f`

evalAtextnopsextopextsubsophasmapmatchopsubsexsubsop

subset_subset_notsubset

Purpose

Relation “is a subset of”

Syntax

```
A subset B
_subset(A, B)
not A subset B
_notsubset(A, B)
```

Description

`A subset B` represents the expression A subset B$A \subset B$.

A is a subset of B if $x \ A \Rightarrow x \ B$.

The function `_notsubset` exists for typesetting purposes. It is returned as the result of negating a `subset` expression. See “Example 4” on page 1-1832.

If called with symbolic arguments (anything but sets), these functions return a symbolic expression of type _in or the unevaluated input.

Examples

Example 1

When called with two sets, these functions return a Boolean value:
{1} subset {1,2,3}, {} subset {1}, {1} subset {1}, {1} subset {}TRUE, TRUE, TRUE, FALSE

```
TRUE, TRUE, TRUE, FALSE
```

Example 2

Note: identifiers in sets are not assumed to be place-holders. See ?= for details on syntactic equality.
{x} subset {1,2}FALSE

```
FALSE
```

Example 3

If one of the arguments is not a set, these functions return an equivalent symbolic expression:

{1} subset A, A subset {1}1 in A, A subset {1}

$1 \in A, A \subset \{1\}$

Example 4

For “pretty typesetting”, the negation of `subset`is implemented in a special function environment:
not A subset Bnot A subset B

$A \not\subset B$

type(%)"_notsubset"

"_notsubset"

Parameters

A

B

subsex

Purpose

Extended substitution

Syntax

```
subsex(f, old = new, <Unsimplified>)
subsex(f, old_1 = new_1, old_2 = new_2,  , <Unsimplified>)
subsex(f, [old_1 = new_1, old_2 = new_2,  ], <Unsimplified>)
subsex(f, {old_1 = new_1, old_2 = new_2,  }, <Unsimplified>)
subsex(f, table(old_1 = new_1, old_2 = new_2,  ), <Unsimplified>)
subsex(f, s_1, s_2,  , <Unsimplified>)
```

Description

`subsex(f, old = new)` returns a copy of the object `f` in which all expressions matching `old` are replaced by the value `new`. In contrast to the function subs, `subsex` also replaces "incomplete" subexpressions.

`subsex` returns a modified copy of the object, but does not change the object itself.

`subsex(f, old = new)` searches `f` for subexpressions matching `old`. Each such subexpression is replaced by `new`.

In most cases, `subsex` leads to the same result as subs. However, in contrast to `subs`, `subsex` allows to replace "incomplete" subexpressions such as `a + b` in a sum `a + b + c`. In general, combinations of the operands of the n-ary "operators" +, *, and, _exprseq, intersect, or, _lazy_and, _lazy_or, and union can be replaced. In particular, partial sums and partial products can be replaced. Note that these operations are assumed to be commutative, e.g., `subsex(a*b*c, a*c = new)` does replace the partial product `a*c` by `new`. See "Example 1" on page 1-1834 and "Example 2" on page 1-1835.

`subsex` additionally replaces powers with the same base, if the exponent of the expression is an integer multiple of the replacement power, e.g. like in `subsex(a^4, a^2 = new)`. This rule also matches inverted expressions like in `subsex(1/sqrt(x), sqrt(x)=new)`, which is internally equivalent to `subsex(x^(-1/2), x^(1/2)=new)`. Cf. "Example 3" on page 1-1835.

`subsex` is much slower than `subs`! If subs can do the substitution, use subs rather than `subsex`.

The call `subsex(f, old1 = new1, old2 = new2, ...)` invokes a "sequential substitution". See the subs help page for details.

The call `subsex(f, [old1 = new1, old2 = new2, ...])` invokes a "parallel substitution". See the subs help page for details.

The call `subsex(f, s1, s2, ...)` describes the most general form of substitution which may combine sequential and parallel substitutions. This call is equivalent to `subsex(... subsex(subsex(f, s1), s2), ...)`. Depending on the form of `s1`, `s2`, ..., sequential or parallel substitutions are carried out in each step. An example can be found on the subs help page.

After substitution, the result is not evaluated. Use the function eval to enforce evaluation. Cf. "Example 5" on page 1-1837.

Operands of expression sequences can be replaced by `subsex`. Such objects are not flattened. Cf. "Example 6" on page 1-1837.

The call `subsex(f)` is allowed; it returns `f` without modifications.

Examples

Example 1

We demonstrate some simple substitutions; `subsex` finds and replaces partial sums and products:
subsex(a + b + c, a + c = x)b + x

$$b + x$$

subsex(a*b*c, a*c = x)b*x

$$b\,x$$

subsex(a * (b + c) + b + c, b + c = a)a^2 + a

$$a^2 + a$$

subsex(a + b*c*d + b*d, b*d = c);c^2 + c + a

$$c^2 + c + a$$

Example 2

We replace subexpressions inside an expression sequence and a symbolic union of sets:
subsex((a, b, c, d), (b, d) = w)a, c, w

a, c, w

subsex(a union b union c, a union b = w)c union w

$c \cup w$

The same can be achieved by using the functional equivalent union of the operator union:
subsex(_union(a, b, c), _union(a, b) = w)c union w

$c \cup w$

Example 3

`subsex` replaces powers with with the same base, if the exponent of the expression is an integer multiple of the replacement power:
subsex(1/a^4, a^2 = X)1/X^2

$\frac{1}{X^2}$

This holds even for exponents which are expressions:
subsex(1/a^(6*x), a^(2*x) = X)1/X^3

$\frac{1}{X^3}$

`1/sqrt(x)` is internally `x^(-1/2)`, so the replacement of `sqrt(x)` which is internally `x^(1/2)` works, too:
subsex(1/sqrt(n), sqrt(n) = X)1/X

$\frac{1}{X}$

Example 4

`subsex` (and also subs) are often useful to convert the output of one command into a form required by the next one. As an example, we compute the Laplace transform of the two-dimensional ODE

x'(t) = x(t) + 2*y(t), x(0) = 1

$x'(t) = x(t) + 2\,y(t),\ x(0) = 1$

y'(t) = 5*x(t) + 2*y(t), y(0) = -2

$y'(t) = 5\,x(t) + 2\,y(t),\ y(0) = -2$

and transform the result into a form suitable for calling solve by replacing the unknown Laplace transforms by symbolic names: xfrm1 := laplace(x'(t) = x(t) + 2*y(t), t, s); xfrm2 := laplace(y'(t) = 5*x(t) + 2*y(t), t, s)s*laplace(x(t), t, s) - x(0) = laplace(x(t), t, s) + 2*laplace(y(t), t, s)

$s\,\mathrm{laplace}(x(t), t, s) - x(0) = \mathrm{laplace}(x(t), t, s) + 2\,\mathrm{laplace}(y(t), t, s)$

s*laplace(y(t), t, s) - y(0) = 5*laplace(x(t), t, s) + 2*laplace(y(t), t, s)

$s\,\mathrm{laplace}(y(t), t, s) - y(0) = 5\,\mathrm{laplace}(x(t), t, s) + 2\,\mathrm{laplace}(y(t), t, s)$

For readability, we give names to both substitutions: sub_x := laplace(x(t),t,s) = X: sub_y := laplace(y(t),t,s) = Y:Leqn1 := subs(xfrm1, sub_x, sub_y, x(0) = 1); Leqn2 := subs(xfrm2, sub_x, sub_y, y(0) =-2)X*s - 1 = X + 2*Y

$X\,s - 1 = X + 2\,Y$

Y*s + 2 = 5*X + 2*Y

$$Y s + 2 = 5 X + 2 Y$$

solve({Leqn1, Leqn2}, {X, Y})piecewise([s^2 = 3*s + 8, {}], [s^2 <> 3*s + 8, {[X = -(s - 6)/(- s^2 + 3*s + 8), Y = (2*s - 7)/(- s^2 + 3*s + 8)]}])

$$\begin{cases} \emptyset & \text{if } s^2 = 3 s + 8 \\ \left\{\left[X = -\frac{s-6}{-s^2+3 s+8},\ Y = \frac{2 s-7}{-s^2+3 s+8}\right]\right\} & \text{if } s^2 \neq 3 s + 8 \end{cases}$$

(This example was suggested by MuPAD user Brad Cooper.)

Example 5

The result of `subsex` is not evaluated. In the following call, the identifier `sin` is not replaced by its value, i.e., by the procedure defining the behavior of the system's sine function. Consequently, `sin(2*PI)` is not simplified to 0 by this procedure:
subsex(sin(2*x*y), x*y = PI)sin(2*PI)

$$\sin(2\,\pi)$$

The function eval enforces evaluation:
eval(subsex(sin(2*x*y), x*y = PI))0

$$0$$

Example 6

Operands of expression sequences can be subtituted. Note that sequences need to be enclosed in brackets:
subsex((a, b, a*b*c), a*b = x)a, b, c*x

$$a,\ b,\ c\,x$$

Example 7

The option `Unsimplified` suppresses simplification:
subsex(2 + a + b, a + b = 0, Unsimplified)2 + 0

```
2 + 0
```

Parameters

f

An arbitrary MuPAD object

old, old_1, old_2, ...

Arbitrary MuPAD objects

new, new_1, new_2, ...

Arbitrary MuPAD objects

s_1, s_2, ...

Either equations `old = new`, or lists or sets of such equations, or tables whose entries are interpreted as such equations.

Options

Unsimplified

Prevents simplification of the returned object after substitution

As the last step of a substitution, the modified object is simplified (however, not evaluated). This option suppresses this final simplification. An example can be found on the subs help page.

Return Values

Copy of the input object with replaced operands.

Overloaded By

`f`

See Also

evalAtextnopsextopextsubsophasmapmatchopsubssubsop

subsop

Purpose

Replace operands

Syntax

```
subsop(object, i1 = new1, i2 = new2,  , <Unsimplified>)
```

Description

`subsop` returns a modified copy of the object, but does not change the object itself.

`subsop(object, i = new)` replaces the operand `op(object, i)` by `new`. Operands are specified in the same way as with the function op: `i` may be an integer or a list of integers. E.g., `subsop(object, [j, k] = new)` replaces the suboperand `op(op(object, j), k)`. Cf. "Example 2" on page 1-1840. In contrast to op, ranges cannot be used in `subsop` to specify more than one operand to replace. Several substitution equations have to be specified instead.

If several operands are to be replaced, the specified substitutions are processed in sequence from left to right. Each substitution is carried out and the result is processed further with the next substitution. The intermediate objects are not simplified.

The result of `subsop` is not evaluated further. It can be evaluated via the function eval. Cf. "Example 3" on page 1-1840.

Operands of expression sequences can be replaced by `subsop`. Such objects are not flattened.

Note that the order of the operands may change by replacing operands and evaluating the result. Cf. "Example 4" on page 1-1841.

`FAIL` is returned if an operand cannot be accessed.

Substitution via `subsop` is faster than via subs or subsex.

The call `subsop(object)` is allowed; it returns the object without modifications.

Examples

Example 1

We demonstrate how to replace one or more operands of an expression: x := a + b: subsop(x, 2 = c)a + c

$a + c$

subsop(x, 1 = 2, 2 = c)c + 2

$c + 2$

Also the 0-th operand of an expression (the “operator”) can be replaced:
subsop(x, 0 = _mult)a*b

$a\,b$

The variable `x` itself was not affected by the substitutions:
xa + b

$a + b$

delete x:

Example 2

The following call specifies the suboperand `c` by a list of integers:
subsop([a, b, f(c)], [3, 1] = x)[a, b, f(x)]

$[a, b, f(x)]$

Example 3

This example demonstrates the effect of simplification. The following substitution replaces the first operand `a` by 2. The result simplifies to 3:
subsop(a + 1, 1 = 2)3

3

The option `Unsimplified` suppresses the simplification:
subsop(a + 1, 1 = 2, Unsimplified)2 + 1

$2 + 1$

The next call demonstrates the difference between *simplification* and *evaluation*. After substitution of `PI` for `x`, the identifier `sin` is not evaluated, i.e., the body of the system function `sin` is not executed:
subsop(sin(x), 1 = PI)sin(PI)

$\sin(\pi)$

Evaluation of `sin` simplifies the result:
eval(%)0

0

Example 4

The order of operands may change by substitutions. Substituting `z` for the identifier `b` changes the internal order of the terms in `x`:
x := a + b + c: op(x)a, b, c

a, *b*, *c*

x := subsop(x, 2 = z): op(x)a, c, z

a, *c*, *z*

delete x:

Parameters

object

Any MuPAD object

i_1, i_2, ...

Integers or lists of integers

new_1, new_2, ...

Arbitrary MuPAD objects

Options

Unsimplified

As the last step of a substitution, the modified object is simplified (however, not evaluated). This option suppresses this final simplification. Cf. “Example 3” on page 1-1840.

Return Values

Input object with replaced operands or FAIL.

Overloaded By

`object`

Algorithms

For overloading `subsop`, it is sufficient to handle the cases `subsop(object)` and `subsop(object, i = new)`.

The case where the position of the operand to be replaced is given by a list is always handled recursively: First, op is called with the list bar the last element to find the object to substitute in (using the overloading of op if present, storing all the intermediate results), then the substitution is performed on that sub-object (using the overloading of `subsop` of the form `subsop(subobj, i = new)`). The result is substituted into the last-but-one result of the recursive op call, again respecting any overloading of `subsop`, and so on up to the front of the list.

substring

Purpose

Extract a substring from a string

Syntax

```
substring(string, i)
substring(string, i, l)
substring(string, i .. j)
```

Description

`substring(string, i)` returns the *i*-th character of a string.

`substring(string, i, l)` returns the substring of length `l` starting with the *i*-th character of the string.

`substring(string, i..j)` returns the substring consisting of the characters *i* through *j*, inclusive.

The empty string `""` is returned if the length `l = 0` is specified.

`substring` is considered obsolete. You should use index access to strings instead.

Examples

Example 1

We extract individual characters from a string:
substring("123456789", i) $ i = 1..9"1", "2", "3", "4", "5", "6", "7", "8", "9"

"1", "2", "3", "4", "5", "6", "7", "8", "9"

Substrings of various lengths are extracted:
substring("123456789", 1, 2), substring("123456789", 4, 4)"12", "4567"

"12", "4567"

Substrings of length 0 are empty strings:
substring("123456789", 4, 0)""

""

Ranges may be used to specify the substrings:

substring("123456789", 1..9)"123456789"

"123456789"

Example 2

The following while loop removes all trailing blank characters from a string:
string := "MuPAD ": while substring(string, length(string)) = " " do
string := substring(string, 1..length(string) - 1) end_while"MuPAD"

"MuPAD"

Parameters

string

A nonempty character string

i

An integer between `1` and `length(string)`

I

An integer between `1` and `length(string)`

j

An integer between `i` and `length(string)`

Return Values

Character string

See Also

lengthstrmatchstringlib::subs

_subtract

Purpose

Subtract expressions

Syntax

```
_subtract(x, y)
```

Description

`_subtract(x, y)` subtracts `y` from `x`.

The difference operator `-` does not call `_subtract(x, y)`. The difference `x - y` is equivalent to `x + (-y) = _plus (x, _negate(y))`.

To implement the slot `d::_subtract` for your domain `d`, use the following convention:

- If both `x` and `y` are elements of `d`, the slot must return an appropriate difference of type `d`.
- If `x` or `y` is not an element of `d` and cannot be converted to an element of `d`, the slot must return FAIL.
- If `x` or `y` is not an element of `d`, but can be converted to type `d`, use the following approach. This object must be converted to an element of `d` only if the mathematical semantics is obvious to all users of `d`, including the users who treat this domain as a "black box". For example, you can regard integers as rational numbers because of the natural mathematical embedding, but you must make sure that all users are aware of this approach. Otherwise, the `"_subtract"` method must return FAIL instead of using implicit conversions. If you use implicit conversions for the elements of your domain, document these conversions.

In the MuPAD standard installation, most of the library domains comply with this convention.

`_subtract` can subtract polynomials of the DOM_POLY type from a polynomial of the same type. The polynomials must have the same indeterminates and the same coefficient ring.

`_subtract` can subtract finite sets from a finite set. For finite sets `X` and `Y`, the difference is the set ImageSet(x-y, x in X, y in Y)$\{x-y \mid x \in X, y \in Y\}$.

Examples

Example 1

Compute the difference of the following arithmetical expressions by using the `_subtract` method. Then, compute the difference of the same expressions by using the difference operator:
_subtract(x, y), x - yx - y, x - y

$$x - y,\ x - y$$

Although both `_subtract` and the difference operator return the same result for these expressions, the `_subtract` call is not equivalent to `x - y`:
type(hold(x - y)), type(hold(_subtract(x, y)))"_plus", "_subtract"

"_plus", "_subtract"

Example 2

Use the `_subtract` function when combining the following lists:
zip([a, b, c, d], [1, 2, 3, 4], _subtract)[a - 1, b - 2, c - 3, d - 4]

$$[a - 1,\ b - 2,\ c - 3,\ d - 4]$$

Parameters

x

y

arithmetical expressions, polynomials of type DOM_POLY, or sets

Return Values

arithmetical expression, a polynomial, or a set.

Overloaded By

x, y

See Also

+-*/^_invertpolyPref::keepOrder

sum

Purpose

Definite and indefinite summation

Syntax

```
sum(f, i)
sum(f, i = a .. b)
sum(f, i = RootOf(p, x))
```

Description

`sum(f, i)` computes a symbolic antidifference of $f(i)$ with respect to i.

`sum(f, i = a..b)` tries to find a closed form representation of the sum sum(f(i), i=a..b)$\sum_{i=a}^{b} f(i)$.

`sum` serves for simplifying *symbolic* sums (the discrete analog of integration). It should *not* be used for simply adding a finite number of terms: if `a` and `b` are integers of type DOM_INT, the call `_plus(f $ i = a..b)` gives the desired result, while `sum(f, i = a..b)` may return unevaluated. expand may be used to sum such an unevaluated finite sum. See “Example 3” on page 1-1849.

`sum(f, i)` computes the indefinite sum of `f` with respect to `i`. This is an expression `g` such that $f(i) = g(i + 1) - g(i)$.

It is implicitly assumed that `i` runs through integers only.

`sum(f, i = a..b)` computes the definite sum with `i` running from `a` to `b`.

If `a` and `b` are numbers, then they must be integers.

If `b - a` is a nonnegative integer, then the explicit sum $f(a) + f(a + 1) + \ldots + f(b)$ is returned, provided that this sum has no more than 1000 terms.

`sum(f, i = RootOf(p, x))` computes the sum with `i` extending over all roots of the polynomial `p` with respect to `x`.

If `f` is a rational function of `i`, a closed form of the sum will be found.

See “Example 2” on page 1-1849.

The system returns a symbolic call of `sum` if it cannot compute a closed form representation of the sum.

Infinite symbolic sums without symbolic parameters can be evaluated numerically via float or numeric::sum. Cf. “Example 4” on page 1-1850.

Examples

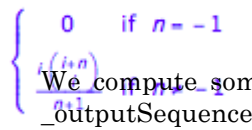
Example 1

We compute some indefinite sums:

```
sum(1/(i^2 - 1), i)- 1/(2*(i - 1)) - 1/(2*i)
```

```
sum(1/i/(i + 2)^2, i)psi(i + 2, 1)/2 - 1/(4*i + 4) - 1/(4*i)
```

```
sum(binomial(n + i, i), i)piecewise([n = -1, 0], [n <> -1, (i*binomial(i
+ n, i))/(n + 1)])
```



We compute some definite sums. Note that _outputSequence(Symbol::pm, infinity) are valid boundaries:

```
sum(1/(i^2 + 21*i), i = 1..infinity)18858053/108636528
```

```
sum(1/i, i = a .. a + 3)psi(a + 4) - psi(a)
```

```
expand(%)1/(a + 1) + 1/(a + 2) + 1/(a + 3) + 1/a
```

Example 2

We compute some sums over all roots of a polynomial:
sum(i^2, i = RootOf(x^3 + a*x^2 + b*x + c, x))a^2 - 2*b

$$a^2 - 2\,b$$

sum(1/(z + i), i = RootOf(x^4 - y*x + 1, x))(4*z^3 + y)/(z^4 + y*z + 1)

$$\frac{4\,z^3 + y}{z^4 + y\,z + 1}$$

Example 3

`sum` can compute finite sums if indefinite summation succeeds:
sum(1/(i^2 + i), i = 1..100)100/101

$$\frac{100}{101}$$

_plus yields the same result more quickly if the number of summands is small:
_plus(1/(i^2 + i) $ i = 1..100)100/101

$$\frac{100}{101}$$

In such cases, `sum` is much more efficient than _plus if the number of summands is large:
sum(1/(i^2 + i), i = 1..10^30)100000000000000000000000000000/100000000000000000000000000001

$$\frac{100000000000000000000000000000}{100000000000000000000000000001}$$

Finite sums for which no indefinite summation is possible are expanded if they have no more than 1000 terms:
sum(binomial(n, i), i = 0..4)n + binomial(n, 2) + binomial(n, 3) + binomial(n, 4) + 1

$$n + \binom{n}{2} + \binom{n}{3} + \binom{n}{4} + 1$$

An application of expand is necessary to expand the binomials:
expand(%)n^4/24 - n^3/12 + (11*n^2)/24 + (7*n)/12 + 1

$$\frac{n^4}{24} - \frac{n^3}{12} + \frac{11\,n^2}{24} + \frac{7\,n}{12} + 1$$

Finite sums with more than 1000 terms are not expanded:
sum(binomial(n, i), i = 0..1000)sum(binomial(n, i), i = 0..1000)

$$\sum_{i=0}^{1000} \binom{n}{i}$$

You might use expand here to expand the sum and obtain a huge expression. If you really want to do that, we recommend using _plus directly.

However, if one of the boundaries is symbolic, then _plus cannot be used:
_plus(1/(i^2 + i) $ i = 1..n)_plus(1/(i^2 + i) $ i = 1..n)

$$\mathrm{\_plus}\left(\frac{1}{i^2+i}\ \$\ i = 1..n\right)$$

_plus(binomial(n, i) $ i = 0..n)_plus(binomial(n, i) $ i = 0..n)

$$\mathrm{\_plus}\left(\binom{n}{i}\ \$\ i = 0..n\right)$$

sum(1/(i^2 + i), i = 1..n), sum(binomial(n, i), i = 0..n)n/(n + 1), 2^n

$$\frac{n}{n+1},\ 2^n$$

Example 4

The following infinite sum cannot be computed symbolically:
sum(ln(i)/i^5, i = 1..infinity)sum(ln(i)/i^5, i = 1..infinity)

$$\sum_{i=1}^{\infty} \frac{\ln(i)}{i^5}$$

We obtain a floating-point approximation via float:
float(%)0.02857378051

0.02857378051

Alternatively, the function numeric::sum can be used directly. This is usually much faster than applying float, since it avoids the overhead of `sum` attempting to compute a symbolic representation:
numeric::sum(ln(i)/i^5, i = 1..infinity)0.02857378051

0.02857378051

Parameters

f

An arithmetical expression depending on `i`

i

The summation index: an identifier or indexed identifier

a

b

The boundaries: arithmetical expressions

p

A polynomial of type DOM_POLY or a polynomial expression

x

An indeterminate of `p`

Return Values

arithmetical expression.

Algorithms

The function `sum` implements Abramov's algorithm for rational expressions, Gosper's algorithm for hypergeometric expressions, and Zeilberger's algorithm for the definite summation of holonomic expressions.

sum::addpattern

Purpose

Add patterns for definite and indefinite summation

Syntax

```
sum::addpattern(pat, k, res, <[var,  ], <[cond,  ]>>)
sum::addpattern(pat, k = a .. b, res, <[var,
 ], <[cond,  ]>>)
```

Description

`sum::addpattern(pat, k, res)` teaches sum to make use of sum(pat, k)=res$\sum_k pat = res$.

`sum::addpattern(pat, k=a..b, res)` teaches sum that sum(pat, x=a..b)=res$\sum_{x=a}^{b} pat = res$.

A part of a computer algebra system's summation abilities stems from mathematical pattern matching. The MuPAD pattern matcher can be extended at runtime with `sum::addpattern`.

For definite summation, each bound is either an arithmetical expression which may contain pattern variables, or an identifier which can be used as a variable in the result and condition terms.

Users can include pattern variables and conditions on these by giving additional arguments. These conditions, as well as the result, are protected from premature evaluation, i.e., it is not necessary to write `hold( _not @ iszero )(a^2-b)`, a simple `not iszero(a^2-b)` suffices.

The difference between `not iszero(a^2-b)` and `a^2-b <> 0` when given as a condition is that the latter takes into account assumptions on the identifiers encountered, while the first does not. Cf. "Example 4" on page 1-1855.

Patterns introduced by `sum::addpattern` are also used in recursive calls of sum and are automatically extended to include simple applications of summation by change of variables. Cf. "Example 1" on page 1-1854.

Environment Interactions

Calling `sum::addpattern` changes the expressions returned by future calls to sum.

Examples

Example 1

Not surprisingly, MuPAD does not know how to do an indefinite summation with the function *foo*:
sum(foo(n), n)sum(foo(n), n)

$$\sum_n \mathrm{foo}(n)$$

We add a pattern for this function:
sum::addpattern(foo(k), k, bar(k))sum(foo(n), n)bar(n)

$$\mathrm{bar}(n)$$

Note that this pattern is also used indirectly:
sum(foo(k+3),k)bar(k + 3)

$$\mathrm{bar}(k+3)$$

Example 2

Definite sums can be added similarly:
sum::addpattern(foo(k), k=1..infinity, bar(k))sum(foo(k), k=1..infinity)bar(k)

$$\mathrm{bar}(k)$$

The above pattern will also match this definite sum with different bounds:
sum(foo(k), k=3..infinity)bar(k) - foo(2) - foo(1)

$$\mathrm{bar}(k) - \mathrm{foo}(2) - \mathrm{foo}(1)$$

Note that this pattern is also used indirectly:
sum(foo(k)+1/k^3, k=1..infinity)zeta(3) + bar(k)

$$\zeta(3) + \mathrm{bar}(k)$$

The bounds may also be variables occuring in the pattern or the result:
sum::addpattern(foo(k,a), k=0..a, bar(a), [a])sum(foo(k,7), k=0..7)bar(7)

bar(7)

Example 3

The name of the summation variable used in the call to `sum::addpattern` does not restrict later calls to sum:
sum::addpattern(x^(2*i+1)/(2*i+1), i=0..infinity, piecewise([abs(x) < 1, arccoth(x) + PI/2*sqrt(-1/x^2)*x]), [x])sum(x^(2*n+1)/(2*n+1),n=0..infinity)piecewise([abs(x) < 1, arccoth(x) + (PI*x*sqrt(-1/x^2))/2])

$$\begin{cases} \operatorname{arccoth}(x) + \frac{\pi\, x \sqrt{-\frac{1}{x^2}}}{2} & \text{if } |x| < 1 \end{cases}$$

Example 4

Conditions are checked using is and therefore react to assumptions:
sum::addpattern(binomial(-1/2, k) * x^(2*k+1)/(2*k+1), k = 0..infinity, arcsinh(x), [x], [abs(x) < 1])sum(binomial(-1/2, k) * x^(2*k+1)/(2*k+1), k = 0..infinity) assuming -1 < x < 1arcsinh(x)

arcsinh(x)

sum(binomial(-1/2, k) * x^(2*k+1)/(2*k+1), k = 0..infinity) assuming x > 1sum((x^(2*k + 1)*binomial(-1/2, k))/(2*k + 1), k = 0..infinity)

$$\sum_{k=0}^{\infty} \frac{x^{2\,k+1} \binom{-\frac{1}{2}}{k}}{2\,k+1}$$

If MuPAD cannot decide whether the conditions are satisfied, a piecewise defined object is returned:
sum(binomial(-1/2, k) * x^(2*k+1)/(2*k+1), k = 0..infinity)piecewise([abs(x) < 1, arcsinh(x)])

$$\begin{cases} \operatorname{arcsinh}(x) & \text{if } |x| < 1 \end{cases}$$

If either the conditions are not satisfied or substituting the values into the result yields an error, the pattern is ignored. There is no need to include a condition to guard against an error, MuPAD simply computes the sum as usual:
sum::addpattern(c^k, k=0..n, (c^n-1)/(c-1), [c]); sum(1^k, k=0..n)n + 1

$$n + 1$$

Parameters

pat

The pattern to match: an arithmetical expression in `k`.

k

The summation index: an identifier.

a .. b

The boundaries for a definite summation: arithmetical expressions or identifiers.

res

The pattern for the result of the summation: an arithmetical expression

var, ...

"pattern variables": placeholders in `pat` and `ret`, i.e., identifiers or indexed identifiers. They do not represent themselves but almost arbitrary MuPAD expressions not containing `k`. You may restrict them by the conditions in the 5th parameter.

cond, ...

Conditions on the pattern variables

Return Values

Object of type DOM_NULL

See Also sum

surd

Purpose

N -th root

Syntax

```
surd(x, n)
```

Description

For a complex number `x` and integer `n`, `surd(x, n)` returns the n-th root of x whose (complex) argument is closest to that of `x`.

If `x` is a positive real number, `surd(x, n)` coincides with `x^(1/n)`. If `x` is a negative real number and `n` is odd, then `surd(x, n)` coincides with `-|x|^(1/n)`.

`surd(x, n)` returns that complex solution y of $y^n = x$ with polar angle closest to that of x; among two equally distant y's, the one with smaller argument is chosen. In contrast, `x^(1/n)` represents the solution with the smallest absolute value of the polar angle in the range Interval(-PI,[PI]) $(-\pi, \pi]$.

If `n` is a numerical value, it must be a non-zero integer. If it is symbolic, it is understood to represent a non-zero integer.

`surd(x, 2)` is mathematically equivalent to `sqrt(x)`. Unlike sqrt, however, `surd` may return an unevaluated symbolic call.

Environment Interactions

When called with a floating-point argument, the function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

If n is odd and x is real, then `surd(x, n)` is real, too. On the other hand, `x^(1/n)` is not real if x is negative:
surd(-27, 3), surd(-27.0, 3), (-27)^(1/3), (-27.0)^(1/3)-3, -3.0, (-27)^(1/3), 1.5 + 2.598076211*I

$$-3,\ -3.0,\ (-27)^{1/3},\ 1.5 + 2.598076211\,i$$

Example 2

`surd` may be called with symbolic arguments:
surd(3, n)3^(1/n)

$$3^{1/n}$$

Sometimes, `surd` returns an unevaluated function call:
surd(x, 3), surd(x, n^2 + n)surd(x, 3), surd(x, n^2 + n)

$$\sqrt[3]{x},\ \sqrt[n^2+n]{x}$$

Parameters

x

An arithmetical expression

n

An arithmetical expression

Return Values

Arithmetical expression.

_powersqrt

sysname

Purpose

Name of the operating system

Syntax

```
sysname(<Arch>)
```

Description

`sysname()` returns information on the operating system on which MuPAD is currently executed. It can return one of the following strings:

- `"UNIX"` for UNIX operating systems including Mac OS X and Linux,
- `"MSDOS"` for MS-DOS® operating systems including Microsoft Windows,

`sysname(Arch)` returns a more specific name of the operating system as a character string.

Examples

Example 1

On a 64-bit Microsoft Windows operating system, `sysname` returns the following values:
sysname(), sysname(Arch)"MSDOS", "win64"

```
"MSDOS", "win64"
```

On a 32-bit Microsoft Windows operating system, `sysname(Arch)` returns:
sysname(Arch)"win32"

```
"win32"
```

Example 2

On a 64-bit Linux operating system, `sysname` returns the following values:
sysname(), sysname(Arch)"UNIX", "glnxa64"

```
"UNIX", "glnxa64"
```

Example 3

On a 64-bit Apple Macintosh operating system, `sysname` returns the following values:
sysname(), sysname(Arch)"UNIX", "maci64"

```
"UNIX", "maci64"
```

Options

Arch

Makes `sysname` return more specific information on the architecture

Return Values

character string.

See Also

system

sysorder

Purpose

Compare objects according to the internal order

Syntax

```
sysorder(object1, object2)
```

Description

`sysorder(object1, object2)` returns TRUE if the MuPAD internal order of `object1` is less than or equal to the order of `object2`. Otherwise, `FALSE` is returned.

Note The exceptions are domains.

One should not try and use the internal order to sort objects according to specific criteria. E.g., its does not necessarily reflect the natural ordering of numbers or strings. Further, the internal order may differ between different MuPAD versions.

The only feature one may rely upon is its uniqueness. Cf. “Example 2” on page 1-1863.

Examples

Example 1

We give some examples how `sysorder` behaves in the current MuPAD version. For numbers, the internal order is equal to the natural order: sysorder(3, 4) = bool(3 <= 4), sysorder(45, 33) = bool(45 <= 33), sysorder(0, 4) = bool(0 <= 4)TRUE = TRUE, FALSE = FALSE, TRUE = TRUE

TRUE = TRUE, FALSE = FALSE, TRUE = TRUE

sysorder(1/3, 1/4) = bool(1/3 <= 1/4), sysorder(-4, 2) = bool(-4 <= 2), sysorder(-4, -2) = bool(-4 <= -2)FALSE = FALSE, TRUE = TRUE, TRUE = TRUE

FALSE = FALSE, TRUE = TRUE, TRUE = TRUE

Example 2

We give a simple application of `sysorder`. Suppose, we want to implement a function `f`, say, whose only known property is its skewness `f(-x) = -f(x)`. Expressions involving `f` should be simplified automatically, e.g., `f(x) + f(-x)` should yield zero for any argument `x`. To achieve this, we use `sysorder` to decide, whether a call `f(x)` should return `f(x)` or `-f(-x)`:

```
f := proc(x) begin if sysorder(x, -x) then return(-procname(-x)) else
return(procname(x)) end_if; end_proc:
```

For numerical arguments, `f` prefers to rewrite itself with positive arguments:

```
f(-3), f(3), f(-4.5), f(4.5), f(-2/3), f(2/3)-f(3), f(3), -f(4.5), f(4.5), -f(2/3), f(2/3)
```

$$-f(3),\ f(3),\ -f(4.5),\ f(4.5),\ -f\left(\frac{2}{3}\right),\ f\left(\frac{2}{3}\right)$$

For other arguments, the result is difficult to predict:

```
f(x), f(-x), f(sqrt(2) + 1), f(-sqrt(2) - 1)-f(-x), f(-x), f(sqrt(2) + 1), -f(sqrt(2)
+ 1)
```

$$-f(-x),\ f(-x),\ f(\sqrt{2}+1),\ -f(\sqrt{2}+1)$$

With this implementation, expressions involving `f` simplify automatically:

```
f(x) + f(-x) - f(3)*f(x) + f(-3)*f(-x) + sin(f(7)) + sin(f(-7))0
```

$$0$$

delete f:

Parameters

object1

object2

Arbitrary MuPAD objects

Return Values TRUE or FALSE.

See Also _lesslistlib::removeDupSortedsort

system

Purpose

Execute a command of the operating system

Syntax

```
! command
system(command)
```

Description

`system("command")` executes a command of the operating system or a program, respectively.

`!command` is equivalent to `system("command");` note that `!command` will suppress output of its return value.

The syntax `!command` is allowed during interactive input only, not when reading MuPAD input from a file. "`!`" must be the first character on the input line.

`system` is not available in all MuPAD versions. If not available, a call to `system` results in the following error message:

```
Error:  Function not available for this client [system].
```

`system("command")` sends the command to the operating system. E.g., this command may start another application program on the computer. The return value 0 indicates that the command was executed successfully. Otherwise, an integer error code is returned which depends on the operating system and the command.

If the called command writes output to `stderr` on UNIX systems, the output will go to the MuPAD `stderr`. Outputs on the standard output channel will be inserted in the command's output, but are not accessible programmatically.

Examples

Example 1

On a UNIX system, the `date` command is executed. The command output is printed to the screen, the error code 0 for successful execution is returned to the MuPAD session:

```
errorcode := system("date"):Fri Sep 29 14:42:13 MEST 2000 errorcode0
```

```
0
```

Now the `date` command is called with the command line option `'+%m'` in order to display the current month only:
errorcode := system("date '+%m'"):09

Missing the prefix `'+'` in the command line option of `date`, `date` and therefore `system` returns an error code. Note that the error output goes to `stderr`:
system("date '%m'")1

```
1
```

delete errorcode:

Example 2

The output of a program started with the `system` command cannot be accessed in MuPAD directly, but it can be redirected into a file and then be read using the read or ftextinput command:
system("echo communication example > comm_file"):
ftextinput("comm_file")"communication example"

```
"communication example"
```

system("rm -f comm_file"):

Parameters

command

A command of the operating system or a name of a program as a MuPAD character string

Return Values

"error code": an integer.

See Also

sysname

table

Purpose

Create a table

Syntax

```
table()
table(index1 = entry1, index2 = entry2,  , <default>)
table(<list>, <set>, <tab>,  , <default>)
```

Description

`table()` creates a new empty table.

`table(index1 = entry1, index2 = entry2, ...)` creates a new table with the given indices and entries.

In MuPAD, tables are the most flexible objects for storing data. In contrast to arrays or lists, arbitrary MuPAD objects can be used as indices. Indexed access to table entries is fast and nearly independent of the size of the table. Thus, tables are suitable containers for large data.

For a table`T`, say, an indexed call `T[index]` returns the corresponding entry. If no such entry exists, the default value of the table is returned, if the table has one. If no default value has been set and, the indexed expression `T[index]` is returned symbolically.

An indexed assignment of the form `T[index] := entry` adds a new entry to an existing table `T` or overwrites an existing entry associated with the index.

`table` can be used to create tables from other tables, lists or sets of equations. Cf. “Example 2” on page 1-1869.

`table` is used for the explicit creation of a table. There also is the following mechanism for creating a table implicitly.

If the value of an identifier `T`, say, is neither a table nor an array nor an hfarray nor a list, then an indexed assignment `T[index] := entry` is equivalent to `T := table(index = entry)`. I.e., implicitly, a new table with one entry is created. Cf. “Example 3” on page 1-1869.

If the value of `T` was either a table or an array or an hfarray or a list, then the indexed assignment only inserts a new entry without changing the type of `T` implicitly.

Table entries can be deleted with the function `delete`. Cf. “Example 4” on page 1-1870.

Examples

Example 1

The following call creates a table with two entries:
T := table(a = 13, c = 42)table(c = 42, a = 13)

a	13
c	42

The data may be accessed via indexed calls. Note the symbolic result for the index `b` which does not have a corresponding entry in the table:
T[a], T[b], T[c]13, T[b], 42

13, T_b, 42

Entries of a table may be changed via indexed assignments:
T[a] := T[a] + 10: Ttable(c = 42, a = 23)

a	23
c	42

Expression sequences may be used as indices or entries, respectively. Note, however, that they have to be enclosed in brackets when using them as input parameters for `table`:
T := table((a, b) = "hello", a + b = (50, 70))table((a, b) = "hello", a + b = (50, 70))

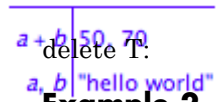
a + b	50, 70
a, b	"hello"

T[a + b]50, 70

50, 70

Indexed access does not require additional brackets:

T[a, b] := T[a, b]." world": Ttable((a, b) = "hello world", a + b = (50, 70))



delete T:

Example 2

A `table` can be created from other tables, lists or sets:
table(table(a = 1, b = 2), {a = 3, c = 4}, [b = 5, e = 6])table(e = 6, c = 4, b = 5, a = 3)

Please note that a set has no order of operands. When a set contains several values under the same index, the table entry is chosen "randomly":
table({a = 3, a = 4}); table({a = 4, a = 3})table(a = 4)

table(a = 3)

Example 3

Below, a new table is created implicitly by an idexed assigment using an identifier `T` without a value:
delete T: T[4] := 7: Ttable(4 = 7)

delete T:

Example 4

Use delete to delete entries:
T := table(a = 1, b = 2, (a, b) = (1, 2))table((a, b) = (1, 2), b = 2, a = 1)

a	1
b	2
a, b	1, 2

delete T[b], T[a, b]: Ttable(a = 1)

a	1

delete T:

Example 5

One of the uses of tables is to count the number of occurrences of some objects. In this situation, an implementation not using default values would have to look like this:
T := table(): L := [1,2,3,a,b,c,a,b,a]: for i in L do if contains(T, i) then T[i] := T[i] + 1; else T[i] := 1; end_if; end_for: Ttable(c = 1, b = 2, a = 3, 3 = 1, 2 = 1, 1 = 1)

1	1
2	1
3	1
a	3
b	2
c	1

Note the test whether `T[i]` has already been set. If it has not, we cannot use its previous value, because that would remain symbolic:
T := table(): T[a] := T[a] + 1: Ttable(a = T[a] + 1)

a	$T_a + 1$

By creating `T` as `table(0)` instead of `table()`, we can tell MuPAD to regard `T[i]` as `0` if it has not been told anything else and the code from above becomes substantially shorter and, much more important, much easier to read:

```
T := table(0): L := [1,2,3,a,b,c,a,b,a]: for i in L do T[i] := T[i] + 1; end_for:
T
```

1	1
2	1
3	1
a	3
b	2
c	1

A slightly more complicated version counting all identifiers in an expression:

```
ex := sin(a*x+b)-cos(c+x): cnt := table(0): misc::maprec(ex,
{DOM_IDENT} = (x -> (cnt[x] := cnt[x]+1; x))): cnt
```

_mult	2
_plus	3
a	1
b	1
c	1
cos	1
sin	1
x	2

Parameters

$index_1$, $index_2$, ...

The indices: arbitrary MuPAD objects

$entry_1$, $entry_2$, ...

The corresponding entries: arbitrary MuPAD objects

list

A list of equations

set

A set of equations

tab

A table

default

The default value: A MuPAD object which is not an equation, a list, a set, nor a table

Return Values

Object of type DOM_TABLE.

See Also

DOM_ARRAYDOM_HFARRAYDOM_LISTDOM_TABLE_assign_indexarrayassignEle

taylor

Purpose

Compute a Taylor series expansion

Syntax

```
taylor(f, x, <order>, <mode>, <NoWarning>)
taylor(f, x = x0, <order>, <mode>, <NoWarning>)
taylor(f, x, <AbsoluteOrder = order>, <NoWarning>)
taylor(f, x = x0, <AbsoluteOrder = order>, <NoWarning>)
taylor(f, x, <RelativeOrder = order>, <NoWarning>)
taylor(f, x = x0, <RelativeOrder = order>, <NoWarning>)
```

Description

`taylor(f, x = x0)` computes the first terms of the Taylor series of `f` with respect to the variable `x` around the point `x0`.

Three cases can occur:

1. `taylor` is able to compute the corresponding Taylor series. In this case, the result is a series expansion of domain type Series::Puiseux. Use expr to convert it to an arithmetical expression of domain type DOM_EXPR. Cf. “Example 1” on page 1-1874.

2. `taylor` is able to decide that the corresponding Taylor series does not exist. In this case, an error is raised. Cf. “Example 2” on page 1-1875.

3. `taylor` is not able to determine whether the corresponding Taylor series exists or not. Internally, the function series is called; it returns a symbolical call. In this case, also `taylor` returns a symbolic expression of type `"taylor"`. Cf. “Example 3” on page 1-1875.

Mathematically, the expansion computed by `taylor` is valid in some open disc around the expansion point in the complex plane.

If `x0` is complexInfinity, then an expansion around the complex infinity, i.e., the north pole of the Riemann sphere, is computed. If `x0` is infinity or -infinity, a directed series expansion valid along the real axis is computed.

Such an expansion is computed as follows: The series variable `x` in `f` is replaced by x= _outputSequence(Symbol::pm ,1/u)$x = \pm\frac{1}{u}$. Then

a directed series expansion at $u = 0$ from the right is computed. If `x0 = complexInfinity`, then an undirected expansion around $u = 0$ is computed. Finally, u=_outputSequence(Symbol::pm ,1/x)$_{u = \pm\frac{1}{x}}$ is substituted in the result.

Mathematically, the result of an expansion around complexInfinity or ±infinity is a power series in 1/x$_{\frac{1}{x}}$. Cf. “Example 4” on page 1-1876.

With the default mode `RelativeOrder`, the number of requested terms for the expansion is `order` if specified. If no `order` is is specified, the value of the environment variable ORDER used. You can change the default value 6 by assigning a new value to ORDER.

The number of terms is counted from the lowest degree term on for finite expansion points, and from the highest degree term on for expansions around infinity, i.e., “`order`” has to be regarded as a “relative truncation order”.

If `AbsoluteOrder` is specified, `order` represents the truncation order of the series (i.e., the `x` power in the Big-Oh term).

`taylor` uses the more general series function series to compute the Taylor expansion. See the corresponding help page for `series` for details about the parameters and the data structure of a Taylor series expansion.

Environment Interactions

The function is sensitive to the environment variable ORDER, which determines the default number of terms in series computations.

Examples

Example 1

We compute a Taylor series around the default point 0:
s := taylor(exp(x^2), x)1 + x^2 + x^4/2 + O(x^6)

$$1 + x^2 + \frac{x^4}{2} + O(x^6)$$

The result of `taylor` is of the following domain type:
domtype(s)‘Series::Puiseux‘

Series::Puiseux

If we apply the function expr to a series, we get an arithmetical expression without the order term:
expr(s)x^4/2 + x^2 + 1

$\frac{x^4}{2} + x^2 + 1$
domtype(%)DOM_EXPR

DOM_EXPR
delete s:

Example 2

A Taylor series expansion of f(x)=(1)/(x^2-1) $f(x) = \frac{1}{x^2-1}$ around $x = 1$ does not exist. Therefore, `taylor` responds with an error message:
taylor(1/(x^2 - 1), x = 1) Error: Cannot compute a Taylor expansion of '1/(x^2 - 1)'. Try 'series' for a more general expansion. [taylor]

Following the advice given in this error message, we try series to compute a more general series expansion. A Laurent expansion does exist:
series(1/(x^2 - 1), x = 1)1/(2*(x - 1)) - 1/4 + (x - 1)/8 - (x - 1)^2/16 + (x - 1)^3/32 - (x - 1)^4/64 + O((x - 1)^5)

$\frac{1}{2\,(x-1)} - \frac{1}{4} + \frac{x-1}{8} - \frac{(x-1)^2}{16} + \frac{(x-1)^3}{32} - \frac{(x-1)^4}{64} + O((x-1)^5)$

Example 3

If a Taylor series expansion cannot be computed, then the function call with evaluated arguments is returned symbolically together with a warning:

taylor(1/exp(x^a), x = 0) Warning: Cannot compute a Taylor expansion of 'exp(-x^a)'. Try 'series' with the 'Left', 'Right', or 'Real' option for a more general expansion. [taylor] taylor(exp(-x^a), x = 0)

$$\text{taylor}\left(e^{-x^a}, x = 0\right)$$

In this example, also series returns a symbolic function call. Even if you try one of the proposed options, `series` is not able to compute a series expansion.

Here is another example where no Taylor expansion can be computed. However, series with an optional argument yields a more general type of expansion in this case:
taylor(psi(1/x), x = 0) Warning: Cannot compute a Taylor expansion of 'psi(1/x)'. Try 'series' with the 'Left', 'Right', or 'Real' option for a more general expansion. [taylor] taylor(psi(1/x), x = 0)

$$\text{taylor}\left(\psi\left(\frac{1}{x}\right), x = 0\right)$$

series(psi(1/x), x = 0, Right)- ln(x) - x/2 - x^2/12 + x^4/120 + O(x^6)

$$-\ln(x) - \frac{x}{2} - \frac{x^2}{12} + \frac{x^4}{120} + O(x^6)$$

Example 4

This is an example of a directed Taylor expansion along the real axis around infinity:
taylor(exp(1/x), x = infinity)1 + 1/x + 1/(2*x^2) + 1/(6*x^3) + 1/(24*x^4) + 1/(120*x^5) + O(1/x^6)

$$1 + \frac{1}{x} + \frac{1}{2\,x^2} + \frac{1}{6\,x^3} + \frac{1}{24\,x^4} + \frac{1}{120\,x^5} + O\left(\frac{1}{x^6}\right)$$

In fact, this is even an undirected expansion:
taylor(exp(1/x), x = complexInfinity)1 + 1/x + 1/(2*x^2) + 1/(6*x^3) + 1/(24*x^4) + 1/(120*x^5) + O(1/x^6)

$$1 + \frac{1}{x} + \frac{1}{2\,x^2} + \frac{1}{6\,x^3} + \frac{1}{24\,x^4} + \frac{1}{120\,x^5} + O\left(\frac{1}{x^6}\right)$$

Parameters

f

An arithmetical expression representing a function in `x`

x

An identifier or an indexed identifier

x0

The expansion point: an arithmetical expression. Also expressions involving infinity or complexInfinity are accepted.

If not specified, the default expansion point 0 is used.

order

The truncation order (in conjunction with `AbsoluteOrder`) or, in conjunction with `RelativeOrder`, the number of terms to be computed, respectively. A nonnegative integer; the default order is given by the environment variable ORDER (default value 6).

mode

One of the flags `AbsoluteOrder` or `RelativeOrder`. The default is `RelativeOrder`.

Options

AbsoluteOrder

With this flag, the integer value `order` is the truncation order of the computed series (i.e., the exponent of `x` in the Big-Oh term).

RelativeOrder

With this flag, the exponents of `x` in the computed series range from some leading order `v` to the highest exponent `v + order - 1` (i.e., the exponent of `x` in the Big-Oh term is `v + order`). In this case, `order` essentially is the "number of `x` powers" in the computed series if the series involves all integer powers of `x`.

NoWarning

Supresses warning messages printed during the series computation. This can be useful if `taylor` is called within user-defined procedures.

Return Values

Object of domain type Series::Puiseux or a symbolic expression of type `"taylor"`.

Overloaded By

`f`

tbl2text

Purpose

Concatenate the strings in a table

Syntax

```
tbl2text(strtab)
```

Description

`tbl2text` concatenates all entries of a table of character strings.

The table must be indexed by `1`, `2`, `3` etc. All entries must be character strings. They are concatenated in the order of their indices.

`tbl2text` restores strings split by text2tbl.

Examples

Example 1

A character string can be created from an arbitrary number of table entries:
tbl2text(table(1 = "Hell", 2 = "o", 3 = " ", 4 = "world."))"Hello world."

"Hello world."

Parameters

strtab

A table of character strings

Return Values

Character string.

See Also

_concatcoerceexpr2textint2texttext2exprtext2listtext2tbl

tcoeff

Purpose

Trailing coefficient of a polynomial

Syntax

```
tcoeff(p, <order>)
tcoeff(f, <vars>, <order>)
```

Description

`tcoeff(p)` returns the trailing coefficient of the polynomial `p`.

The returned coefficient is "trailing" with respect to the lexicographical ordering, unless a different ordering is specified via the argument `order`. Cf. "Example 1" on page 1-1880.

A polynomial expression `f` is first converted to a polynomial with the variables given by `vars`. If no variables are given, they are searched for in `f`. See poly about details of the conversion. The result is returned as polynomial expression. FAIL is returned if `f` cannot be converted to a polynomial. Cf. "Example 3" on page 1-1881.

The result of `tcoeff` is not fully evaluated. Evaluation can be enforced by the function eval. Cf. "Example 2" on page 1-1881.

Examples

Example 1

We demonstrate how various orderings influence the result:
p := poly(5*x^2*y^3 + 4*x^3*y*z + 3*x*y^4*z, [x, y, z]): tcoeff(p), tcoeff(p, DegreeOrder), tcoeff(p, DegInvLexOrder)3, 5, 4

```
3, 5, 4
```

The following call uses the reverse lexicographical order on 3 indeterminates:
tcoeff(p, Dom::MonomOrdering(RevLex(3)))4

```
4
```

delete p:

Example 2

The result of `tcoeff` is not fully evaluated:
p := poly(27*x^2 + a*x, [x]): a := 5: tcoeff(p), eval(tcoeff(p))a, 5

a, 5

delete p, a:

Example 3

The expression `1/x` may not be regarded as polynomial:
lterm(1/x)FAIL

FAIL

Parameters

p

A polynomial of type DOM_POLY

f

A polynomial expression

vars

A list of indeterminates of the polynomial: typically, identifiers or indexed identifiers

order

The term ordering: either `LexOrder`, or `DegreeOrder`, or `DegInvLexOrder`, or a user-defined term ordering of type Dom::MonomOrdering. The default is the lexicographical ordering `LexOrder`.

Return Values

Element of the coefficient domain of the polynomial or FAIL.

Overloaded By

p

See Also coeffcollectdegreedegreevecgroundlcoeffldegreelmonomialltermmonomialsntermsnthcoeffnthn

testargs

Purpose

Decide whether procedure arguments should be tested

Syntax

```
testargs()
testargs(b)
```

Description

Inside a procedure, `testargs` indicates whether the procedure should check its arguments.

Checking the input parameters of a procedure may be costly. For this reason, most functions of the MuPAD libraries are implemented according to the following philosophy:

If a procedure is called on the interactive level, i.e., if its parameters are supplied interactively by the user, then the parameters should be checked. If the input parameters do not comply with the documented specification of the procedure, then appropriate error messages should be returned to notify the user of wrong usage.

If the procedure is called by another procedure, then no check of the parameters should be performed to improve efficiency. The calling procedure is supposed to make sure that appropriate parameters are passed.

`testargs` is the tool to check whether the arguments should be tested: called inside the body of a procedure, `testargs()` returns `TRUE` if the procedure was called on the interactive level. Otherwise, it returns `FALSE`.

`testargs` has two modes. In the “standard mode”, its functionality is as described above. In the “argument checking mode”, the call `testargs()` always returns `TRUE`. This supports the debugging of procedures: any function using `testargs` checks its parameters and returns useful error messages if called in an inappropriate way.

The call `testargs(TRUE)` switches to the “argument checking mode”, i.e., parameter testing is switched on globally.

The call `testargs(FALSE)` switches to the “standard mode”, i.e., parameter testing is used only on the interactive level.

The call `testargs(b)` returns the previously set value.

`testargs` should not be used to change the behavior of a function other than performing type-checks, since the user may have switched to "argument checking mode".

Checking the input parameters of a procedure can also be controlled with the function Pref::typeCheck.

Examples

Example 1

The following example demonstrates how `testargs` should be used inside a procedure. The function `p` is to generate a sequence of `n` zeroes; its argument should be a positive integer:
testargs(FALSE):p := proc(n) begin if testargs() then if not testtype(n, Type::PosInt) then error("expecting a positive integer"); end_if; end_if; return(0 $ n) end_proc:

Its argument is checked when `p` is called on the interactive level:
p(13/2) Error: expecting a positive integer [p]

Calling `p` from within a procedure with an inappropriate parameter does not invoke the argument testing. The following strange output is caused by the attempt to evaluate `0 $ n`:
f := proc(n) begin p(n) end_proc: f(13/2)0 $ 13/2

We switch on the "argument checking mode" of `testargs`:
testargs(TRUE):

Now also a non-interactive call to `p` produces an informative error message:
f(13/2) Error: expecting a positive integer [p]

We clean up, restoring the "standard mode" of `testargs`:
testargs(FALSE): delete f, g:

Parameters **b**

TRUE or FALSE

Return Values TRUE or FALSE.

See Also proctesttypePref::typeCheck

testeq

Purpose

Check the mathematical equivalence of expressions

Syntax

```
testeq(ex1, options)
testeq(ex1, ex2, options)
```

Description

`testeq(ex1, ex2)` checks whether the expressions `ex1` and `ex2` are mathematically equivalent.

`testeq(ex1, ex2)` returns `TRUE` if the difference `ex1 - ex2` can be simplified to zero.

`testeq` returns `FALSE` if `ex1` and `ex2` attain different values for at least one choice of variables contained in them.

By default, `testeq` performs five random tests. If randomly chosen values of the variables are inconsistent with the assumptions on these variables or the test returns the value undefined, the `testeq` function performs an additional test. The number of additional tests cannot exceed the number of initial tests. By default, the maximal total number of tests is 10. See "Example 4" on page 1-1888.

If the equivalence of `ex1` and `ex2` cannot be decided, `testeq` returns `UNKNOWN`.

If only one expression is passed to `testeq`, it is checked whether this expression is equivalent to zero.

After `setuserinfo(testeq, 1)`, any call to `testeq` provides information about the internal tests.

`testeq` uses `Simplify(ex1 - ex2)` and `is(ex1 - ex2 = 0)` to determine its result. The result `UNKNOWN` can be caused by weaknesses of Simplify and is.

Using the options, the simplification process can be made stronger at the cost of increased run time.

Examples

Example 1

Check the mathematical equivalence of expressions:

testeq(sin(x)^2, 1 - cos(x)^2)TRUE

TRUE

testeq(sin(2*x), 2*sin(x)*cos(x))TRUE

TRUE

testeq((cos(a) + sin(a))^2, 2*(cos(PI/4 - a)^2))TRUE

TRUE

In order to be equivalent, two expressions must be equivalent for all values their variables can attain. For certain values of the parameter a the following two expressions are equivalent, but for other values they are not; therefore, they are not equivalent:
testeq((cos(a) + sin(a))^2, 3*(cos(PI/4 - a)^2))FALSE

FALSE

Example 2

Applying expand and rewrite to an expression always produces an equivalent expression. However, with the default setting of 100 steps for the internal simplification procedure, the equivalence is not recognized in the following example:
f:= cos(PI/4 + 6*I*arctan(2^x)): g:= rewrite(expand(f), ln): testeq(f, g)UNKNOWN

UNKNOWN

After 300 steps, however, the expressions are recognized as being equivalent:
testeq(f, g, Steps = 300); delete f, g:TRUE

TRUE

Example 3

When trying to prove the equivalence of two expressions, the `testeq` command runs random tests before applying `IgnoreAnalyticConstraints`. If tests for random values of identifiers show that expressions are not equivalent, `testeq` disregards the `IgnoreAnalyticConstraints` option and returns FALSE:
testeq(x^(ln(a)) * x^(ln(b)) = x^(ln(a*b)), IgnoreAnalyticConstraints)FALSE

FALSE

If, for a given number of attempts, random tests do not find the inequality between expressions, `testeq` applies the `IgnoreAnalyticConstraints` option:
testeq(ln(a) + ln(b) = ln(a*b), IgnoreAnalyticConstraints)TRUE

TRUE

By default, random tests check the equality of expressions for five random sets of values of identifiers. Increasing the number of attempts can prove inequality:
testeq(ln(a) + ln(b) = ln(a*b), NumberOfRandomTests = 10, IgnoreAnalyticConstraints)FALSE

FALSE

Example 4

When `testeq` performs tests, it takes into account the assumptions on variables that you specify:
testeq(x, abs(x)) assuming x > 0TRUE

TRUE

If `testeq` chooses values of the variables that are inconsistent with the assumptions on these variables, it performs an additional test. The

number of tests cannot exceed `2n`, where `n` is the original number of tests defined by the `NumberOfRandomTests` option. If `testeq` performs `2n` tests and all values of the variables are inconsistent with the assumptions on the variables, `testeq` returns UNKNOWN:
testeq(x, abs(x)) assuming x^2 + x + 7 = x^13 + 11UNKNOWN

UNKNOWN

For this particular assumption, MuPAD cannot find a closed-form expression to substitute for `x`:
solve(x^2 + x + 7 = x^13 + 11, x)RootOf(z^13 - z^2 - z + 4, z)

$\mathrm{RootOf}(z^{13} - z^2 - z + 4,\ z)$

Therefore, increasing the number of tests does not help `testeq` decide if the expressions are equivalent:
testeq(x, abs(x), NumberOfRandomTests = 100) assuming x^2 + x + 7 = x^13 + 11UNKNOWN

UNKNOWN

Parameters

ex1

ex2

Any MuPAD expressions

Options

Steps

Option, specified as `Steps = n`

This option is directly passed to Simplify and determines the maximum number of steps allowed for the internal simplification process. The default value of `n` is `100`. Increasing the number of steps can give you a simpler result, often at the costs of increased runtime. For details, see the Simplify help page.

Seconds

Option, specified as `Seconds = t`

This option is directly passed to Simplify and sets a time limit `t` in seconds for the internal simplification process. The default setting is `infinity`, i.e., the simplification process will not terminate due to a time limitation, but due to other internal stopping criteria. See the documentation of Simplify for details.

RuleBase

Option, specified as `RuleBase = base`

This option is directly passed to Simplify and determines the rule base that is used for the internal simplification process. See the documentation of Simplify for details.

The default value of `base` is `Simplify`.

The advanced user can specify her own rule base (see Simplify). This allows the construction of specialized and fast tests for special classes of expressions.

NumberOfRandomTests

Option, specified as `NumberOfRandomTests = n`

This option determines the number of times `testeq` tries to disprove the equivalence of `ex1` and `ex2` by plugging in some random values for all identifiers.

The default value of `n` is 5. If randomly chosen values of the variables are inconsistent with the assumptions on these variables or the test returns the value undefined, the `testeq` function performs an additional test. The total number of tests does not exceed `2n`. See “Example 4” on page 1-1888.

IgnoreAnalyticConstraints

This option applies purely algebraic simplifications to expressions `ex1` and `ex2`. For the list of rules, see the documentation of Simplify. These simplification rules are not generally valid.

Note that random tests have higher priority than `IgnoreAnalyticConstraints`. When trying to prove the equivalence of two expressions, the `testeq` command runs random tests before applying the `IgnoreAnalyticConstraints` option. If random tests prove the expressions are not equivalent, `testeq` returns the value FALSE. See "Example 3" on page 1-1888.

Return Values

`TRUE`, `FALSE`, or `UNKNOWN`

See Also

isSimplifysimplify

Concepts

- "Test Results"

testtype

Purpose

Syntactical type checking

Syntax

```
testtype(object, T)
```

Description

`testtype(object, T)` checks whether the object is syntactically of type `T`.

The type object `T` may be either a domain type such as DOM_INT, DOM_EXPR etc., a string as returned by the function type, or a Type object. The latter are probably the most useful predefined values for the argument `T`.

Note `testtype` performs a purely syntactical check. Use is for semantical checks taking into account properties of identifiers!

See the Algorithms section below for details on the overloading mechanism.

Examples

Example 1

The following call tests, whether the first argument is an expression. Expressions are basic objects of domain type DOM_EXPR:
testtype(x + y, DOM_EXPR)TRUE

```
TRUE
```

The type function distinguishes expressions. The corresponding type string is a valid type object for `testtype`:
type(x + y), testtype(x + y, "_plus")"_plus", TRUE

```
"_plus", TRUE
```

The following call tests, whether the first argument is an integer by querying, whether it is of domain type DOM_INT:

testtype(7, DOM_INT)TRUE

TRUE

Note that `testtype` performs a purely syntactical test. Mathematically, the integer 7 is a rational number. However, the domain type DOM_RAT does not encompass DOM_INT:
testtype(7, DOM_RAT)FALSE

FALSE

The Type library provides more flexible type objects. E.g., Type::Rational represents the union of DOM_INT and DOM_RAT:
testtype(7, Type::Rational)TRUE

TRUE

The number 7 matches other types as well:
testtype(7, Type::PosInt), testtype(7, Type::Prime), testtype(7, Type::Numeric), testtype(7, Type::Odd)TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE

Example 2

Subtypes of expressions can be specified via character strings:
type(f(x)), type(sin(x))"function", "sin"

"function", "sin"

testtype(sin(x), "function"), testtype(sin(x), "sin"), testtype(sin(x), "cos")TRUE, TRUE, FALSE

TRUE, TRUE, FALSE

Example 3

We demonstrate how to implement a customized type object “div3” which is to represent integer multiples of 3. One has to create a new domain with a “testtypeDom” attribute:
div3 := newDomain("divisible by 3?"): div3::testtypeDom := x -> testtype(x/3, Type::Integer):

Via overloading, the command `testtype(object, div3)` calls this slot:
testtype(5, div3), testtype(6, div3), testtype(sin(1), div3)FALSE, TRUE, FALSE

```
FALSE, TRUE, FALSE
```

delete div3:

Parameters

object

Any MuPAD object

T

A type object

Return Values

`TRUE` or `FALSE`.

Overloaded By

`object`, `T`

Algorithms

Overloading of `testtype` works as follows: First, it is checked whether `domtype(object) = T` or `type(object) = T` holds. If so, `testtype` returns `TRUE`.

Next, the method `"testtype"` of the domain `object::dom` is called with the arguments `object, T`. If this method returns a result other than FAIL, then `testtype` returns this value.

If the method `object::dom::testtype` does not exist or if this method returns `FAIL`, then overloading by the second argument is used:

- If `T` is a domain, then the method `"testtypeDom"` of `T` is called with the arguments `object, T`.
- If `T` is not a domain, then the method `"testtypeDom"` of `T::dom` is called with the arguments `object, T`.

See Also coercedomtypehastypeistype

text2expr

Purpose

Convert a character string to an expression

Syntax

```
text2expr(text)
```

Description

`text2expr(text)` interprets the character string `text` as MuPAD input and generates the corresponding object.

The text must correspond to syntactically correct MuPAD input. Otherwise, `text2expr` produces an error. Typically, strings created from MuPAD objects via expr2text can be reconverted to corresponding objects.

The object is returned without being further evaluated. Evaluation can be enforced using the function eval.

The `text` does not need to be terminated with a "`;`" or a "`:`" character, respectively.

`text` cannot refer to local variables of an enclosing procedure by their name. The text is parsed as if entered interactively. Cf. "Example 4" on page 1-1897.

Examples

Example 1

A character string is converted to a simple expression. The newly created expression is not evaluated automatically:
text2expr("21 + 21")21 + 21

```
21 + 21
```

It may be evaluated via eval:
eval(%)42

```
42
```

Example 2

A character string is converted to a statement sequence:

text2expr("x:= 3; x + 2 + 1"); eval(%) (x := 3; x + 2 + 1) 6

6

x3

3

delete x:

Example 3

A matrix is converted to a string:
matrix([[a11, a12], [a21, a22]])matrix([[a11, a12], [a21, a22]])

$$\begin{pmatrix} a11 & a12 \\ a21 & a22 \end{pmatrix}$$

expr2text(%)"matrix([[a11, a12], [a21, a22]])"

"matrix([[a11, a12], [a21, a22]])"

The string is reconverted to a matrix:
text2expr(%)matrix([[a11, a12], [a21, a22]])

$$\begin{pmatrix} a11 & a12 \\ a21 & a22 \end{pmatrix}$$

eval(%)matrix([[a11, a12], [a21, a22]])

$$\begin{pmatrix} a11 & a12 \\ a21 & a22 \end{pmatrix}$$

Example 4

`text2expr` will not create a DOM_VAR of an enclosing procedure from its name:
a := "global identifier": g := proc() local a; begin a := "local variable"; print(a); print(eval(text2expr("a"))); end_proc: g();"local variable"

```
"local variable"
   "global identifier"

"global identifier"
```

Parameters

text

A character string

Return Values

MuPAD object.

See Also

coerceexpr2textinputint2texttbl2texttext2inttext2listtext2tbl

text2int

Purpose

Convert a character string to an integer

Syntax

```
text2int(text, <b>)
```

Description

`text2int(text, b)` converts a character string corresponding to an integer in `b`-adic representation to an integer of type DOM_INT.

It must consist of the first `b` characters in 0, 1, …, 9, *A*, *B*, …, *Z*, *a*, *b*, …, *z*. The letters are used to represent the `b`-adic digits larger than 9.

For bases larger than 10 but smaller than 37 the letters are not case sensitive. The lower case letters *a*, *b*, …, *z* are accepted: $a = A = 10$, …, $z = Z = 35$.

`text2int` is the inverse of int2text.

Examples

Example 1

Relative to the default base 10, `text2int` provides a mere datatype conversion from DOM_STRING to DOM_INT:
text2int("123"), text2int("-45678")123, -45678

```
123, -45678
```

Example 2

The characters of the input string are interpreted as digits with respect to the specified base, the return value is a standard MuPAD integer represented with respect to the decimal system. The following example converts integers from the base 2 and 16, respectively, to the base 10:
text2int("101", 2), text2int("101", 16)5, 257

```
5, 257
```

The digit “3” does not exist in a binary representation:
text2int("103", 2) Error: The argument is invalid. [text2int]

Example 3

For bases larger than 10 but smaller than 37, the letters are not case-sensitive:
text2int("3B9ACA00", 16), text2int("Z", 36) = text2int("z", 36)1000000000, 35 = 35

For bases larger than 37 however, the case makes a difference:
text2int("Z", 62) <> text2int("z", 62)35 <> 61

Parameters

text

A character string

b

The base: an integer between 2 and 62. The default base is 10.

Return Values

Integer.

See Also

coerceexpr2textgenpolyint2textnumlib::g_adictbl2texttext2exprtext2listtext2tbl

text2list

Purpose

Split a character string into a list of substrings

Syntax

```
text2list(text, separators, <Cyclic>)
```

Description

`text2list` splits a character string into a list of substrings, using the strings in the list `separators` as delimiters. `text2list` returns a list containing the substrings.

Without the option `Cyclic`, the text is split as follows. The first occurrence of one of the delimiters in `separators` is located in `text`. If no delimiter is found, the full text is returned as the only substring. Otherwise, the substring up to the delimiter defines the first substring. The delimiter is the second substring. The remaining text is processed as above until there are no more characters left.

Without `Cyclic`, the result does not depend on the order of the delimiters.

With the option `Cyclic`, the first delimiter in `separators` is used to identify the first substring. The delimiter itself is the second substring. Then the second delimiter in `separators` is used to identify the third substring etc.

After using the last delimiter of the list, the first one is used again, until the whole text is processed or until the current delimiter is not found in the remaining text.

With `Cyclic`, the result depends on the order of the delimiters.

`text2list` is a function of the system kernel.

Examples

Example 1

The following example demonstrates the difference in calling `text2list` with and without the option `Cyclic`:
text2list("This is a simple example!", ["is", "mp"])["Th", "is", " ", "is", " a si", "mp", "le exa", "mp", "le!"]

["Th", "is", " ", "is", " a si", "mp", "le exa", "mp", "le!"]
text2list("This is a simple example!", ["is", "mp"], Cyclic)["Th", "is", " is a si", "mp", "le example!"]

["Th", "is", " is a si", "mp", "le example!"]

Example 2

The following example demonstrates the difference in calling `text2tbl` with and without the option `Cyclic`:
text2tbl("This is a simple example!", ["is", "mp"])table(9 = "le!", 8 = "mp", 7 = "le exa", 6 = "mp", 5 = " a si", 4 = "is", 3 = " ", 2 = "is", 1 = "Th")

1	"Th"
2	"is"
3	" "
4	"is"
5	" a si"
6	"mp"
7	"le exa"
8	"mp"
9	"le!"

text2tbl("This is a simple example!", ["is", "mp"], Cyclic)table(5 = "le example!", 4 = "mp", 3 = " is a si", 2 = "is", 1 = "Th")

1	"Th"
2	"is"
3	" is a si"
4	"mp"
5	"le example!"

Parameters

text

The text to be analyzed: a character string

separators

Delimiters: a list of character strings. The empty string " " is not accepted as a delimiter.

Options

Cyclic

The delimiter list is used cyclicly

Return Values

List, respectively a table, of character strings.

See Also

text2tblcoerceexpr2textint2texttbl2texttext2exprtext2int

text2tbl

Purpose

Split a character string into a table of substrings

Syntax

```
text2tbl(text, separators, <Cyclic>)
```

Description

`text2tbl` splits a character string into a table of substrings, using the strings in the list `separators` as delimiters. `text2tbl` returns a table, using the indices `1`, `2`, `3` etc.

Without the option `Cyclic`, the text is split as follows. The first occurrence of one of the delimiters in `separators` is located in `text`. If no delimiter is found, the full text is returned as the only substring. Otherwise, the substring up to the delimiter defines the first substring. The delimiter is the second substring. The remaining text is processed as above until there are no more characters left.

Without `Cyclic`, the result does not depend on the order of the delimiters.

With the option `Cyclic`, the first delimiter in `separators` is used to identify the first substring. The delimiter itself is the second substring. Then the second delimiter in `separators` is used to identify the third substring etc.

After using the last delimiter of the list, the first one is used again, until the whole text is processed or until the current delimiter is not found in the remaining text.

With `Cyclic`, the result depends on the order of the delimiters.

tbl2text restores strings split by `text2tbl`.

`text2tbl` is a function of the system kernel.

Examples

Example 1

The following example demonstrates the difference in calling `text2list` with and without the option `Cyclic`:
text2list("This is a simple example!", ["is", "mp"])["Th", "is", " ", "is", " a si", "mp", "le exa", "mp", "le!"]

["Th", "is", " ", "is", " a si", "mp", "le exa", "mp", "le!"]
text2list("This is a simple example!", ["is", "mp"], Cyclic)["Th", "is", " is a si", "mp", "le example!"]

["Th", "is", " is a si", "mp", "le example!"]

Example 2

The following example demonstrates the difference in calling `text2tbl` with and without the option `Cyclic`:
text2tbl("This is a simple example!", ["is", "mp"])table(9 = "le!", 8 = "mp", 7 = "le exa", 6 = "mp", 5 = " a si", 4 = "is", 3 = " ", 2 = "is", 1 = "Th")

1	"Th"
2	"is"
3	" "
4	"is"
5	" a si"
6	"mp"
7	"le exa"
8	"mp"
9	"le!"

text2tbl("This is a simple example!", ["is", "mp"], Cyclic)table(5 = "le example!", 4 = "mp", 3 = " is a si", 2 = "is", 1 = "Th")

1	"Th"
2	"is"
3	" is a si"
4	"mp"
5	"le example!"

Parameters

text

The text to be analyzed: a character string

separators

Delimiters: a list of character strings. The empty string " " is not accepted as a delimiter.

Options

Cyclic

The delimiter list is used cyclicly

Return Values

List, respectively a table, of character strings.

See Also

text2listcoerceexpr2textint2texttbl2texttext2exprtext2int

textinput

Purpose

Interactive input of text

Syntax

```
textinput(<prompt1>)
textinput(<prompt1>, x1, <prompt2>, x2,  )
```

Description

`textinput` allows interactive input of text.

`textinput()` displays the prompt "`Please enter text:`" and waits for input by the user. The input is converted to a character string, which is returned as the function's return value.

`textinput(prompt1)` uses the character string `prompt1` instead of the default prompt "`Please enter text:`".

`textinput( prompt1 x1)` converts the input to a character string and assigns this string to the identifier or local variable `x1`. The default prompt is used, if no prompt string is specified.

Several input values can be read with a single `textinput` command. Each identifier in the sequence of arguments makes `textinput` return a prompt, waiting for input to be assigned to the identifier or variable. A character string preceeding the identifier or variable in the argument sequence replaces the default prompt. Cf. "Example 3" on page 1-1908. Arguments that are neither prompt strings nor identifiers or variables are ignored.

The input may extend over several lines. In the output string, MuPAD uses the character `\n` (carriage return) to separate lines.

Input characters with a leading `\` are not interpreted as control characters, but as two separate characters.

The identifiers or variables `x1` etc. may have values. These are overwritten by `textinput`.

Examples

Example 1

The default prompt is displayed, the input is converted to a character string and returned:

textinput()Please enter text input: << myinput >> "myinput"

"myinput"

Example 2

A user-defined prompt is used, the input is assigned to the identifier x:
textinput("enter your name: ", x)enter your name: << Turing >> "Turing"

"Turing"
x"Turing"

"Turing"
delete x:

Example 3

If several values are to be read, separate prompts can be defined for each value:
textinput("She: ", hername, "He: ", hisname)She: << Bonnie >> He: << Clyde >> "Clyde"

"Clyde"
hername, hisname"Bonnie", "Clyde"

"Bonnie", "Clyde"
delete hername, hisname:

Parameters

prompt1, prompt2, ...

Input prompts: character strings

x1, x2, ...

identifiers or local variables

Return Values Last input, converted to a character string.

TEXTWIDTH

Purpose

Maximum number of characters in an output line

Description

The environment variable `TEXTWIDTH` determines the maximum number of characters in one line of screen output.

Possible values: Positive integer smaller than 2^{31}.

Output is broken into several lines if it needs more than `TEXTWIDTH` characters per line.

Deletion via the statement "`delete TEXTWIDTH`" resets `TEXTWIDTH` to its default value. Executing the function reset also restores the default value.

The minimal value of `TEXTWIDTH` is 10.

`TEXTWIDTH` is set to its maximum value 2^{31} - 1 when printing to a text file using fprint. Thus, no additional line breaks occur in the output.

`TEXTWIDTH` does not influence the typesetting of expressions which is available for some user interfaces of MuPAD.

`TEXTWIDTH` is set to the new number of available columns every time the console is resized.

Examples

Example 1

The following procedure adds empty characters to produce output that is flushed right:
myprint := proc(x) local l; begin if domtype(x) <> DOM_STRING then x := expr2text(x); end_if; l := length(x); print(Unquoted, _concat(" " $ TEXTWIDTH - l, x)) end_proc:myprint("hello world"): myprint(30!): myprint("bye bye"): hello world 265252859812191058636308480000000 bye bye delete myprint:

fprintprintPRETTYPRINT

theta

Purpose

Theta series

Syntax

```
theta(x)
```

Description

`theta(x)` represents the value of the theta series sum(exp(-PI*x*n^2), n=-infinity..infinity)$\sum_{n=-\infty}^{\infty} e^{-\pi x n^2}$.

The theta series converges for all complex numbers `x` with positive real part.

Floating-point results are computed for floating-point arguments. For other arguments, the function returns symbolically with the imaginary part of complex numbers normalized to lie between zero and 2.

Environment Interactions

When called with a floating-point argument, the function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

The theta series takes on large values for small positive arguments. Small values are taken on near *I*:
theta(0.001), theta(0.001 + I)31.6227766, 5.092623095e-340

$$31.6227766,\ 5.092623095\ 10^{-340}$$

Example 2

Since the theta series is (2i)-periodic, the imaginary part of complex arguments may be reduced:
theta(7 + 5*I)theta(7 + I)

$$\theta(7 + i)$$

For exact or symbolic arguments, a symbolic call is returned:
theta(3), theta(x)theta(3), theta(x)

theta(3), theta(*x*)

Parameters

x

An arithmetical expression

Return Values

Arithmetical expression

dedekindEtazeta

rtime

Purpose

Measure real time

Syntax

```
rtime()
rtime(a1, a2,  )
```

Description

`rtime()` returns the real time in milliseconds that elapsed since the start of the current MuPAD session.

`rtime(a1, a2, ...)` returns the real time needed to evaluate all arguments.

The result of `rtime` is the real time. Thus, `rtime` can be used to measure the total time spent by the MuPAD process as well as by external processes spawned from inside the MuPAD session. Note that an interactive call of `rtime()` is not very useful, since the idle time of the user is included. However, `rtime(a1, a2, ...)` often yields a useful and more realistic timing than `time(a1, a2, ...)` if the evaluation of the arguments spawns external processes. Such a situation may arise in a numerical computation because some routines of the `numeric` library call external numerical tools using hardware floats. Cf. “Example 4” on page 6-82.

If no external process besides MuPAD are running, the timings returned by `rtime(a1, a2, ...)` and `time(a1, a2, ...)` roughly coincide.

On computers without “time-sharing”, such as the Macintosh computer, real time and CPU time roughly coincide.

`rtime` is a function of the system kernel.

Examples

Example 1

This example shows how to do a time measurement and assign the computed value to an identifier at the same time. Note that the assignment needs extra parenthesis when passed as argument:
time((a := int(exp(x)*sin(x), x)))464.029

```
464.029
```

a-(exp(x)*(cos(x) - sin(x)))/2

$$-\frac{e^{x}\,(\cos(x)-\sin(x))}{2}$$

delete a:

Alternatively, one may time groups of statements in the following way: t0 := time(): command1 command2 ... time() - t0

Example 2

Here we use `rtime` to compute the elapsed hours, minutes and seconds since this session was started:
t := rtime()/1000: h := trunc(t/3600): m := trunc(t/60 - h*60): s := trunc(t - m*60 - h*3600):print(Unquoted, "This session is running for " . h . " hours, " . m . " minutes and " . s . " seconds.")This session is running for 0 hours, 0 minutes and 10 seconds. delete t, h, m, s:

Example 3

To obtain a nicer output, the measured time can be multiplied with the appropriate time unit:
time(isprime(2^1000000000 - 1))*unit::msec280.018*unit::msec

280.018 msec

Alternatively, use stringlib::formatTime:
stringlib::formatTime(time(isprime(2^1000000000 - 1)))"0.280017 seconds"

"0.280017 seconds"

Parameters

a1, a2, ...

Arbitrary MuPAD objects

Return Values

Nonnegative integer giving the elapsed time in milliseconds.

See Also timeprog::profile

Concepts

- "Measure Time"

time

Purpose

Measure CPU time

Syntax

```
time()
time(a1, a2,  )
```

Description

`time()` returns the total CPU time in milliseconds that was spent by the current MuPAD process.

`time(a1, a2, ...)` returns the CPU time needed by the current MuPAD process to evaluate all arguments.

The result of `time()` comprises all the computation time spent by the MuPAD process. This includes the time for system initialization and reading input (parsing). However, it excludes the time spent by other external processes, even if they were spawned from inside the MuPAD session or if they were started by a system command. Further, in an interactive session, the idle time between the execution of MuPAD commands is excluded.

If no external process besides MuPAD are running, the timings returned by `rtime(a1, a2, ...)` and `time(a1, a2, ...)` roughly coincide.

The time returned by `time` is computed in a system-dependent way, usually counting the number of clock ticks of the system clock. Hence, the result is a multiple of the system's time unit and cannot be more precise than 1 such unit. E.g., the time unit is 10 milliseconds for many UNIX systems.

On computers without "time-sharing", such as the Macintosh computer, real time and CPU time roughly coincide.

`time` is a function of the system kernel.

Examples

Example 1

This example shows how to do a time measurement and assign the computed value to an identifier at the same time. Note that the assignment needs extra parenthesis when passed as argument:
time((a := int(exp(x)*sin(x), x)))464.029

```
464.029
```

```
a-(exp(x)*(cos(x) - sin(x)))/2
```

$$\_ \frac{e^x (\cos(x) - \sin(x))}{2}$$

delete a:

Alternatively, one may time groups of statements in the following way: t0 := time(): command1 command2 ... time() - t0

Example 2

Here we use `rtime` to compute the elapsed hours, minutes and seconds since this session was started:
t := rtime()/1000: h := trunc(t/3600): m := trunc(t/60 - h*60): s := trunc(t - m*60 - h*3600):print(Unquoted, "This session is running for " . h . " hours, " . m . " minutes and " . s . " seconds.")This session is running for 0 hours, 0 minutes and 10 seconds. delete t, h, m, s:

Example 3

To obtain a nicer output, the measured time can be multiplied with the appropriate time unit:
time(isprime(2^1000000000 - 1))*unit::msec280.018*unit::msec

```
280.018 msec
```

Concepts

- “Measure Time”

transpose

Purpose

Transpose of a matrix

Syntax

```
transpose(A)
```

Description

`transpose(A)` returns the transpose A^t of the matrix A.

The transpose of the m n matrix A is the n m matrix B with $B_{i,j} = A_{j,i}$.

If the input is a matrix of category Cat::Matrix, then linalg::transpose is called to compute the result. In contrast to the linalg routines, the function `transpose` also operates on arrays and hfarrays.

If the argument does not evaluate to a matrix of one of the types mentioned above, symbolic call `transpose(A)` is returned.

Examples

Example 1

The following matrix is real. Thus, the Hermitean transpose coincides with the transpose:
A := array(1..2, 1..2, [[1, 2], [3, PI]])array(1..2, 1..2, [[1, 2], [3, PI]])

$$\begin{pmatrix} 1 & 2 \\ 3 & \pi \end{pmatrix}$$

transpose(A) = htranspose(A)array(1..2, 1..2, [[1, 3], [2, PI]]) = array(1..2, 1..2, [[1, 3], [2, PI]])

$$\begin{pmatrix} 1 & 3 \\ 2 & \pi \end{pmatrix} - \begin{pmatrix} 1 & 3 \\ 2 & \pi \end{pmatrix}$$

In general, this does not hold for complex matrices:
A := hfarray(1..2, 1..3, [[1, I, 3 + I], [PI*I, 4, 5]])hfarray(1..2, 1..3, [1.0, 1.0*I, 3.0 + 1.0*I, 3.141592654*I, 4.0, 5.0])

$$\begin{pmatrix} 1.0 & 1.0\,i & 3.0 + 1.0\,i \\ 3.141592654\,i & 4.0 & 5.0 \end{pmatrix}$$

transpose(A) <> htranspose(A)hfarray(1..3, 1..2, [1.0, 3.141592654*I, 1.0*I, 4.0, 3.0 + 1.0*I, 5.0]) <> hfarray(1..3, 1..2, [1.0, -3.141592654*I, -1.0*I, 4.0, 3.0 - 1.0*I, 5.0])

$$\begin{pmatrix} 1.0 & 3.141592654\,i \\ 1.0\,i & 4.0 \\ 3.0 + 1.0\,i & 5.0 \end{pmatrix} \neq \begin{pmatrix} 1.0 & -3.141592654\,i \\ -1.0\,i & 4.0 \\ 3.0 - 1.0\,i & 5.0 \end{pmatrix}$$

delete A:

Example 2

We compute the product $A^H A$ of a matrix given by a hardware float array. This data type allows matrix multiplication using the operator *: A := hfarray(1..2, 1..3, [[1, I, 3], [PI*I, 4, 5 + I]])hfarray(1..2, 1..3, [1.0, 1.0*I, 3.0, 3.141592654*I, 4.0, 5.0 + 1.0*I])

$$\begin{pmatrix} 1.0 & 1.0\,i & 3.0 \\ 3.141592654\,i & 4.0 & 5.0 + 1.0\,i \end{pmatrix}$$

AH:= htranspose(A)hfarray(1..3, 1..2, [1.0, -3.141592654*I, -1.0*I, 4.0, 3.0, 5.0 - 1.0*I])

$$\begin{pmatrix} 1.0 & -3.141592654\,i \\ -1.0\,i & 4.0 \\ 3.0 & 5.0 - 1.0\,i \end{pmatrix}$$

The product $A^H A$ is Hermitean:

AH*A = htranspose(AH*A)hfarray(1..3, 1..3, [10.8696044, -11.56637061*I, 6.141592654 - 15.70796327*I, 11.56637061*I, 17.0, 20.0 + 1.0*I, 6.141592654 + 15.70796327*I, 20.0 - 1.0*I, 35.0]) = hfarray(1..3, 1..3, [10.8696044, -11.56637061*I, 6.141592654 - 15.70796327*I, 11.56637061*I, 17.0, 20.0 + 1.0*I, 6.141592654 + 15.70796327*I, 20.0 - 1.0*I, 35.0])

delete A, AH:

$$\begin{pmatrix} 10.8696044 & -11.56637061\,i & 6.141592654 - 15.70796327\,i \\ 11.56637061\,i & 17.0 & 20.0 + 1.0\,i \\ 6.141592654 - 15.70796327\,i & 20.0 - 1.0\,i & 35.0 \end{pmatrix} =$$

$$\begin{pmatrix} 10.8696044 & -11.56637061\,i & 6.141592654 - 15.70796327\,i \\ 11.56637061\,i & 17.0 & 20.0 + 1.0\,i \\ 6.141592654 + 15.70796327\,i & 20.0 - 1.0\,i & 35.0 \end{pmatrix}$$

Example 3

If the input does not evaluate to a matrix, then symbolic calls are returned:

delete A, B: transpose(A) + 2*htranspose(B)2*htranspose(B) + transpose(A)

$$2\,\vec{B} + A^{t}$$

Parameters

A

A matrix: either a 2-dimensional array, a 2-dimensional hfarray, or an object of the category Cat::Matrix

Return Values

Matrix of the same domain type as A.

Overloaded By

A

Concepts

- “Transpose Matrices”

htranspose

Purpose

The Hermitean transpose of a matrix

Syntax

```
htranspose(A)
```

Description

`htranspose(A)` returns the Hermitean transpose A^H of the matrix A (the complex conjugate of the transpose of A).

The Hermitean transpose of the m n matrix A is the n m matrix B with B[i, j] = conjugate(A[j, i]) $B_{i,j} = \overline{A_{j,i}}$.

If the input is a matrix of category Cat::Matrix, then linalg::htranspose is called to compute the result. In contrast to the linalg routines, the function `htranspose` also operates on arrays and hfarrays.

If the argument does not evaluate to a matrix of one of the types mentioned above, symbolic call `htranspose(A)` is returned.

Examples

Example 1

The following matrix is real. Thus, the Hermitean transpose coincides with the transpose:
A := array(1..2, 1..2, [[1, 2], [3, PI]])array(1..2, 1..2, [[1, 2], [3, PI]])

$$\begin{pmatrix} 1 & 2 \\ 3 & \pi \end{pmatrix}$$

transpose(A) = htranspose(A)array(1..2, 1..2, [[1, 3], [2, PI]]) = array(1..2, 1..2, [[1, 3], [2, PI]])

$$\begin{pmatrix} 1 & 3 \\ 2 & \pi \end{pmatrix} = \begin{pmatrix} 1 & 3 \\ 2 & \pi \end{pmatrix}$$

In general, this does not hold for complex matrices:
A := hfarray(1..2, 1..3, [[1, I, 3 + I], [PI*I, 4, 5]])hfarray(1..2, 1..3, [1.0, 1.0*I, 3.0 + 1.0*I, 3.141592654*I, 4.0, 5.0])

$$\begin{pmatrix} 1.0 & 1.0\,i & 3.0 + 1.0\,i \\ 3.141592654\,i & 4.0 & 5.0 \end{pmatrix}$$

transpose(A) <> htranspose(A)hfarray(1..3, 1..2, [1.0, 3.141592654*I, 1.0*I, 4.0, 3.0 + 1.0*I, 5.0]) <> hfarray(1..3, 1..2, [1.0, -3.141592654*I, -1.0*I, 4.0, 3.0 - 1.0*I, 5.0])

$$\begin{pmatrix} 1.0 & 3.141592654\,i \\ 1.0\,i & 4.0 \\ 3.0 + 1.0\,i & 5.0 \end{pmatrix} \neq \begin{pmatrix} 1.0 & -3.141592654\,i \\ -1.0\,i & 4.0 \\ 3.0 - 1.0\,i & 5.0 \end{pmatrix}$$

delete A:

Example 2

We compute the product $A^H A$ of a matrix given by a hardware float array. This data type allows matrix multiplication using the operator *: A := hfarray(1..2, 1..3, [[1, I, 3], [PI*I, 4, 5 + I]])hfarray(1..2, 1..3, [1.0, 1.0*I, 3.0, 3.141592654*I, 4.0, 5.0 + 1.0*I])

$$\begin{pmatrix} 1.0 & 1.0\,i & 3.0 \\ 3.141592654\,i & 4.0 & 5.0 + 1.0\,i \end{pmatrix}$$

AH:= htranspose(A)hfarray(1..3, 1..2, [1.0, -3.141592654*I, -1.0*I, 4.0, 3.0, 5.0 - 1.0*I])

$$\begin{pmatrix} 1.0 & -3.141592654\,i \\ -1.0\,i & 4.0 \\ 3.0 & 5.0 - 1.0\,i \end{pmatrix}$$

traperror

Purpose

Trap errors

Syntax

```
traperror(object)
traperror(object, t)
traperror(object, MaxSteps = s)
```

Description

`traperror(object)` traps errors produced by the evaluation of `object`.

`traperror(object, t)` does the same. Moreover, it stops the evaluation if it is not finished after a real time of `t` seconds.

`traperror` traps errors caused by the evaluation of the object. Syntactical errors, i.e., errors on parsing the object, cannot be caught. The same holds true for fatal errors causing the termination of MuPAD.

`traperror` returns the error code `0` if no error happened. The error code is `1320` if the given time limit `t` is exceeded ("`Execution time exceeded`") and `1321` if the given number of "execution steps" is exceeded. The error code is `1028` if the error was raised by the command error.

If `traperror` is called with a numerical second argument, this number is taken as a time limit, measured in seconds, of "process time" (see the documentation of the time function for a discussion of this term).

When using the option `MaxSteps = s`, the caller sets a time limit which is not system-dependent, but rather measured in terms of MuPAD evaluation steps.

The number `s` does *not* refer directly to evaluation steps, but rather to a fixed (large) number of steps which may change from one MuPAD release to the next, but is fixed within one release. The number `s` is twice the number of outputs caused by `Pref::report(9)` for a calculation using the maximum time allowed.

If `traperror` has no time limit set and an "`Execution time exceeded`" error is raised by an enclosing `traperror(..., t)` command, then this error is not trapped by the inner `traperror`. It is trapped by the

traperror call that has set the time limit. Cf. “Example 5” on page 1-1928.

The object can be an assignment which, for syntactical reasons, must be enclosed in additional brackets. The following code fragment demonstrates a typical application of traperror:

```
if traperror((x := SomeErrorProneFunction())) = 0 then
     DoSomethingWith(x);
else RespondToTheError();
end_if;
```

Use lasterror to reproduce the trapped error.

Examples

Example 1

Errors that happen during the execution of kernel functions have various error codes, depending on the problem. E.g., “Division by zero” produces the error code 1025:
y := 1/x: traperror(subs(y, x = 0))1025

```
1025
```

lasterror() Error: Division by zero. [_power]

Example 2

All errors raised using the function error have the error code 1028. Errors during the execution of library functions are of this kind:
traperror(error("My error!"))1028

```
1028
```

lasterror() Error: My error!

Example 3

We try to factor a polynomial, but give up after ten seconds:

traperror(factor(x^1000 + 4*x + 1), 10)1320

```
1320
```

lasterror() Error: Execution time exceeded; Evaluating: faclib::univ_mod_gcd

Example 4

For use inside other routines, it is preferable to use `MaxSteps` instead of a time limit, to achieve consistent results across slower and faster machines:
traperror(factor(x^1000 + 4*x + 1), MaxSteps=10)1321

```
1321
```

lasterror() Error: Execution MaxSteps exceeded [traperror]; Evaluating: faclib::ddf

Note that evaluation steps may take vastly different amounts of time, so even on the same machine, different expressions evaluated with the same value of `MaxSteps` may be terminated after very different lengths of time:
time(traperror(factor(x^1000 + 4*x + 1), MaxSteps=1));
time(traperror(while TRUE do 1 end_while, MaxSteps=1));
time(traperror(int(1/sqrt(1/r-1/r0), r=0..r0), MaxSteps=1))2204

```
2204
```

40

```
40
```

468

```
468
```

Example 5

Here we have two nested `traperror` calls. The inner call contains an unterminated loop and the outer call has a time limit of `2` seconds. When the execution time is exceeded, this special error is not trapped by the inner `traperror` call. Because of the error, `print(1)` is never executed: traperror((traperror((while TRUE do 1 end)); print(1)), 2)1320

```
1320
```

lasterror() Error: Execution time is exceeded.

Parameters

object

Any MuPAD object

t

The time limit: a positive integer

s

The execution limit: a positive integer

Return Values

Nonnegative integer.

See Also

getlasterrorerrorlasterror

triangularPulse

Purpose

Triangular pulse function

Syntax

```
triangularPulse(a, b, c, x)
triangularPulse(a, c, x)
```

Description

`triangularPulse(a, b, c, x)` represents the triangular function.

`triangularPulse(a, c, x)` is a shortcut for `triangularPulse(a, (a + c)/2, c, x)`.

`triangularPulse(x)` is a shortcut for `triangularPulse(-1, 0, 1, x)`.

`triangularPulse` represents the triangular pulse function. This function is also called the triangle function, hat function, tent function, or sawtooth function.

If `a`, `b`, and `c` are variables or expressions with variables, `triangularPulse` assumes that `a <= b <= c`. If `a`, `b`, and `c` are numerical values that do not satisfy this condition, `triangularPulse` throws an error.

If `a < x < b`, the triangular function equals `(x - a)/(b - a)`. If `b < x < c`, the triangular function equals `(c - x)/(c - b)`. Otherwise, it equals 0. See “Example 1” on page 1-1930 and “Example 2” on page 1-1930.

If `a = b` or `b = c`, the triangular function can be expressed in terms of the rectangular function. See “Example 3” on page 1-1930.

If `a = b = c`, `triangularPulse` returns 0. See “Example 4” on page 1-1931.

`triangularPulse(x)` is equivalent to `triangularPulse(-1, 0, 1, x)`. See “Example 5” on page 1-1931.

`triangularPulse(a, c, x)` is equivalent to `triangularPulse(a, (a + c)/2, c, x)`. See “Example 6” on page 1-1931.

`triangularPulse` also accepts infinities as its arguments. See “Example 9” on page 1-1932.

`triangularPulse` and tripulse are equivalent.

Examples

Example 1

Compute the triangular pulse function for these input arguments: [triangularPulse(-2, 0, 2, -3), triangularPulse(-2, 0, 2, -1/2), triangularPulse(-2, 0, 2, 0), triangularPulse(-2, 0, 2, 3/2), triangularPulse(-2, 0, 2, 3)][0, 3/4, 1, 1/4, 0]

$$\left[0, \frac{3}{4}, 1, \frac{1}{4}, 0\right]$$

Example 2

Compute the triangular pulse function for `a < x < b`: triangularPulse(a, b, c, x) assuming a < x < b(a - x)/(a - b)

$$\frac{a - x}{a - b}$$

Compute the triangular pulse function for `b < x < c`: triangularPulse(a, b, c, x) assuming b < x < c-(c - x)/(b - c)

$$-\frac{c - x}{b - c}$$

Example 3

Compute the triangular pulse function for `a = b` and `c = b`: triangularPulse(b, b, c, x) assuming b < c-((c - x)*rectangularPulse(b, c, x))/(b - c)

$$-\frac{(c - x)\ \text{rectangularPulse}(b, c, x)}{b - c}$$

triangularPulse(a, b, b, x) assuming a < b((a - x)*rectangularPulse(a, b, x))/(a - b)

$$\frac{(a - x)\,\mathrm{rectangularPulse}(a, b, x)}{a - b}$$

Example 4

For `a = b = c`, the triangular pulse function returns 0: triangularPulse(a, a, a, x)0

$$0$$

Example 5

Use `triangularPulse` with one input argument as a shortcut for computing `triangularPulse(-1, 0, 1, x)`: triangularPulse(x)triangularPulse(-1, 0, 1, x)

$$\mathrm{triangularPulse}(-1, 0, 1, x)$$

[triangularPulse(-10), triangularPulse(-3/4), triangularPulse(0), triangularPulse(2/3), triangularPulse(1)][0, 1/4, 1, 1/3, 0]

$$\left[0, \frac{1}{4}, 1, \frac{1}{3}, 0\right]$$

Example 6

Use `triangularPulse` with three input arguments as a shortcut for computing `triangularPulse(a, (a + c)/2, c, x)`: triangularPulse(a, c, x)triangularPulse(a, a/2 + c/2, c, x)

$$\mathrm{triangularPulse}\left(a, \frac{a}{2} + \frac{c}{2}, c, x\right)$$

[triangularPulse(-10, 10, 3), triangularPulse(-1/2, -1/4, -2/3), triangularPulse(2, 4, 3), triangularPulse(2, 4, 6), triangularPulse(-1, 4, 0)][7/10, 0, 1, 0, 2/5]

$$\left[\frac{7}{10}, 0, 1, 0, \frac{2}{5}\right]$$

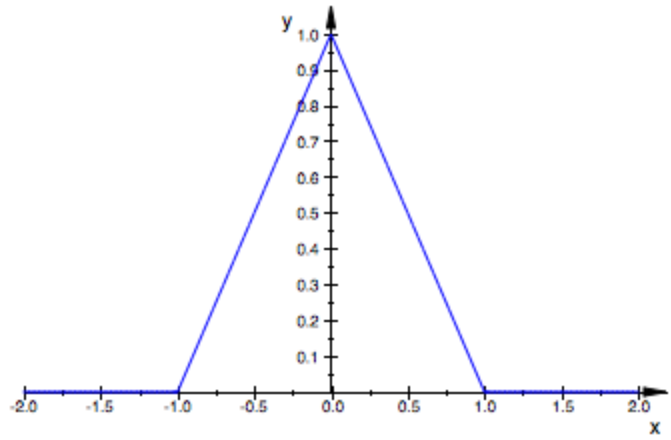
Example 7

Rewrite the triangular pulse function in terms of the Heaviside step function:
rewrite(triangularPulse(a, b, c, x), heaviside)(heaviside(x - a)*(a - x))/(a - b) - (heaviside(x - b)*(a - x))/(a - b) - (heaviside(x - b)*(c - x))/(b - c) + (heaviside(x - c)*(c - x))/(b - c)

$$\frac{\text{heaviside}(x-a)\,(a-x)}{a-b} - \frac{\text{heaviside}(x-b)\,(a-x)}{a-b} - \frac{\text{heaviside}(x-b)\,(c-x)}{b-c} + \frac{\text{heaviside}(x-c)\,(c-x)}{b-c}$$

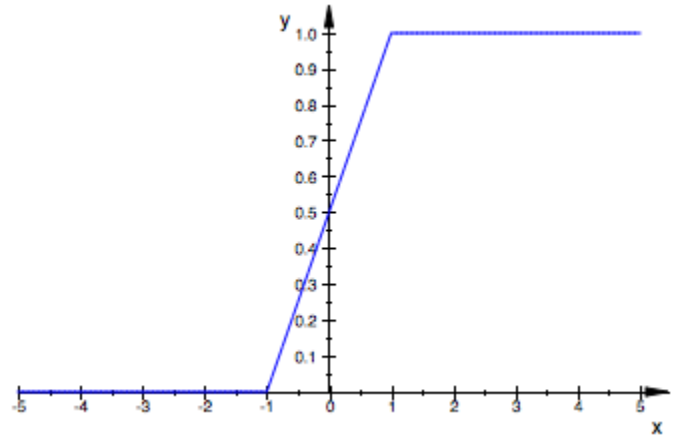
Example 8

Plot the triangular pulse function:
plot(triangularPulse(x), x = -2..2)



Example 9

Plot the triangular pulse function for which the argument c is a positive infinity:
plot(triangularPulse(-1, 1, infinity, x))



Parameters

a

b

c

x

Arithmetical expressions.

Return Values

Arithmetical expression.

Overloaded By

x

See Also

heavisidepiecewiserectangularPulse

tripulse

Purpose

Triangular pulse function

Syntax

```
tripulse(a, b, c, x)
tripulse(a, c, x)
```

Description

`tripulse(a, b, c, x)` represents the triangular function.

`tripulse(a, c, x)` is a shortcut for `tripulse(a, (a + c)/2, c, x)`.

`tripulse(x)` is a shortcut for `tripulse(-1, 0, 1, x)`.

`tripulse` and triangularPulse are equivalent. These functions represent the triangular pulse function. For details and examples, see triangularPulse.

Parameters

a

b

c

x

Arithmetical expressions.

Return Values

Arithmetical expression.

Overloaded By

x

See Also

triangularPulseheavisidepiecewiserectangularPulse

TRUE

Purpose

Boolean constant TRUE

Description

MuPAD uses a three state logic with the Boolean constants `TRUE`, `FALSE`, and `UNKNOWN`.

The Boolean constants `TRUE`, `FALSE`, `UNKNOWN` are of domain type DOM_BOOL.

See and, or, not for the logical rules of the MuPAD three state logic.

Boolean constants are returned by system functions such as bool and is. These functions evaluate Boolean expressions such as equations and inequalities.

Examples

Example 1

The Boolean constants may be combined via and, or, and not:
(TRUE and (not FALSE)) or UNKNOWNTRUE

```
TRUE
```

Example 2

The function bool serves for reducing Boolean expressions such as equations or inequalities to one of the Boolean constants:
bool(x = x and 2 < 3 and 3 <> 4 or UNKNOWN)TRUE

```
TRUE
```

The function is evaluates symbolic Boolean expressions with properties:
assume(x > 2): is(x^2 > 4), is(x^3 < 0), is(x^4 > 17)TRUE, FALSE, UNKNOWN

```
TRUE, FALSE, UNKNOWN
```

unassume(x):

Example 3

Boolean constants occur in the conditional part of program control structures such as if, repeat, or while statements. The following loop searches for the smallest Mersenne prime larger than 500 (see numlib::mersenne for details). The function isprime returns TRUE if its argument is a prime, and FALSE otherwise. Once a Mersenne prime is found, the while-loop is interrupted by the break statement:
p := 500: while TRUE do p := nextprime(p + 1): if isprime(2^p - 1) then print(p); break; end_if; end_while:521

```
521
```

Note that the conditional part of if, repeat, and while statements must evaluate to TRUE or FALSE. Any other value leads to an error:
if UNKNOWN then "true" else "false" end_if Error: Cannot evaluate to Boolean. [if] delete p:

See Also

DOM_BOOLFALSEUNKNOWN_lazy_and_lazy_orandboolifisnotorrepeatwhile

FALSE

Purpose

Boolean constant FALSE

Description

MuPAD uses a three state logic with the Boolean constants `TRUE`, `FALSE`, and `UNKNOWN`.

The Boolean constants `TRUE`, `FALSE`, `UNKNOWN` are of domain type DOM_BOOL.

See and, or, not for the logical rules of the MuPAD three state logic.

Boolean constants are returned by system functions such as bool and is. These functions evaluate Boolean expressions such as equations and inequalities.

Examples

Example 1

The Boolean constants may be combined via and, or, and not:
(TRUE and (not FALSE)) or UNKNOWNTRUE

```
TRUE
```

Example 2

The function bool serves for reducing Boolean expressions such as equations or inequalities to one of the Boolean constants:
bool(x = x and 2 < 3 and 3 <> 4 or UNKNOWN)TRUE

```
TRUE
```

The function is evaluates symbolic Boolean expressions with properties:
assume(x > 2): is(x^2 > 4), is(x^3 < 0), is(x^4 > 17)TRUE, FALSE, UNKNOWN

```
TRUE, FALSE, UNKNOWN
```

unassume(x):

Example 3

Boolean constants occur in the conditional part of program control structures such as if, repeat, or while statements. The following loop searches for the smallest Mersenne prime larger than 500 (see numlib::mersenne for details). The function isprime returns TRUE if its argument is a prime, and FALSE otherwise. Once a Mersenne prime is found, the while-loop is interrupted by the break statement:
p := 500: while TRUE do p := nextprime(p + 1): if isprime(2^p - 1) then print(p); break; end_if; end_while:521

```
521
```

Note that the conditional part of if, repeat, and while statements must evaluate to TRUE or FALSE. Any other value leads to an error:
if UNKNOWN then "true" else "false" end_if Error: Cannot evaluate to Boolean. [if] delete p:

DOM_BOOLTRUEUNKNOWN_lazy_and_lazy_orandboolifisnotorrepeatwhile

UNKNOWN

Purpose

Boolean constant UNKNOWN

Description

MuPAD uses a three state logic with the Boolean constants `TRUE`, `FALSE`, and `UNKNOWN`.

The Boolean constants `TRUE`, `FALSE`, `UNKNOWN` are of domain type DOM_BOOL.

See and, or, not for the logical rules of the MuPAD three state logic.

Boolean constants are returned by system functions such as bool and is. These functions evaluate Boolean expressions such as equations and inequalities.

Examples

Example 1

The Boolean constants may be combined via and, or, and not:
(TRUE and (not FALSE)) or UNKNOWNTRUE

```
TRUE
```

Example 2

The function bool serves for reducing Boolean expressions such as equations or inequalities to one of the Boolean constants:
bool(x = x and 2 < 3 and 3 <> 4 or UNKNOWN)TRUE

```
TRUE
```

The function is evaluates symbolic Boolean expressions with properties:
assume(x > 2): is(x^2 > 4), is(x^3 < 0), is(x^4 > 17)TRUE, FALSE, UNKNOWN

```
TRUE, FALSE, UNKNOWN
```

unassume(x):

Example 3

Boolean constants occur in the conditional part of program control structures such as if, repeat, or while statements. The following loop searches for the smallest Mersenne prime larger than 500 (see numlib::mersenne for details). The function isprime returns TRUE if its argument is a prime, and FALSE otherwise. Once a Mersenne prime is found, the while-loop is interrupted by the break statement:
p := 500: while TRUE do p := nextprime(p + 1): if isprime(2^p - 1) then print(p); break; end_if; end_while:521

```
521
```

Note that the conditional part of if, repeat, and while statements must evaluate to TRUE or FALSE. Any other value leads to an error:
if UNKNOWN then "true" else "false" end_if Error: Cannot evaluate to Boolean. [if] delete p:

See Also

DOM_BOOLTRUEFALSE_lazy_and_lazy_orandboolifisnotorrepeatwhile

type

Purpose

Type of an object

Syntax

```
type(object)
```

Description

`type(object)` returns the type of the object.

If `object` is not an expression of domain type DOM_EXPR, then `type(object)` is equivalent to domtype`(object)`, i.e., `type` returns the domain type of the object.

If `object` is an expression of domain type DOM_EXPR, then its type is determined by its 0-th operand (the “operator”). If the operator has a `"type"` slot, then `type` returns this value, which usually is a string. If the operator has no `"type"` slot, then `type` returns the string `"function"`.

In contrast to most other functions, `type` does not flatten arguments that are expression sequences. Cf. “Example 4” on page 1-1942.

Examples

Example 1

If an object is not an expression, its type equals its domain type:
type(3)DOM_INT

DOM_INT

Example 2

The operator of a sum is _plus; the type slot of that operator is `"_plus"`:
type(x + y*z)"_plus"

"_plus"

`type` evaluates its argument: thereby, the difference of `x` and `y` becomes the sum of `x` and `(-1)*y`. Its type is not `"_subtract"`, but `"_plus"`:
type(x - y)"_plus"

```
"_plus"
```

Example 3

If the operator of an expression is not a function environment having a type slot, the expression is of type `"function"`:

```
type(f(2))"function"
```

```
"function"
```

Example 4

The following call to `type` is *not* regarded as a call with two arguments, because expression sequences in the argument are not flattened:

```
type((2, 3))"_exprseq"
```

```
"_exprseq"
```

Parameters

object

Any MuPAD object

Return Values

Domain type of type DOM_DOMAIN or a character string.

Overloaded By

`object`

See Also

coercedomtypehastypetesttype

unassume

Purpose

Delete the properties of an identifier

Syntax

```
unassume(x)
```

Description

`unassume(x)` deletes the properties of the identifier `x`.

`unassume` serves for deleting properties of identifiers set via assume. See “Properties and Assumptions” for a description of the property mechanism.

If `x` is a list or a set of identifiers, then the properties of all specified identifiers are deleted.

The command delete x deletes the value and the properties of the identifier `x`.

Examples

Example 1

Properties are attached to the identifiers `x` and `y`:
assume(x > 0): assume(y < 0): getprop(x), getprop(y)Dom::Interval(0, infinity), Dom::Interval(-infinity, 0)

$(0, \infty), (-\infty, 0)$

sign(x), sign(y)1, -1

$1, -1$

`unassume` or delete deletes the properties:
unassume(x): delete y: getprop(x), getprop(y)C_, C_

$\mathbb{C}, \mathbb{C}$

sign(x), sign(y)sign(x), sign(y)

$\mathrm{sign}(x), \mathrm{sign}(y)$

The properties of several identifiers can be deleted simultaneously by passing a list or a set to `unassume`:
assume(x > y): unassume([x, y]): getprop(x), getprop(y)C_, C_

ℂ, ℂ

Parameters

x

An identifier or a list or a set of identifiers

Return Values

Void object `null()`.

See Also

assumedeletegetpropis

undefined

Purpose

Undefined value

Description

`undefined` indicates results of mathematically undefined operations.

MuPAD uses the special value `undefined` to indicate the results of operations that are not defined in mathematics.

You can use the `undefined` value as an input. Arithmetical operations involving `undefined` also return `undefined`. Multiplying infinities by 0 returns `undefined`.

For floating-point intervals, MuPAD uses the special value `RD_NAN` instead of `undefined`. If you use typeset mode, MuPAD displays `RD_NAN` as `NaN` in output regions. Multiplying infinities `RD_INF` and `RD_NINF` by 0 returns `RD_NAN`.

Examples

Example 1

Perform the following operations with infinities. MuPAD returns the `undefined` value for these operations:
0*infinity, infinity - infinity, infinity/infinityundefined, undefined, undefined

```
undefined, undefined, undefined
```

Example 2

Compute the limit of the sine function at infinity. Since this limit does not exist (is not mathematically defined), MuPAD returns `undefined`:
limit(sin(x), x = infinity)undefined

```
undefined
```

Example 3

Multiply infinities by 0:
infinity*0, -infinity*0undefined, undefined

```
undefined, undefined
```

RD_INF*0, RD_NINF*0RD_NAN, RD_NAN

```
NaN, NaN
```

unit

Purpose

Physical units

Syntax

```
unit::nam
```

Description

Objects such as `unit::m`, `unit::kg`, `unit::sec` etc. represent the physical units “meters”, “kilograms”, “seconds” etc.

`unit` domain provides some methods for simplifying and converting arithmetical expressions involving such units.

`unit` objects such as `unit::m` or `unit::kg` serve for representing physical units. They are domain objects of domain type `unit`.

These objects behave like symbolic names (identifiers) and can be used to build arithmetical expressions involving numbers and symbols such as `3*unit::m^2` or `a*unit::cm + b*unit::inch^2/unit::mm`.

Expressions such as `20*unit::cm + 0.3*unit::m` involving several units of the same type (‘length,’ ‘mass,’ ‘time’ etc.) are *not* simplified automatically. Use `unit::convert`, `unit::simplify`, simplify, or Simplify to convert all subexpressions to common units. These routines are described further down below.

On input, use the prefix `unit::` as in `unit::mm`, `unit::km` for millimeters, kilometers etc. On the screen, this prefix is stripped off. For example, `1.23*unit::mm` is displayed as `1.23 mm`.

The available units are listed further down below.

Note that some units such as `unit::mm`, `unit::millimeter` and `unit::millimeters` represent the same physical unit. Use an interactive command such as `info(unit::oz)` to find information on `unit::oz` including all the alternative names that can be used in MuPAD. Cf. “Example 6” on page 1-1961.

Note Beware: If you mix different MuPAD units representing the same physical unit, *no automatic simplifications* are done! Use simplify to simplify an expression such as `2*unit::m + 3*unit::meter` to `5*unit::m`.

Expressions such as `unit::kg*(unit::m/unit::s)^2` can be used to represent a composite unit. You can convert them to other units such as `unit::Joule` via `unit::convert`.

Some of the conversion factors between the various units are given by exact rational numbers (e.g., `unit::inch = 127/50*unit::cm`), while others are linked by floating-point factors (e.g., `unit::cal = 4.1868*unit::Joule`). Use float to approximate exact values by floats. Use numeric::rationalize to approximate floats by rational numbers.

Most system functions such as diff, factor, normal etc. accept expressions containing units, treating the units like symbolic identifiers. See “Example 8” on page 1-1961.

The available units are listed below. If the required unit is not available, you can use `unit::newUnit` to add your own unit to the `unit` domain. See “Example 3” on page 1-1957.

Example 1

Units not convertible are left alone by `unit::convert`:
unit::convert(1.23*unit::kg*unit::inch^2/unit::mm,
unit::cm)79.35468*unit::cm*unit::kg

$$79.35468\ \text{cm kg}$$

unit::convert(unit::km/unit::hour,
unit::m/unit::sec)(5/18)*(unit::m/unit::sec)

$$\frac{5\ \frac{m}{sec}}{18}$$

Example 2

`unit::simplify` favors kg over pounds:
unit::simplify(1.23*unit::kg^2/unit::pound*unit::inch^2/unit::mm)68.87681995*unit

$$68.87681995\ \text{inch kg}$$

Example 3

We add new velocity units to the `unit` domain:
unit::newUnit(SpeedOfLight =
300000*unit::km/unit::sec)unit::SpeedOfLight

SpeedOfLight

Now, the unit `unit::SpeedOfLight` exists and can be used like any other unit in the `unit` domain. We use it to define yet another velocity unit:

```
unit::newUnit(Warp9 = 1.516*unit::SpeedOfLight)unit::Warp9
```

Warp9

We convert the velocity of 123.4 miles per hour into the new speed units:

```
unit::convert(123.4*unit::mile/unit::hour,
unit::SpeedOfLight)0.0000001838824533*unit::SpeedOfLight
```

0.0000001838824533 SpeedOfLight

```
unit::convert(123.4*unit::mile/unit::hour,
unit::Warp9)0.0000001212944943*unit::Warp9
```

0.0000001212944943 Warp9

We verify the new units:

```
unit::convert(unit::SpeedOfLight,
unit::km/unit::sec)300000*(unit::km/unit::sec)
```

300000 $\frac{km}{sec}$

```
unit::convert(unit::Warp9,
unit::SpeedOfLight)1.516*unit::SpeedOfLight
```

1.516 SpeedOfLight

```
unit::convert(unit::Warp9,
unit::km/unit::sec)454800.0*(unit::km/unit::sec)
```

454800.0 $\frac{km}{sec}$

Example 4

We create a symbolic expression involving different units of type 'length':
27*unit::cm + 30*unit::mm27*unit::cm + 30*unit::mm

$$27\ \mathrm{cm} + 30\ \mathrm{mm}$$

This expression is not simplified automatically. We apply simplify:
simplify(%)30*unit::cm

$$30\ \mathrm{cm}$$

We convert this length to inch:
unit::convert(%, unit::inch)(1500/127)*unit::inch

$$\frac{1500\ \mathrm{inch}}{127}$$

float(%)11.81102362*unit::inch

$$11.81102362\ \mathrm{inch}$$

Here is another example for simplification and conversion:
1234*unit::g + 1.234*unit::kg*unit::m^2/unit::inch^21234*unit::g + 1.234*((unit::kg*unit::m^2)/unit::inch^2)

$$1234\ g + 1.234\ \frac{\mathrm{kg}\ m^2}{\mathrm{inch}^2}$$

simplify(%)1913937.825*unit::g

$$1913937.825\ g$$

unit::convert(%, unit::ounce)67512.17003*unit::ounce

$$67512.17003\ \mathrm{ounce}$$

The target unit in `unit::convert` may be an expression:
unit::convert(unit::pound*unit::km/unit::hour,
unit::kg*unit::m/unit::s)(45359237/360000000)*((unit::kg*unit::m)/unit::s)

$$\frac{45359237\ \frac{kg\ m}{s}}{360000000}$$

Example 5

The probably most interesting method of the `unit` domain is the conversion routine `unit::convert`. Given any expression involving units, you can specify a target unit which is to be used to express the units:
unit::convert(unit::ounce,
unit::kilogram)(45359237/1600000000)*unit::kilogram

$$\frac{45359237\ \text{kilogram}}{1600000000}$$

The target unit needs not be of the same physical type as the expression that is to be rewritten. In the following example, we wish to rewrite a torque (given in “Newton meters”) in terms of units involving the power unit “Watt.” Note that a torque is an energy, i.e., “power” multiplied by “time”:
unit::convert(1.23*unit::Nm, unit::W)1.23*unit::W*unit::s

$$1.23\ W\,s$$

We wish to rewrite “Newton meters” in terms of units involving “centimeters”:
unit::convert(unit::Nm, unit::cm)10000*((unit::cm^2*unit::kg)/unit::s^2)

$$10000\ \frac{cm^2\ kg}{s^2}$$

The target unit may be a composite expression. We wish to rewrite “Newton meters” in terms of “grams,” “centimeters,” and “milliseconds”:

unit::convert(unit::Nm,
unit::g*unit::cm^2/unit::msec^2)10*((unit::cm^2*unit::g)/unit::msec^2)

$$10\ \frac{cm^2\ g}{msec^2}$$

Example 6

The info command provides information on units. In particular, it lists alternative names that can be used in MuPAD:
info(unit::nm) nanometer: a length unit Alternative names: unit::nanom, unit::nanometer, unit::nanometers, unit::nm
info(unit::Joule) joule: a unit of energy Alternative names: unit::J, unit::Joule, unit::Newtonmeter, unit::Nm, unit::Ws, unit::joule, unit::newtonmeter

Example 7

We use `unit::convert2SIunits` to convert a mass expressed in non-metric units to SI base units:
mass := 2*unit::cal*unit::msec^2/unit::inch^2 - 45*unit::carat2*((unit::cal*unit::msec^2)/unit::inch^2) - 45*unit::carat

$$2\ \frac{cal\ msec^2}{inch^2} - 45\ carat$$

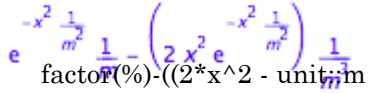
unit::convert2SIunits(mass)0.003979105958*unit::kg

$$0.003979105958\ kg$$

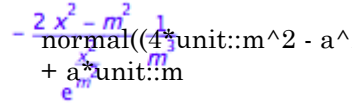
delete mass:

Example 8

Most system functions such as diff, factor, normal etc. treat units like ordinary symbolic identifiers:
diff(x/unit::m*exp(-x^2/unit::m^2),
x)exp(-x^2*(1/unit::m^2))*(1/unit::m) -
(2*x^2*exp(-x^2*(1/unit::m^2)))*(1/unit::m^3)



factor(%)-((2*x^2 - unit::m^2)/exp(x^2/unit::m^2))*(1/unit::m^3)



normal((4*unit::m^2 - a^2*unit::m^2)/(2*unit::m - a*unit::m))2*unit::m + a*unit::m

Parameters

nam

The name of the physical unit, see the list below. Some units such as `unit::mm` and `unit::millimeter` represent the same physical unit.

Methods

convertConvert an expression to other units

`convert(x, targetunit)` converts all units in the arithmetical expression `x` to multiples of the `targetunit` if possible. The `targetunit` may be one of the unit objects of type 'length,' 'mass' etc. It may also be an arithmetical expression such as `unit::km/unit::sec`. In this case, x is rewritten in terms of the units found in `targetunit`.

convert2SIunitsRewrite to SI units

`convert2SIunits(x)` rewrites all units in the arithmetical expression `x` in terms of corresponding SI base units.

simplifyCombine like units in an expression

`unit:: simplify(x)` converts all units in the arithmetical expression `x` to some basic unit found in `x`, i.e., all length units are expressed by the same length unit, all mass units are expressed by the same mass unit, all time units are expressed by the same time unit etc.

newUnitDefine a new unit

`newUnit(newname = expression)`

`unit::newUnit(newname = f*oldunit)` creates a new unit that may be addressed by `unit::newname`. Its name `newname` must be an identifier. It is declared as the `f`-fold of some unit `oldunit` that must be an expression such as `unit::mm/unit::sec` involving units provided by the unit domain. The conversion factor f must be an arithmetical expression (typically, a numerical conversion factor).
displayFormat for output

`display(x)` formats the screen output of the arithmetical expression `x` such that the units appear as a separate factor at the end of each term.
findUnitsFind all units in expression

`findUnits(x)` returns a set of all units found in the arithmetical expression `x`.
Celsius2FahrenheitConvert degrees Celsius to degrees Fahrenheit

`unit::Celsius2Fahrenheit(x)` converts a numerical value `x` representing a temperature in degrees Celsius into a numerical value representing this temperature in degrees Fahrenheit.
Celsius2KelvinConvert degrees Celsius to Kelvin

`unit::Celsius2Kelvin(x)` converts a numerical value `x` representing a temperature in degrees Celsius into a numerical value representing this temperature in degrees Kelvin.
Celsius2RankineConvert degrees Celsius to degrees Rankine

`unit::Celsius2Rankine(x)` converts a numerical value `x` representing a temperature in degrees Celsius into a numerical value representing this temperature in degrees Rankine.
Celsius2ReaumurConvert degrees Celsius to degrees Reaumur

`unit::Celsius2Reaumur(x)` converts a numerical value `x` representing a temperature in degrees Celsius into a numerical value representing this temperature in degrees Reaumur.
Fahrenheit2CelsiusConvert degrees Fahrenheit to degrees Celsius

`unit::Fahrenheit2Celsius(x)` converts a numerical value `x` representing a temperature in degrees Fahrenheit into a numerical value representing this temperature in degrees Celsius.
Fahrenheit2KelvinConvert degrees Fahrenheit to Kelvin

`unit::Fahrenheit2Kelvin(x)` converts a numerical value `x` representing a temperature in degrees Fahrenheit into a numerical value representing this temperature in degrees Kelvin.
Fahrenheit2RankineConvert degrees Fahrenheit to degrees Rankine

`unit::Fahrenheit2Rankine(x)` converts a numerical value `x` representing a temperature in degrees Fahrenheit into a numerical value representing this temperature in degrees Rankine.
Fahrenheit2ReaumurConvert degrees Fahrenheit to degrees Reaumur

`unit::Fahrenheit2Reaumur(x)` converts a numerical value `x` representing a temperature in degrees Fahrenheit into a numerical value representing this temperature in degrees Reaumur.
Kelvin2FahrenheitConvert Kelvin to degrees Fahrenheit

`unit::Kelvin2Fahrenheit(x)` converts a numerical value `x` representing a temperature in degrees Kelvin into a numerical value representing this temperature in degrees Fahrenheit.
Kelvin2CelsiusConvert Kelvin to degrees Celsius

`unit::Kelvin2Celsius(x)` converts a numerical value `x` representing a temperature in degrees Kelvin into a numerical value representing this temperature in degrees Celsius.
Kelvin2RankineConvert Kelvin to degrees Rankine

`unit::Kelvin2Rankine(x)` converts a numerical value `x` representing a temperature in degrees Kelvin into a numerical value representing this temperature in degrees Rankine.
Kelvin2ReaumurConvert Kelvin to degrees Reaumur

`unit::Kelvin2Reaumur(x)` converts a numerical value `x` representing a temperature in degrees Kelvin into a numerical value representing this temperature in degrees Reaumur.
Rankine2FahrenheitConvert degrees Rankine to degrees Fahrenheit

`unit::Rankine2Fahrenheit(x)` converts a numerical value `x` representing a temperature in degrees Rankine into a numerical value representing this temperature in degrees Fahrenheit.
Rankine2KelvinConvert degrees Rankine to Kelvin

`unit::Rankine2Kelvin(x)` converts a numerical value `x` representing a temperature in degrees Rankine into a numerical value representing this temperature in degrees Kelvin.
Rankine2CelsiusConvert degrees Rankine to degrees Celsius

`unit::Rankine2Celsius(x)` converts a numerical value `x` representing a temperature in degrees Rankine into a numerical value representing this temperature in degrees Celsius.
Rankine2ReaumurConvert degrees Rankine to degrees Reaumur

`unit::Rankine2Reaumur(x)` converts a numerical value `x` representing a temperature in degrees Rankine into a numerical value representing this temperature in degrees Reaumur.
Reaumur2FahrenheitConvert degrees Reaumur to degrees Fahrenheit

`unit::Reaumur2Fahrenheit(x)` converts a numerical value `x` representing a temperature in degrees Reaumur into a numerical value representing this temperature in degrees Fahrenheit.
Reaumur2KelvinConvert degrees Reaumur to Kelvin

`unit::Reaumur2Kelvin(x)` converts a numerical value `x` representing a temperature in degrees Reaumur into a numerical value representing this temperature in degrees Kelvin.
Reaumur2RankineConvert degrees Reaumur to degrees Rankine

`unit::Reaumur2Rankine(x)` converts a numerical value `x` representing a temperature in degrees Reaumur into a numerical value representing this temperature in degrees Rankine.
Reaumur2CelsiusConvert degrees Reaumur to degrees Celsius

`unit::Reaumur2Celsius(x)` converts a numerical value `x` representing a temperature in degrees Reaumur into a numerical value representing this temperature in degrees Celsius.

universe

Purpose

Set-theoretical universe

Description

`universe` represents the set-theoretical universe of all objects.

`universe` is the only element of the domain `stdlib::Universe`.

The standard set operations such as union, intersection and subtraction can be used with `universe`.

Examples

Example 1

We show some basic set operations involving `universe`:
universe union {a}universe

universe

universe intersect {a}{a}

{a}

{a} minus universe{}

∅

See Also

DOM_SETunionintersectminus

unprotect

Purpose

Remove protection of identifiers

Syntax

```
unprotect(x)
```

Description

`unprotect(x)` removes any write protection of the identifier `x`.

`unprotect(x)` is equivalent to protect`(x, ProtectLevelNone)`.

`unprotect` does not evaluate its argument. Cf. “Example 2” on page 1-1967.

Examples

Example 1

`unprotect` allows to assign values to system functions:
unprotect(sign): sign(x) := 11

```
1
```

However, we strongly advise not to change identifiers protected by the system. We undo the previous assignment:
delete sign(x): protect(sign, ProtectLevelError):

Example 2

`unprotect` does not evaluate its argument. Here the identifier `x` is unprotected and not its value `y`:
x := y: protect(y): unprotect(x): y := 1 Warning: The protected variable 'y' is overwritten. [_assign] 1

```
1
```

Warning: Protected variable 'y' overwritten. [_assign] 1

```
1
```

unprotect(y): delete x, y:

Example 3

The identifier `a` is protected with various levels. `unprotect` returns the previous protection level:
protect(a): unprotect(a)ProtectLevelWarning

ProtectLevelWarning
protect(a, ProtectLevelError): unprotect(a)ProtectLevelError

ProtectLevelError

At this place, `a` is not protected:
unprotect(a)ProtectLevelNone

ProtectLevelNone

Parameters

x

An identifier

Return Values

Previous protection level of `x`: either `ProtectLevelError` or `ProtectLevelWarning` or `ProtectLevelNone` (see protect).

See Also

protect

use

Purpose

Use library functions by a short name

Syntax

```
use(L, <Alias>, f1, f2,  )
use(L, <Alias>)
```

Description

`use(L, f)` 'exports' the public function `L::f` of the library `L` to the global namespace such that it can be accessed as `f` without the prefix `L`.

`use(L)` exports all public functions of the library `L`.

A library contains *public* functions which may be called by the user. The collection of these functions forms the *interface* of the library. (There may be other, private, functions, too, which are not intended to be called by the user directly, and are not documented.) The standard way of accessing the public function `f` from the library `L` is via `L::f`. When the function `f` is *exported*, it can be accessed more briefly as `f`. Technically, exporting means that the global identifier `f` is assigned the value `L::f`. Alternatively, when the option `Alias` is used, an alias is created.

Unexporting the library function `f` means that the value of the global identifier `f` is deleted. Afterwards, the library function is available only as `L::f`.

`use(L, f1, f2, ...)` exports the given functions `f1, f2, ...` of `L`. However, if one of the identifiers already has a value, the corresponding function is not exported. A warning is printed instead. An error is returned if one of the identifiers is not the name of a public library function.

`use(L)` exports all public functions of `L`.

A function that is already exported will not be exported twice.

`use` evaluates its first argument `L`, but it does not evaluate the remaining arguments `f1, f2, ...`, if any.

The function info displays the interface functions and the exported functions of a library.

Some libraries have functions that are always exported. These functions cannot be unexported. The function append from the library `listlib` is such an example.

Environment Interactions

When a function is exported, it is assigned to the corresponding global identifier. When it is unexported, the corresponding identifier is deleted.

Examples

Example 1

We export the public function `invphi` of the library numlib and then undo the export:
numlib::invphi(4!)[35, 39, 45, 52, 56, 70, 72, 78, 84, 90]

```
[35, 39, 45, 52, 56, 70, 72, 78, 84, 90]
```

use(numlib, invphi):invphi(4!)[35, 39, 45, 52, 56, 70, 72, 78, 84, 90]

```
[35, 39, 45, 52, 56, 70, 72, 78, 84, 90]
```

unuse(numlib, invphi):invphi(4!)invphi(24)

```
invphi(24)
```

We export and unexport all public functions of the library numlib: use(numlib): invphi(100) Warning: Identifier 'contfrac' already has a value. It is not exported. [use] [101, 125, 202, 250]

```
[101, 125, 202, 250]
```

As you can see `use` issued a warning because `contfrac` already has a value. Here, the reason in the existence of a global function contfrac (which makes use of numlib::contfrac for numerical arguments). unuse(numlib): invphi(100)invphi(100)

```
invphi(100)
```

Example 2

use issues a warning if a function cannot be exported since the corresponding identifier already has a value:
invphi := 17: use(numlib, invphi) Warning: Identifier 'invphi' already has a value. It is not exported. [use]

Parameters

L

The library: a domain

f1, f2, ...

Public functions of L: identifiers

Options

Alias

Use alias(f = L::f) to create an alias f for L::f rather than exporting L::f by the assignment f:= L::f.

Return Values

Void object null() of type DOM_NULL.

Algorithms

The names of the public functions of a library L are stored in the set L::interface. This set is used by the function info and for exporting.

The names of functions exported from a library L are stored in the set L::_exported.

See Also

unuse:=aliasdeleteinfoloadprocpackage

Related Examples

- "Avoid Name Conflicts Between MuPAD Objects and Library Functions"

unuse

Purpose

Undo the use command

Syntax

```
unuse(L, f1, f2,  )
unuse(L)
```

Description

`unuse(L, f)` undoes the export of the public function `L::f` of the library `L` such that it is no longer available as `f`.

`unuse(L)` undoes the export of all previously exported public functions of the library `L`.

A library contains *public* functions which may be called by the user. The collection of these functions forms the *interface* of the library. (There may be other, private, functions, too, which are not intended to be called by the user directly, and are not documented.) The standard way of accessing the public function `f` from the library `L` is via `L::f`. When the function `f` is *exported*, it can be accessed more briefly as `f`. Technically, exporting means that the global identifier `f` is assigned the value `L::f`. Alternatively, when the option `Alias` is used, an alias is created.

Unexporting the library function `f` means that the value of the global identifier `f` is deleted. Afterwards, the library function is available only as `L::f`.

`unuse(L, f1, f2, ...)` unexports all given functions of `L`. Note that `unuse` does not evaluate the identifiers. Thus, it is not necessary to use hold to protect them from being evaluated.

`unuse(L)` unexports all public functions of the library `L`.

`unuse` evaluates its first argument `L`, but it does not evaluate the remaining arguments `f1, f2, ...`, if any.

The function info displays the interface functions and the exported functions of a library.

Some libraries have functions that are always exported. These functions cannot be unexported. The function append from the library `listlib` is such an example.

Environment Interactions

When a function is exported, it is assigned to the corresponding global identifier. When it is unexported, the corresponding identifier is deleted.

Examples

Example 1

We export the public function `invphi` of the library `numlib` and then undo the export:
numlib::invphi(4!)[35, 39, 45, 52, 56, 70, 72, 78, 84, 90]

[35, 39, 45, 52, 56, 70, 72, 78, 84, 90]
use(numlib, invphi):invphi(4!)[35, 39, 45, 52, 56, 70, 72, 78, 84, 90]

[35, 39, 45, 52, 56, 70, 72, 78, 84, 90]
unuse(numlib, invphi):invphi(4!)invphi(24)

invphi(24)

We export and unexport all public functions of the library numlib: use(numlib): invphi(100) Warning: Identifier 'contfrac' already has a value. It is not exported. [use] [101, 125, 202, 250]

[101, 125, 202, 250]

As you can see `use` issued a warning because `contfrac` already has a value. Here, the reason in the existence of a global function contfrac (which makes use of numlib::contfrac for numerical arguments). unuse(numlib): invphi(100)invphi(100)

invphi(100)

Example 2

`use` issues a warning if a function cannot be exported since the corresponding identifier already has a value:

invphi := 17: use(numlib, invphi) Warning: Identifier 'invphi' already has a value. It is not exported. [use]

Parameters

L

The library: a domain

f1, f2, ...

Public functions of `L`: identifiers

Options

Alias

Use `alias(f = L::f)` to create an alias `f` for `L::f` rather than exporting `L::f` by the assignment `f:= L::f`.

Return Values

Void object `null()` of type DOM_NULL.

Algorithms

The names of the public functions of a library `L` are stored in the set `L::interface`. This set is used by the function info and for exporting.

The names of functions exported from a library `L` are stored in the set `L::_exported`.

Concepts

- "Use the MuPAD Libraries"

userinfo

Purpose

Print progress information

Syntax

```
userinfo(<Text>, <NoNL>, n, message1, message2,  )
userinfo(<Text>, <NoNL>, n1 .. n2, message1, message2,  )
```

Description

`userinfo(n, message)` prints a message if an information level larger or equal to `n` is set via setuserinfo.

`userinfo(n1..n2, message)` prints a message if the information level set by setuserinfo is between `n1` and `n2`.

`userinfo` must not be used on the interactive level. It should be built into the body of a procedure or of a domain method to print status information such as the chosen algorithm, intermediate results etc. If a `userinfo` command is built into a procedure by the name `f`, say, then it is activated by setting an appropriate information level via setuserinfo`(f, n)`. The information is printed during subsequent calls to `f`.

The print output consists of the evaluation of the message arguments, possibly followed by the name of the procedure (see the function setuserinfo). Strings are printed without quotes. The pretty printer is not used. Unless one of the options `Text` or `NoNL` is given, the message arguments are separated by commas in the output. Unless the option `NoNL` is given, the print output is preceded by the string `"Info:  "` and a new line is started after the output.

The information level of a single procedure, of all procedures of a domain, or, of all procedures in general can be specified using setuserinfo. All three levels may apply to a procedure simultaneously.

Most of the functions in the MuPAD library provide status information via `userinfo`. See “Example 3” on page 1-1976.

Environment Interactions

`userinfo` prints the messages on the screen, if an appropriate information level is set.

Examples

Example 1

The function expr2text is useful for incorporating MuPAD objects in a text message:
f := proc(x) begin userinfo(2, "the argument is " . expr2text(x)); x^2 end_proc:setuserinfo(f, 2, Name): f(12)Info: the argument is 12 [f] 144

144

setuserinfo(f, 0): delete f:

Example 2

A call of the form `userinfo(n, message)` causes `message` to be displayed if the information level is at least as high as `n`. If you want `message` to be displayed only if the information level equals `n`, use a range that consists of one point only:
f := proc() begin userinfo(2..2, "Infolevel = 2"); userinfo(2, "Infolevel >= 2"); end_proc:setuserinfo(f, 2): f():Info: Infolevel = 2 Info: Infolevel >= 2 setuserinfo(f, 3): f():Info: Infolevel >= 2 setuserinfo(f, 0): delete f:

Example 3

By setting the information level of `faclib` to 5, we get information on the algorithms used for factorization:
setuserinfo(faclib, 5): factor(x^2 + 2*x + 1)Info: faclib::monomial called with poly(x^2 + 2*x + 1, [x]) Info: Squarefree factorization (Yun's algorithm) called (x + 1)^2

$(x + 1)^2$

setuserinfo(faclib, 0):

Parameters

n

n_1

n_2

The information levels: positive integers

$message_1$, $message_2$, ...

Arbitrary MuPAD objects. Typically, character strings.

Options

Text

Do not separate the arguments by commas in the output

NoNL

Do not separate the arguments by commas in the output, do not start a new line after the output, and do not precede the output by the string `"Info:  "`.

Return Values

Void object of type DOM_NULL.

Algorithms

`userinfo` does not evaluate the messages unless they are printed.

The global table of information levels for all procedures can be obtained by the call `setuserinfo()`.

printsetuserinfowarning

val

Purpose

Value of an object

Syntax

```
val(object)
```

Description

`val(object)` replaces every identifier in `object` by its value.

`val` does not perform any simplification of the result.

If the result of `val` is a set, duplicate elements are removed from that set.

`val` does not work recursively, i.e., if the value of an identifier in turn contains identifiers, then these are not replaced by their values. See "Example 3" on page 1-1979.

`val` does not flatten its argument. Hence, an expression sequence is accepted as argument. Cf. "Example 2" on page 1-1978.

Examples

Example 1

`val` replaces identifiers by their values, but does not call arithmetical functions such as _plus:

```
a := 0: val(a*b + 4 + 0)0*b + 4 + 0
```

$$0\ b + 4 + 0$$

Duplicate elements in sets are removed:

```
a := b: val({a, b, a*0}){b, 0*b}
```

$$\{b, 0\ b\}$$

delete a:

Example 2

`val` does not flatten its argument, nor does it remove void objects of type DOM_NULL:

```
a := null(): val((a, null())) null(), null()
```

However, it is not legal to pass several arguments:
val(a, null()) Error: The number of arguments is incorrect. [val] delete a:

Example 3

`val` does not recursively substitute values for the identifiers:
delete a, b: a := b: b := c: val(a)b

b

Parameters

object

Any MuPAD object

Return Values

“evaluated” object.

See Also

evalholdlevelLEVELMAXLEVEL

vectorPotential

Purpose

Vector potential of a three-dimensional vector field

Syntax

```
vectorPotential(j, [x1, x2, x3], <Test>)
```

Description

`vectorPotential(j, x)` returns the vector potential of the vector field ‘j→‘(‘x→‘)$\vec{j}(\vec{x})$ with respect to ‘x→‘$\vec{x}$. This is a vector field ‘v→‘$\vec{v}$ with curl[‘v→‘](‘x→‘) = ‘j→‘$\mathrm{curl}_{\vec{v}}(\vec{x}) = \vec{j}$.

The vector potential of a vector function `j` exists if and only if the divergence of `j` is zero. It is uniquely determined.

If the vector potential of `j` does not exist, then `vectorPotential` returns `FALSE`.

If `j` is a vector then the component ring of `j` must be a field (i.e., a domain of category Cat::Field) for which definite integration can be performed.

If `j` is given as a list of three arithmetical expressions, then `vectorPotential` returns a vector of the domain Dom::Matrix().

`vectorPotential` and linalg::vectorPotential are equivalent.

Examples

Example 1

We check if the vector function ‘j→‘(x, y, z)=fenced(x^2 * y, -(1)/(2) * y^2 * x, -x * y * z)$\vec{j}(x, y, z) = \left(x^2\, y, -\frac{y^2\, x}{2}, -x\, y\, z\right)$ has a vector potential: delete x, y, z: vectorPotential([x^2*y, -1/2*y^2*x, -x*y*z], [x, y, z], Test)TRUE

```
TRUE
```

The answer is yes, so let us compute the vector potential of ‘j→‘$\vec{j}$: vectorPotential([x^2*y, -1/2*y^2*x, -x*y*z], [x, y, z])matrix([[-(x*y^2*z)/2], [-x^2*y*z], [0]])

$$\begin{pmatrix} -\frac{x y^2 z}{2} \\ -x^2 y z \\ 0 \end{pmatrix}$$

We check the result:
curl(%, [x, y, z])matrix([[x^2*y], [-(x*y^2)/2], [-x*y*z]])

$$\begin{pmatrix} x^2 y \\ -\frac{x y^2}{2} \\ -x y z \end{pmatrix}$$

Example 2

The vector function ‘j→‘=fenced(x^2, 2 * y, z)$\vec{j} = (x^2, 2\,y, z)$ does not have a vector potential:
vectorPotential([x^2, 2*y, z], [x, y, z])FALSE

FALSE

Parameters

j

A list of three arithmetical expressions, or a 3-dimensional vector (i.e., a 3 1 or 1 3 matrix of a domain of category Cat::Matrix)

x_1

x_2

x_3

(indexed) identifiers

Options

Test

Check whether the vector field `j` has a vector potential and return `TRUE` or `FALSE`, respectively.

Return Values Vector with three components, i.e., an 3 1 or 1 *n* matrix of a domain of category Cat::Matrix, or a boolean value.

See Also curldivergencegradientlaplacianpotential

version

Purpose

Version number of the MuPAD library

Syntax

```
version()
```

Description

`version()` returns the version number of the installed MuPAD library.

The call Pref::kernel() returns the version number of the installed MuPAD kernel.

The version numbers of the kernel and the library may differ: `version` refers to the library, whereas the call Pref::kernel() returns the version number of the kernel.

Examples

Example 1

The version of this MuPAD library is:
version()[5, 9, 0]

```
[5, 9, 0]
```

Return Values

Version number: a list of three nonnegative integers.

See Also

buildnumberPref::kernel

warning

Purpose

Print a warning message

Syntax

```
warning(message)
```

Description

`warning(message)` prints the message with the prefix "`Warning:`".

`warning` may be used to print information about potential problems in an algorithm. E.g., it is used in limit to provide hints.

Examples

Example 1

A warning:
warning("You should not do this!"): Warning: You should not do this!

Example 2

This example shows a simple procedure which divides two numbers. If the second argument is omitted, a warning is printed and the computation continues:
mydivide := proc(x, y) begin if args(0) < 2 then warning("Denominator not given, using 1."); y := 1; end_if: x/y end_proc: mydivide(10) Warning: Denominator not given, using 1. [mydivide] 10

10

Parameters

message

A character string

Return Values

Void object of type DOM_NULL.

errorprintuserinfo

whittakerM

Purpose

The Whittaker M function

Syntax

```
whittakerM(a, b, z)
```

Description

The `whittakerM` function $M_{a,\,b}(z)$ is related to the confluent hypergeometric function _outputSequence("[p],F[q](a,b,z)) = Symbol::Phi(a,b,z) ${}_pF_q(a,\,b,\,z) = \Phi(a,\,b,\,z)$ by the formula:

M[a,b](z) = exp(-z/2) * z^(1/2+b) * Symbol::Phi(1/2+b-a, 1+2*b, z)

$$M_{a,\,b}(z) = e^{-\frac{z}{2}}\, z^{\frac{1}{2}+b}\, \Phi\left(\frac{1}{2}+b-a,\ 1+2\,b,\ z\right)$$

The WhittakerM function is defined for complex arguments a, b, and z.

For most of the values of the parameters, an unevaluated function call is returned. Cf. "Example 1" on page 1-1986.

Explicit symbolic expressions are returned for some particular values of the parameters. Cf. "Example 2" on page 1-1986.

Note MuPAD defines _outputSequence("[1],F[1](a,a,z)) = exp(x) ${}_1F_1(a,\,a,\,z) = e^x$ for all complex numbers a. As a consequence, the MuPAD `whittakerM` differs from the corresponding function in M. Abramowitz and I. A. Stegun, "Handbook of Mathematical Functions" when 1/2+b-a $\frac{1}{2}+b-a$ and $1 + 2b$ are negative integers and 1/2+b-a>=1+2 * b $\frac{1}{2}+b-a \geq 1+2\,b$. Some of the formulas in Chapter 13 of the "Handbook of Mathematical Functions" do not hold for the MuPAD `whittakerM` with such arguments. Cf. "Example 4" on page 1-1987.

Environment Interactions

When called with floating-point arguments, these functions are sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

Unevaluated calls are returned for exact or symbolic arguments:
whittakerM(a, b, x), whittakerW(-3/2, 1/2, 1)whittakerM(a, b, x), whittakerW(-3/2, 1/2, 1)

$$M_{a,b}(x),\ W_{-\frac{3}{2},\frac{1}{2}}(1)$$

Floating point values are returned for floating-point arguments:
whittakerM(-2, 0.5, -50), whittakerW(-3/2, 1/2, 0.0)0.00000001666553264, 0.7522527781

$$0.00000001666553264,\ 0.7522527781$$

Example 2

Explicit expressions are returned for some specific values of the parameters:
whittakerM(0, b, x), whittakerW(0, b, x), whittakerW(-3/2, 1/2, 0), whittakerM(-3/2, 0 ,x), whittakerW(a, -a + 1/2, x)4^b*sqrt(x)*gamma(b + 1)*besselI(b, x/2), (x^(b + 1/2)*besselK(b, x/2))/(sqrt(PI)*x^b), 4/(3*sqrt(PI)), sqrt(x)*exp(x/2)*(x + 1), x^(1 - a)*x^(2*a - 1)*exp(-x/2)

$$4^b\sqrt{x}\,\Gamma(b+1)\,I_b\left(\frac{x}{2}\right),\ \frac{x^{b+\frac{1}{2}}\,K_b\left(\frac{x}{2}\right)}{\sqrt{\pi}\,x^b},\ \frac{4}{3\sqrt{\pi}},\ \sqrt{x}\,e^{\frac{x}{2}}\,(x+1),\ x^{1-a}\,x^{2\,a-1}\,e^{-\frac{x}{2}}$$

Example 3

The functions diff, float, limit, and series handle expressions involving the Whittaker functions
diff(whittakerM(a,b,z),z), float(whittakerW(-3/2,1/2,0))(whittakerM(a + 1, b, z)*(a + b + 1/2))/z - (a/z - 1/2)*whittakerM(a, b, z), 0.7522527781

$$\frac{M_{a+1,b}(z)\,\left(a+b+\frac{1}{2}\right)}{z}-\left(\frac{a}{z}-\frac{1}{2}\right)M_{a,b}(z),\ 0.7522527781$$

series(whittakerW(-3/2,1/2,x),x,3)4/(3*sqrt(PI)) + x*((2*(EULER - 2*ln(2) + ln(x) + 5/3))/sqrt(PI) - 2/(3*sqrt(PI))) + x^2*((2*((5*EULER)/4 - (5*ln(2))/2 + (5*ln(x))/4 + 17/24))/sqrt(PI) - (EULER - 2*ln(2) + ln(x) + 5/3)/sqrt(PI) + 1/(6*sqrt(PI))) + O(x^3)

$$\frac{4}{3\sqrt{\pi}} + x\left(\frac{2\left(\text{EULER} - 2\ln(2) + \ln(x) + \frac{5}{3}\right)}{\sqrt{\pi}} - \frac{2}{3\sqrt{\pi}}\right) + x^2\left(\frac{2\left(\frac{5\,\text{EULER}}{4} - \frac{5\ln(2)}{2} + \frac{5\ln(x)}{4} + \frac{17}{24}\right)}{\sqrt{\pi}} - \frac{\text{EULER} - 2}{}\right.$$

Example 4

For some values of the input parameters, recurrence and differential relations in Chapter 13 of M. Abramowitz and I. A. Stegun, “Handbook of Mathematical Functions” may not hold for the MuPAD `whittakerM` functions. For example, Formula 13.4.32

z*diff(M[a,b](z),z) = (z/2 - a) * M[a,b](z) + (a+b+1/2)*M[a+1,b](z)

$$z\,\frac{\partial}{\partial z}M_{a,b}(z) = \left(\frac{z}{2} - a\right)M_{a,b}(z) + \left(a + b + \frac{1}{2}\right)M_{a+1,b}(z)$$

is not satisfied for $a = 0$ and $b=-3/2$ $b = -\frac{3}{2}$:

expand(x*diff(whittakerM(0, -3/2, x), x) <> x/2*whittakerM(0, -3/2, x) - whittakerM(1, -3/2, x))- exp(-x/2)/2 - (x*exp(-x/2))/4 - exp(-x/2)/x <> exp(-x/2)/2 + (x*exp(-x/2))/4 - exp(x/2)/x

$$-\frac{e^{-\frac{x}{2}}}{2} - \frac{x\,e^{-\frac{x}{2}}}{4} - \frac{e^{-\frac{x}{2}}}{x} \neq \frac{e^{-\frac{x}{2}}}{2} + \frac{x\,e^{-\frac{x}{2}}}{4} - \frac{e^{\frac{x}{2}}}{x}$$

Parameters

a

b

z

arithmetical expressions

Return Values

Arithmetical expression.

Overloaded By

z

Algorithms

$M_{a,\,b}(z)$ and $W_{a,\,b}(z)$ satisfy Whittaker's differential equation:

diff(y,z,z) + (-1/4 + a/z + (1/4-b^2)/z^2)*y = 0

$$\frac{\partial^2}{\partial z^2} y + \left(-\frac{1}{4} + \frac{a}{z} + \frac{\frac{1}{4} - b^2}{z^2} \right) y = 0$$

whittakerWhypergeomkummerU

whittakerW

Purpose

The Whittaker W function

Syntax

```
whittakerW(a, b, z)
```

Description

The `whittakerW` function $W_{a,\,b}(z)$ is related to the confluent hypergeometric function $kummerU(a, b, z) = U(a, b, z)$ by the formula:

W[a,b](z) = exp(-z/2) * z^(1/2+b) * U(1/2+b-a, 1+2*b, z)

$$W_{a,\,b}(z) = e^{-\frac{z}{2}}\, z^{\frac{1}{2}+b}\, U\left(\frac{1}{2}+b-a,\ 1+2\,b,\ z\right)$$

The WhittakerW function is defined for complex arguments a, b, and z.

For most of the values of the parameters, an unevaluated function call is returned. Cf. “Example 1” on page 1-1989.

Explicit symbolic expressions are returned for some particular values of the parameters. Cf. “Example 2” on page 1-1990.

Environment Interactions

When called with floating-point arguments, these functions are sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

Unevaluated calls are returned for exact or symbolic arguments: whittakerM(a, b, x), whittakerW(-3/2, 1/2, 1)whittakerM(a, b, x), whittakerW(-3/2, 1/2, 1)

$$M_{a,\,b}(x),\ W_{-\frac{3}{2},\,\frac{1}{2}}(1)$$

Floating point values are returned for floating-point arguments: whittakerM(-2, 0.5, -50), whittakerW(-3/2, 1/2, 0.0)0.00000001666553264, 0.7522527781

0.00000001666553264, 0.7522527781

Example 2

Explicit expressions are returned for some specific values of the parameters:
whittakerM(0, b, x), whittakerW(0, b, x), whittakerW(-3/2, 1/2, 0), whittakerM(-3/2, 0 ,x), whittakerW(a, -a + 1/2, x)4^b*sqrt(x)*gamma(b + 1)*besselI(b, x/2), (x^(b + 1/2)*besselK(b, x/2))/(sqrt(PI)*x^b), 4/(3*sqrt(PI)), sqrt(x)*exp(x/2)*(x + 1), x^(1 - a)*x^(2*a - 1)*exp(-x/2)

$$4^b \sqrt{x}\,\Gamma(b+1)\,I_b\left(\frac{x}{2}\right),\ \frac{x^{b+\frac{1}{2}}\,K_b\left(\frac{x}{2}\right)}{\sqrt{\pi}\,x^b},\ \frac{4}{3\sqrt{\pi}},\ \sqrt{x}\,e^{\frac{x}{2}}\,(x+1),\ x^{1-a}\,x^{2\,a-1}\,e^{-\frac{x}{2}}$$

Example 3

The functions diff, float, limit, and series handle expressions involving the Whittaker functions
diff(whittakerM(a,b,z),z), float(whittakerW(-3/2,1/2,0))(whittakerM(a + 1, b, z)*(a + b + 1/2))/z - (a/z - 1/2)*whittakerM(a, b, z), 0.7522527781

$$\frac{M_{a+1,\,b}(z)\,\left(a+b+\frac{1}{2}\right)}{z}-\left(\frac{a}{z}-\frac{1}{2}\right)M_{a,\,b}(z),\ 0.7522527781$$

series(whittakerW(-3/2,1/2,x),x,3)4/(3*sqrt(PI)) + x*((2*(EULER - 2*ln(2) + ln(x) + 5/3))/sqrt(PI) - 2/(3*sqrt(PI))) + x^2*((2*((5*EULER)/4 - (5*ln(2))/2 + (5*ln(x))/4 + 17/24))/sqrt(PI) - (EULER - 2*ln(2) + ln(x) + 5/3)/sqrt(PI) + 1/(6*sqrt(PI))) + O(x^3)

$$\frac{4}{3\sqrt{\pi}}+x\left(\frac{2\,(\mathrm{EULER}-2\,\ln(2)+\ln(x)+\frac{5}{3})}{\sqrt{\pi}}-\frac{2}{3\sqrt{\pi}}\right)+x^2\left(\frac{2\,(\frac{5\,\mathrm{EULER}}{4}-\frac{5\,\ln(2)}{2}+\frac{5\,\ln(x)}{4}+\frac{17}{24})}{\sqrt{\pi}}-\frac{\mathrm{EULER}-2\,\ln(2)}{\sqrt{\pi}}\right.$$

Example 4

For some values of the input parameters, recurrence and differential relations in Chapter 13 of M. Abramowitz and I. A. Stegun, “Handbook

of Mathematical Functions" may not hold for the MuPAD `whittakerM` functions. For example, Formula 13.4.32

z*diff(M[a,b](z),z) = (z/2 - a) * M[a,b](z) + (a+b+1/2)*M[a+1,b](z)

$$z\,\frac{\partial}{\partial z}\,M_{a,\,b}(z) = \left(\frac{z}{2} - a\right)\,M_{a,\,b}(z) + \left(a + b + \frac{1}{2}\right)\,M_{a+1,\,b}(z)$$

is not satisfied for $a = 0$ and $b=-3/2$:

expand(x*diff(whittakerM(0, -3/2, x), x) <> x/2*whittakerM(0, -3/2, x) - whittakerM(1, -3/2, x))- exp(-x/2)/2 - (x*exp(-x/2))/4 - exp(-x/2)/x <> exp(-x/2)/2 + (x*exp(-x/2))/4 - exp(x/2)/x

$$-\frac{e^{-\frac{x}{2}}}{2} - \frac{x\,e^{-\frac{x}{2}}}{4} - \frac{e^{-\frac{x}{2}}}{x} \neq \frac{e^{-\frac{x}{2}}}{2} + \frac{x\,e^{-\frac{x}{2}}}{4} - \frac{e^{\frac{x}{2}}}{x}$$

Parameters

Algorithms

$M_{a,\,b}(z)$ and $W_{a,\,b}(z)$ satisfy Whittaker's differential equation:

diff(y,z,z) + (-1/4 + a/z + (1/4-b^2)/z^2)*y = 0

$$\frac{\partial^2}{\partial z^2}\,y + \left(-\frac{1}{4} + \frac{a}{z} + \frac{\frac{1}{4} - b^2}{z^2}\right)\,y = 0$$

See Also whittakerMhypergeomkummerU

wrightOmega

Purpose

The Wright ω function

Syntax

```
wrightOmega(x)
```

Description

wrightOmega(x)$\omega(x)$ is defined in terms of Lambert's W function as wrightOmega(x) = lambertW(ceil((Im(x)-PI)/(2*PI)), exp(x))$\omega(x) = W_{\left\lceil \frac{\Im(x)-\pi}{2\pi} \right\rceil}(e^x)$.

For $x \neq t$ - iπ with $t \leq$ - 1, y = wrightOmega(x)$y = \omega(x)$ is a solution of the equation $y + ln(y) = x$. The complete solution set of this equation is

y = piecewise([Re(x) <= -1 and Im(x) = -PI, {}], [Re(x) <= -1 and Im(x) = PI, {wrightOmega(x), wrightOmega(x - 2*PI*I)}], [Otherwise, {wrightOmega(x)}])

$$y = \begin{cases} \varnothing & \text{if } \Re(x) \le -1 \wedge \Im(x) = -\pi \\ \{\omega(x), \omega(x - 2\pi i)\} & \text{if } \Re(x) \le -1 \wedge \Im(x) = \pi \\ \{\omega(x)\} & \text{otherwise} \end{cases}$$

A floating-point value is computed if the argument is a floating point value. Unevaluated symbolic calls are returned for most exact arguments. For some special cases explicit symbolic representations are returned.

Environment Interactions

When called with a floating-point argument, the function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

Most calls with exact arguments return themselves unevaluated: wrightOmega(1/2); wrightOmega(I*PI);wrightOmega(1/2)

$$\omega\left(\frac{1}{2}\right)$$

wrightOmega(PI*I)

$\omega(\pi\, i)$

Some special arguments return explicit symbolic representations:
wrightOmega(-1+I*PI); wrightOmega(ln(2)+6*PI*I);-1

-1

lambertW(3, 2)

$W_3(2)$

If the argument is a floating-point value, then a floating-point result will be returned:
wrightOmega(0.5)0.7662486082

0.7662486082

Parameters

x

An arithmetical expression, the “argument”

Return Values

Arithmetical expression

See Also

lambertW

write

Purpose

Write the values of variables into a file

Syntax

```
write(<Bin | Text>, filename, <x1, x2,  >)
write(n, <x1, x2,  >)
```

Description

`write` serves for storing information from the current MuPAD session in a file. The file contains the values of identifiers of the current session. These identifiers are assigned the stored values when this file is read into another MuPAD session via the function read.

`write(filename, x1, x2, ...)` stores the current values of the identifiers x_1, x_2 etc. to the file `filename`.

`write(filename)` stores the values of all identifiers defined in the current session to the file `filename`.

`write(n)` and `write(n, x1, x2, ...)` store the data in the file associated with the file descriptor `n`.

If the file is specified by its name, `write` creates a new file or overwrites an existing file; `write` opens and closes the file automatically.

If WRITEPATH does not have a value, `write` interprets the file name as a pathname relative to the “working directory”.

Note that the meaning of “working directory” depends on the operating system. On Microsoft Windows systems and on Mac OS X systems, the “working directory” is the folder where MuPAD is installed. On UNIX systems, it is the current working directory in which MuPAD was started; when started from a menu or desktop item, this is typically the user’s home directory.

Also absolute path names are processed by `write`.

Instead of a file name, also a file descriptor of a file opened via fopen can be used. Cf. “Example 2” on page 1-1997. In this case, the data written by `write` are appended to the corresponding file. The file is not closed automatically by `write` and must be closed by a subsequent call to fclose.

Note that `fopen(filename)` opens the file in read-only mode. A subsequent `write` command to this file causes an error. Use the `Write` or `Append` option of fopen to open the file for writing.

The file descriptor 0 represents the screen.

`write` stores procedures with the option noExpose in encrypted format.

Note `write` stores the *values* of the given identifiers, not *their full evaluation*! Cf. "Example 3" on page 1-1997.

Environment Interactions

The function is sensitive to the environment variable WRITEPATH. If this variable has a value, the file is created in the corresponding directory. Otherwise, the file is created in the "working directory."

Examples

Example 1

The variable `a` and its value `b + 1` are stored in a file named `test`:
a := b + 1: fid := fopen(TempFile, Write, Text): write(fid, a):

Use fname to return the name of the temporary file you created:
file := fname(fid):

The content of this file is displayed via ftextinput:
ftextinput(file)"a := hold(_plus)(hold(b), 1):"

```
"a := hold(_plus)(hold(b), 1):"
```

We delete the value of `a`. Reading the file `test` restores the previous value:
delete a: read(file): ab + 1

$$b + 1$$

For identifiers that have no value, `write` writes a delete command to the file:
delete a: write(Text, 0, a):delete a: shell::removeFile(file):

Example 2

The file `test` is opened for writing using the MuPAD binary format:
fid := fopen(TempFile): file := fname(fid): n := fopen(file, Write):fid := fopen(TempFile): file := fname(fid): n := fopen(file, Write) 17

```
17
```

This number is the descriptor of the file and can be used in a write command:
a := b + 1: write(n, a): fclose(n):delete a: read(file): ab + 1

```
b + 1
```

We clean up:
delete n, a:shell::removeFile(file):

Example 3

The value `b + 1` is assigned to the identifier `a`. After assigning the value `2` to `b`, complete evaluation of `a` yields `3`:
a := b + 1: b := 2: a3

```
3
```

Note, however, that the value of `a` is the expression `b + 1`. This value is stored by a `write` command:
fid := fopen(TempFile, Write, Text): write(fid, a): file := fname(fid): ftextinput(file)"a := hold(_plus)(hold(b), 1):"

```
"a := hold(_plus)(hold(b), 1):"
```

Consequently, this value is restored after reading the file into a MuPAD session:
delete a, b: read(file): ab + 1

```
b + 1
```

delete a:shell::removeFile(file):

Example 4

`write`, when writing binary format, can store procedures with the option `noExpose` set. They are encrypted before writing:
f := proc(a) option noExpose; begin print(a, a^2, a*a); end_proc:write("hidden_proc.mb", f):delete f:read("hidden_proc.mb"):f(-2...3); expose(f)hull(-2.0, 3.0), hull(0.0, 9.0), hull(-6.0, 9.0)

```
-2.0 ... 3.0, 0.0 ... 9.0, -6.0 ... 9.0
```

```
proc(a) name f; option noDebug, noExpose; begin /* Hidden */ end_proc
```

This is the intention behind option `noExpose`: You can develop code you wish not to publish, then include `option noExpose` in your sources, rerun your tests, use `write` to write a binary version of your library and distribute that.

Parameters

filename

The name of a file: a character string

x_1, x_2, ...

identifiers

n

A file descriptor provided by fopen: a nonnegative integer

Options

Bin

Text

With `Bin`, the data are stored in the MuPAD binary format. With `Text`, standard ASCII format is used. The default is `Bin`.

In ASCII format, assignments of the form `identifier := hold(value):` or `delete identifier:` are written into the file. See “Example 1” on page 1-1996.

Return Values Void object of type DOM_NULL.

See Also doprintfclosefinputfnamefopenfprintfreadftextinputimport::readbitmapimport::readdataps

zeta

Purpose

The Riemann zeta function

Syntax

```
zeta(z)
zeta(z, n)
```

Description

`zeta(z)` represents the Riemann zeta function Symbol::zeta(z) = sum(k^(-z), k = 1..infinity)$\zeta(z) = \sum_{k=1}^{\infty} \frac{1}{k^z}$.

`zeta(z, n)` represents the n-th derivative sum((-ln(k))^n*k^(-z), k = 1..infinity)$\sum_{k=1}^{\infty} \frac{(-\ln(k))^n}{k^z}$ of the zeta function.

The zeta function is defined for all complex arguments z except for the simple pole $z = 1$ by analytic continuation.

The calls `zeta(z)` and `zeta(z, 0)` are equivalent.

A floating-point result is returned for floating-point arguments z.

The following special exact values are implemented:

Symbol::zeta(0)=-1/2$\zeta(0) = -\frac{1}{2}$, Symbol::zeta(0, 1)=-ln(PI)/2-ln(2)/2$\zeta(0, 1) = -\frac{\ln(\pi)}{2} - \frac{\ln(2)}{2}$,

$\zeta(z) = 0$ for even integers $z < 0$,

Symbol::zeta(z)=-bernoulli(1-z)/(1-z)$\zeta(z) = -\frac{\text{bernoulli}(1-z)}{1-z}$ for odd integers z satisfying - *Pref*::*autoExpansionLimit*() $\le z < 0$,

Symbol::zeta(z)=fenced(2 * PI)^z *

abs(bernoulli(z))/(2*z!)$\zeta(z) = \frac{(2\pi)^z \,|\text{bernoulli}(z)|}{2\,z!}$ for even integers z satisfying $0 \le z \le$ *Pref*::*autoExpansionLimit*(),

$\zeta(\infty) = 1$, $\zeta(\infty, n) = 0$ for $n > 0$.

`zeta` returns a symbolic function call, if the argument does not evaluate to one of the above numbers.

Note Floating point evaluation is rather slow for large values of n. Further, for large n, evaluation for $\Re(z) < 0$ is much slower than the evaluation for $\Re(z) \geq 0$.

Environment Interactions

When called with a floating-point argument z, the function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We demonstrate some calls with exact and symbolic input data:
zeta(-6), zeta(-5), zeta(-4), zeta(-3), zeta(-2), zeta(-1)0, -1/252, 0, 1/120, 0, -1/12

$$0, -\frac{1}{252}, 0, \frac{1}{120}, 0, -\frac{1}{12}$$

zeta(0), zeta(2), zeta(3), zeta(4), zeta(5), zeta(6), zeta(7)-1/2, PI^2/6, zeta(3), PI^4/90, zeta(5), PI^6/945, zeta(7)

$$-\frac{1}{2}, \frac{\pi^2}{6}, \zeta(3), \frac{\pi^4}{90}, \zeta(5), \frac{\pi^6}{945}, \zeta(7)$$

zeta(1/2), zeta(1 + I, 1), zeta(z^2 -I, 2)zeta(1/2), zeta(1 + I, 1), zeta(z^2 - I, 2)

$$\zeta\left(\frac{1}{2}\right), \zeta'(1+i), \zeta''(z^2-i)$$

Here are some values of the derivative of the zeta function:
zeta(0, 1), zeta(infinity, 1)- ln(2)/2 - ln(PI)/2, 0

$$-\frac{\ln(2)}{2} - \frac{\ln(\pi)}{2}, 0$$

Floating point values are computed for floating-point arguments:

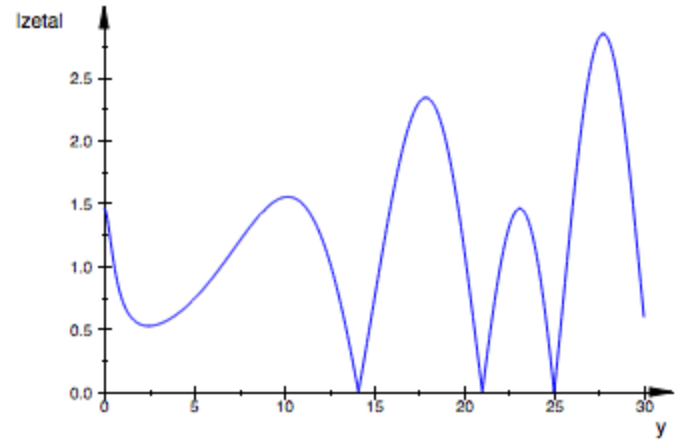
zeta(-1001.0), zeta(12.3, 1), zeta(0.5 + 14.13472514*I, 2)-1.348590824e1771, -0.0001389996909, - 0.614409794 + (-0.2297836439*I)

$$-1.348590824\,10^{1771},\ -0.0001389996909,\ -0.614409794-0.2297836439\,i$$

`zeta` has a pole at the point $z = 1$:
zeta(1) Error: Singularity. [zeta]

Example 2

Looking for nontrivial roots of the Zeta function, we plot the function $f(z) = |\zeta(z)|$ along the "critical line" of complex numbers with real part 1/2:
plotfunc2d(abs(zeta(1/2 + y*I)), y = 0..30, Mesh = 500, AxesTitles = ["y", "|zeta|"])



The following calls search for numerical roots along the critical line:
numeric::solve(zeta(1/2 + I*y), y = 10..20), numeric::solve(zeta(1/2 + I*y), y = 20..22), numeric::solve(zeta(1/2 + I*y), y = 22..26){14.13472514}, {21.02203964}, {25.01085758}

{14.13472514}, {21.02203964}, {25.01085758}

Parameters

z

An arithmetical expression

n

An arithmetical expression representing a nonnegative integer

Return Values

Arithmetical expression.

Overloaded By

z

See Also

bernoulli

zip

Purpose

Combine lists

Syntax

```
zip(list1, list2, f)
zip(list1, list2, f, default)
```

Description

`zip(list1, list2, f)` combines two lists via a function `f`. It returns a list whose *i*-th entry is `f(list1[i], list2[i])`. Its length is the minimum of the lengths of the two input lists.

`zip(list1, list2, f, default)` returns a list whose length is the maximum of the lengths of the two input lists. The shorter list is padded with the `default` value.

If `f` produces the void object of type DOM_NULL, then this element is removed from the resulting list.

`zip` is recommended for fast manipulation of lists. It is a function of the system kernel.

Examples

Example 1

The fastest way of adding the entries of two lists is to 'zip' them via the function _plus:
zip([a, b, c, d], [1, 2, 3, 4], _plus)[a + 1, b + 2, c + 3, d + 4]

$$[a+1, b+2, c+3, d+4]$$

If the input lists have different lengths, then the shorter list determines the length of the returned list:
zip([a, b, c, d], [1, 2], _plus)[a + 1, b + 2]

$$[a+1, b+2]$$

The longer list determines the length of the returned list if a value for padding the shorter list is provided:
zip([a, b, c, d], [1, 2], _plus, 17)[a + 1, b + 2, c + 17, d + 17]

$$[a+1, b+2, c+17, d+17]$$

Parameters

list1

list2

lists of arbitrary MuPAD objects

f

Any MuPAD object. Typically, a function of two arguments.

default

Any MuPAD object

Return Values

List.

mapopselectsplit

ztrans

Purpose

Z transform

Syntax

```
ztrans(f, k, z)
```

Description

`ztrans(f, k, z)` computes the Z transform of the expression `f = f(k)` with respect to the index `k` at the point `z`.

The Z transform `F(z)` of the function `f(k)` is defined as follows:

F(z) = sum(f(k)/z^k, k = 0..infinity)

$$F(z) = \sum_{k=0}^{\infty} \frac{f(k)}{z^k}$$

If `ztrans` cannot find an explicit representation of the transform, it returns an unevaluated function call. See “Example 4” on page 1-2007.

If `f` is a matrix, `ztrans` applies the Z transform to all components of the matrix.

To compute the inverse Z transform, use iztrans.

Examples

Example 1

Compute the Z transform of these expressions:
ztrans(1/k!, k, z)exp(1/z)

$$e^{\frac{1}{z}}$$

ztrans(sin(k), k, z)(z*sin(1))/(z^2 - 2*cos(1)*z + 1)

$$\frac{z \sin(1)}{z^2 - 2\cos(1) z + 1}$$

Example 2

Compute the Z transform of this expression and then simplify the result:

ztrans(cos(a*k + b), k, z)(z*cos(b)*(z - cos(a)))/(z^2 - 2*cos(a)*z + 1) - (z*sin(a)*sin(b))/(z^2 - 2*cos(a)*z + 1)

$$\frac{z\cos(b)\,(z-\cos(a))}{z^2-2\cos(a)\,z+1}-\frac{z\sin(a)\sin(b)}{z^2-2\cos(a)\,z+1}$$

Simplify(%)-(z*(cos(a - b) - z*cos(b)))/(z^2 - 2*cos(a)*z + 1)

$$-\frac{z\,(\cos(a-b)-z\cos(b))}{z^2-2\cos(a)\,z+1}$$

Example 3

Compute the Z transform of this expression with respect to the variable `k`:
F := ztrans(2*k + 3, k, z)(3*z)/(z - 1) + (2*z)/(z - 1)^2

$$\frac{3z}{z-1}+\frac{2z}{(z-1)^2}$$

Evaluate the Z transform of the expression at the points $z = 2a + 3$ and $z = 1 + i$. You can evaluate the resulting expression `F` using `|` (or its functional form evalAt):
F | z = 2*a + 3(3*(2*a + 3))/(2*a + 2) + (2*(2*a + 3))/(2*a + 2)^2

$$\frac{3\,(2a+3)}{2a+2}+\frac{2\,(2a+3)}{(2a+2)^2}$$

Also, you can evaluate the Z transform at a particular point directly:
ztrans(2*k + 3, k, 1 + I)1 + (- 5*I)

$$1-5\,i$$

Example 4

If `ztrans` cannot find an explicit representation of the transform, it returns an unevaluated call:

ztrans(f(k), k, z)ztrans(f(k), k, z)

$$\mathrm{ztrans}(f(k), k, z)$$

iztrans returns the original expression:
iztrans(%, z, k)f(k)

$$f(k)$$

Example 5

Compute the following Z transforms that involve Kronecker's Delta function and the Heaviside function:
ztrans(f(k)*kroneckerDelta(k, 1) + g(k)*kroneckerDelta(k, -5), k, z)f(1)/z

$$\frac{f(1)}{z}$$

ztrans(binomial(k, 2)*heaviside(5 - k), k, z)z/(z - 1)^3 + 5/z^5 + (6*z - z^6/(z - 1)^3 + 3*z^2 + z^3)/z^5

$$\frac{z}{(z-1)^3} + \frac{5}{z^5} + \frac{6z - \frac{z^6}{(z-1)^3} + 3z^2 + z^3}{z^5}$$

Simplify the last expression using simplify:
simplify(%)(z^3 + 3*z^2 + 6*z + 5)/z^5

$$\frac{z^3 + 3z^2 + 6z + 5}{z^5}$$

Example 6

Compute the Z transforms of this expression that involves the Heaviside function:
ztrans(heaviside(k - 3), k, z)(1/(z - 1) + 1/2)/z^3

$$\frac{\frac{1}{z-1}+\frac{1}{2}}{z^3}$$

Note that MuPAD uses the value `heaviside(0) = 1/2`. You can define a different value for `heaviside(0)`:
unprotect(heaviside): heaviside(0) := 1:

For better performance, MuPAD remembers the previously computed value of the Z transform. To force the system to recalculate the transform, clear its remember table:
ztrans(Remember, Clear):

For details about the remember mechanism, see Remember Mechanism.

Defining a different value for `heaviside(0)` produces a different value of the Z transform::
ztrans(heaviside(k - 3), k, z)(1/(z - 1) + 1)/z^3

$$\frac{\frac{1}{z-1}+1}{z^3}$$

For further computations, restore the original value:
heaviside(0):= 1/2: protect(heaviside):

Example 7

Compute the Z tranforms of these expressions:
ztrans(k*f(k), k, z)-z*diff(ztrans(f(k), k, z), z)

$$-z\,\frac{\partial}{\partial z}\,\mathrm{ztrans}(f(k),\,k,\,z)$$

ztrans(f(k + 1), k, z)z*ztrans(f(k), k, z) - z*f(0)

$$z\,\mathrm{ztrans}(f(k),\,k,\,z)-z\,f(0)$$

Parameters

f

Arithmetical expression or matrix of such expressions

k

Identifier or indexed identifier

z

Arithmetical expression representing the evaluation point

Return Values

Arithmetical expression or unevaluated function call of type `ztrans`. An explicit result can be a piecewise object. If the first argument is a matrix, the result is returned as a matrix.

ztrans::addpatterniztransiztrans::addpattern

Related Examples

- "Z-Transforms"

ztrans::addpattern

Purpose

Add patterns for the Z transform

Syntax

```
ztrans::addpattern(pat, k, z, res, <vars, <conds>>)
```

Description

`ztrans::addpattern(pat, k, z, res)` teaches ztrans to return ztrans(pat, k, z) = sum(pat/z^k, k = 0

..infinity)=res$\mathsf{ztrans(pat,\ k,\ z) = \sum_{k=0}^{\infty} \frac{pat}{z^k} = res}$.

The ztrans function uses a set of patterns for computing Z transforms. You can extend the set by adding your own patterns. To add a new pattern to the pattern matcher, use `ztrans::addpattern`. MuPAD does not save custom patterns permanently. The new patterns are available in the *current* MuPAD session only.

Variable names that you use when calling `ztrans::addpattern` can differ from the names that you use when calling ztrans. See “Example 2” on page 1-2012.

You can include a list of free parameters and a list of conditions on these parameters. These conditions and the result are protected from premature evaluation. This means that you can use `not iszero(a^2 - b)` instead of `hold( _not @ iszero )(a^2 - b)`.

The following conditions treat assumptions on identifiers differently:

- `a^2 - b <> 0` takes into account assumptions on identifiers.
- `not iszero(a^2 - b)` disregards assumptions on identifiers.

See “Example 3” on page 1-2012.

Environment Interactions

Calling `ztrans::addpattern` changes the expressions returned by future calls to ztrans.

Examples

Example 1

Compute the Z transform of the function `foo`. By default, MuPAD does not have a pattern for this function:
ztrans(foo(k), k, z)ztrans(foo(k), k, z)

$$\mathrm{ztrans}(\mathrm{foo}(k), k, z)$$

Add a pattern for the Z transform of `foo` using `ztrans::addpattern`:
ztrans::addpattern(foo(k), k, z, bar(z)):

Now ztrans returns the Z transform of `foo`:
ztrans(foo(k), k, z)bar(z)

$$\mathrm{bar}(z)$$

After you add a new transform pattern, MuPAD can use that pattern indirectly:
ztrans(foo(k + 3), k, z)z^3*bar(z) - z*foo(2) - z^2*foo(1) - z^3*foo(0)

$$z^3\,\mathrm{bar}(z) - z\,\mathrm{foo}(2) - z^2\,\mathrm{foo}(1) - z^3\,\mathrm{foo}(0)$$

Example 2

Define the Z transform of `foo(x)` using the variables `x` and `y` as parameters:
ztrans::addpattern(x, x, y, y/(y^2-2*y+1)):

The ztrans function recognizes the added pattern even if you use other variables as parameters:
ztrans(s, s, t)t/(t^2 - 2*t + 1)

$$\frac{t}{t^2 - 2\,t + 1}$$

Example 3

Use assumptions when adding this pattern for the Z transform:

ztrans::addpattern(FOO(x*k), k, z, sin(1/(x-1/2))*BAR(z), [x], [abs(x) < 1]): ztrans(FOO(x*k), k, z) assuming -1 < x < 1sin(1/(x - 1/2))*BAR(z)

$$\sin\left(\frac{1}{x-\frac{1}{2}}\right)\,\mathrm{BAR}(z)$$

If $|x| \geq 1$, you cannot apply this pattern:
ztrans(FOO(x*k), k, z) assuming x >= 1ztrans(FOO(k*x), k, z)

$$\mathrm{ztrans}(\mathrm{FOO}(k\,x),\,k,\,z)$$

If MuPAD cannot determine whether the conditions are satisfied, it returns a piecewise object:
ztrans(FOO(x*k), k, z)piecewise([abs(x) < 1, sin(1/(x - 1/2))*BAR(z)])

$$\begin{cases} \sin\left(\frac{1}{x-\frac{1}{2}}\right)\,\mathrm{BAR}(z) & \text{if } |x| < 1 \end{cases}$$

Note that the resulting expression defining the Z transform of `FOO(x*k)` implicitly assumes that the value of `x` is not 1/2. A strict definition of the pattern is:
ztrans::addpattern(BAR(x*k), k, z, sin(1/(x - 1/2))*FOO(z), [x], [abs(x) < 1, x <> 1/2]):

If either the conditions are not satisfied or substituting the values into the result gives an error, ztrans ignores the pattern. For this particular pattern, you can omit specifying the assumption `x <> 1/2`. If `x = 1/2`, MuPAD throws an internal "Division by zero." error and ignores the pattern:
ztrans(FOO(s/2),s,t)ztrans(FOO(s/2), s, t)

$$\mathrm{ztrans}\left(\mathrm{FOO}\left(\frac{s}{2}\right),\,s,\,t\right)$$

Parameters

pat

Arithmetical expression in the variable `k` representing the pattern to match

k

Identifier or indexed identifier used as a variable in the pattern

z

Identifier or indexed identifier used as a variable in the result

res

Arithmetical expression in the variable `k` representing the pattern for the result of the transformation

vars

List of identifiers or indexed identifiers used as "pattern variables" (placeholders in `pat` and `res`). You can use pattern variables as placeholders for almost arbitrary MuPAD expressions not containing `k` or `z`. You can restrict them by conditions given in the optional parameter `conds`.

conds

List of conditions on the pattern variables

Return Values

Object of type DOM_NULL

See Also

ztransiztransiztrans::addpattern

adt – Abstract Datatypes

==REFNAME==

adt::Heap

Purpose

Abstract data type “Heap”

Syntax

```
adt::Heap()
```

Description

`adt::Heap` implements the abstract data type “Heap”.

A “heap” or “priority queue” is a data type that stores a collection of elements. Elements can be compared and the minimal element can be read and deleted from the heap.

In `adt::Heap`, each element is associated with a comparison key, typically a real number. The keys must be comparable with one another using <.

To get access to the largest element in an `adt::Heap`, you can simply negate the comparison keys.

`adt::Heap` returns a function environment. This object has slots `"insert"`, `"nops"`, `"min_pair"`, `"min_element"`, and `"delete_min"` which allow operations on the heap. See the examples.

`adt::Heap` does not allow access to other elements than the minimal one.

Examples

Example 1

`adt::Heap()` creates an empty heap:
h := adt::Heap()‘adt::Heap(...)‘

```
adt::Heap(...)
```

The slot `"nops"` of `h` shows the number of elements in the heap:
h::nops()0

```
0
```

`h::insert` is the method to insert new elements. It expects two arguments: the comparison key and the data. For now, we simply insert some numbers, so we repeat the number in both arguments:
h::insert(3,3): h::insert(1,1): h::insert(2,2):h::nops()3

```
3
```

When retrieving the elements with `h::delete_min`, we see that they are returned in increasing order:
h::delete_min(), h::delete_min(), h::delete_min()1, 2, 3

```
1, 2, 3
```

The heap is now empty:
h::nops()0

```
0
```

Calling `delete_min` on an empty heap returns FAIL:
h::delete_min()FAIL

```
FAIL
```

Algorithms

`adt::Heap` uses a complete binary tree stored in a list. Insertions operate in expected constant time, with a worst case time logarithmic in the number of elements in the heap. For `"delete_min"`, both the average and the worst-case running time are $O(logn)$, with n the size of the heap.

See Also

adt::Queueadt::Stackadt::Tree

adt::Queue

Purpose

Abstract data type “Queue”

Syntax

```
adt::Queue(queue)
```

Description

`adt::Queue` implements the abstract data type “Queue”. To create a queue, an expression sequence of any MuPAD objects can be given to initialize the queue, otherwise an empty queue is built.

Note The methods of all abstract data types must be called especially and will result changing the object itself as side effect.

With `Q := adt::Queue()` an empty queue is built and assigned to the variable `Q`.

Every queue will be displayed as `Queue` followed by a number. This name is generated by genident.

Note *All following methods changes the value of* `Q` *itself.* A new assignment to the variable (in this example `Q`) is not necessary, in contrast to all other MuPAD functions and data types.

The methods `clear`, `dequeue`, `empty`, `enqueue`, `front`, `length`, `reverse` are available for handling with queues.

Examples

Example 1

Create a new queue with strings as arguments.

```
Q := adt::Queue("1", "2", "3", "4")
```

Queue1

Show the length of the queue.

Q::length()4

```
4
```

Fill up the queue with a new element. The queue will be changed by the method, no new assignment to `Q` is necessary!
Q::enqueue("5")"5"

```
"5"
```

Show the front of the queue. This method does not change the queue.
Q::front(), Q::front()"1", "1"

```
"1", "1"
```

After twice getting an element of the queue, the third element is the new front of the queue, and the length is `3`.
Q::dequeue(), Q::dequeue(), Q::front(), Q::length()"1", "2", "3", 3

```
"1", "2", "3", 3
```

Now revert the queue. The last element will be the first element.
Q::reverse(): Q::front()"5"

```
"5"
```

Enlarge the queue with `"2"`.
Q::enqueue("2"): Q::empty()FALSE

```
FALSE
```

Finally collect all elements of the queue in the list assigned to `ARGS`, until the queue is empty.
ARGS := []: while not Q::empty() do ARGS := append(ARGS, Q::dequeue()) end: ARGS["5", "4", "3", "2"]

Parameters

queue

An expression sequence of objects to initialize the queue

Methods

clearClear the queue

`clear()`
dequeueGet an element from the queue

`dequeue()`
emptyI the queue empty

`empty()`
enqueueFill up the queue

`enqueue(x)`
frontFront of the queue

`front()`
lengthLength of the queue

`length()`
reverseRevert the queue

`reverse()`

adt::Stack

Purpose

Abstract datatype “Stack”

Syntax

```
adt::Stack(stack)
```

Description

`adt::Stack` implements the abstract data type “Stack.” To create a stack, an expression sequence of any MuPAD objects can be given to initialize the stack, otherwise an empty stack is built.

Note The methods `adt::Stack`, like those of all abstract data types, change their argument as a side effect.

With `S := adt::Stack()` an empty stack is built and assigned to the variable `S`.

Note *All following methods change the value of `S` itself.* A new assignment to the variable (in this example `S`) is not necessary, in contrast to most other MuPAD functions and data types.

The stacks created in a session are named `Stack1, Stack2,...` and printed as such.

Examples

Example 1

We create an empty stack, and fill it with some values:
S := adt::Stack(); S::push(a): S::push(b): S::push(c):Stack1

Stack1

The stack now contains 3 elements:
S::nops()3

3

The top of the stack is the last valued pushed:
S::top()c

c

Now, we fetch successively the values contains in `S`; they come back in reversed order:
S::pop(); S::pop(); S::pop()c

c b

b a

a

Now, the stack is empty. Trying to pop again an element from it results in a FAIL value being returned:
S::pop()FAIL

FAIL

Parameters

stack

An expression sequence of objects to initialize the stack

Return Values

Object of the domain `adt::Stack`

Methods

S::emptyI the stack empty

```
S::empty()
```
S::nopsSize of the stack

```
S::nops()
```
S::depthDepth of the stack

```
S::depth()
```
S::topTop element of the stack

```
S::top()
```
S::pushPush an element on the stack

```
S::push(x)
```
S::popPop an element from the stack

```
S::pop()
```
S::reverseRevert the stack

```
S::reverse()
```
S::copyCopy of the stack

```
S::copy()
```

adt::Tree

Purpose

Abstract data type “Tree”

Syntax

```
adt::Tree(tree)
```

Description

`adt::Tree` implements the abstract data type “Tree”.

A tree must be given as a special MuPAD list. The first object of the list is the root of the tree. All further objects are leaves or subtrees of the tree. A subtree is again a special list (as described), and any other MuPAD object will be interpreted as leaf of the tree (see “Example 1” on page 2-11).

A tree can be used to display data in tree structure using the function output::tree (or the method `"print"` of a tree). The nodes and leaves of the tree will be printed by MuPAD when the tree will be displayed.

A tree can also be used as datatype to keep and handle any MuPAD data.

Note The methods of all abstract data types must be called especially and will result changing the object itself as side effect.

`T := adt::Tree([_plus, 3, 4, [_mult, 5, 3], 1])` builds a tree and assigns it to the variable `T`.

Every tree will be displayed as `Tree` followed by a number. This name is generated by genident.

To display the content of a tree, the function expose or the method `"print"` of the tree itself must be used.

Note *All following methods changes the value of `T` itself.* A new assignment to the variable (in this example `T`) is not necessary, in contrast to all other MuPAD functions and data types.

The methods `nops`, `op`, `expr`, `print`, `indent`, `chars` are now available for handling with trees.

Examples

Example 1

Creating a simple tree with only two leaves. To access and display a tree it must be assigned to a variable:
T := adt::Tree(["ROOT", "LEFT", "RIGHT"])Tree1

```
Tree1
```

The tree will only be printed by its name. To display the tree, the function expose or the method `"print"` of the tree must be used:
T::print() ROOT | +-- LEFT | '-- RIGHT expose(T) ROOT | +-- LEFT | '-- RIGHT

The next tree contains two subtrees as leaves:
T := adt::Tree(["ROOT", ["LROOT", "LLEFT", "LRIGHT"], ["RROOT", "RLEFT", "RRIGHT"]]): T::print() ROOT | +-- LROOT | | | +-- LLEFT | | | '-- LRIGHT | '-- RROOT | +-- RLEFT | '-- RRIGHT

Example 2

Get the operands of a tree: Also a subtree can be an operand:
T := adt::Tree(["ROOT", ["LROOT", "LLEFT", "LRIGHT"], "MIDDLE", ["RROOT", "RLEFT", "RRIGHT"]]): T::op()Tree4, "MIDDLE", Tree5

```
Tree4, "MIDDLE", Tree5
```

Use expose to display subtrees:
map(%, expose) LROOT RROOT | | +-- LLEFT , "MIDDLE", +-- RLEFT | | '-- LRIGHT '-- RRIGHT

Get all operands including the root:
T::op(0..T::nops())"ROOT", Tree6, "MIDDLE", Tree7

```
"ROOT", Tree6, "MIDDLE", Tree7
```

Access to various operands:

T::op(0); T::op(2..3); T::op([1, 2])"ROOT"

"ROOT"
"MIDDLE", Tree9

"MIDDLE", Tree9
"LRIGHT"

"LRIGHT"

Example 3

The default characters are `["|", "+", "-", " ", " "]`:
T := adt::Tree(["ROOT", ["LROOT", "LLEFT", "LRIGHT"], ["RROOT", "RLEFT", "RRIGHT"]]): T::print() ROOT | +-- LROOT | | | +-- LLEFT | | | `-- LRIGHT | `-- RROOT | +-- RLEFT | `-- RRIGHT

The characters can be changed:
T::chars(["|", "|", "_", "|", " "]): T::print() ROOT | |__ LROOT | | | |__ LLEFT | | | |__ LRIGHT | |__ RROOT | |__ RLEFT | |__ RRIGHT

Example 4

A tree visualizes the structure of an expression:
T:= adt::Tree([_plus, [_power, [sin, x], 2], [_power, [cos, x], 2]]): T::print() _plus | +-- _power | | | +-- sin | | | | | `-- x | | | `-- 2 | `-- _power | +-- cos | | | `-- x | `-- 2

A tree can be converted to a MuPAD expression:
T::expr(), simplify(T::expr())cos(x)^2 + sin(x)^2, 1

$\cos(x)^2 + \sin(x)^2$, 1

Parameters

tree

The tree, given as a special list (see details)

Methods

nopsNumber of operands

`nops()`

In this example `T` has `4` operands, the numbers `3`, `4`, `1` and the subtree `adt::Tree([_mult, 5, 3])`.
opOperand of a tree

`op(<n>)`

`T::op(n)` returns the specified operands of the tree. `n` can be a number between `0` and `T::nops()` (`0` gives the root of the tree), a sequence `i..j` (to return the *i*th to *j*th operand), or a list to specify operands of subtrees (exactly as for the kernel function op). `T::op()` returns all operands except the `0`-th as expression sequence. See “Example 2” on page 2-11.
exprConvert a tree to an expression

`expr()`
printDisplay a tree

`print()`
indentIndent width of each operand

`indent(<n>)`
charsIndent width of each operand

`chars(<list>)`

See Also

output::tree

Ax – Axioms

==REFNAME==

Ax::canonicalOrder

Purpose

Axiom of canonically ordered sets

Description

`Ax::canonicalOrder` states that a domain has an order < (_less) which is defined by the canonical order of the MuPAD expressions.

This implies that the order of two elements is defined by the system function _less.

Ax::canonicalRep

Purpose

Axiom of canonical representation

Description

`Ax::canonicalRep` states that domain elements are canonically represented, i.e. that each element of the domain has only one unique expression which represents it.

This axiom implies that for an abelian monoid the axiom Ax::normalRep also holds. This is not enforced by the category but must be stated by the implementor of a domain.

Ax::canonicalUnitNormal

Purpose

Axiom of canonical unit normals

Description

`Ax::canonicalUnitNormal` states that the method `"unitNormal"` of an integral domain (category Cat::IntegralDomain) returns a unique unit normal.

This means that for each non-zero element `x` of the integral domain there exists an unique associate among the associate class of `x`, i.e. for any `x` and `y` of a domain `dom` of category Cat::IntegralDomain where `dom::associates(x, y)` returns TRUE the equation `dom::equal(dom::unitNormal(x), dom::unitNormal(y)) = TRUE` must hold.

Note that this axiom does not imply that the unit normals are canonically represented. The unit normals of `x` and `y` must be mathematically equal in the sense of the method `"equal"`, they need not be structurally equal as MuPAD objects.

Ax::closedUnitNormals

Purpose

Axiom of closed unit normals

Description

`Ax::closedUnitNormals` states that the unit normals of an integral domain are closed under multiplication, i.e., that `dom::equal(x, dom::unitNormal(a) * dom::unitNormal(b)) = TRUE` implies `dom::equal(x, dom::unitNormal(x)) = TRUE` for all elements `x`, `a` and `b` of the domain `dom`.

This axiom may be used only in conjunction with the axiom Ax::canonicalUnitNormal. If an integral domain has no unique unit normals, this axiom may not be stated.

Ax::efficientOperation

Purpose

Axiom of efficient operations

Syntax

```
Ax::efficientOperation(oper)
```

Description

`Ax::efficientOperation(oper)` states that operation `oper` can be performed efficiently.

The string `oper` must be the name of the operation's slot in the domain stating the axiom. Examples are `"_mult"`, `"_invert"` or `"_divide"`.

Parameters

oper

A string which defines the efficient operation.

Ax::indetElements

Purpose

Axiom that indeterminates may be elements

Description

`Ax::indetElements` states that there exist domain elements that may also be regarded as being transcendental over the domain.

`Ax::indetElements` has no mathematical meaning: elements of a ring are always algebraic (of degree 1) over the ring. However, since there are domains in MuPAD that comprise all MuPAD identifiers, insisting on this viewpoint would mean that polynomials over such domains could not be constructed. Hence MuPAD allows the user to regard an identifier as being transcendental over the set of all identifiers.

Ax::normalRep

Purpose

Axiom of normal representation

Description

`Ax::normalRep` states that an abelian monoid has a canonical representation of its zero element, i.e., that there is only one unique expression to represent zero.

If the axiom `Ax::normalRep` holds for a domain `dom`, one may test for zero by comparing an element with `dom::zero` using the system function _equal.

Ax::noZeroDivisors

Purpose

Axiom of rings with no zero divisor

Description

`Ax::noZeroDivisors` states that a ring without a unit has no zero divisors, i.e., that the product of two non-zero elements is never zero.

Note that an integral domain implicitly has no zero divisors.

Ax::systemRep

Purpose

Axiom of façade domains

Description

`Ax::systemRep` states that domain elements are represented by elements of built-in domains.

There are principally two ways to represent the elements of a domain: On the one hand the elements may be created explicitly by the system function new, on the other hand one may use the built-in (or basic) domains of MuPAD (like DOM_INT) to represent the elements.

Domains which don't create elements of their own but use elements of basic domains instead are called *façade domains*.

The usage of basic domains for the representation has the advantage that system functions may be used directly as methods of the domain without the overhead caused by overloading and procedure calls. But it has some severe limitations, see the domain Dom::Expression for details.

The axiom `Ax::systemRep` is used to state that the elements of a domain are represented by basic domains and are not created by new.

Cat – Categories

==REFNAME==

Cat::BaseCategory

Purpose

Base category

Description

`Cat::BaseCategory` is the most general super-category of all categories defined by the Cat package. Any domain in the Dom package is of this category.

The methods defined by `Cat::BaseCategory` are related to type conversion and equality testing, they are not related to an algebraic structure.

Methods

Basic Methods

convertConvert into this domain

```
convert(x)
```

convert_toConvert to certain type

```
convert_to(x, T)
```

equalTest for equality

```
equal(x, y)
```

Note that this method does *not* overload the function _equal, i.e. the = operator. The function _equal cannot be overloaded.

exprConvert into expression

```
expr(x)
```

Conversion Methods

coerceCoerce into this domain

```
coerce(x)
```

The implementation provided tries to convert `x` into an element of this domain by first calling `dom::convert(x)` and then, if this fails, `x::dom::convert_to(x, dom)`; it retuns `FAIL` if both methods fail.

equivTest for equivalence

```
equiv(x, y)
```

The implementation provided tries to convert `x` and `y` into elements of this domain and then calls `dom::equal` with these elements. It returns `FAIL` if the conversion fails or the equality test returns UNKNOWN.

newCreate element of this domain

```
new(x)
```

Given a domain `D`, an expression of the form `D(x,...)` results in a call of the form `D::new(x,...)`.

The implementation provided here tries to convert `x` by calling `dom::convert(x)` and returns the result. It raises an error if `dom::convert` returns `FAIL`.

printReturn expression to print an element

```
print(x)
```

Please do *not* print directly in this method by calling the function print for example!

The implementation provided here is `dom::expr`.

testtypeTest type of object

```
testtype(x, T)
```

This method must return `TRUE` if it can decide that `x` is of type `T`, `FALSE` if it can decide that `x` is not of type `T` and `FAIL` if it can not decide the test.

This method is called in three different situations: Either if the argument `x` is of this domain, or if `T` is this domain, or if `T` is an element of this domain. Thus the following three situations can arise:

- `x` is an element of the current domain.

  In this case it must be tested if `x` may be regarded as an element of the type `T`, which may either be a domain or type expression. By default, this is only true if the domain type of `x` is `T`, or if `T` is a domain constructor for which `x::dom::hasProp(x, T)` is TRUE. In particular, `x` is, by default, not of type `T` if `T` is a type of the Type library.

- `T` is the current domain.

In this case it must be tested if `x` may be regarded as an element of this domain. By the default implementation provided, this is TRUE only if the domain type of `x` is `dom`.

- `T` is an element of the current domain.

  In this case `T` is regarded as a type expression. The default implementation provided returns TRUE if the domain type of `x` is `T`, and FAIL if not. A special rule holds if `T` is a façade domain: in that case, `coerce(x,T)` is called, if this is successful `TRUE` is returned and `FAIL` if not.

Technical Methods

new_extelementCreate element of kernel or façade domain

```
new_extelement(x,  )
```

When an expression `new(D,x,...)` is evaluated and `D` is a domain with method `"new_extelement"`, then `D::new_extelement(D,x,...)` is evaluated and returned as result.

Kernel or façade domains must define this method because otherwise the function new would return a “container” element of `D` rather than a “raw” element as intended.

The implementation provided here returns the result of `D::new(x,...)`.

Cat::AbelianGroup

Purpose

Category of Abelian groups

Description

`Cat::AbelianGroup` represents the category of Abelian groups.

A `Cat::AbelianGroup` is an Abelian monoid with cancellation law where the operation `+` is invertible.

Categories

Cat::CancellationAbelianMonoid

Methods

Basic Methods

_negateReturn opposite

```
_negate(x)
```

Mathematical Methods

equalTest for equality

```
equal(x, y)
```

intmultReturn integer multiple

```
intmult(x, n)
```

_subtractSubtract two elements

```
_subtract(x, y)
```

Cat::AbelianMonoid

Purpose

Category of Abelian monoids

Description

`Cat::AbelianMonoid` represents an Abelian monoid.

An `Cat::AbelianMonoid` is an Abelian semi-group with a neutral element `dom::zero` according to the operation + (`_plus`).

Use the axiom Ax::normalRep to state that zero is always represented in a unique way (i.e. canonically).

If an Abelian monoid has not the axion Ax::normalRep then `dom::zero` is only one possible representation of the neutral element. An Abelian semi-group must at least have the method `"iszero"` to test for zero in such a case.

Axioms

If the domain has Ax::canonicalRep, then Ax::normalRep.

Categories

Cat::AbelianSemiGroup

Entries

"zero"	Must hold the neutral element according to the operation +.

Methods

Mathematical Methods

intmultReturn integer multiple

```
intmult(x, n)
```

iszeroTest if element is zero

```
iszero(x)
```

Cat::AbelianSemiGroup

Purpose

Category of Abelian semi-groups

Description

`Cat::AbelianSemiGroup` represents the category of Abelian semi-groups where the operation is written as addition. Hence an `Cat::AbelianSemiGroup` is a set with an associative and commutative operation `+` (`_plus`).

Note that non-Abelian semi-groups with operation `*` have category Cat::SemiGroup.

Categories

Cat::BaseCategory

Methods

Basic Methods

_plusReturn the sum of its arguments

```
_plus(x,  )
```

Mathematical Methods

intmultReturn integer multiple

```
intmult(x, n)
```

Cat::Algebra

Purpose

Category of associative algebras

Syntax

```
Cat::Algebra(R)
```

Description

`Cat::Algebra(R)` represents the category of associative algebras over the commutative ring `R`.

A `Cat::Algebra(R)` is a module over a commutative ring `R` which also is a ring.

Categories

Cat::Ring, Cat::Module(R)

Parameters

`R`

A domain which is a commutative ring. The algebra will be an algebra over this ring.

Cat::CancellationAbelianMonoid

Purpose

Category of abelian monoids with cancellation

Description

`Cat::CancellationAbelianMonoid` represents the category of Abelian monoids with cancellation.

A `Cat::CancellationAbelianMonoid` is an Abelian monoid where the cancellation law holds according to the operation +, i.e. $a + b = a + c$ implies $b = c$.

Categories

Cat::AbelianMonoid

Methods

Basic Methods

_subtractSubtract two elements

```
_subtract(x, y)
```

Mathematical Methods

equalTest for equality

```
equal(x, y)
```

The method `"iszero"` is used to test for zero.

_negateNegate element

```
_negate(x)
```

intmultReturn integer multiple

```
intmult(x, n)
```

Cat::CommutativeRing

Purpose

Category of commutative rings

Description

`Cat::CommutativeRing` represents the category of commutative rings.

A `Cat::CommutativeRing` is a ring with unit `dom::one` where the multiplication `*` (`_mult`) is commutative. It is also a right module over itself.

This implementation additionally assumes that the elements are always constant with respect to differentiation and derivates. One must re-implement the methods `"diff"` and `"D"` if this assumption is false.

Categories

Cat::Ring, Cat::RightModule`(dom)`

Methods

Mathematical Methods

diffDifferentiate element

```
diff(x, <v,  >)
```

DReturn derivative

```
D(l, x)
```

Cat::DifferentialRing

Purpose

Category of ordinary differential rings

Description

`Cat::DifferentialRing` represents the category of ordinary differential rings.

A `Cat::DifferentialRing` is a commutative ring with a single derivation operator `D`.

A derivation is a linear operator with product rule, i.e. D(f * g)=D(f) * g+f * D(g)$(f\,g)' = f'\,g + f\,g'$ holds for all f and g.

Categories

Cat::PartialDifferentialRing

Methods

Basic Methods

DReturn derivative

```
D(f)
```

diffDifferentiation with respect to a variable

```
diff(f, x)
```

Cat::EntireRing

Purpose

Category of entire rings

Description

`Cat::EntireRing` represents the category of entire rings.

An `Cat::EntireRing` is a ring with unit `"one"` which has no zero divisors: Given non-zero ring elements a and b the product a times b is never zero.

Axioms

Ax::noZeroDivisors

Categories

Cat::Ring, Cat::RightModule`(dom)`

Cat::EuclideanDomain

Purpose

Category of Euclidean domains

Description

`Cat::EuclideanDomain` represents the category of Euclidean domains.

A `Cat::EuclideanDomain` is a principal ideal domain with an "Euclidean degree" function `"euclideanDegree"` and operations `"quo"` and `"rem"` computing the Euclidean quotient and Euclidean remainder.

The Euclidean degree returns nonnegative integers such that for each non-zero x and y there exist s and r such that $x = ys + r$ and either the Euclidean degree of r is less than that of s or r is zero.

In addition s is equal to `quo(x,y)` and r is equal to `rem(x,y)`.

Categories

Cat::PrincipalIdealDomain

Methods

Basic Methods

euclideanDegreeReturn Euclidean degree

`euclideanDegree(x)`

divideDivision with remainder

`divide(x, y)`

Mathematical Methods

_divideExact division

`_divide(x, y)`

gcdGreatest common divisor

`gcd(x,  )`

gcdexExtended greatest common divisor

`gcdex(x, y)`

idealGeneratorGenerator of finitely generated ideal

`idealGenerator(x,  )`

quoEuclidean quotient

`quo(x, y)`

The default implementation provided here uses the basic method `"divide"`.

remEuclidean remainder

```
rem(x, y)
```

The default implementation provided here uses the basic method `"divide"`.

Cat::FactorialDomain

Purpose

Category of factorial domains

Description

`Cat::FactorialDomain` represents the category of factorial domains (i.e., unique factorization domains).

A `Cat::FactorialDomain` is an integral domain with gcd where an unique factorization can be computed.

The factorization methods are named `"factor"` and `"sqrfree"` and must return elements of the domain Factored over this domain.

Categories

Cat::GcdDomain

Methods

Basic Methods

factorUnique factorization

```
factor(x)
```

See Factored for details about the representation of the factorization.

Mathematical Methods

irreducibleTest if element is irreducible

```
irreducible(x)
```

sqrfreeSquare-free factorization

```
sqrfree(x)
```

See Factored for details about the representation of the factorization.

The default implementation provided here uses the method `"factor"` and therefore may be very inefficient.

Cat::Field

Purpose

Category of fields

Description

`Cat::Field` represents the category of fields.

A `Cat::Field` is a factorial domain, an Euclidean domain and a skew field. As a Euclidean domain, it has a commutative multiplication * (_mult) and as a skew field, the multiplication is invertible.

Many of the methods defined for factorial and Euclidean domains are trivial for a field.

Axioms

Ax::canonicalUnitNormal, Ax::closedUnitNormals

Categories

Cat::EuclideanDomain, Cat::FactorialDomain, Cat::SkewField

Methods

Mathematical Methods

associatesTest for associate elements

```
associates(x, y)
```

_divideExact division

```
_divide(x, y)
```

divideDivision with remainder

```
divide(x, y)
```

dividesTest if division is exact

```
divides(x, y)
```

euclideanDegreeReturn Euclidean degree

```
euclideanDegree(x)
```

factorUnique factorization

```
factor(x)
```

gcdGreatest common divisor

```
gcd(x,  )
```

irreducibleTest if element is irreducible

```
irreducible(x)
```

isUnitTest if element is an unit

```
isUnit(x)
```

quoReturn Euclidean quotient

```
quo(x, y)
```

remReturn Euclidean remainder

```
rem(x, y)
```

sqrfreeSquare-free factorization

```
sqrfree(x)
```

unitNormalUnit normal form

```
unitNormal(x)
```

unitNormalRepUnit normal representation

```
unitNormalRep(x)
```

Cat::FiniteCollection

Purpose

Category of finite collections

Description

`Cat::FiniteCollection` represents the category of finite collections, i.e., the category of "universal" bags.

A finite collection is a data structure where each element represents a finite bag of "things" of any type.

The elements are numbered `1,...,nops(c)`, where `nops(c)` is the number of elements in the bag.

Categories

Cat::BaseCategory

Methods

Basic Methods

_indexReturn element given its index

```
_index(x, i)
```

mapMap function on elements

```
map(x, f, <a,  >)
```

nopsReturn number of elements

```
nops(x)
```

opReturn certain elements

```
op(x)
```

```
op(x, i)
```

Must return the `i`-th element of `x` or `FAIL` if an element with the given index does not exist.

Operand ranges or paths need not be handled by this method because they are handled directly by op.

set_indexChange element with given index

```
set_index(x, i, v)
```

Overloads the function _assign with an _index expression on the left hand side. The result is assigned to `x`.

subsSubstitute in elements

`subs(x, e = f)`
subsopSubstitute operands

`subsop(x, i = v)`
Technical Methods
mapCanFailMap function on elements

`mapCanFail(x, f, <a,  >)`
testEachTest each element with a predicate

`testEach(x, f, <a,  >)`
testOneTest if element exists fulfilling a predicate

`testOne(x, f, <a,  >)`

Cat::GcdDomain

Purpose

Category of integral domains with gcd

Description

`Cat::GcdDomain` represents the category of integral domains with a gcd.

A `Cat::GcdDomain` is an integral domain where the greatest common divisor of two elements can be computed by the method `"gcd"`.

Categories

Cat::IntegralDomain

Methods

Basic Methods

gcdGreatest common divisor

```
gcd(x,  )
```

The method must satisfy the following conditions:

1. `x` and `y` must divide `dom::gcd(x,y)`,
2. if `z` divides both `x` and `y`, then `z` must divide `dom::gcd(x,y)`,
3. if a domain has the axiom Ax::canonicalUnitNormal then `dom::gcd(x,y)` must be equal to `dom::unitNormal(dom::gcd(x,y))`.

Remember that `x` divides `y` if `_divide(x,y)` does not return FAIL.

Mathematical Methods

lcmLeast common multiple

```
lcm(x,  )
```

Cat::Group

Purpose

Category of groups

Description

`Cat::Group` represents the category of groups.

A `Cat::Group` is a (potentially non-Abelian) monoid where the group operation `*` (`_mult`) is invertible.

Categories

Cat::Monoid

Methods

Mathematical Methods

_divideReturn quotient

```
_divide(x, y)
```

Cat::HomogeneousFiniteCollection

Purpose

Category of homogeneous finite collections

Syntax

```
Cat::HomogeneousFiniteCollection(T)
```

Description

`Cat::HomogeneousFiniteCollection(T)` represents the category of homogeneous finite collections (i.e. bags) of elements of the domain `T`.

A `Cat::HomogeneousFiniteCollection` is a finite collection where each element of the collection must be from the same domain `T`.

Categories

Cat::FiniteCollection

If `T` is a Cat::OrderedSet, then Cat::OrderedSet.

Parameters

`T`

A domain which must be from the category Cat::BaseCategory. Only elements of this domain may be contained in the collection.

Entries

"elemDom"	The parameter domain `T`.

Methods

Mathematical Methods

_lessCompare two elements

```
_less(x, y)
```

Returns TRUE if `x` is less than `y`.

The collections `x` and `y` are ordered by the lexical ordering of their elements.

Cat::HomogeneousFiniteProduct

Purpose

Category of homogeneous finite products

Syntax

```
Cat::HomogeneousFiniteProduct(T)
```

Description

`Cat::HomogeneousFiniteProduct(T)` represents the category of homogeneous finite products of elements of the domain `T`.

A `Cat::HomogeneousFiniteProduct(T)` is a homogeneous finite collection where each collection has the same number of elements of the domain `T`.

The number of elements must be given by the entry `"card"`, which must be defined by domains of this category. It is not given as a category parameter simply because it is not needed. Thus no unnecessary instances of the category are created.

One could principally implement all the algebraic operations here, but they will be slow if the methods `"_index"` and `"set_index"` are slow, which most often will be the case. So we avoid the work and let the domain implementors do it.

Categories

Cat::HomogeneousFiniteCollection(T)

If `T` is a Cat::DifferentialRing, then Cat::DifferentialRing.

If `T` is a Cat::PartialDifferentialRing, then Cat::PartialDifferentialRing.

If `T` is a Cat::CommutativeRing, then Cat::CommutativeRing.

If `T` is a Cat::SkewField, then Cat::SkewField.

If `T` is a Cat::Ring, then Cat::Ring.

If `T` is a Cat::Rng, then Cat::Rng.

If `T` is a Cat::AbelianGroup, then Cat::AbelianGroup.

If `T` is a Cat::CancellationAbelianMonoid, then Cat::CancellationAbelianMonoid.

If `T` is a Cat::AbelianMonoid, then Cat::AbelianMonoid.

If `T` is a Cat::AbelianSemiGroup, then Cat::AbelianSemiGroup.

If `T` is a Cat::Group, then Cat::Group.

If `T` is a Cat::Monoid, then Cat::Monoid.

If `T` is a Cat::SemiGroup, then Cat::SemiGroup.

If `T` is a Cat::CommutativeRing, then `Cat::Algebra(T)`.

If `T` is a Cat::Ring, then `Cat::LeftModule(T)`.

If `T` is a Cat::Ring, then `Cat::RightModule(T)`.

Parameters

`T`

A domain which must be from the category Cat::BaseCategory. This defines the domain of the products elements.

Entries

"card"	Must hold the number of elements of a collection.
"characteristic"	Defined if `T` is a ring: In this case the characteristic of the product domain is the same as that of `T`.

Methods

Basic Methods

zipCombine elements

```
zip(x, y, f)
```

zipCanFailCombine elements, may fail

```
zipCanFail(x, y, f)
```

Access Methods

nopsReturn number of elements

```
nops(x)
```

Cat::IntegralDomain

Purpose

Category of integral domains

Description

`Cat::IntegralDomain` represents the category of integral domains.

A `Cat::IntegralDomain` is a commutative and entire ring which has a "partial" division method `"_divide"`: If `b` divides `a` then `dom::_divide(a,b)` must return the quotient, otherwise FAIL. The result of the method `"_divide"` must be unique.

Use the axiom Ax::canonicalUnitNormal to state in addition that there exists a canonical unit normal form for each element of the ring. If a ring has the axiom Ax::canonicalUnitNormal the method `"unitNormal"` must return the unique unit normal for a ring element. If the axiom is not valid the method may return any associate.

Use the axiom Ax::closedUnitNormals in addition to state that the unit normals which are computed by the method `"unitNormal"` are closed under multiplication, i.e. that the product of two unit normals returns a unit normal.

These two axioms are not implicitly valid for an `Cat::IntegralDomain` because there are integral domains for which one can't compute a canonical unit normal for each element.

Categories

Cat::EntireRing, Cat::CommutativeRing, Cat::Algebra`(dom)`

Methods

Basic Methods

_divideReturn quotient

```
_divide(x, y)
```

The result must be unique:

1. the product `y * dom::_divide(x,y)` must be equal to `x` provided that `y` is not zero and `y` divides `x`,
2. if `x` is equal to `y * z` then `y` must divide `x`.

It is an error if `y` is zero.
isUnitTest if element is a unit

```
isUnit(x)
```

unitNormalReturn an associate

```
unitNormal(x)
```

If the ring has the axiom Ax::canonicalUnitNormal the method must return the unique unit normal of `x`.

An implementation is provided if the ring has *not* the axiom Ax::canonicalUnitNormal: In this case simply `x` is returned.

Mathematical Methods

associatesTest if elements are associates

```
associates(x, y)
```

dividesTest if elements divides another

```
divides(x, y)
```

unitNormalRepReturn the unit normal representation

```
unitNormalRep(x)
```

If the ring has the axiom Ax::canonicalUnitNormal the method must return the unique unit normal of `x`. The default implementation uses the method `"unitNormal"` to compute the unit normal `n` in this case.

If the ring dos not have the axiom Ax::canonicalUnitNormal the method simply returns `[x, dom::one, dom::one]`.

Cat::LeftModule

Purpose

Category of left R -modules

Syntax

```
Cat::LeftModule(R)
```

Description

`Cat::LeftModule(R)` represents the category of left `R`-modules.

A `Cat::LeftModule(R)` is an Abelian group together with a rng `R` (a ring without unit) and a left multiplication `*` (`_mult`).

The left multiplication is an operation taking an element of rng `R` and a module element and returning a module element.

Given ring elements a, b and module elements x, y the following 3 distibutive laws must hold:

1 $(ab)x = a(bx)$,

2 $(a + b)x = ax + bx$,

3 $a(x + y) = ax + ay$.

Beware: The operation of a non-Abelian semi-group is also written as `*` (`_mult`). The method `"_mult"` must handle the situation if a left module is also a non-Abelian semi-group. In such a case it must both implement the group operation and the left multiplication by elements of the rng.

Categories

Cat::AbelianGroup

Parameters

`R`

A domain which must be from the category Cat::Rng.

Methods

Basic Methods

_multLeft multiplication by a rng element

```
_mult(r, x)
```

Cat::Matrix

Purpose

Category of matrices

Syntax

```
Cat::Matrix(R)
```

Description

`Cat::Matrix(R)` represents the category of matrices over the rng `R`.

A `Cat::Matrix(R)` is a matrix of arbitrary dimension over a component ring `R`.

In the following description of the methods, we use the following notations for a matrix *A* from a domain of category `Cat::Matrix(R)`:

nrows(*A*) denotes the number of rows and *ncols*(*A*) the number of columns of *A*.

Further on, a *row index* is an integer ranges from 1 to *nrows*(*A*), and a *column index* is an integer ranges from 1 to *ncols*(*A*).

Categories

Cat::BaseCategory

Parameters

`R`

A domain which must be from the category Cat::Rng (a ring without unit).

Entries

"coeffRing"	is set to `R`.

Methods

Basic Methods

_indexMatrix indexing

```
_index(A, i, j)
```

matdimMatrix dimension

```
matdim(A)
```

newMatrix definition

```
new(m, n)
```

Of course, this method may implement further possibilites to create matrices (for example, see the method `"new"` of the domain constructor Dom::Matrix).
set_indexSetting matrix components

```
set_index(A, i, j, x)
```

Mathematical Methods

_negateNegate a matrix

```
_negate(A)
```

_plusAdd matrices

```
_plus(A1, A2,  )
```

The matrices must be of the same domain type, otherwise `FAIL` is returned.

_subtractSubtract two matrices

```
_subtract(A, B)
```

equalTest on equality of matrices

```
equal(A, B)
```

identityIdentity matrix

```
identity(n)
```

It only exists if `R` is of category Cat::Ring, i.e., a ring with unit.

iszeroTest on zero matrices

```
iszero(A)
```

Note that there may be more than one representation of the zero matrix of a given dimension if `R` does not have the axiom Ax::canonicalRep.

transposeTranspose of a matrix

```
transpose(A)
```

Access Methods

colExtracting columns

```
col(A, c)
```

concatMatrixHorizontal concatenation of matrices

```
concatMatrix(A, B)
```

An error message is issued if the two matrices do not have the same number of rows.

delColDeleting columns

```
delCol(A, c)
```

If A only consists of one column then NIL is returned.

delRowDeleting rows

```
delRow(A, r)
```

If A only consists of one row then NIL is returned.

rowExtracting rows

```
row(A, r)
```

setColReplacing columns

```
setCol(A, c, v)
```

setRowReplacing rows

```
setRow(A, r, v)
```

stackMatrixAppending of matrices vertically

```
stackMatrix(A, B)
```

An error message is issued if the two matrices do not have the same number of columns.

swapColSwapping matrix columns

```
swapCol(A, c1, c2)
```

swapRowSwapping matrix rows

```
swapRow(A, r1, r2)
```

Cat::Module

Purpose

Category of R-modules

Syntax

```
Cat::Module(R)
```

Description

`Cat::Module(R)` represents the category of `R`-modules.

A `Cat::Module(R)` is a left and right `R`-module over a commutative ring `R`.

Right and left multiplications must be both implemented by the method `"_mult"`.

Categories

Cat::LeftModule(`R`), Cat::RightModule(`R`)

Parameters

`R`

A domain which must be from the category Cat::CommutativeRing.

Cat::Monoid

Purpose

Category of monoids

Description

`Cat::Monoid` represents the category of monoids.

`Cat::Monoid` is a non-Abelian semi-group with a neutral element one (`dom::one`) according to the group operation `*` (`_mult`).

Categories

Cat::SemiGroup

Entries

"one"	Must hold the neutral element according to the operation `*`.

Methods

Basic Methods

_invertReturn inverse

```
_invert(x)
```

Mathematical Methods

isoneTest if element is one

```
isone(x)
```

_powerRaise to the nth power

```
_power(x, n)
```

This implementation does “repeated squaring”.

Cat::OrderedSet

Purpose

Category of ordered sets

Description

`Cat::OrderedSet` represents the category of ordered sets.

An `Cat::OrderedSet` is a set with a (complete) order relation < (_less).

Use the axiom Ax::canonicalOrder to state that elements of a domain are canonically ordered as MuPAD expressions (i.e. ordered with respect to the kernel function _less).

Categories

Cat::BaseCategory

Methods

Basic Methods

_lessCompare if element is less

```
_less(x, y)
```

An implementation is provided if this domain has axiom Ax::canonicalOrder.

Mathematical Methods

_leequalCompare if element is less or equal

```
_leequal(x, y)
```

The implementation provided uses the methods `"_less"` and `"equal"`.

maxReturn maximum

```
max(x,  )
```

minReturn minimum

```
min(x,  )
```

sortSort list of elements

```
sort(l)
```

Cat::PartialDifferentialRing

Purpose

Category of partial differential rings

Description

`Cat::PartialDifferentialRing` represents the category of partial differential rings.

A `Cat::PartialDifferentialRing` is a commutative ring with a finite set of derivation operators `D_i`.

A derivation is a linear operator with product rule, i.e. `D_i(f * g)` equals `D_i(f) * g + f * D_i(g)` for all `f` and `g`.

For many partial differential rings the derivations are differentiations with respect to some indeterminates. Thus in order to support a natural notion it is also supposed that a method `"diff"` exists, such that `diff(f, x)` returns the partial derivation of `f` with respect to the indeterminate `x`.

Categories

Cat::CommutativeRing

Methods

Basic Methods

DReturn derivative

```
D(l, x)
```

diffReturn partial derivative

```
diff(x, <v,  >)
```

Cat::Polynomial

Purpose

Category of multivariate polynomials

Syntax

```
Cat::Polynomial(R)
```

Description

`Cat::Polynomial(R)` represents the category of multivariate polynomials over `R`.

A `Cat::Polynomial(R)` is a multivariate polynomial ring over a commutative coefficient ring `R`.

Axioms

If `R` has Ax::canonicalUnitNormal, then Ax::canonicalUnitNormal.

If `R` has Ax::closedUnitNormals, then Ax::closedUnitNormals.

Categories

Cat::PartialDifferentialRing, Cat::Algebra`(R)`

If `R` is a Cat::FactorialDomain, then Cat::FactorialDomain.

If `R` is a Cat::GcdDomain, then Cat::GcdDomain.

If `R` is a Cat::IntegralDomain, then Cat::IntegralDomain.

Parameters

`R`

A domain which must be from the category Cat::CommutativeRing.

Entries

"coeffRing"	The coefficient ring `R`.
"characteristic"	The characteristic of this domain, which is the same as that of the ring `R`.

Methods

Basic Methods

coeffReturn coefficients

```
coeff(p)
```

```
coeff(p, x, n)
```

```
coeff(p, n)
```

Must return the coefficient of `x^n` of `p`, which is a polynomial in the remaining indeterminates.

Must return the coefficient of `x^n` of `p`, where `x` is the main variable of `p`.
degreeReturn total degree

```
degree(p)
```

```
degree(p, x)
```

Must return the degree of `p` with respect to the indeterminate `x`.
degreevecReturn degree vector

```
degreevec(p)
```
evalpEvaluate at a point

```
evalp(p, x = v,  )
```

More than one evaluation point may be given. The result must be a polynomial in the remaining indeterminates or an element of `R`.
indetsReturn indeterminates

```
indets(p)
```
lcoeffReturn leading coefficient

```
lcoeff(p)
```
lmonomialReturn leading monomial

```
lmonomial(p)
```
ltermReturn leading term

```
lterm(p)
```
mainvarReturn main variable

```
mainvar(p)
```
mapcoeffsMap coefficients

```
mapcoeffs(p, f, <a,  >)
```
multcoeffsMultiply coefficients

```
multcoeffs(p, c)
```

ntermsReturn number of terms

```
nterms(p)
```

nthcoeffReturn `n`-th coefficient

```
nthcoeff(p, n)
```

nthmonomialReturn `n`-th monomial

```
nthmonomial(p, n)
```

nthtermReturn `n`-th term

```
nthterm(p, n)
```

tcoeffReturn trailing coefficient

```
tcoeff(p)
```

unitNormalReturn unit normal

```
unitNormal(p)
```

An implementation is provided if `R` has the axiom Ax::canonicalUnitNormal: In this case `p` is multiplied by an unit of `R` such that the leading coefficient has unit normal representation in `R`.

unitNormalRepReturn unit normal representation

```
unitNormalRep(p)
```

An implementation is provided if `R` has the axiom Ax::canonicalUnitNormal.

Mathematical Methods

contentReturn content

```
content(p)
```

isUnitTest if element is a unit

```
isUnit(p)
```

primpartReturn primitive part

```
primpart(p)
```

poly2listConvert into a list

```
poly2list(p)
```

solveSolve polynomial equation

```
solve(p, x, <opt,  >)
```

```
solve(p, x = T, <opt,  >)
```

```
solve(p)
```

Solves the polynomial equation `p = 0` with respect to `x` over the domain `T`. See the function solve for details about the optional arguments `opt, ...`

The polynomial `p` must be univariate. Solves the polynomial equation `p = 0` with respect to the indeterminate of `p` over the domain `R`.

Cat::PrincipalIdealDomain

Purpose

Category of principal ideal domains

Description

`Cat::PrincipalIdealDomain` represents the category of principal ideal domains.

A `Cat::PrincipalIdealDomain` is an integral domain with gcd where each ideal is principal. Note that the method `"idealGenerator"` has to find generators for finitely generated ideals only.

Categories

Cat::GcdDomain

Methods

Basic Methods

idealGeneratorReturn generator of ideal

```
idealGenerator(x,  )
```

Cat::QuotientField

Purpose

Category of quotient fields

Syntax

```
Cat::QuotientField(R)
```

Description

`Cat::QuotientField(R)` represents the category of quotient fields over `R`.

A `Cat::QuotientField` is the field of fractions over the integral domain `R`.

Categories

Cat::Field, Cat::Algebra`(R)`

If `R` has Cat::OrderedSet, then Cat::OrderedSet.

Parameters

`R`

A domain which must be from the category Cat::IntegralDomain.

Entries

"characteristic"	The characteristic of this domain, which is the same as that of `R`.

Methods

Basic Methods

denomReturn denominator

```
denom(x)
```

numerReturn numerator

```
numer(x)
```

Mathematical Methods

equalTest for equality

```
equal(x, y)
```

iszeroTest for zero

```
iszero(x)
```

_lessTest if element is less

`_less(x, y)`
retractReturn retracted element

`retract(x)`

The default implementation uses the method "`_divide`" to divide numerator and denominator.

Cat::RightModule

Purpose

Category of right R-modules

Syntax

```
Cat::RightModule(R)
```

Description

`Cat::RightModule(R)` represents the caregory of right `R`-modules.

A `Cat::RightModule` is an Abelian group together with a ring `R` and a right multiplication `*` (`_mult`).

The right multiplication is an operation taking an element of ring `R` and a module element and returning a module element.

Given ring elements a, b and module elements x, y the following 3 distributive laws must hold:

1 $x(ab) = (xa)b$,

2 $x(a + b) = xa + xb$,

3 $(x + y)a = xa + ya$.

Beware: The operation of a non-Abelian semi-group is also written as `*` (`_mult`). The method `"_mult"` must handle the situation if a right module is also a non-Abelian semi-group. In such a case it must both implement the group operation and the right multiplication by elements of the ring.

Categories

Cat::AbelianGroup

Parameters

`R`

A domain which must be from the category Cat::Ring.

Methods

Basic Methods

_multRight multiplication by a ring element

```
_mult(x, r)
```

Cat::Ring

Purpose

Category of rings

Description

`Cat::Ring` represents the category of rings.

A `Cat::Ring` is a ring with a unit `dom::one`, i.e., an Abelian group according to the operation + (_plus) and a non-Abelian monoid according to the operation * (_mult) where in addition the two distributive laws $a(b + c) = ab + ac$ and $(a + b)c = ac + bc$ hold.

A `Cat::Ring` is also a left module over itself. The left multiplication of the module is also written as * (_mult).

Note that a ring without unit is a Cat::Rng.

Categories

Cat::Rng, Cat::Monoid, Cat::LeftModule(`dom`)

Entries

"characteristic"	Must hold the characteristic of this ring.

Cat::Rng

Purpose

Category of rings without unit

Description

`Cat::Rng` represents the category of rings without unit.

A `Cat::Rng` is a ring without a unit, i.e. an Abelian group according to the operation + (_plus) and a non-Abelian semi-group according to the operation * (_mult) where in addition the two distributive laws $a(b + c) = ab + ac$ and $(a + b)c = ac + bc$ hold.

Use the axiom Ax::noZeroDivisors to state that there are no zero divisors according to *, i.e. that the product of non-zero elements never is zero.

Categories

Cat::AbelianGroup, Cat::SemiGroup

Cat::SemiGroup

Purpose

Category of semi-groups

Description

`Cat::SemiGroup` represents the category of semi-groups.

A `Cat::SemiGroup` represents the category of non-Abelian semi-groups, where the group operation is written as multiplication. Hence a `Cat::SemiGroup` is a set with an associative operation `*` (_mult).

Note that Abelian semi-groups with operation + have category Cat::AbelianSemiGroup.

Categories

Cat::BaseCategory

Methods

Basic Methods

_multReturn product

```
_mult(x,  )
```

Mathematical Methods

_powerReturn integer power

```
_power(x, n)
```

Cat::Set

Purpose

Category of sets of complex numbers

Description

`Cat::Set` represents the category of subsets of the complex numbers.

Sets of this category allow set-theoretic operations as well as pointwise arithmetical operations.

The main feature of `Cat::Set` is a particular overloading mechanism. It provides `n`-ary operators that can handle operands from different domains of category `Cat::Set`, as well as mixed input where some operands are of types not belonging to `Cat::Set`. *Hence, in the methods of `Cat::Set`, operands of arbitrary type are allowed.*

There are three kinds of operators: `n`-ary (associative and commutative), binary (not assumed to be commutative), and unary (mapping a function). `Cat::Set` provides generic methods for generating these kinds of operators, and uses them to define default methods overloading the common set-theoretic and arithmetical functions.

By default, any operation of sets is defined, but returns unevaluated since the arithmetical or set-theoretic expression cannot be simplified. Each domain of type `Cat::Set` must provide particular slots and tables in order to achieve simplifications in certain special cases.

Arithmetical operations are defined pointwise. It is not an error if some operation is not defined for all elements of a set.

`Cat::Set` is mainly used by domains of sets returned by solve.

Categories

Cat::BaseCategory

Methods

Mathematical Methods

commassopReturn an `n`-ary commutative and associative operator for sets

```
commassop(operatorname)
```

The returned procedure first sorts its operands (which it may do because of commutativity). Those operands not belonging to a domain of category `Cat::Set` are handled by the usual overloading mechanism, i.e. by the slot

operatorname of one of their domains. Out of the others, several operands belonging to the same domain are handled by the slot "homog".operatorname of that domain. Finally, the returned method tries to combine each possible pair of operands. If they are from the same domain, "bin".operatorname is called for them. The following is done if the operands are from different domains: let T1 and T2 be their types; then their "inhomog".operatorname slots are used. If such a slot exists in the domain T1, it must contain a table indexed by possible types T2, and the entry at that index must be a procedure that carries out the operation for exactly two arguments, the first being a T1, the second being a T2. Conversely, if such a slot exists in the domain T2, it must contain a table indexed by possible types T1, and the entry at that index must be a procedure that carries out the operation for exactly two arguments, the first being a T2, the second being a T1.

The slot "homog".operatorname, or a table entry in the slot "inhomog".operatorname, may return FAIL in order to indicate that it could not simplify its input; if they are missing, this indicates that a simplification is generally not possible for input of this type. In these cases, the returned procedure proceeds by trying to combine another two of the given arguments.

A slot "bin".operatorname usually won't exist, except for the case that there is no "homog".operatorname; usually the latter can also take care for the case of exactly two operands.

The whole process is repeated over and over until no new simplifications occur or only one operand is left. If no more simplifications occur, an unevaluated call to the operator is returned, the arguments being all remaining operands that could not be combined further.
binopReturn a binary operator for sets

```
binop(operatorname)
```

The returned procedure uses the slot "bin".operatorname of its first argument if both arguments are of the same type. Otherwise it uses the slot "inhomogleft".operatorname of its first argument; if that fails, it uses the slot "inhomogright".operatorname of its second argument; each of these slots, if it exists, must contain tables, indexed by the type of the other argument, such that slot(T1, "inhomogleft".operatorname)[T2] and

`slot(T2, "inhomogright".operatorname)[T1]` carry out the operation for objects of type `T1` and `T2`, in this order.

No commutativity of the operation is assumed.

If the slots or table entries do not exist or return `FAIL`, an unevaluated call to the operator is returned.
homogassopReturn an `n`-ary operator for sets belonging to the same domain

`homogassop(operatorname)`
_unionUnion of sets

`_union(`S_1`, )`
_intersectIntersection of sets

`_intersect(`S_1`, )`
_plusSet of sums of set elements

`_plus(`S_1`, )`

The sum of sets is computed by the commutative-associative operator generated by `"commassop"`, using the slots `"homog_plus"` and `"inhomog_plus"` of the domains of its operands.
_multSet of product of set elements

`_mult(`S_1`, )`

The product of sets is computed by the commutative-associative operator generated by `"commassop"`, using the slots `"homog_mult"` and `"inhomog_mult` of the domains of its operands.
_minusSet of subtractions

`_minus(`S_1`, `S_2`)`
_powerPointwise power

`_power(`S_1`, `S_2`)`

The power of sets is computed by the binary operator generated by `"binop"`, using the slots `"homog_power"`, `"inhomogleft_power"`, and `"inhomogright_power"` of its operands.
mapMap an operation to a set

`map(S, f)`

By overloading this method in a particular domain, the behavior of sets changes whenever a special function is applied to them.

Cat::SkewField

Purpose

Category of skew fields

Description

`Cat::SkewField` represents the category of skew fields (division rings).

A `Cat::SkewField` represents a ring with unit where each non-zero element is invertible. This structure is also called division ring in the literature.

Categories

Cat::Ring

Cat::SquareMatrix

Purpose

Category of square matrices

Syntax

```
Cat::SquareMatrix(R)
```

Description

`Cat::SquareMatrix(R)` represents the category of square matrices over the rng `R`.

A `Cat::SquareMatrix(R)` represents the rng (ring without unit) of square matrices over the coefficient domain `R`.

Categories

Cat::Rng, Cat::Matrix`(R)`

If `R` has Cat::Ring, then Cat::Ring.

Parameters

`R`

A domain which must be from the category Cat::Rng.

Entries

"characteristic"	Defined if `R` is a ring: In this case the characteristic of the matrix domain is the same as that of `R`.

Cat::UnivariatePolynomial

Purpose

Category of univariate polynomials

Syntax

```
Cat::UnivariatePolynomial(R)
```

Description

`Cat::UnivariatePolynomial(R)` represents the category of univariate polynomials over `R`.

A `Cat::UnivariatePolynomial(R)` is a univariate polynomial over the commutative ring `R`.

Categories

Cat::Polynomial(`R`), Cat::DifferentialRing

If `R` has Cat::Field, then Cat::EuclideanDomain.

Parameters

`R`

A domain which must be from the category Cat::CommutativeRing.

Methods

Basic Methods

pdividePseudo-divide polynomials

```
pdivide(p, q)
```

Must return a sequence `(b, s, r)` of a ring element `b` and polynomials `s` and `r` such that $multcoeffs(p, b) = sq + r$ holds with $b = lcoeff(q)^{degree(p) - degree(q) + 1}$.

pquoReturn pseudo-quotient

```
pquo(p, q)
```

premReturn pseudo-remainder

```
prem(p, q)
```

Cat::VectorSpace

Purpose

Category of vector spaces

Syntax

```
Cat::VectorSpace(F)
```

Description

`Cat::VectorSpace(F)` represents the category of vector spaces over the field `F`.

A vector space is an Abelian group with an operation + (_plus).

The scalar product has to be implemented via the method `"_mult"`. Other kinds of multiplication are not defined.

Categories

Cat::Module(F)

Parameters

`F`

A domain which must be from the category Cat::Field.

Methods

Basic Methods

_multReturn scalar product

```
_mult(c, x)
```

```
_mult(x, c)
```

Must return the scalar product of `x` and `c`.

combinat – Combinatorics

==REFNAME==

combinat::bell

Purpose

Bell numbers

Syntax

```
combinat::bell(n)
combinat::bell(expression)
```

Description

`combinat::bell(n)` computes the n-th Bell number.

The `n`-th Bell number is defined by the exponential generating function:

e^(e^(x)-1)=sum(bell(n)/n!*x^n, n=0..infinity)

$$e^{e^x-1} = \sum_{n=0}^{\infty} \frac{\mathrm{bell}(n)}{n!} x^n$$

Often another definition is used. The `n`-th Bell number is the number of different ways of partitioning the set {1, 2, …, *n*} into disjoint nonempty subsets, and *bell*(0) is defined to be 1.

Bell numbers are computed using the formula:

- *bell*(0) = 1

  bell(n+1) = sum(binomial(n,i) * bell(i), i=0..n) for $n > 0$

  $$\mathrm{bell}(n+1) = \sum_{i=0}^{n} \binom{n}{i} \mathrm{bell}(i)$$

Examples

Example 1

The third Bell number is 5:

```
combinat::bell(3)
```

```
5
```

This means that you can partition the set {1, 2, 3} into disjoint subsets in 5 different ways. These are {{1, 2, 3}}, {{1}, {2, 3}}, {{2}, {1, 3}}, {{3}, {1, 2}}, and {{1}, {2}, {3}}. Or, that you can write 105 = 357 as 5 different products. These are 105 = 335 = 521 = 715 = 357.

Example 2

If one uses a wrong argument, an error message is returned.
combinat::bell(3.4) Error: A nonnegative integer is expected.
[combinat::bell]

Example 3

It can be useful to return the unevaluated function call.
a := combinat::bell(x); x := 4; a ; delete(a);combinat::bell(x)

```
combinat::bell(x)
```

4

```
4
```

15

```
15
```

Parameters

n

Nonnegative integer

expression

An expression of type Type::Arithmetical which must be a nonnegative integer if it is a number.

Return Values

Positive integer value if `n` was a nonnegative integer. Otherwise `combinat::bell` returns the unevaluated function call.

combinat::cartesianProduct

Purpose

Cartesian product

Syntax

```
combinat::cartesianProduct(S1,  )
```

Description

`combinat::cartesianProduct(S1, ...)` returns the cartesian product of the sets or lists *S1*, ... as a list of lists.

The cartesian product of S_1 through S_n consists of all lists of length n whose i-th entry is an operand of the set or list S_i, for $1 \le i \le n$.

Any integer k among the arguments is identified with the set of the first k positive integers.

The ordering of the output is unspecified.

Examples

Example 1

The following calls are equivalent:
combinat::cartesianProduct({1, 2}, {a, b}), combinat::cartesianProduct(2, [b, a])[[1, a], [2, a], [1, b], [2, b]], [[1, b], [2, b], [1, a], [2, a]]

$$[[1, a], [2, a], [1, b], [2, b]], [[1, b], [2, b], [1, a], [2, a]]$$

Parameters

S1

Set, list, or nonnegative integer

Return Values

List of lists, each of them having as many operands as there were arguments passed to `combinat::cartesianProduct`.

combinat::catalan

Purpose

Catalan numbers

Syntax

```
combinat::catalan(n)
```

Description

`combinat::catalan`(n) returns the `n`-th Catalan number.

The Catalan numbers are ubiquitous in combinatorics. For example, `combinat::catalan(n)` counts the Dyck words of size `n`, the ordered trees with `n` nodes, the binary trees with `n+1` nodes, the complete binary trees with `2n+1` nodes, the standard tableaux with two rows of size `n`, the triangulations of a regular `n+2`-gone, or the non-crossing partitions of {1, 2, …, *n*}.

`combinat::catalan(n)` is calculated using the formula

catalan(n)=1/(n+1) * binomial(2*n,n)

Examples

$$\text{catalan}(n) = \frac{1}{n+1}\binom{2n}{n}$$

Example 1

We compute the first Catalan numbers:
combinat::catalan(n) $ n = 0..6

1, 1, 2, 5, 14, 42, 132

Example 2

If one uses a wrong argument, an error message is returned
combinat::catalan(-1) Error: The type of argument number 1 must be 'Type::NonNegInt'. The object '-1' is incorrect. Evaluating: combinat::catalan

Parameters

n

Nonnegative integer

Return Values

Positive integer.

combinat::choose

Purpose

Subsets of a given size

Syntax

```
combinat::choose(S, k)
```

Description

`combinat::choose(S, k)` returns all subsets of `S` that have exactly `k` elements.

If `S` is an integer, it represents the set of the first `S` positive integers.

Examples

Example 1

There are three subsets of a three-element set that have exactly two elements:
combinat::choose({a, b, c}, 2){a, b}, {a, c}, {b, c}

$$\{a, b\}, \{a, c\}, \{b, c\}$$

Parameters

S

Set or nonnegative integer

k

Nonnegative integer

Return Values

Sequence of sets.

combinat::compositions

Purpose

Compositions of an integer

Syntax

```
combinat::compositions(n, <MinPart = k>, <MaxPart
= l>, <Length = m>)
```

Description

`combinat::compositions(n)` returns all compositions of the nonnegative integer `n`.

A *composition* of a nonnegative integer `n` is a list of positive integers with total sum `n`.

Examples

Example 1

We output all compositions of the integer 4:
combinat::compositions(4)[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]

[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]

Example 2

It is possible to output only the compositions of a certain length:
combinat::compositions(4, Length=2)[[3, 1], [2, 2], [1, 3]]

[[3, 1], [2, 2], [1, 3]]

Example 3

The options `MinPart` and `MaxPart` can be used to set constraints on the sizes of all parts. Using `MaxPart`, you can select compositions having only small entries. This is the list of the compositions of 4 with all parts at most 2:
combinat::compositions(4, MaxPart=2)[[2, 2], [2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]

[[2, 2], [2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]

`MinPart` is complementary to `MaxPart` and selects compositions having only large parts (it takes a non-negative value). This is the list of the compositions of 4 with all parts at least 2:
combinat::compositions(4, MinPart=2)[[4], [2, 2]]

```
[[4], [2, 2]]
```

By default, the parts of a composition have to be positive. This can be changed using the option `MinPart`. In the following example, the options `Length` and `MinPart` are combined together to obtain the list of the compositions of 4 with 3 nonnegative parts:
combinat::compositions(4, Length=3, MinPart=0)[[4, 0, 0], [3, 1, 0], [3, 0, 1], [2, 2, 0], [2, 1, 1], [2, 0, 2], [1, 3, 0], [1, 2, 1], [1, 1, 2], [1, 0, 3], [0, 4, 0], [0, 3, 1], [0, 2, 2], [0, 1, 3], [0, 0, 4]]

```
[[4, 0, 0], [3, 1, 0], [3, 0, 1], [2, 2, 0], [2, 1, 1], [2, 0, 2], [1, 3, 0], [1, 2
[0, 4, 0], [0, 3, 1], [0, 2, 2], [0, 1, 3], [0, 0, 4]]
```

If no length is given, `MinPart=0` is not allowed.

Parameters

n

Nonnegative integer

Options

MinPart

Option, specified as `MinPart = k`

Return only compositions consisting of integers greater or equal than `k`. The option `MinPart = 0` is only allowed if also the option `Length` is given. Default is 1.

MaxPart

Option, specified as `MaxPart = l`

Return only compositions consisting of integers less or equal than `l`.

Length

Option, specified as `Length = m`

Return only compositions consisting of exactly `m` integers.

combinat::modStirling

Purpose

Modified Stirling numbers

Syntax

```
combinat::modStirling(q, n, k)
```

Description

`combinat::modStirling` computes the modified Stirling numbers.

`combinat::modStirling(q,n,k)` takes the elementary symmetric polynomial in `n` variables of degree `k` and evaluates it for the values $q + 1, \ldots, q + n$. Note that `k` must not be greater than `n`.

Examples

Example 1

combinat::modStirling(2,4,2)119

```
119
```

Parameters

q

The argument: an integer

n

The number of variables: a nonnegative integer

k

The degree: a nonnegative integer

Return Values

Positive integer.

combinat::partitions

Purpose

Partitions of an integer

Syntax

```
combinat::partitions(n)
```

Description

`cominat::partitions(n)` returns the number of partitions of the integer `n`.

A *partition* of a nonnegative integer `n` is a non-increasing list of positive integers with total sum `n`.

Examples

Example 1

There are 5 partitions of 4:
combinat::partitions(4)5

```
5
```

Parameters

n

Nonnegative integer

Algorithms

Counting is done efficiently with Euler's pentagonal formula for small values of *n* and Hardy-Ramanujan-Rademacher's formula otherwise.

combinat::permute

Purpose

Permutations of a list

Syntax

```
combinat::permute(l, <Duplicate>)
combinat::permute(n, <Duplicate>)
```

Description

For a list `l`, the call `combinat::permute(l)` returns all permutations of `l`.

For an integer `n`, the call `combinat::permute(n)` returns all permutations of the list `[1, ..., n]`.

A permutation of a list is a list that contains the same elements, and each of them the same number of times, as the original list.

Equivalently, a permutation of a list `l` of n elements is any `f(l)` where `f` is an element of the symmetric group `Dom::SymmetricGroup(n)`. Different `f` may produce the same `f(l)`; with the option `Duplicate`, every permutation is listed as many times as it occurs in that way; without that option, every permutation is listed only once.

Examples

Example 1

There are six permutations of three letters:
combinat::permute([a, b, c])[[b, c, a], [c, b, a], [a, c, b], [c, a, b], [a, b, c], [b, a, c]]

$$[[b, c, a], [c, b, a], [a, c, b], [c, a, b], [a, b, c], [b, a, c]]$$

To permute the first three integers, the following syntax is also possible:
combinat::permute(3)[[2, 3, 1], [3, 2, 1], [1, 3, 2], [3, 1, 2], [1, 2, 3], [2, 1, 3]]

$$[[2, 3, 1], [3, 2, 1], [1, 3, 2], [3, 1, 2], [1, 2, 3], [2, 1, 3]]$$

If some list entry occurs several times, the number of permutations decreases:

combinat::permute([a, a, b])[[a, b, a], [b, a, a], [a, a, b]]

$$[[a, b, a], [b, a, a], [a, a, b]]$$

However, the same permutation is listed as often as it can be obtained by applying different elements of the symmetric group S_3 if the option `Duplicate` is given.
combinat::permute([a, a, b], Duplicate)[[a, b, a], [b, a, a], [a, b, a], [b, a, a], [a, a, b], [a, a, b]]

$$[[a, b, a], [b, a, a], [a, b, a], [b, a, a], [a, a, b], [a, a, b]]$$

We could have achieved the same by permuting three different symbols and then setting two of them equal:
subs(combinat::permute([a, b, c]), c=a)[[b, a, a], [a, b, a], [a, a, b], [a, a, b], [a, b, a], [b, a, a]]

$$[[b, a, a], [a, b, a], [a, a, b], [a, a, b], [a, b, a], [b, a, a]]$$

Parameters

l

List

n

Positive integer

Options

Duplicate

List every permutation as often as it can be produced in different ways by applying some bijective mapping (element of the symmetric group) to the original list.

combinat::powerset

Purpose

Subsets of a set

Syntax

```
combinat::powerset(S)
```

Description

If `S` is a set, `combinat::powerset(S)` returns the set of all subsets of `S`. If `l` is a list, `combinat::powerset(l)` returns the set of all sublists of `l`.

The powerset of a list `l` is the set of all lists that can be obtained by deleting some elements of `l` and leaving the others in order.

`combinat::powerset` has been overloaded for multisets of type Dom::Multiset. The powerset of a multiset `S` consists of all multisets that contain only elements occurring also in `S`, each of them at most as many times as it occurs in `S`.

Examples

Example 1

Given a finite set, `combinat::powerset` returns the powerset (set of all subsets) of the input:
combinat::powerset({a, b, c}){{}, {c}, {a}, {b}, {b, c}, {a, b}, {a, c}, {a, b, c}}

$$\{\emptyset, \{c\}, \{a\}, \{b\}, \{b, c\}, \{a, b\}, \{a, c\}, \{a, b, c\}\}$$

The same works for multisets:
combinat::powerset(Dom::Multiset(a, a, b)){{}, {[a, 1]}, {[a, 2]}, {[b, 1]}, {[a, 1], [b, 1]}, {[a, 2], [b, 1]}}

$$\{\emptyset, \{[a, 1]\}, \{[a, 2]\}, \{[b, 1]\}, \{[a, 1], [b, 1]\}, \{[a, 2], [b, 1]\}\}$$

Example 2

The powerset of a list `l` of pairwise different elements is the same as the powerset of the set of these elements, except that it consists of lists in which the order of elements is the same as in `l`:
combinat::powerset([c, a, b]){[], [a], [b], [c], [a, b], [c, a], [c, b], [c, a, b]}

$$\{[], [a], [b], [c], [a, b], [c, a], [c, b], [c, a, b]\}$$

In general, the powerset of a list `l` is the same as the powerset of the multiset of its elements, except that it consists of lists in which the original order is preserved:
combinat::powerset([a, b, a]){[], [a], [b], [a, a], [a, b], [b, a], [a, b, a]}

$$\{[], [a], [b], [a, a], [a, b], [b, a], [a, b, a]\}$$

Parameters

s

Set

l

List

combinat::stirling1

Purpose

Stirling numbers of the first kind

Syntax

```
combinat::stirling1(n, k)
```

Description

`combinat::stirling1(n,k)` computes the Stirling numbers of the first kind.

Let $S(n, k)$ be the number of permutations of `n` symbols that have exactly `k` cycles. Then `combinat::stirling1(n,k)` computes $(-1)^{(n+k)}S(n, k)$.

Let $S_1(n, k)$ be the Stirling number of the first kind, then we have:

sum(S_1(n, k)*x^k, k=0..n)=_outputSequence(x,fenced(x-1),Symbol::cdots,fenced(x-n+1))

$$\sum_{k=0}^{n} S_1(n, k)\, x^k = x(x-1)\cdots(x-n+1)$$

Examples

Example 1

Let us have a look what's the result of $x(x - 1)(x - 2)(x - 3)(x - 4)(x - 5)$ written as a sum.

```
expand(x*(x-1)*(x-2)*(x-3)*(x-4)*(x-5))x^6 - 15*x^5 + 85*x^4 - 225*x^3
+ 274*x^2 - 120*x
```

$$x^6 - 15\,x^5 + 85\,x^4 - 225\,x^3 + 274\,x^2 - 120\,x$$

Now let us "prove" the formula mentioned in the "Details" section by calculating the proper Stirling numbers:

```
combinat::stirling1(6,1);  combinat::stirling1(6,2);
combinat::stirling1(6,3);  combinat::stirling1(6,4);
combinat::stirling1(6,5); combinat::stirling1(6,6)-120
```

$$-120$$

274

```
274
```
-225

```
-225
```
85

```
85
```
-15

```
-15
```
1

```
1
```

Example 2

combinat::stirling1(3,-1) Error: Nonnegative integers are expected. [combinat::stirling1]

Parameters

n

k

Nonnegative integers

Return Values

Integer.

References

combinat::stirling2

Purpose

Stirling numbers of the second kind

Syntax

```
combinat::stirling2(n, k)
```

Description

`combinat::stirling2(n,k)` computes the number of ways of partitioning a set of `n` elements into `k` non-empty subsets.

`combinat::stirling2(n,k)` is calculated using the formula

stirling2(n, k)=(1)/(k!) * sum(fenced(-1)^(k-j) * binomial(k,j)* j^n, j=0..k)

Examples

$$\text{stirling2}(n, k) = \frac{1}{k!}\left(\sum_{j=0}^{k}(-1)^{k-j}\binom{k}{j}j^n\right)$$

Example 1

One can partition the set {1, 2, 3} into {1, 2, 3} = {1, 2} ∪ {3} = {1, 3} ∪ {2} = {2, 3} ∪ {1}
combinat::stirling2(3,2)3

```
3
```

Example 2

combinat::stirling2(3) Error: Two arguments are expected. [combinat::stirling2]

Parameters

n

k

Nonnegative integers

Return Values

Nonnegative integer.

combinat::subwords

Purpose

Subwords of a word

Syntax

```
combinat::subwords(w)
```

Description

The function `combinat::subwords(w)` returns a list of all subwords (sublists) of the list `w`.

A subword of a word w is a word obtained by deleting the letters at some of the positions in w. A subword is generated as many times as it appears in the word.

To obtain each subword only once, combinat::powerset should be used.

Examples

Example 1

There are 8 subwords of the word `[a, b, c]`:
combinat::subwords([a, b, c])[[], [a], [b], [a, b], [c], [a, c], [b, c], [a, b, c]]

[[], [a], [b], [a, b], [c], [a, c], [b, c], [a, b, c]]

Parameters

w

List

6

Dom – Domains

==REFNAME==

DOM_ARRAY

Purpose

(symbolic, multidimensional) arrays

Description

`DOM_ARRAY` is a multidimensional container type, storing arbitrary MuPAD objects at integer indices.

Arrays are a fundamental data type in many programming languages: For a fixed number of indices ("dimensions"), for each index an integer from a fixed range, an array provides space to store an arbitrary piece of data at this combination.

Function Calls

Using an array as a function symbol creates the list obtained by using each array entry as a function symbol for the operands used, i.e., `array(1..2, [f, g])(x, y)` results in `array(1..2, [f(x, y), g(x, y)])`.

Operations

As with any container, the most important operation on an array is reading and writing its entries, which is performed by indexed access, as in `A[1, 2]` or `B[1, 3, 2] := exp(x)`. Trying to access an element outside the boundaries of an array raises an error.

The function map applies some function or transformation to each element of an array, returning an array of the same format as its input, with the results of the calls as its entries.

If `A` is an array, `nops(A)` returns the number of elements in `A`.

Operands

If `A` is an array, the 0th operand of `A`, `op(A, 0)`, will be the sequence starting with the number of dimensions (an integer n) followed by n ranges of integers, which denote the acceptable ranges of indices for each dimension, including both numbers listed in the range.

For $1 \le i \le nops(A)$, the ith operand of `A` is the ith entry of `A`, in the lexicographic order of indices.

Uninitialized entries of arrays will be displayed symbolically while still in the array. When being accessed by op or indexed access, NIL is returned.

Output

One-dimensional arrays are displayed as row vectors, two-dimensional arrays as matrices. Higher-dimensional arrays are written in functional form, using the `index = value` notation, and do not have a typesetting version. This also causes typesetting to be disabled for any surrounding expression in the same output.

Element Creation

The primary way of creating arrays is the function array. Beside that, obviously, coerce can convert a number of data types, such as matrices into arrays and a number of MuPAD functions, especially in the `numeric` library, return arrays.

DOM_BOOL

Purpose

Boolean constants

Description

`DOM_BOOL` is the data type of the truth values TRUE, FALSE, and UNKNOWN.

MuPAD uses a three-valued logic system, with these values (constants) TRUE, FALSE, and UNKNOWN.

Function Calls

Using a Boolean constant as a function returns that constant unchanged. The arguments of the call are *not* evaluated.

Operations

The most important operations on Boolean values are the logical operators and, not, or, xor, ==>, <=>, and using them in conditions of if or piecewise.

Operands

Boolean constants are atomic.

Output

TRUE is displayed as *TRUE*, FALSE is displayed as *FALSE*, and UNKNOWN is shown as *UNKNOWN*.

Element Creation

The three constants can be types in as shown above. Additionally, many MuPAD functions returns Boolean values, the most generic/prominent two being bool and is.

boolifis

DOM_COMPLEX

Purpose

(Simple) Complex Numbers

Description

`DOM_COMPLEX` is the type of complex numbers with integer, rational, or floating-point components.

Complex numbers of type `DOM_COMPLEX` have two operands, their real and imaginary part. These are objects of type DOM_FLOAT, DOM_INT, or DOM_RAT. Complex numbers with other components (such as sqrt(2)+I*PI$\sqrt{2} + i\,\pi$) are not of domain type `DOM_COMPLEX`, but DOM_EXPR.

Function Calls

Calling a complex number as a function returns that number unchanged. The arguments of the call are *not* evaluated.

Operations

Most MuPAD functions operate on complex numbers. Use Re and Im to access the real and imaginary part, respectively.

Operands

Every object of type `DOM_COMPLEX` has two operands, the real and the imaginary part.

Output

Objects of type `DOM_COMPLEX` are essentially written as expressions in rectangular form. The imaginary unit is displayed as *I*.

Element Creation

Complex numbers can be constructed by typing in the corresponding expression, such as `3+4*I`. The keyword for typing the imaginary unit *I* is `I` (a capital letter i).

DOM_FLOATDOM_INTDOM_RAT

DOM_DOMAIN

Purpose

Data type of data types

Description

`DOM_DOMAIN` is the data type of datatypes.

Each MuPAD object has a unique data type. Since a data type is a MuPAD object, too, it must itself have a data type; the data type comprising all data types (including itself) is `DOM_DOMAIN`.

There are two kinds of elements of `DOM_DOMAIN`: data types of the kernel, and data types defined in the library or by the user (*domains*). Objects that have a data type of the latter kind are called *domain elements*.

A data type has the same internal structure as a table; its entries are called slots. One particular slot is the *key*; no two different data types can have the same key. Most of the other slots determine how arguments of that data type are handled by functions.

Once a user-defined domain has been constructed, it cannot be destroyed.

Examples

Example 1

Our first example stems from ethnology: some languages in Polynesia do not have words for numbers greater than three; every integer greater than three is denoted by the word “many”. Hence two plus two does not equal four but “many”. We are going to implement a domain for this kind of integers; in other words, we are going to implement a data type for the finite set {1, 2, 3, *many*}.

```
S := newDomain("Polynesian integer")‘Polynesian integer‘
```

```
Polynesian integer
```

At this point, we have defined a new data type: a MuPAD object can be a Polynesian integer now. No operations are available yet; the domain consists of its key only:

```
op(S)"key" = "Polynesian integer"
```

"key" = "Polynesian integer"

Even though there are no methods for input and output of domain elements yet, Polynesian integers can be entered and displayed right now. You have to use the function new for defining domain elements:
x := new(S, 5)new(‘Polynesian integer‘, 5)

new(Polynesian integer, 5)

Now, `x` is a Polynesian integer:
type(x)‘Polynesian integer‘

Polynesian integer

Of course, MuPAD cannot know what meaning a Polynesian integer has and what its internal structure should be. The arguments of the call to the function new are just stored as the zeroth, first, etc. operand of the domain element, without checking them. You may call new with as many arguments as you want:
new(S, 1, 2, 3, 4); op(%)new(‘Polynesian integer‘, 1, 2, 3, 4)

new(Polynesian integer, 1, 2, 3, 4)

1, 2, 3, 4

1, 2, 3, 4

new cannot know that Polynesian integers should have exactly one operand and that we want `5` to be replaced by `many`. To achieve this, we implement our own method `"new"`; this also allows us to check the argument. We have one more problem: domain methods should refer to the domain; but they should not depend on the fact that the domain

is currently stored in `S`. For this purpose, MuPAD has a special local variable `dom` that always refers to the domain a procedure belongs to:
S::new := proc(i : Type::PosInt) begin if args(0) <> 1 then error("There must be exactly one argument") end_if; if i > 3 then new(dom, hold(many)) else new(dom, i) end_if end_proc:

A function call to the domain such as `S(5)` now implicitly calls the `"new"` method:
S(5)new('Polynesian integer', many)

new(Polynesian integer, many)

S("nonsense") Error: The type of argument number 1 must be 'Type::PosInt'. The object '"nonsense"' is incorrect. Evaluating: S::new

In the next step, we define our own output method. A Polynesian integer `i`, say, shall not be printed as `new(Polynesian integer, i)`, only its internal value `1`, `2`, `3`, or `many` shall appear on the screen. Note that this value is the first operand of the data structure:
S::print := proc(x) begin op(x, 1) end_proc: S(1), S(2), S(3), S(4), S(5)1, 2, 3, many, many

1, 2, 3, many, many

By now, the input and output of elements of `S` have been defined. It remains to define how the functions and operators of MuPAD should react to Polynesian integers. This is done by *overloading* them. However, it is not necessary to overload each of the thousands of functions of MuPAD; for some of them, the default behavior is acceptable. For example, expression manipulation functions leave domain elements unaltered:
x := S(5): expand(x), simplify(x), combine(x); delete x:many, many, many

many, many, many

Arithmetical operations handle domain elements like identifiers; they automatically apply the associative and commutative law for addition and multiplication:
(S(3) + S(2)) + S(4)2 + 3 + many

```
2 + 3 + many
```

In our case, this is not what we want. So we have to overload the operator +. Operators are overloaded by overloading the corresponding "underline-functions"; hence, we have to write a method `"_plus"`:
S::_plus := proc() local argv; begin argv := map([args()], op, 1); if has(argv, hold(many)) then new(dom, hold(many)) else dom(_plus(op(argv))) end_if end_proc:

Now, the sum of Polynesian integers calls this slot:
S(1) + S(2), S(2) + S(3) + S(7)3, many

```
3, many
```

Deleting the identifier `S` does not destroy our domain. It can still be reconstructed using newDomain.
delete S: op(newDomain("Polynesian integer"))"key" = "Polynesian integer", "new" = 'proc S::new(i) ... end', "print" = 'proc S::print(x) ... end', "_plus" = 'proc S::_plus() ... end'

```
"key" = "Polynesian integer", "new" = proc S::new(i) ... end, "print"
```

Example 2

We could now give a similar example for more advanced Polynesian mathematics with numbers up to ten, say. This leads to the question whether it is necessary to enter all the code again and again whenever we decide to count a bit farther. It is not; this is one of the advantages

of *domain constructors*. A domain constructor may be regarded as a function that returns a domain depending on some input parameters. It has several additional features. Firstly, the additional keywords `category` and `axiom` are available for specifying the mathematical structure of the domain; in our case, we have the structure of a commutative semigroup where different domain elements have different mathematical meanings (we call this a domain with a canonical representation). Secondly, an initialization part may be defined that is executed exactly once for every domain returned by the constructor; it should at least check the parameters passed to the constructor. Each domain created in such a way may inherit methods from other domains, and it must at least inherit the methods of Dom::BaseDomain.
domain CountingUpTo(n : Type::PosInt) inherits Dom::BaseDomain; category Cat::AbelianSemiGroup; axiom Ax::canonicalRep; new := proc(x : Type::PosInt) begin if args(0) <> 1 then error("There must be exactly one argument") end_if; if x > n then new(dom, hold(many)) else new(dom, x) end_if end_proc; print := proc(x) begin op(x, 1) end_proc; _plus := proc() local argv; begin argv:= map([args()], op, 1); if has(argv, hold(many)) then new(dom, hold(many)) else dom(_plus(op(argv))) end_if end_proc; // initialization part begin if args(0) <> 1 then error("Wrong number of arguments") end_if; end:

Now, `CountingUpTo` is a domain constructor:
type(CountingUpTo)DomainConstructor

DomainConstructor

We have defined the domain constructor `CountingUpTo`, but we have not created a domain yet. This is done by calling the constructor:
CountingUpToNine := CountingUpTo(9); CountingUpToTen := CountingUpTo(10)CountingUpTo(9)

CountingUpTo(9)

CountingUpTo(10)

CountingUpTo(10)

We are now able to create, output, and manipulate domain elements as in the previous example:
x := CountingUpToNine(3): y := CountingUpToNine(7): x, x + x, y, x + y, y + y3, 6, 7, many, many

3, 6, 7, many, many

x := CountingUpToTen(3): y := CountingUpToTen(7): x, x + x, y, x + y, y + y3, 6, 7, 10, many

3, 6, 7, 10, many

delete CountingUpToNine, CountingUpToTen, CountingUpTo, x, y:

No domain constructor with the same name may be used again during the same session.

Example 3

Suppose that your domain does not really depend on a parameter, but that you need some of the other features of domain constructors. Then you may define a domain constructor `dc`, say, that is called without parameters. From such a domain constructor, you can construct exactly one domain `dc()`. Instead of defining the constructor via `domain dc() ... end` first and then using `d := dc()` to construct the domain `d`, say, you may directly enter `domain d ... end`, thereby saving some work.

Continuing the previous examples, suppose that we want to count up to three, knowing that we never want to count farther. However, we want to declare our domain to be an Abelian semigroup with a canonical representation of the elements. This is not possible with a construction of the domain using newDomain as in “Example 1” on page 6-6: we have to use the keyword domain. You will notice at once that the following source code is almost identical to the one in the previous example—we just removed the dependence on the parameter `n`.

domain CountingUpToThree inherits Dom::BaseDomain; category Cat::AbelianSemiGroup; axiom Ax::canonicalRep; new := proc(x : Type::PosInt) begin if args(0) <> 1 then error("There must be exactly one argument") end_if; if x > 3 then new(dom, hold(many)) else new(dom, x) end_if end_proc; print := proc(x) begin op(x, 1) end_proc; _plus := proc() local argv; begin argv:= map([args()], op, 1); if has(argv, hold(many)) then new(dom, hold(many)) else dom(_plus(op(argv))) end_if end_proc; end:

Now, `CountingUpToThree` is a domain and not a domain contructor:
type(CountingUpToThree)DOM_DOMAIN

DOM_DOMAIN

You may use this domain in the same way as `CountingUpTo(3)` in "Example 2" on page 6-9.

Function Calls

When called as a function, the data type creates a new object of this data type out of the arguments of the call. E.g., the call `DOM_LIST(1, 2, x)` generates the list `[1, 2, x]` of domain type DOM_LIST (although, in this case, you probably prefer to type in `[1, 2, x]` directly which results in the same object). It depends on the particular type which arguments are admitted here.

In the case of a domain, the `"new"` method of that domain is called.

Operations

You can obtain the slots of a domain using slot. The function slot can also be used on the left hand side of an assignment to define new slots, or to re-define existing slots. Use delete to delete slots.

Operands

A data type consists of an arbitrary number of equations (objects of type `"equal"`). If `a = b` is among these equations, we say that the *slot*`a` of the data type equals `b`. By convention, `a` is usually a string. Each domain has at least one slot indexed by `"key"`.

Element Creation

The names of the data types provided by the MuPAD kernel are of the form `DOM_XXX`, such us DOM_ARRAY, DOM_HFARRAY, DOM_IDENT, DOM_INT, DOM_LIST, DOM_TABLE etc.

You can create further data types using the function newDomain (cf. “Example 1” on page 6-6) or via the keyword domain (cf. “Example 3” on page 6-11).

You can also create new data types by calling a *domain constructor*. Various pre-defined domain constructors can be found in the library Dom. You can also define your own domain constructors using the keyword domain. Cf. “Example 2” on page 6-9.

The domain type (data type) of any MuPAD object can be queried by the function domtype.

Algorithms

Only one domain with a given key may exist. If it is stored in two variables `S` and `T`, say, assigning or deleting a slot `slot(S, a)` implicitly also changes `slot(T, a)` (reference effect). This also holds if `a = "key"`.

Note You get no warning even if `T` is protected.

DOM_EXEC

Purpose

Kernel functions

Description

Objects of type `DOM_EXEC` represent kernel functions implemented in C++.

Unlike functions defined at the library level (which are stored in objects of type DOM_PROC), functions defined in C++ in the MuPAD kernel are represented by objects of type `DOM_EXEC`.

Users normally need not care about `DOM_EXEC`s except for the cases where explicitly testing the domtype of arguments; in those cases, `DOM_EXEC` should often be treated identically to DOM_PROC.

Most kernel functions are actually stored inside function environments of type DOM_FUNC_ENV, and therefore, you can see `DOM_EXEC` only when explicitly accessing the first or second operand of those function environments.

Function Calls

An object of type `DOM_EXEC` essentially represents a function; using it in this way calls the corresponding function.

Operands

The operands of a `DOM_EXEC` are used internally, may change at any time and remain undocumented.

See Also

DOM_FUNC_ENVDOM_PROC

DOM_EXPR

Purpose

Type of “general expressions”

Description

`DOM_EXPR` is the data type of symbolic function calls. This includes expressions such as $a + b$ which is internally stored as `_plus(a, b)`.

In MuPAD, non-atomic symbolic expressions which are not elements of special domains have type `DOM_EXPR`.

Objects of type `DOM_EXPR` have a 0th operand which contains the functor (the function symbol, the f in $f(x)$). This operand is not counted in the result of nops. The subsequent operands can be of arbitrary type (although most functions will limit the number and type of operands when evaluated).

The 0th operand of a `DOM_EXPR` will be a procedure or function environment only in exceptional circumstances. In usual circumstances, expressions only have expressions, domain elements, or identifiers as their 0th operands.

Examples

Example 1

Function calls are of type `DOM_EXPR`:
domtype(sin(x))DOM_EXPR

DOM_EXPR

The 0th operand of a function call is the function symbol:
op(sin(x), 0)sin

sin

This operand is taken into account neither by nops nor by op if called with one argument:
nops(sin(x)), op(sin(x))1, x

```
1, x
```

Function Calls

The effect of using an expression of type `DOM_EXPR` as a function to call depends on the 0th operand of the expression. For many system functions, the result is that of using all operands of the expression as functions, passing the *unevaluated* arguments. (These functions may in turn evaluate their arguments.)

Operations

Most MuPAD functions (documented as accepting "arithmetical expressions") are built to work on elements of type `DOM_EXPR`.

Often, the operands of an expression will be expressions themselves. This creates a so-called "expression tree" which can be visualized using prog::exprtree.

Operands

All expressions are internally represented as function calls. The 0th operand is the function symbol of this call.

Evaluation

Evaluating an expression results in calling the 0th operand as a function. For library functions without option hold, the operands are evaluated first.

DOM_BOOLDOM_FLOATDOM_IDENTDOM_INTDOM_INTERVALDOM_LISTDOM_

DOM_FLOAT

Purpose

Real Floating Point Numbers

Description

`DOM_FLOAT` is the type of (arbitrary precision) real floating-point numbers.

Apart from exact symbolic calculations, MuPAD can also compute numerical approximations with arbitrary precision.

MuPAD uses the values `RD_INF` and `RD_NINF` for real positive and negative infinities in floating-point intervals.

MuPAD uses the value `RD_NAN` to indicate undefined values in floating-point intervals. If you use typeset mode, MuPAD displays this value as RD_NANNaN in output regions.

Function Calls

Calling a floating-point number as a function returns the number unchanged. The arguments of the call are *not* evaluated.

Operations

Just about any arithmetical operation can be performed with floating-point numbers.

Operands

`DOM_FLOAT`s are atomic.

Output

The output format of `DOM_FLOAT` depends on the setting of Pref::floatFormat and is documented there.

Element Creation

Floating point numbers are typed in with an optional sign (an arbitrary number of `+` and `-` signs), an optional integer part (consisting of digits), a decimal point (irrespective of locale settings of the operating system, MuPAD always expects a decimal point), a fractional part (one or more decimal digits) and optionally a decimal shift, written as the letter `e` followed by an optionally signed integer.

The decimal shift is interpreted as a power of ten, i.e., `6.022e23` is the Avogadro number 6.02210^{23}.

Additionally, the function float and most calls to functions of the `numeric` library create floating-point numbers as well.

DOM_INTERVALDOM_RATDOM_COMPLEXDIGITSfloat

DOM_FUNC_ENV

Purpose

Data type of function environments

Description

`DOM_FUNC_ENV` is the data type of function environments.

MuPAD uses function environments (domain type `DOM_FUNC_ENV`) to integrate functions into the system. All MuPAD library functions and most kernel functions are implemented as function environments.

A function environment stores special function attributes (slots) in an internal table. When an overloadable system function, such as diff, expand, or float, encounters an object of type `DOM_FUNC_ENV`, it searches the function environment for a corresponding slot.

Operands

A function environment consists of three operands. The first operand is a procedure that computes the return value of a function call. The second operand is a procedure for printing a symbolic function call on the screen. The third operand is a table that specifies how the system functions handle symbolic function calls.

Element Creation

funcenv and fp::unapply (or its equivalent -->) create function environments of type `DOM_FUNC_ENV`.

See Also

DOM_PROCDOM_EXECfuncenvfp::unapply

DOM_HFARRAY

Purpose

Hardware floating-point arrays

Description

`DOM_HFARRAY` is a multidimensional container type, storing hardware floating-point numbers at integer indices.

Unlike generic arrays, objects of type `DOM_HFARRAY` are containers of hardware floating-point numbers, real or complex. They take up considerably less space than the corresponding arrays of software floats (DOM_FLOAT) would, but the range of hardware floating-point numbers is much more limited.

Function Calls

Using an hf-array as the symbol of a function call returns that hf-array unchanged. The arguments of the call are not evaluated.

Operations

Read and write access to an hf-array is performed using indexed access, as in `A[1]`, which automatically converts between hardware and software floats. Trying to write a value which cannot be converted into a hardware float into an hf-array causes an error to be raised, as does accessing an element out of bounds.

The function map applies some function or transformation to each element of an hf-array, returning an hf-array of the same format as its input, with the results of the calls as its entries. If a result cannot be converted to a hardware float, an error is raised.

If `A` is an hf-array, `nops(A)` returns the number of elements in `A`.

Basic arithmetic works on hf-arrays: Addition and subtraction of hf-arrays of identical format combines the containers element-wise, addition and subtraction of constants is applied to the main diagonal. For two-dimensional hf-arrays, multiplication performs matrix multiplication. Division is possible for completeness, but should be avoided, as it numerically inverts the dividend first, and this is hardly ever the algorithmically "right" way to handle a numerical problem.

Operands

If `A` is an hf-array, the 0th operand of `A`, `op(A, 0)`, will be the sequence starting with the number of dimensions (an integer n) followed by n

ranges of integers, which denote the acceptable ranges of indices for each dimension, including both numbers listed in the range.

For $1 \leq i \leq nops(A)$, the ith operand of `A` is the ith entry of `A`, in the lexicographic order of indices.

Output

One-dimensional hf-arrays are displayed as row vectors, two-dimensional hf-arrays as matrices. Higher-dimensional hf-arrays are written in functional form, writing the entries as a flat list, and do not have a typesetting version. This also causes typesetting to be disabled for any surrounding expression in the same output.

Element Creation

The primary way of creating hf-arrays is the function hfarray. Other important functions (optionally) returning hardware float arrays include several functions of the `numeric` library and import::readbitmap.

DOM_ARRAYDOM_LISTDOM_TABLEhfarrayfloat

DOM_IDENT

Purpose

Symbolic Identifiers

Description

`DOM_IDENT` is the data type of symbolic identifiers, used for example for indeterminates.

To perform symbolic computations, it is often necessary to represent indeterminates, which may or may not carry assumptions. These indeterminates (which in some contexts may also be bound identifers and which may also be assigned specific values) are called “identifiers” in MuPAD and have the domain type `DOM_IDENT`.

Function Calls

Calling a `DOM_IDENT` as a function creates a DOM_EXPR. If the identifier has a value, the evaluation of that DOM_EXPR may result in an arbitrary value.

Operations

Identifiers are valid arithmetical expressions, so most MuPAD functions happily accept identifiers.

To get and analyze the name of an identifier, you can use `coerce(identifier, DOM_STRING )` and look at the resulting string. (The call `"".identifier` returns the same string and is shorter to type.)

Operands

Identifiers are atomic.

Output

Identifiers are displayed with their names, with the following special cases in typesetting:

- The backticks used for input are not typeset. They are present with typesetting switched off such as when using print without the `Typeset` option.
- Underscores (_) in the middle of identifiers cause subscripting: `x_2` is displayed as x_2.
- Certain constructs of the form `` `&...;` `` in identifiers are replaced by special typeset characters. For example, `` `&alpha;&rarr;` `` is displayed as ‘α→’$\vec{\alpha}$. To generate these identifiers,

we suggest using the Symbol library, which would use `Symbol::accentRightArrow(Symbol::alpha)` for the example above.

Element Creation

A sequence of characters, underscores and digits which does not start with a digit is considered an identifier. Examples: `x`, `x0`, `t_0`.

Additionally, an arbitrary string of characters enclosed in 'backticks' `` is also an identifier. Examples: `` `x+y` ``, `` `a plus 1` ``. If the string of characters between the back ticks is a valid identifier already, this input form creates the same identifier as the one without the backticks.

DOM_EXPRDOM_VARgenidentindets

DOM_INT

Purpose

Integers

Description

`DOM_INT` is the domain of integer constants such as 42 or -56412564156717653. The size of integers is limited to $2^{2^{21}} - 1$ in absolute value.

Function Calls

Calling an integer as a function returns that integer unchanged. The arguments are *not* evaluated.

Operations

Integers are arithmetical expressions and thus accepted by almost every MuPAD function.

To represent an integer in a basis different from 10, please use int2text.

Operands

Integers are atomic.

Element Creation

Integers are given by an optional sign (an arbitrarily long string of + and - signs) and a sequence of decimal digits. Apart from this direct input method, many MuPAD commands such as text2int return integers.

See Also

DOM_FLOATDOM_RAT

DOM_INTERVAL

Purpose

Floating point intervals

Description

Object of type `DOM_INTERVAL` represents an interval of complex numbers. Either border may be *infinity* or - ∞. The borders are represented by floating point numbers (DOM_FLOAT).

Objects of type `DOM_INTERVAL` represent numerical enclosures of rectangles in the complex plane or finite unions thereof. Numerical enclosures of real intervals are an important special case.

Because an element of type `DOM_INTERVAL` contains floating-point numbers of type DOM_FLOAT, its exact value depends on the value of the environment variable DIGITS at the time of creation.

The result of all arithmetical operations on elements of type `DOM_INTERVAL` is rounded outwards, that is, the resulting (union of) rectangle(s) is *guaranteed* to contain the exact result. If the result interval is purely real, the lower bound of the result is guaranteed to be no larger than the exact value of the exact result, while the upper value of the result is guaranteed to be no smaller than the exact value. The exact values may not be representable as floating-point numbers. In this case, the result of a single operation such as + or * is the smallest representable interval containing the exact result. In other words, operations on `DOM_INTERVAL` are locally optimal.

Note that the representation of an element of `DOM_INTERVAL` on the screen is generated with outward rounding, too. This may lead to "apparent overestimation," as you can see in "Example 1" on page 6-25.

For generating matrix or polynomial rings over floating-point intervals, use the façade domain Dom::FloatIV.

Examples

Example 1

An interval of type `DOM_INTERVAL` can only hold floating-point numbers, which are internally stored as binary numbers. For this reason, it cannot hold symbolic expressions as its operands:

```
iv := hull(PI)hull(3.141592653, 3.141592654)
```

3.141592653 ... 3.141592654

This intervals certainly does contain π. However, the value printed on the screen does not accurately describe the interval generated, as you can see when you print the same interval with a larger value of DIGITS: DIGITS := 15: iv; delete DIGITS:hull(3.14159265358979, 3.1415926535898)

3.14159265358979 ... 3.1415926535898

In the first output, it looked as if the difference between the two borders (the width of the interval) was 10^{-8}, while in the latter output we can see that it is at most 10^{-13}. Actually, the difference is even smaller: op(iv,2) - op(iv,1)6.938893904e-18

$6.938893904\ 10^{-18}$

This rounding does not take place for symbolic values which can be represented exactly in both the internal (binary) and the on-screen (decimal) format:
iv := hull(1); op(iv,2) - op(iv,1)hull(1.0, 1.0)

1.0 ... 1.0
0.0

0.0

However, floating-point values in the input are assumed to be approximations up to the current computing precision:
iv := hull(1.0); op(iv,2) - op(iv,1)hull(0.9999999999, 1.000000001)

$0.9999999999 \ldots 1.000000001$

5.204170428e-18

$5.204170428\ 10^{-18}$

Example 2

If you convert infinity or `-infinity` into an interval of type `DOM_INTERVAL`, the resulting interval will contain the corresponding floating-point infinity, which are displayed as `RD_INF` or `RD_NINF`, respectively:

hull(infinity), hull(-infinity)hull(2.098578716e323228496, RD_INF), hull(RD_NINF, -2.098578716e323228496)

$2.098578716\ 10^{323228496} \ldots \mathrm{RD\_INF}, \mathrm{RD\_NINF} \ldots -2.098578716\ 10^{}$

Since the range of floating-point numbers is limited, also conversion of finite values may generate floating-point infinities. The exact limit of floating-point numbers may change from one MuPAD version to the next. Currently, the following command exceeds the representable range::

hull(exp(10^9))hull(2.098578716e323228496, RD_INF)

$2.098578716\ 10^{323228496} \ldots \mathrm{RD\_INF}$

As for calculating with intervals with infinities as their borders, note that any multiplication where one factor is exactly zero and the other factor contains either infinity results in the interval encompassing the whole real axis:

(0...0) * (1e30...infinity)hull(RD_NINF, RD_INF)

$\mathrm{RD\_NINF} \ldots \mathrm{RD\_INF}$

Example 3

Objects of type DOM_INTERVAL represent rectangular subsets of the complex plane with the sides parallel to the coordinate axes or unions of such rectangles. In the following example, the exact result would be a rotated rectangle. Interval arithmetics returns the smallest non-rotated rectangle enclosing the precise result:
(1...2+I)*(1+I)hull(0.0, 2.0) + hull(1.0, 3.0)*I

$$0.0 \ldots 2.0 + 1.0 \ldots 3.0\,i$$

Example 4

When computing with floating-point numbers, you can easily run into cancellation and round-off errors without noticing:
(1+1e-18) - 1.00.0

$$0.0$$

sin(1e42)0.4587729978

$$0.4587729978$$

The fundamental problem of numerical computations is that there is no indication to these errors. Of course, you can get around most problems of this type by increasing the number of significant digits, if you know that problems are lurking:
DIGITS:=50: (1+1e-18) - 1.0,
sin(1e42)0.00000000000000000099999999999999999999999999999999999999943374
-0.792997954776061445870308228307543879958514076277 68

$$9.9999999999999999999999999999999999999994337442995\ 10^{-19}$$

$$-0.792997954776061445870308228307543879958514076277 68$$

Interval calculations, amongst other things, provide a way to be notified of cancellation since the result of an operation over DOM_INTERVAL is certain to contain the exact result:
DIGITS:=10: (1+1e-18) - hull(1.0)hull(-5.204170428e-18, 5.204170428e-18)

$$-5.204170428\,10^{-18} \ldots 5.204170428\,10^{-18}$$

sin(hull(1e42))hull(-1.0, 1.0)

$$-1.0 \ldots 1.0$$

DIGITS:=50:
sin(hull(1e42))hull(-0.79299795477606165563526882849270558686988301102149, -0.79299795477606111453539571969660597818990980366 84)

$$-0.79299795477606165563526882849270558686988301102149$$

So, in the latter case we know that the first 17 digits are correct and that the 18th digit is 3, 4, or 5.

Function Calls

The result of a call to an interval is the interval itself, regardless of the arguments. The arguments are not evaluated.

Operations

You can access the borders of an interval using op. See below for the details.

Intervals can be viewed as sets, and the corresponding functions union, intersect, and minus work on intervals, too.

As of version 2.5, MuPAD implements the following operations on elements of type DOM_INTERVAL:

- The basic arithmetical operations: +, -, *, /, ^, sqrt.

- The trigonometric functions and their inverses: sin, cos, tan, sec, csc, cot, arcsin, arccos, arctan, arccsc, arccot.
- The exponential function and the logarithm.
- The hyperbolic functions and their inverses: sinh, cosh, tanh, sech, csch, coth, arcsinh, arccosh, arctanh, arccsch, arccoth.
- The functions Re, Im (real- and imaginary part), abs, sign and arg (the 'argument' = polar angle of a complex number).
- For real intervals, gamma and beta.
- ceil, floor, trunc, round.

For legal combinations of arguments, all computations are carried out in interval arithmetics, see "Example 4" on page 6-28.

Operands

The operands of an interval depend on its value:

- An interval of type `DOM_INTERVAL` may be a union of rectangles in the complex plane. In this case, the 0th operand is the identifier union, while the remaining operands are the corresponding rectangles, which are of type `DOM_INTERVAL`.
- Rectangles with non-zero imaginary part, which are not unions, have two operands of type `DOM_INTERVAL`: Their real and imaginary parts, both of which are real intervals.
- Real intervals, i.e., non-union rectangles with vanishing imaginary part, have two operands, their left and right borders.

Output

A real interval is displayed in the form "left `...` right", where "left" and "right" are the borders of the interval, printed as floating-point numbers.

A complex interval is displayed as "(real part) + (imaginary part) * I", with the real and imaginary part displayed as real intervals.

A union of rectangles is displayed as "interval union interval", with the intervals inside written as specified above.

The output of an interval depends on the environment variable DIGITS as well as on the preference settings Pref::floatFormat and Pref::trailingZeroes.

Note that the borders are rounded outwards for printing. “Example 1” on page 6-25 shows how this effects the output.

Element Creation

Elements of type `DOM_INTERVAL` can be constructed in the following ways:

- With the function hull:
  DIGITS := 10:hull(PI, -3, 1/2), hull(1/3)hull(-3.0, 3.141592654), hull(0.3333333333, 0.3333333334)

$$-3.0 \ldots 3.141592654,\ 0.3333333333 \ldots 0.3333333334$$

- With the operator ... (which in turn calls hull):
  1 ... 4+Ihull(1.0, 4.0) + hull(0.0, 1.0)*I

$$1.0 \ldots 4.0 + 0.0 \ldots 1.0\,i$$

- The function interval creates elements of type `DOM_INTERVAL` as well, but may return expressions:
  interval(x^2+sin(1))x^2 + hull(0.8414709848, 0.8414709849)

$$x^2 + 0.8414709848 \ldots 0.8414709849$$

Note that floating-point values in the input of hull or interval are considered to be approximations, even if the value displayed in the decimal system can be represented exactly in the internal binary format. This is because hull cannot decide whether, for example, 0.25 has actually been typed in as such or if it should have been some 0.25 + . If you want zero-width intervals, use a rational number as input which can be represented exactly in binary:

Algorithms

Intervals of type `DOM_INTERVAL` are always interpreted as *closed* intervals, i.e., the endpoints belong to the set. It is reasonable not to have open intervals included, since most operations will enlarge the resulting interval anyway (although only marginally so).

DOM_LIST

Purpose

Lists of Objects

Description

Lists (of domain type `DOM_LIST`) are ordered collections of an arbitrary number of arbitrary MuPAD objects, except for sequences and the null object.

In MuPAD, the mathematical construct of an n-tuple is implemented as the data type `DOM_LIST`. Lists consist of an arbitrary (finite) number of arbitrary objects, with the exception of expression sequences, which are split into their operands when placed into a list.

Unlike sets, lists can contain multiple copies of the same element. The order of elements in a list is preserved.

Lists can be empty.

Examples

Example 1

To create a list for our first example, we use the operator $:
L := [x_.i $ i=1..10][x_1, x_2, x_3, x_4, x_5, x_6, x_7, x_8, x_9, x_10]

$$[x_1, x_2, x_3, x_4, x_5, x_6, x_7, x_8, x_9, x_10]$$

This list contains 10 elements:
nops(L)10

$$10$$

The fifth element of the list is x_5 and the list of elements from x_3 through x_6 can also be accessed very easily:
L[5], L[3..6]x_5, [x_3, x_4, x_5, x_6]

$$x_5, [x_3, x_4, x_5, x_6]$$

To change an element of the list, we use the indexed form on the left hand side of an assignment:
L[5] := 55

5

L[x_1, x_2, x_3, x_4, 5, x_6, x_7, x_8, x_9, x_10]

$[x_1, x_2, x_3, x_4, 5, x_6, x_7, x_8, x_9, x_10]$

Note that this assignment only changes `L`, not x_5:
x_5x_5

x_5

Likewise, we can change a sublist by assigning another list to it. This may change the length of the list:
L[3..6] := [1, 2][1, 2]

[1, 2]

nops(L), L8, [x_1, x_2, 1, 2, x_7, x_8, x_9, x_10]

8, $[x_1, x_2, 1, 2, x_7, x_8, x_9, x_10]$

Function Calls

Using a list as a function symbol creates the list obtained by using each list element as a function symbol for the operands used, i.e., `[f, g](x, y)` results in `[f(x, y), g(x, y)]`.

Operations

Assuming that `L` is a list, the number of elements in `L` can be determined by calling `nops(L)`.

Individual elements of the list are accessed in the form `L[1]`, `L[2]` etc. when counting from the beginning or `L[-1]`, `L[-2]` etc. when counting

from the end. Trying to access an element "outside" the list or `L[0]` raises an error.

Continuous sub-lists can be extracted by using a range in an indexed access: `L[2..4]` returns the list `[L[2], L[3], L[4]]`; `L[2..-2]` returns the list `L` without its first and last element.

Both forms of indexed access can also be used as the left hand side of an assignment, cf. "Example 1" on page 6-33.

Lists can be concatenated with the dot operator, as in `L1 . L2` or its functional form, _concat.

The function contains finds the first occurrence of a given MuPAD object in a list. select and split can be used to extract those elements from a list fulfilling an arbitrary predicate.

Lists can be sorted with sort or prog::sort.

The function map applies a function to all elements of a list, returning the list of results. To combine two lists element-wise with some function, use zip.

Assigning a list to a list of identifiers is possible and results in a simultaneous assignment, cf. ?_assign.

Operands

The operands of a list are its elements.

Element Creation

The most direct way of creating a list is to place a sequence of MuPAD objects (separated by commas) between rectangular brackets, as in `[1, 2, 3]`.

See Also

DOM_ARRAYDOM_HFARRAYDOM_SET

DOM_PROC

Purpose

Data type of procedures

Description

`DOM_PROC` is the data type of procedures.

MuPAD procedures belong to the kernel domain `DOM_PROC`.

You can enclose procedures of type `DOM_PROC` into function environments of type DOM_FUNC_ENV.

Element Creation

proc and its equivalent `->` create procedures of type `DOM_PROC`.

See Also

DOM_PROC_ENVprocfuncenv

DOM_PROC_ENV

Purpose

Data type of procedure environments

Description

Procedure environments are mostly ephemeral objects and are only rarely seen by the user (and even more rarely useful to examine). A procedure environment represents a procedure that is currently being executed: formal parameters and local variables have values.

Procedure environments do rarely become visible, and you do not need to manipulate them directly. They serve only one purpose: if a procedure is generated inside another procedure, variable names in the body of the inner procedure that are not declared local there refer to names in the outer procedure, provided they are declared local in the outer procedure. (See the Programming Manual for more information on the scoping rules for MuPAD.) Consequently, the inner procedure must contain information on the current values of local variables of the outer procedure. Hence, the status of the outer procedure is encoded into an object of type `DOM_PROC_ENV`, and that object is stored in the returned procedure as its twelfth operand.

You never need to generate objects of this type. There are no operations available.

Examples

Example 1

The only occasion on which you should come across a procedure environment is the following: an outer procedure returns an inner procedure depending on formal parameters or local variables of the outer procedure:
outer := proc(x) option escape; begin /* inner procedure to return : */ y -> x + y end_proc: add5 := outer(5)y -> x + y

$$y \to x + y$$

In spite of the (slightly confusing) output, `x` has a special meaning here: it points to the parameter `x` of `outer`. That parameter currently has the value `5` and won't be changed any more. To be able to access that

value, the particular instance of `outer` in the status of being executed has to be stored in `add5`:
expr2text(op(add5, 12))"DOM_PROC_ENV(0x1f9d904)"

```
"DOM_PROC_ENV(0x1f9d904)"
```

Operands

The number of operands of a procedure environment depends on the number of local and saved variables of the outer procedure. Details about the operands remain undocumented.

Algorithms

The integers appearing in the output of objects of type `DOM_PROC_ENV` have no mathematical meaning; they denote positions in memory.

DOM_RAT

Purpose

Rational Numbers

Description

`DOM_RAT` is the data type of rational numbers.

Examples

Example 1

The operands of a rational number are its numerator and denominator:
op(2/3)2, 3

$$2, 3$$

When substituting an operand, the resulting `DOM_RAT` is again normalized:
subsop(2/3, 2=6)1/3

$$\frac{1}{3}$$

Function Calls

Using a rational number as a function returns that number unchanged. The function arguments are *not* evaluated.

Operations

Rational numbers are arithmetical expressions and therefore valid inputs to most MuPAD functions.

The numerator and denominator of a rational number can be accessed using numer and denom or by using op directly.

Elements of `DOM_RAT` are always normalized, cf. “Example 1” on page 6-39.

Operands

A rational number has two operands, which are integers: Its numerator and its denominator.

Element Creation The division of two integers results in an integer or a rational number.

See Also DOM_COMPLEXDOM_INTDOM_FLOATDom::Rational

DOM_SET

Purpose

Sets of Objects

Description

Set of type `DOM_SET` can store an arbitrary finite number of arbitrary MuPAD objects, except for sequences and the null object.

In MuPAD, finite sets are implemented with the data type `DOM_SET`. Sets are unordered collections of arbitrary objects, with identical objects appearing only once. Sequences (objects separated by commas) are "flattened" when put into a set, i.e., instead of the sequence, its elements are placed into the set. The null object is treated as the empty sequence, i.e., it does not result in an element in the set.

Sets can be empty. The empty set is displayed as $\varnothing$.

Function Calls

Using a set as a function symbol creates the set obtained by using each element as a function symbol for the operands used, i.e., `{f, g}(x, y)` results in `{f(x, y), g(x, y)}`.

Operations

Assuming that S is a set, the number of elements in S can be obtained by calling `nops(S)`.

Individual elements of the set can be obtained in two subtly different ways:

1. Using an indexed access, as in `S[2]`, returns the n-th element of the set, counted in the order as the set appears on the screen. This is a potentially slow operation, since it requires determining that order for each access, i.e., sorting the set.

   Negative indices are accepted, counting from the end of the sequence of elements. Trying to access an element "outside" the set or `S[0]` raises an error.

2. Using op, as in `op(S, 2)`, returns the n-th element of the set, counted in the internal order. This is a fast operation ($O(n)$ to get the n-th element, irrespective of the size of S), but the internal order of two mathematically identical sets can be completely different and almost

any operation changing a set can completely change its internal order, so no assumptions should be made.

Both of these ways also accept ranges as indices. `S[2..4]` returns the set `{S[2], S[3], S[4]}`, while `op(S, 2..4)` returns the sequence `op(S, 2), op(S, 3), op(S, 4)`.

To iterate over all elements of a set in no particular order, using map or the $ operator is highly superior to using a for-loop with either of the above element access methods. If a for-loop is required, you should use the form `for s in S`, which has linear complexity as well.

The usual set operations are provided as infix operations: union, minus, intersect.

To change an element of a set, the preferred method is to remove it using minus and adding a new one using union. It is also possible to replace an element with subsop; replacing an element with `null()` deletes it from the set. (Note that subsop does not do a side-effect assignment.)

The function contains checks for occurrence of a given MuPAD object in a set; see also the in operator for the same purpose, but with different evaluation semantics. select and split can be used to extract those elements from a set fulfilling an arbitrary predicate.

To get a list of the elements of a set, use coerce. To get such a list with the elements ordered in the same way as printed on the screen, use `DOM_SET::sort(S)`.

Operands

The operands of a set are its elements, in the internal order. (See above for details.)

Output

Sets are ordered for the output.

Element Creation

The most direct way of creating a set is to place a sequence of MuPAD objects (separated by commas) between curly brackets, as in {1, 2, 3}.

See Also

DOM_LISTDom::ImageSetDom::Multiset

DOM_STRING

Purpose

Texts (character strings)

Description

Texts (which are not really “mathematical objects”, but useful to the programmer) in MuPAD are of domain type `DOM_STRING`.

MuPAD can manipulate texts (strings of characters). These are primarily used for output and data input.

Examples

Example 1

As far as op is concerned, a string cannot be dissected:
s := "this is a string": op(s, 1), op(s, 2)"this is a string", FAIL

"this is a string", FAIL

To access individual characters or substrings, use indexed access:
s[1], s[6..7]"t", "is"

"t", "is"

Assigning to a substring may change the length of a string:
s[6..7] := "changes"; s"changes"

"changes"
"this changes a string"

"this changes a string"

Function Calls

Using a string as a function returns the string unchanged. The arguments are *not* evaluated.

Operations

Strings can be concatenated using the dot operator or its functional equivalent, _concat.

The length of a string can be obtained using length.

Substrings and individual characters (which are strings of length 1) can be accessed using substring or indexed access, with indices starting at 1 and negative indices counting from the end of the string: `s[1]`, `s[3..-2]`. It is also possible to perform an indexed assignment to a string, cf. “Example 1” on page 6-43.

To convert a string into the MuPAD expression that would be obtained by using the string as an input, use text2expr. For simple MuPAD expressions, it is possible to get a string that evaluates to that expression using expr2text. Expressions that are not convertible in this way include all expressions containing local variables set with `option escape`. Also, expressions involving floating point numbers usually will change when being converted to strings and back.

Operands

Strings are atomic, i.e., they have exactly one operand, the string itself.

Output

The output form of strings is very similar to their input form. When typesetting, spaces at the beginning and the end of strings are ignored and multiple adjacent blanks as well as newlines are collapsed to a single space.

Element Creation

A string is created by enclosing characters in a pair of typewriter quotes: `"this is a string"`. The following special sequences are supported (but see below for the typeset output; these are useful only for non-typeset output):

- `"\n"` denotes an end-of-line character.
- `"\b"` is almost identical to `"\n"`, except that for “pretty-printing” it encodes the baseline of the current object.
- `"\t"` is a tabulator.
- `"\\"` encodes a backslash.

See the documentation of print for details.

DOM_VAR

Purpose

Local Variables in Procedures

Description

Local variables (variables in the programming sense, with “lexical scoping”) are of domain type `DOM_VAR`.

When writing MuPAD functions, often intermediate results need to be stored and retrieved. Like most programming languages, MuPAD offers “local variables” for this purpose. These local variables do not conflict with global identifiers of the same name nor with other local variables of the same name used at other places.

Local variables use “lexical scoping”, i.e., they can be used in all program code that is written inside the body of the procedure declaring the local variable. Note that returning anything with a reference to a local variable requires the use of `option escape` in the procedure definition.

Operations

Local variables can be assigned values and these values can later be retrieved.

Element Creation

Local variables are created by using either the special names `dom` or `procname` or one of the names declared with the keyword `local` inside a procedure definition.

Dom::AlgebraicExtension

Purpose

Simple algebraic field extensions

Syntax

Domain Creation

```
Dom::AlgebraicExtension(F, f)
Dom::AlgebraicExtension(F, f, x)
Dom::AlgebraicExtension(F, f1 = f2)
Dom::AlgebraicExtension(F, f1 = f2, x)
```

Element Creation

```
Dom::AlgebraicExtension(F,f)(g)
Dom::AlgebraicExtension(F, f)(rat)
```

Description

Domain Creation

For a given field *F* and a polynomial *f* *F[x]*, `Dom::AlgebraicExtension(F, f, x)` creates the residue class field *F[x]/<f>*.

`Dom::AlgebraicExtension(F, f1=f2, x)` does the same for $f = f_1 - f_2$.

`Dom::AlgebraicExtension(F, f, x)` creates the field *F[x]/<f>* of residue classes of polynomials modulo *f*. This field can also be written as *F[x]/<f>*, the field of residue classes of rational functions modulo *f*.

The parameter `x` may be omitted if `f` is a univariate polynomial or a polynomial expression that contains exactly one indeterminate; it is then taken to be the indeterminate occurring in `f`.

The field `F` must have normal representation.

`f` must not be a constant polynomial.

`f` must be irreducible; this is *not* checked.

`f` may be a polynomial over a coefficient ring different from `F`, or multivariate; however, it must be possible to convert it to a univariate polynomial over `F`. See “Example 2” on page 6-49.

Element Creation

`Dom::AlgebraicExtension(F, f)(g)` creates the residue class of `g` modulo `f`.

If `rat` has numerator and denominator `p` and `q`, respectively, then `Dom::AlgebraicExtension(F,f)(rat)` equals `Dom::AlgebraicExtension(F,f)(p)` divided by `Dom::AlgebraicExtension(F,f)(q)`.

Superdomain

Dom::BaseDomain

Axioms

If `F` has Ax::canonicalRep, then Ax::canonicalRep.

Categories

Cat::Field, Cat::Algebra`(F)`, Cat::VectorSpace`(F)`

If `F` is a Cat::DifferentialRing, then Cat::DifferentialRing.

If `F` is a Cat::PartialDifferentialRing, then Cat::PartialDifferentialRing.

Examples

Example 1

We adjoin a cubic root `alpha` of `2` to the rationals.
G := Dom::AlgebraicExtension(Dom::Rational, alpha^3 = 2)Dom::AlgebraicExtension(Dom::Rational, alpha^3 - 2 = 0, alpha)

$$\text{Dom::AlgebraicExtension}(\text{Dom::Rational}, \text{alpha}^3 - 2 = 0, \text{alpha})$$

The third power of a cubic root of `2` equals `2`, of course.
G(alpha)^32

$$2$$

The trace of α is zero:
G::conjTrace(G(alpha))0

$$0$$

You can also create random elements:
G::random() 2 - 814*alpha^2 - 65*alpha + 824

$$2 - 814\ \mathrm{alpha}^2 - 65\ \mathrm{alpha} + 824$$

Example 2

The ground field may be an algebraic extension itself. In this way, it is possible to construct a tower of fields. In the following example, an algebraic extension is defined using a primitive element `alpha`, and the primitive element `beta` of a further extension is defined in terms of `alpha`. In such cases, when a minimal equation contains more than one identifier, a third argument to `Dom::AlgebraicExtension` must be explicitly given.
F := Dom::AlgebraicExtension(Dom::Rational, alpha^2 = 2): G := Dom::AlgebraicExtension(F, bet^2 + bet = alpha, bet)Dom::AlgebraicExtension(Dom::AlgebraicExtension(Dom::Rational, alpha^2 - 2 = 0, alpha), bet^2 + bet - alpha = 0, bet)

$$\mathrm{Dom::AlgebraicExtension}(\mathrm{Dom::AlgebraicExtension}(\mathrm{Dom::Rational},$$

Example 3

We want to define an extension of the field of fractions of the ring of bivariate polynomials over the rationals.
P:= Dom::DistributedPolynomial([x, y], Dom::Rational): F:= Dom::Fraction(P): K:= Dom::AlgebraicExtension(F, alpha^2 = x, alpha)Dom::AlgebraicExtension(Dom::Fraction(Dom::DistributedPolynomial([x, y], Dom::Rational, LexOrder)), alpha^2 - x = 0, alpha)

Dom::AlgebraicExtension(Dom::Fraction(Dom::DistributedPolynomial(

Now K:=_outputSequence(Q,['sqrt(x)', 'y']): $K = Q[\sqrt{x}, y]$. Of course, the square root function has the usual derivative; note that 1/sqrt(x) $\frac{1}{\sqrt{x}}$ can be expressed as Symbol::alpha/x $\frac{\alpha}{x}$:

y], Dom::Rational, LexOrder)), $-x + \alpha^2 = 0$, alpha)

diff(K(alpha), x)alpha/(2*x)

$$\frac{\alpha}{2x}$$

On the other hand, the derivative of sqrt(x) $\sqrt{x}$ with respect to *y* is zero, of course:

diff(K(alpha), y)0

$$0$$

We must not use D here. This works only if we start our construction with a ring of univariate polynomials:

P:= Dom::DistributedPolynomial([x], Dom::Rational): F:= Dom::Fraction(P): K:= Dom::AlgebraicExtension(F, alpha^2 = x, alpha): D(K(alpha))alpha/(2*x)

$$\frac{\alpha}{2x}$$

Parameters

F

The ground field: a domain of category Cat::Field

f

f1

f2

Polynomials or polynomial expressions

x

Identifier

g

Element of the residue class to be defined: polynomial over `F` in the variable `x`, or any object convertible to such.

rat

Rational function that belongs to the residue class to be defined: expression whose numerator and denominator can be converted to polynomials over `F` in the variable `x`. The denominator must not be a multiple of `f`.

Entries

"zero"	the zero element of the field extension
"one"	the unit element of the field extension
"groundField"	the ground field of the extension
"minpoly"	the minimal polynomial `f`
"deg"	the degree of the extension, i.e., of `f`
"variable"	the unknown of the minimal polynomial `f`

"characteristic"	the characteristic, which always equals the characteristic of the ground field. This entry only exists if the characteristic of the ground field is known.
"degreeOverPrimeField"	the dimension of the field when viewed as a vector space over the prime field. This entry only exists if the ground field is a prime field, or its degree over its prime field is known.

Methods

Mathematical Methods

_plusSum of field elements

```
_plus(a,  )
```

This method overloads the function _plus of the system kernel.

_multProduct of field elements

```
_mult(a,  )
```

This method overloads the function _mult of the system kernel.

_powerRaise to the nth power

Inherited from Cat::Monoid.

_negateNegate a field element

```
_negate(a)
```

This method overloads the function _negate of the system kernel.

_subtractDifference of field elements

```
_subtract(a, b)
```

This method overloads the function _subtract of the system kernel.

equalTest for mathematical equality

Inherited from Dom::BaseDomain.

equivTest for equivalence

Inherited from Cat::BaseCategory.
iszeroTest whether a field element is zero.

```
iszero(a)
```

This method overloads the function iszero.
isoneTest if element is one

Inherited from Cat::Monoid.
isUnitTest if element is an unit

Inherited from Cat::Field.
intmultMultiply a field element by an integer

```
intmult(a, b)
```

This method is more efficient than `"_mult"` in this special case.
_invertInverse of a field element

```
_invert(a)
```

This method overloads the function _invert.
_divideExact division

Inherited from Cat::Field.
divideDivision with remainder

Inherited from Cat::Field.
quoReturn Euclidean quotient

Inherited from Cat::Field.
remReturn Euclidean remainder

Inherited from Cat::Field.
euclideanDegreeReturn Euclidean degree

Inherited from Cat::Field.
idealGeneratorGenerator of finitely generated ideal

Inherited from Cat::EuclideanDomain.
dividesTest if division is exact

Inherited from Cat::Field.
gcdGcd of field elements

```
gcd(a,  )
```

This method overloads the function gcd.
gcdexExtended greatest common divisor

Inherited from Cat::EuclideanDomain.
associatesTest for associate elements

Inherited from Cat::Field.
unitNormalUnit normal form

Inherited from Cat::Field.
unitNormalRepUnit normal representation

Inherited from Cat::Field.
lcmLeast common multiple

Inherited from Cat::GcdDomain.
sqrfreeSquare-free factorization

Inherited from Cat::Field.
irreducibleTest if element is irreducible

Inherited from Cat::Field.
factorUnique factorization

Inherited from Cat::Field.
conjNormNorm of an element

```
conjNorm(a)
```
conjTraceTrace of an element

```
conjTrace(a)
```
minimalPolynomialMinimal polynomial of an element

```
minimalPolynomial(a)
```
DDifferential operator

```
D(a)
```

This method overloads the function D.

This method must not be called for inseparable extensions; note that MuPAD cannot check whether an extension is separable.

See “Example 3” on page 6-49.
diffPartial differentiation

```
diff(a, x1,  )
```

Differentiation is defined to be the continuation of differentiation of the ground field; this method exists only if the ground field has a method `"diff"`, too.

Differentiation is not possible in inseparable extensions.

This method overloads the function diff.

This method must not be called for inseparable extensions; note that MuPAD cannot check whether an extension is separable.

See “Example 3” on page 6-49.
randomRandom element of the field

```
random()
```

The `random` method of the ground field is used to generate coefficients of a random polynomial of the ground field; the residue class of that polynomial is the return value. Hence the probability distribution of the elements returned depends on that of the `random` method of the ground field.

Conversion Methods

convertConvert into a field element

```
convert(x)
```

If the conversion fails, then `FAIL` is returned.

convert_toConvert a field element into another type

```
convert_to(a, T)
```

Field elements can be converted to polynomials or expressions. Field elements represented by constant polynomials can also be converted to the same types as the elements of the ground field; in particular, they can be converted to elements of the ground field.

coerceCoerce into this domain

Inherited from Cat::BaseCategory.

newCreate element of this domain

Inherited from Cat::BaseCategory.

exprConvert an element of the field into an expression

```
expr(a)
```

This method overloads the function expr.
subsAvoid substitution

Inherited from Dom::BaseDomain.
subsexAvoid extended substitution

Inherited from Dom::BaseDomain.
testtypeTest type of object

Inherited from Cat::BaseCategory.
printReturn expression to print an element

Inherited from Cat::BaseCategory.

Dom::GaloisField

Dom::ArithmeticalExpression

Purpose

Domains of arithmetical expressions

Syntax

```
Dom::ArithmeticalExpression(x)
```

Description

`Dom::ArithmeticalExpression` is a façade domain of arithmetical expressions built up by the system functions and operators like `+` and `*`.

This domain has almost no algebraic structure because unqualified expressions have no normal form. (For example, there are rational expressions for zero which are not normalized to `0`.) The main purpose of `Dom::ArithmeticalExpression` is to provide implementations for methods used by façade sub-domains like Dom::Integer which are represented by a subset of the arithmetical expressions.

Elements of `Dom::ArithmeticalExpression` are usually not created explicitly. However, if one creates elements using the usual syntax, the input is converted to an expression using expr, then it is checked whether the result is an arithmetical expression.

Superdomain

Dom::Expression

Axioms

Ax::systemRep

Categories

Cat::BaseCategory

Examples

Example 1

For brevity, we will use `AE` as a shorthand notation for `Dom::ArithmeticalExpression`:
AE := Dom::ArithmeticalExpressionDom::ArithmeticalExpression

Dom::ArithmeticalExpression

An element of this domain can *not* be created as follows:
e := AE(2*sin(x) + f(x)/y)2*sin(x) + f(x)/y

$$2\sin(x) + \frac{f(x)}{y}$$

Since `Dom::ArithmeticalExpression` is a façade domain, `e` is not a domain element, but an expression:
domtype(e)DOM_EXPR

DOM_EXPR

The fact that no error was returned yields the information that `e` is an arithmetical expression. This can also be checked as follows:
testtype(e,AE)TRUE

TRUE

In contrast to its super-domain Dom::Expression, this domain only allows elements which are valid arguments for the arithmetical functions, thus the following yields an error:
AE([a, b]) Error: The arguments are invalid.
[Dom::ArithmeticalExpression::new]

Parameters

x

An arithmetical expression

Entries

"key"	The name of this domain.
"one"	The neutral element w.r.t. `"_mult"`: the constant `1`.
"zero"	The neutral element w.r.t. `"_plus"`: the constant `0`.

Methods

Mathematical Methods

_divideDivide arithmetical expressions

```
_divide(f, g)
```

This method overloads the function _divide.

For details, please see _divide.

_invertInvert an arithmetical expression

```
_invert(f)
```

This method overloads the function _invert.

For details, please see _invert.

_multMultiplie arithmetical expressions

```
_mult(<f, g,  >)
```

This method overloads the function _mult.

For details, please see _mult.

_negateNegate an arithmetical expression

```
_negate(f)
```

This method overloads the function _negate.

For details, please see _negate.

_plusAdd arithmetical expressions

```
_plus(<f, g,  >)
```

This method overloads the function _plus.

For details, please see _plus.

_powerPower operator

```
_power(f, g)
```

This method overloads the function _power.

For details, please see _power.

_subtractSubtract an arithmetical expression

Dom::Expression

Dom::BaseDomain

Purpose

Root of the domain hierarchy

Description

`Dom::BaseDomain` is the root of the domain hierarchy as defined by the Dom package. Every domain of the package inherits from it.

The only purpose of `Dom::BaseDomain` is to supply all domains of the package with some basic methods like `"hasProp"`. Elements of `Dom::BaseDomain` cannot be created.

Unlike other super-domains this domain does not impose any restrictions on the representation of the elements of its sub-domains. Thus it may be a super-domain for any domain created by a domain constructor.

Categories

Cat::BaseCategory

Entries

"create_dom"	This domain entry is used to revive the domain when it is read from a binary MCode stream. If this entry is present it is written to the MCode stream instead of the contents of the domain. When the stream is read it is used to create the domain. If this entry does not exist all entries of the domain are written to the stream and read in later to create the domain. `Dom::BaseDomain` defines `"create_dom"` to have the same value as the key of the domain, as stored in the entry `"key"`. All domains of the Dom package inherit this entry, thus they must

be created by the reader of the MCode stream by evaluating the expression stored in the key.

Methods

Mathematical Methods

equalTest for mathematical equality

```
equal(x, y)
```

If this domain has the axiom Ax::canonicalRep, which implies that two domain elements are mathematically equal if and only if they are structurally equal, the kernel function _equal is used to decide the equality. In this case `UNKNOWN` is never returned.

If the axiom Ax::canonicalRep does not hold the method will return `TRUE` if `x` and `y` are structurally equal (in the sense of the function _equal) and `UNKNOWN` otherwise.

Conversion Methods

convert_toConvert element

```
convert_to(x, T)
```

The implementation provided here can convert `x` to an element of this domain (the trivial case) or to an element of Dom::Expression (by using the method `"expr"`, see Cat::BaseCategory).

TeXGenerate TeX output

```
TeX(x)
```

The default implementation provided here converts `x` into an expression using the method `"expr"` and then uses the function generate::TeX to convert the expression.

Access Methods

allAxiomsReturn all axioms

```
allAxioms()
```

allCategoriesReturn all categories

```
allCategories()
```

allEntriesReturn the names of all entries

`allEntries()`
: allSuperDomainsReturn all super-domains

`allSuperDomains()`

The last, most general, super-domain of all domains of the Dom package is `Dom::BaseDomain`.
: getAxiomsReturn axioms stated in the constructor

`getAxioms()`
: getCategoriesReturn categories stated in the constructor

`getCategories()`
: getSuperDomainReturn super-domain stated in the constructor

`getSuperDomain()`
: hasPropTest for a certain property

`hasProp(d)`

`hasProp(dc)`

`hasProp(a)`

`hasProp(ac)`

`hasProp(c)`

`hasProp(cc)`

`hasProp(dc)` tests if this domain or a super-domain of it was defined by the domain constructor `dc`.

`hasProp(a)` tests if this domain has the axiom `a`.

`hasProp(ac)` tests if an axiom of this domain was defined by the axiom constructor `ac`.

`hasProp(c)` tests if this domain has the category `c`.

`hasProp(cc)` tests if a category of this domain was defined by the category constructor `cc`.
: infoPrint short information about this domain

`info()`

It prints out the super-domains, categories, axioms and entry names of this domain.

If an entry `"info_str"`, which must be a string, is defined for this domain it is used to print the header line.

printMethodsPrint out methods

```
printMethods(<sort>, <Table>)
```

```
printMethods(<sort>, Tree)
```

If no sorting function is given, sort is used as default.

Similar as above, using `Tree` provides only that the names of the entries are inserted into a tree, an element of the domain adt::Tree. The tree is both printed out and returned by the method.

Using neither `Table` nor `Tree` the function does the same as `dom::printMethods(sort, Table)`.

subsAvoid substitution

```
subs(x, ,  )
```

Sub-domains should provide a new implementation of this method with sensible semantics if possible.

subsexAvoid extended substitution

```
subsex(x, ,  )
```

Sub-domains should provide a new implementation of this method with sensible semantics if possible.

undefinedEntriesReturn missing entries

```
undefinedEntries()
```

An entry is missing if it should have a definition according to a category of the domain, but the definition is not present.

whichEntryReturn the domain or category implementing an entry

```
whichEntry(e)
```

`FAIL` is returned if no entry with the given name is defined for this domain.

Dom::Complex

Purpose

Field of complex numbers

Syntax

```
Dom::Complex(x)
```

Description

`Dom::Complex` is the domain of complex constants represented by expressions of type `DOM_INT`, `DOM_RAT`, `DOM_FLOAT` or `DOM_COMPLEX`. An expression of type `DOM_EXPR` is considered a complex number if it is of type Type::Arithmetical and if it contains only indeterminates which are of type Type::ConstantIdents or if it contains no indeterminates, cf. "Example 2" on page 6-70.

`Dom::Complex` is of category Cat::Field due to pragmatism. This domain actually is not a field because `bool(1.0 = float(3) / float(3))` returns `FALSE`, for example.

Elements of `Dom::Complex` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input expression can be converted to a number. This means `Dom::Complex` is a facade domain which creates elements of domain type `DOM_INT`, `DOM_RAT`, `DOM_FLOAT`, `DOM_COMPLEX` or `DOM_EXPR`.

`Dom::Complex` has no normal representation, because `0` and `0.0` both represent the zero.

Viewed as a differential ring, `Dom::Complex` is trivial. It only contains constants.

`Dom::Complex` has the domain Dom::BaseDomain as its super domain, i.e., it inherits each method which is defined by `Dom::BaseDomain` and not re-implemented by `Dom::Complex`. Methods described below are re-implemented by `Dom::Complex`.

Superdomain

Dom::ArithmeticalExpression

Axioms

Ax::systemRep, Ax::efficientOperation(`"_divide"`), Ax::efficientOperation(`"_mult"`), Ax::efficientOperation(`"_invert"`)

Categories

Cat::DifferentialRing, Cat::Field

Examples

Example 1

Creating some complex numbers using `Dom::Complex`:
Dom::Complex(2/3)2/3

$$\frac{2}{3}$$

Dom::Complex(2/3 + 4*I)2/3 + 4*I

$$\frac{2}{3} + 4\,i$$

Example 2

It's also possible to use expressions or constants for creating an element of `Dom::Complex`:
Dom::Complex(PI)PI

$$\pi$$

Dom::Complex(sin(2))sin(2)

$$\sin(2)$$

Dom::Complex(sin(2/3*I) + 3)3 + sinh(2/3)*I

$$3 + \sinh\left(\frac{2}{3}\right) i$$

If the expression cannot be converted to an element of `Dom::Complex` we will get an error message:
Dom::Complex(sin(x)) Error: The arguments are invalid.
[Dom::Complex::new]

Parameters x

An expression of type DOM_INT, DOM_RAT, DOM_FLOAT, DOM_COMPLEX. An expression of type DOM_EXPR is also possible if it is of type Type::Arithmetical and if it contains only indeterminates which are of type Type::ConstantIdents or if it contains no indeterminates.

Entries

"characteristic"	the characteristic of this field is 0.
"one"	the unit element; it equals 1.
"zero"	The zero element; it equals 0.

Description

Domain Creation

`Dom::DenseMatrix(R)` creates domains of matrices over a component domain `R` of category Cat::Rng (a ring, possibly without unit).

If the optional parameter `R` is not given, the domain `Dom::ExpressionField()` is used.

A vector with n entries is either an n 1 matrix (a column vector), or a 1 n matrix (a row vector).

Arithmetical operations with matrices can be performed by using the standard arithmetical operators of MuPAD.

E.g., if `A` and `B` are two matrices defined by `Dom::DenseMatrix(R)`, `A + B` computes the sum, and `A * B` computes the product of the two matrices, provided that the dimensions are correct.

Similarly, `A^(-1)` or `1/A` computes the inverse of a square matrix `A` if it exists, and returns FAIL otherwise. See "Example 1" on page 6-78.

Many system functions have been overloaded for matrices, such as map, subs, has, zip, conjugate to compute the complex conjugate of a matrix, norm to compute matrix norms, or exp to compute the exponential of a matrix.

Most of the functions in the MuPAD linear algebra package `linalg` work with matrices. For example, to compute the determinant of a square matrix `A`, call `linalg::det(A)`. The command `linalg::gaussJordan(A)` performs Gauss-Jordan elimination on `A` to transform `A` to its reduced row echelon form.

The domain `Dom::DenseMatrix(R)` represents matrices over `R` of arbitrary size, and it therefore does not have any algebraic structure (other than being a *set* of matrices).

The domain `Dom::SquareMatrix(n, R)` represents the *ring* of n n matrices over R. The domain `Dom::MatrixGroup(m, n, R)` represents the *Abelian group* of m n matrices over R.

We use the following notations for a matrix A (an element of `Dom::DenseMatrix(R)`):

- *nrows*(A) denotes the number of rows of A.
- *ncols*(A) denotes the number of columns of A.
- A *row index* is an integer in the range from 1 to *nrows*(A).
- A *column index* is an integer in the range from 1 to *ncols*(A).

Note The components of a matrix are no longer evaluated after the creation of the matrix, i.e., if they contain free identifiers they will not be replaced by their values.

Element Creation

`Dom::DenseMatrix(R)(Array)` and `Dom::DenseMatrix(R)(Matrix)` create a new matrix with the dimension and the components of `Array` and `Matrix`, respectively.

The components of `Array` or `Matrix` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::DenseMatrix(R)(List)` creates an m 1 column vector with components taken from the nonempty list, where m is the number of entries of `List`.

`Dom::DenseMatrix(R)(ListOfRows)` creates an m n matrix with components taken from the nested list `ListOfRows`, where m is the number of inner lists of `ListOfRows`, and n is the maximal number of elements of an inner list. Each inner list corresponds to a row of the matrix. Both m and n must be non-zero.

If an inner list has less than n entries, then the remaining components in the corresponding row of the matrix are set to zero.

The entries of the inner lists are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

It might be a good idea first to create a two-dimensional array from that list before calling `Dom::DenseMatrix(R)`. This is due to the fact that creating a matrix from an array is the fastest way one can achieve. However, in this case the sublists must have the same number of elements.

The call `Dom::DenseMatrix(R)(m, n)` returns the m n zero matrix.

Use the method `"identity"` to create the n n identity matrix.

The call `Dom::DenseMatrix(R)(m, n, Array)` creates an m n matrix with components taken from `Array`, which must be an array or an hfarray. `Array` must have mn operands. The first m operands define the first row, the next m operands define the second row, etc. The formatting of the array is irrelevant. E.g., any array with 6 elements can be used to create a matrix of dimension 1 6, or 2 3, or 3 2, or 6 1.

The call `Dom::DenseMatrix(R)(m, n, List)` creates an m n matrix with components taken from the list `List` with mn elements. The first m elements of the list define the first row, the next m elements of the list define the second row, etc.

The call `Dom::DenseMatrix(R)(m, n, ListOfRows)` creates an m n matrix with components taken from the list`ListOfRows`.

If $m \geq 2$ and $n \geq 2$, then `ListOfRows` must consist of at most `m` inner lists, each having at most `n` entries. The inner lists correspond to the rows of the returned matrix.

If an inner list has less than `n` entries, then the remaining components of the corresponding row of the matrix are set to zero. If there are less than `m` inner lists, then the remaining lower rows of the matrix are filled with zeroes.

`Dom::DenseMatrix(R)(m, n, f)` returns the matrix whose (i, j)th component is the value of the function call `f(i,j)`. The row index i ranges from 1 to m and the column index j from 1 to n.

The function values are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::DenseMatrix(R)(1, n, List)` returns the 1 n row vector with components taken from `List`. The list `List` must have at most `n` entries. If there are fewer entries, then the remaining vector components are set to zero.

The entries of the list are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::DenseMatrix(R)(m, 1, List)` returns the m 1 column vector with components taken from `List`. The list `List` must have at most `m` entries. If there are fewer entries, then the remaining vector components are set to zero.

The entries of the list are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

Examples

Example 1

First we create the domain of matrices over the field of rational numbers:
MatQ := Dom::DenseMatrix(Dom::Rational)Dom::DenseMatrix(Dom::Rational)

Dom::DenseMatrix(Dom::Rational)

We assigned this domain to the identifier `MatQ`. Next we define the 2 2 matrix

matrix([[1, 5], [2, 3]])

$$\begin{pmatrix} 1 & 5 \\ 2 & 3 \end{pmatrix}$$

by a list of two rows, where each row is a list of two elements:
A := MatQ([[1, 5], [2, 3]])Dom::DenseMatrix(Dom::Rational)([[1, 5], [2, 3]])

$$\begin{pmatrix} 1 & 5 \\ 2 & 3 \end{pmatrix}$$

In the same way we define the following 2 3 matrix:
B := MatQ([[-1, 5/2, 3], [1/3, 0, 2/5]])Dom::DenseMatrix(Dom::Rational)([[-1, 5/2, 3], [1/3, 0, 2/5]])

$$\begin{pmatrix} -1 & \frac{5}{2} & 3 \\ \frac{2}{3} & 0 & \frac{36}{5} \end{pmatrix}$$

and perform matrix arithmetic using the standard arithmetical operators of MuPAD, e.g., the matrix product AB, the 4th power of A as well as the scalar multiplication of A times $1/3$ $\frac{1}{3}$:

```
A * B, A ^ 4, 1/3 * ADom::DenseMatrix(Dom::Rational)([[2/3, 5/2, 5], [-1,
5, 36/5]]), Dom::DenseMatrix(Dom::Rational)([[281, 600], [240, 521]]),
Dom::DenseMatrix(Dom::Rational)([[1/3, 5/3], [2/3, 1]])
```

$$\begin{pmatrix} \frac{2}{3} & \frac{5}{2} & 5 \\ -1 & 5 & \frac{36}{5} \end{pmatrix}, \begin{pmatrix} 281 & 600 \\ 240 & 521 \end{pmatrix}, \begin{pmatrix} \frac{1}{3} & \frac{5}{3} \\ \frac{2}{3} & 1 \end{pmatrix}$$

The matrices A and B have different dimensions, and therefore the sum of A and B is not defined. MuPAD issues an error message:

```
A + B Error:  The dimensions do not match.
[(Dom::DenseMatrix(Dom::Rational))::_plus]
```

To compute the inverse of A, just enter:

```
1/ADom::DenseMatrix(Dom::Rational)([[-3/7, 5/7], [2/7, -1/7]])
```

$$\begin{pmatrix} -\frac{3}{7} & \frac{5}{7} \\ \frac{2}{7} & -\frac{1}{7} \end{pmatrix}$$

If a matrix is not invertible, `FAIL` is the result of this operation. For example, the matrix:

```
C := densematrix(2, 2, [[2]])densematrix([[2, 0], [0, 0]])
```

$$\begin{pmatrix} 2 & 0 \\ 0 & 0 \end{pmatrix}$$

is not invertible, hence:
C^(-1)FAIL

FAIL

Example 2

We create the domain of matrices over the reals:
MatR := Dom::DenseMatrix(Dom::Real)Dom::DenseMatrix(Dom::Real)

Dom::DenseMatrix(Dom::Real)

Beside standard matrix arithmetic, the library `linalg` offers a lot of functions dealing with matrices. For example, if one wants to compute the rank of a matrix, use linalg::rank:
A := MatR([[1, 2], [2, 4]])Dom::DenseMatrix(Dom::Real)([[1, 2], [2, 4]])

$$\begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix}$$

linalg::rank(A)1

1

Use linalg::eigenvectors to compute eigenvalues and eigenvectors of the matrix *A*:
linalg::eigenvectors(A)[[0, 1, [Dom::DenseMatrix(Dom::Real)([[-2], [1]])]], [5, 1, [Dom::DenseMatrix(Dom::Real)([[1/2], [1]])]]]

$$\left[\left[0,\ 1,\ \begin{pmatrix} -2 \\ 1 \end{pmatrix}\right],\ \left[5,\ 1,\ \begin{pmatrix} \frac{1}{2} \\ 1 \end{pmatrix}\right]\right]$$

Try `info(linalg)` for a list of available functions, or enter `help(linalg)` for details about the library `linalg`.

Some of the functions in the `linalg` package simply serve as "interface" functions for methods of a matrix domain described above. For example, linalg::transpose uses the method `"transpose"` to get the transposed matrix. The function linalg::gaussElim applies Gaussian elimination to a matrix, such as:
linalg::gaussElim(A)Dom::DenseMatrix(Dom::Real)([[1, 2], [0, 0]])

$$\begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix}$$

The computation is performed by the method `"gaussElim"` as described above. Such functions of the `linalg` packages, in contrast to the corresponding methods of the domain `Dom::DenseMatrix(R)`, check their incoming parameters, and some of them offer extended functionalities.

Example 3

In this example, we use the default matrix domain which is created by `Dom::DenseMatrix()`. This domain represents matrices whose components can be arbitrary arithmetical expressions (i.e., the component ring is the domain Dom::ExpressionField()).

This domain is already known to MuPAD by the name matrix:
A := densematrix([[1, 2, 3, 4], [2, 0, 4, 1], [-1, 0, 5, 2]])densematrix([[1, 2, 3, 4], [2, 0, 4, 1], [-1, 0, 5, 2]])

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 0 & 4 & 1 \\ -1 & 0 & 5 & 2 \end{pmatrix}$$

domtype(A)Dom::DenseMatrix()

Dom::DenseMatrix()

Matrix components can be extracted by the index operator [ ]:
A[2, 1] * A[1, 2] - A[3, 1] * A[1, 3]7

7

If one of the indices is not in its valid range, an error message is issued.
Assignments to matrix components are performed similarly:
delete a: A[1, 2] := a^2: Adensematrix([[1, a^2, 3, 4], [2, 0, 4, 1], [-1, 0, 5, 2]])

$$\begin{pmatrix} 1 & a^2 & 3 & 4 \\ 2 & 0 & 4 & 1 \\ -1 & 0 & 5 & 2 \end{pmatrix}$$

Beside the usual indexing of matrix components, it is also possible to extract submatrices from a given matrix. The following call creates the submatrix of *A* which consists of the rows 2 to 3 and columns 1 to 3 of *A*:
A[2..3, 1..3]densematrix([[2, 0, 4], [-1, 0, 5]])

$$\begin{pmatrix} 2 & 0 & 4 \\ -1 & 0 & 5 \end{pmatrix}$$

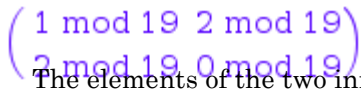
The index operator does not allow to insert submatrices into a given matrix. This is implemented by the function linalg::substitute.

Example 4

In the following examples, we demonstrate the different ways of creating matrices. We work with matrices defined over the field $_{19}$, i.e.,

the field of integers modulo 19. This component ring can be created with the domain constructor Dom::IntegerMod.

We start by giving a list of rows, where each row is a list of row entries:
MatZ19 := Dom::DenseMatrix(Dom::IntegerMod(19)): MatZ19([[1, 2], [2]])Dom::DenseMatrix(Dom::IntegerMod(19))([[Dom::IntegerMod(19)(1), Dom::IntegerMod(19)(2)], [Dom::IntegerMod(19)(2), Dom::IntegerMod(19)(0)]])



The elements of the two inner lists, the row entries, were converted into elements of the domain `Dom::IntegerMod(19)`.

The number of rows is the number of sublists of the argument, i.e., $m = 2$. The number of columns is determined by the length of the inner list with the most entries, which is the first inner list with two entries. Missing entries in the other inner lists are treated as zero components. The call:
MatZ19(4, 4, [[1, 2], [2]])Dom::DenseMatrix(Dom::IntegerMod(19))([[Dom::IntegerMod(19)(1), Dom::IntegerMod(19)(2), Dom::IntegerMod(19)(0), Dom::IntegerMod(19)(0)], [Dom::IntegerMod(19)(2), Dom::IntegerMod(19)(0), Dom::IntegerMod(19)(0), Dom::IntegerMod(19)(0)], [Dom::IntegerMod(19)(0), Dom::IntegerMod(19)(0), Dom::IntegerMod(19)(0), Dom::IntegerMod(19)(0)], [Dom::IntegerMod(19)(0), Dom::IntegerMod(19)(0), Dom::IntegerMod(19)(0), Dom::IntegerMod(19)(0)]])

$$\begin{pmatrix} 1 \bmod 19 & 2 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 2 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \end{pmatrix}$$

fixes the dimension of the matrix. Missing entries and inner lists are treated as zero components and zero rows, respectively.

An error message is issued if one of the given entries cannot be converted into an element over $_{19}$:
MatZ19([[2, 3], [-1, I]]) Error: Cannot define a matrix over 'Dom::IntegerMod(19)'.
[(Dom::DenseMatrix(Dom::IntegerMod(19)))::new]

Example 5

This example illustrates how to create a matrix with components given as values of an index function. First we create the 2 2 Hilbert matrix (see also the functions linalg::hilbert and linalg::invhilbert):
densematrix(2, 2, (i, j) -> 1/(i + j - 1))densematrix([[1, 1/2], [1/2, 1/3]])

$$\begin{pmatrix} 1 & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{3} \end{pmatrix}$$

Note the difference when working with expressions and functions. If you give an expression it is treated as a function in the row and column indices:
delete x: densematrix(2, 2, x), densematrix(2, 2, (i, j) -> x)densematrix([[x(1, 1), x(1, 2)], [x(2, 1), x(2, 2)]]), densematrix([[x, x], [x, x]])

$$\begin{pmatrix} x(1,1) & x(1,2) \\ x(2,1) & x(2,2) \end{pmatrix}, \begin{pmatrix} x & x \\ x & x \end{pmatrix}$$

Example 6

Diagonal matrices can be created with the option `Diagonal` and a list of diagonal components:

```
MatC := Dom::DenseMatrix(Dom::Complex): MatC(3, 4, [1, 2, 3],
Diagonal)Dom::DenseMatrix(Dom::Complex)([[1, 0, 0, 0], [0, 2, 0, 0],
[0, 0, 3, 0]])
```

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 3 & 0 \end{pmatrix}$$

Hence, to define the n n identity matrix, you can enter:

```
MatC(3, 3, [1 $ 3], Diagonal)Dom::DenseMatrix(Dom::Complex)([[1, 0,
0], [0, 1, 0], [0, 0, 1]])
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

or even call:

```
MatC(3, 3, x -> 1, Diagonal)Dom::DenseMatrix(Dom::Complex)([[1, 0,
0], [0, 1, 0], [0, 0, 1]])
```

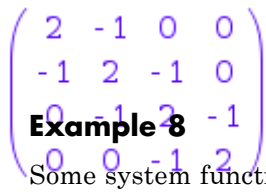
$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

The easiest way to create the identity matrix, however, is to use the method `"identity"`:

```
MatC::identity(3)Dom::DenseMatrix(Dom::Complex)([[1, 0, 0], [0, 1,
0], [0, 0, 1]])
```

Example 7

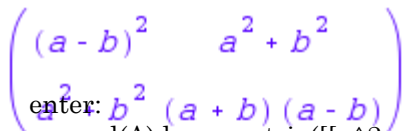
Toeplitz matrices can be defined with the option `Banded`. The following call defines a three-banded matrix with the component 2 on the main diagonal and the component - 1 on the first subdiagonals:
densematrix(4, 4, [-1, 2, -1], Banded)densematrix([[2, -1, 0, 0], [-1, 2, -1, 0], [0, -1, 2, -1], [0, 0, -1, 2]])



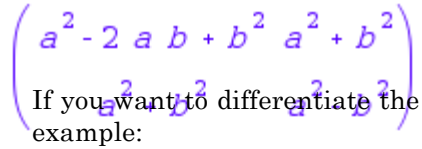
Example 8

Some system functions can be applied to matrices, such as norm, expand, diff, conjugate, or exp.

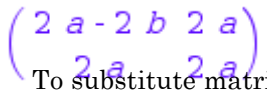
For example, to expand the components of the matrix:
delete a, b: A := densematrix([[(a - b)^2, a^2 + b^2], [a^2 + b^2, (a - b)*(a + b)]])densematrix([[(a - b)^2, a^2 + b^2], [a^2 + b^2, (a + b)*(a - b)]])



enter:
expand(A)densematrix([[a^2 - 2*a*b + b^2, a^2 + b^2], [a^2 + b^2, a^2 - b^2]])

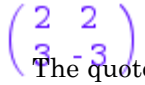


If you want to differentiate the matrix components, then call for example:
diff(A, a)densematrix([[2*a - 2*b, 2*a], [2*a, 2*a]])



To substitute matrix components by some values, enter:
subs(A, a = 1, b = -1)densematrix([[4, 2], [2, 0]])

The function zip can also be applied to matrices. The following call combines two matrices *A* and *B* by dividing each component of *A* by the corresponding component of *B*:
A := densematrix([[4, 2], [9, 3]]): B := densematrix([[2, 1], [3,-1]]): zip(A, B, `/`)densematrix([[2, 2], [3, -3]])



The quoted character `` `/` `` is another notation for the function `_divide`, the functional form of the division operator `/`.

If one needs to apply a function to the components of a matrix, then use the function map. For example, to simplify the components of the matrix:

C := densematrix([[sin(x)^2 + cos(x)^2, cos(x)*tan(x)], [(a^2 - b^2)/(a + b), 1]])densematrix([[cos(x)^2 + sin(x)^2, cos(x)*tan(x)], [(a^2 - b^2)/(a + b), 1]])

$$\begin{pmatrix} \cos(x)^2 + \sin(x)^2 & \cos(x)\tan(x) \\ \frac{a^2 - b^2}{a + b} & 1 \end{pmatrix}$$

call:
map(C, Simplify)densematrix([[1, sin(x)], [a - b, 1]])

$$\begin{pmatrix} 1 & \sin(x) \\ a - b & 1 \end{pmatrix}$$

Example 9

However, there may appear some unexpected results using the function diff in the context of matrices. The derivative of the following unspecified function `f` of a matrix is computed due to the chain rule:
diff(f(densematrix([[a*x^2, b], [c, d]])), x)densematrix([[2*a*x*D(f)(array(1..2, 1..2, [[a*x^2, b], [c, d]])), 0], [0, 0]])

$$\begin{pmatrix} 2\,a\,x\,f'\left(\begin{pmatrix} a\,x^2 & b \\ c & d \end{pmatrix}\right) & 0 \\ 0 & 0 \end{pmatrix}$$

Usually, the function `f` would implicitly be assumed to be scalar. Hence, the derivative of `f` should be scalar as well. In the above situation the chain rule is applied for differentiation: the inner function is the matrix containing the symbolic components `a*x^2`, `b`, `c` and `d`. Its derivative is computed by simply applying diff to each component of the matrix:

diff(densematrix([[a*x^2, b], [c, d]]), x)densematrix([[2*a*x, 0], [0, 0]])

$$\begin{pmatrix} 2\,a\,x & 0 \\ 0 & 0 \end{pmatrix}$$

Finally, the exterior unspecified function `f` is implicitly assumed to be scalar, such that each component of the derivative of the inner function is multiplied by the exterior differentiation.

Example 10

A column vector is represented as a 2 1 matrix:
MatR := Dom::DenseMatrix(Dom::Real): v := MatR(2, 1, [1, 2])Dom::DenseMatrix(Dom::Real)([[1], [2]])

$$\begin{pmatrix} 1 \\ 2 \end{pmatrix}$$

The dimension of this vector is:
MatR::matdim(v)[2, 1]

$$[2,\ 1]$$

Use linalg::vecdim, or even call `nops(v)` to get the length of a vector:
linalg::vecdim(v)2

$$2$$

The *i*th component of this vector can be extracted in two ways: either by `v[i,1]` or by `v[i]`:
v[1], v[2]1, 2

$$1,\ 2$$

We get the 2-norm of `v` by the following call:
norm(v, 2)sqrt(5)

Parameters

R

A ring, i.e., a domain of category Cat::Rng; default is `Dom::ExpressionField()`

Array

A one- or two-dimensional array or hfarray

Matrix

A matrix, i.e., an element of a domain of category Cat::Matrix

m

n

Matrix dimension (positive integers)

List

A list of matrix components

ListOfRows

A list of at most `m` rows; each row given as a list of at most `n` matrix components

f

A function or a functional expression with two parameters (the row and column index)

g

A function or a functional expression with one parameter (the row index)

Options

Diagonal

Create a diagonal matrix

With the option `Diagonal`, diagonal matrices can be created with diagonal elements taken from a list, or computed by a function or a functional expression.

`Dom::DenseMatrix(R)(m, n, List, Diagonal)` creates the m n diagonal matrix whose diagonal elements are the entries of `List`.

`List` must have at most $min(m, n)$ entries. If it has fewer elements, the remaining diagonal elements are set to zero.

The entries of `List` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::DenseMatrix(R)(m, n, g, Diagonal)` returns the matrix whose ith diagonal element is `g(i, i)`, where the index i runs from 1 to $min(m, n)$.

The function values are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

Banded

Create a banded Toeplitz matrix

`Dom::DenseMatrix(R)(m, n, List, Banded)` creates an m n banded Toeplitz matrix with the elements of `List` as entries. The number of entries of `List` must be odd, say $2h + 1$, and must not exceed `n`. The resulting matrix has bandwidth at most $2h + 1$.

A Toeplitz matrix is a matrix where the elements of each band are identical. See also “Example 7” on page 6-86.

All elements of the main diagonal of the created matrix are initialized with the middle element of `List`. All elements of the ith subdiagonal are initialized with the $(h + 1 - i)$th element of `List`. All elements of the ith superdiagonal are initialized with the $(h + 1 + i)$th element of `List`. All entries on the remaining sub- and superdiagonals are set to zero.

The entries of `List` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

Entries

"isSparse"	is always `FALSE`, as elements of `Dom::DenseMatrix(R)` use a dense representation of their matrix components.
"randomDimen"	is set to `[10,10]`. See the method `"random"` below for details.

Methods

Mathematical Methods

_divideDivide matrices

```
_divide(A, B)
```

An error message is issued if the dimensions of `A` and `B` do not match.

This method only exists if `R` is a commutative ring with a unit, i.e., a domain of category Cat::Ring.

This method overloads the function _divide for matrices, i.e., one may use it in the form `A / B`, or in functional notation: `_divide(A, B)`.

_invertCompute the inverse of a matrix

```
_invert(A, Normal = b)
```

If the component ring `R` is the domain Dom::Float, a floating-point approximation of the inverse matrix is computed by the function numeric::inverse.

This method only exists if `R` is a domain of category Cat::Ring.

This method overloads the function _invert for matrices, i.e., one may use it in the form `1/A` or `A^(-1)`, or in functional notation: `_invert(A)`.

If `Normal = TRUE`, then the matrix inverse is always returned in a normalized form. For details about normalization, see normal. If `Normal = FALSE`, then the matrix inverse can appear in a normalized form, but normalization is not guaranteed. By default `Normal = TRUE`.

Normal affects the results only if a matrix contains variables or exact expressions, such as sqrt(5) or sin(PI/7)).
_modMap the modulo operator to a matrix

```
_mod(A, n)
```

n must be non-zero, and a mod n must be defined for every entry a of A.

This method overloads the function mod for matrices; one may use it in the form A mod n, or in functional notation: _mod(A, n).
_multMultiplie matrices by matrices, vectors and scalars

```
_mult(x, y)
```

```
_mult(x, y)
```

If y is of the domain type R or can be converted into such an element, the corresponding scalar multiplication is computed.

Otherwise, y is converted into a matrix of the domain type of x. If this conversion fails, then this method calls the method "_mult" of the domain of y giving all arguments in the same order.

If x is a matrix of the same domain type as y, then the matrix product *xy* is computed. An error message is issued if the dimensions of the matrices do not match.

If x is of the domain type R or can be converted into such an element, the corresponding scalar multiplication is computed.

Otherwise, x is converted into a matrix of the domain type of y. If this conversion fails, then FAIL is returned.

This method handles more than two arguments by calling itself recursively with the first half of all arguments and the last half of all arguments. Then the product of these two results is computed with the system function _mult.

This method overloads the function _mult for matrices, i.e., one may use it in the form x * y, or in functional notation: _mult(x, y).
_negateNegate a matrix

```
_negate(A)
```

This method overloads the function _negate for matrices, i.e., one may use it in the form `-A`, or in functional notation: `_negate(A)`.
_plusAdd matrices

```
_plus(A, B,  )
```

The arguments `A, B , ...` are converted into matrices of the domain type `Dom::DenseMatrix(R)`. `FAIL` is returned if one of these conversions fails.

This method overloads the function _plus for matrices, i.e., one may use it in the form `A + B`, or in functional notation: `_plus(A, B)`.
_powerInteger power of a matrix

```
_power(A, n)
```

If the power `n` is a negative integer then `A` must be nonsingular and `R` must be a domain of category Cat::IntegralDomain. Otherwise `FAIL` is returned.

If `n` is zero and the component ring `R` is a ring with no unit (i.e., of category Cat::Rng, but not of category Cat::Ring), `FAIL` is returned.

This method overloads the function _power for matrices, i.e., one may use it in the form `A^n`, or in functional notation: `_power(A, n)`.
conjugateComplex conjugate of a matrix

```
conjugate(A)
```

This method only exists if `R` implements the method `"conjugate"`, which computes the complex conjugate of an element of the domain `R`.

This method overloads the function conjugate for matrices, i.e., one may use it in the form `conjugate(A)`.
cosCosine of a matrix

```
cos(A)
```

If `A` is not square, an error message is issued. If the component domain of `A` does not allow the computation of `cos(elem)` for an arbitrary element `elem` of the component ring, `FAIL` is returned.

This method uses the function numeric::expMatrix for a floating-point approximation of the exponential of `A` if `A` is defined over the domain Dom::Float.

If some eigenvalues of A do not exist in R or cannot be computed, then FAIL is returned.

In the symbolic case the functions exp and linalg::jordanForm are called. The latter may not be able to compute the Jordan form of A. In this case FAIL is returned. Increasing the level of information (see setuserinfo) can yield useful information.

This method only exists if R is a domain of category Cat::Field.

This method overloads the function cos for matrices, i.e., one may use it in the form cos(A).
diffDifferentiation of matrix components

```
diff(A,  )
```

This method only exists if R implements the method "diff".

This method overloads the function diff for matrices, i.e., one may use it in the form diff(A, ...). See “Example 8” on page 6-86 and “Example 9” on page 6-88.
equalEquality test of matrices

```
equal(A, B)
```

Note that if R has the axiom Ax::systemRep then normal is used to simplify the components of A and B before testing their equality.
expExponential of a matrix

```
exp(A, <t>)
```

If A is not square, an error message is issued. If the component domain of A does not allow the computation of exp(elem) for an arbitrary element elem of the component ring, FAIL is returned.

This method uses the function numeric::expMatrix for a floating-point approximation of the exponential of A if A is defined over the domain Dom::Float and if $t = 1$.

If some eigenvalues of A do not exist in R or cannot be computed, then FAIL is returned.

In the symbolic case the function linalg::jordanForm is called, which may not be able to compute the Jordan form of `A`. In this case `FAIL` is returned. Increasing the level of information (see setuserinfo) can yield useful information.

This method only exists if `R` is a domain of category Cat::Field.

This method overloads the function exp for matrices, i.e., one may use it in the form `exp(A, ...)`.
expandExpand matrix components

```
expand(A)
```

This method only exists if `R` implements the method `"expand"`, or if `R` has the axiom Ax::systemRep (in this case, the system function expand is used).

This method overloads the function expand for matrices, i.e., one may use it in the form `expand(A)`.
factorScalar-matrix factorization

```
factor(A)
```

The factor *s* is the gcd of all components of the matrix `A`. Hence, this method only exists if `R` is of category Cat::GcdDomain.

This method overloads the function factor for matrices, i.e., one may use it in the form `factor(A)`.
floatFloating-point approximation of the matrix components

```
float(A)
```

This method only exists if `R` implements the method `"float"`.

Note Usually the floating-point approximations are not elements of R! For example, Dom::Integer implements such a method, but the floating-point approximation of an integer cannot be re-converted into an integer.

This method checks whether the resulting matrix can be converted into the domain type of A only if testargs returns TRUE (e.g., if one calls this method from the interactive level of MuPAD).

Otherwise, one has to take care that the matrix returned is compatible to its component ring.

gaussElimGaussian elimination

```
gaussElim(A)
```

If the matrix is not square, i.e., the determinant of A is not defined, then the third entry of the list returned is the value FAIL.

This method only exists if the component ring R is an integral domain, i.e., a domain of category Cat::IntegralDomain.

If R has the method "pivotSize", then the pivot element of smallest size is chosen at every pivoting step, whereby pivotSize must return a positive integer representing the “size” of an element.

If no such method is defined, Gaussian elimination without a pivot strategy is applied to A.

If R has the axiom Ax::efficientOperation("_invert") and is of category Cat::Field, then ordinary Gaussian elimination is used. Otherwise, fraction-free elimination is performed on A.

If R implements the method "normal", it is used to simplify subsequent computations of the Gaussian elimination process.

Note that if R does not implement the method "normal", but the elements of R are represented by kernel domains, i.e., R has the axiom Ax::systemRep, the system function normal is used instead.
identityIdentity matrix

```
identity(n)
```

This method only exists if the component ring `R` is of category Cat::Ring, i.e., a ring with unit.
intIntegration of matrix components

```
int(A,  )
```

This method only exists if `R` implements the method `"int"`.

This method overloads the system function `int` for matrices, i.e., one may use it in the form `int(A, ...)`.
iszeroTest for zero matrices

```
iszero(A)
```

Note that there may exist more than one representation of the zero matrix of a given dimension if `R` does not have Ax::canonicalRep.

If `R` implements the method `"normal"`, it is used to simplify the components of `A` for the zero-test.

Note that if `R` does not implement such a method, but the elements of `R` are represented by kernel domains, i.e., `R` has the axiom Ax::systemRep, the system function normal is used instead.

This method overloads the function iszero for matrices, i.e., one may use it in the form `iszero(A)`.
matdimMatrix dimension

```
matdim(A)
```

normNorm of matrices and vectors

```
norm(A, Infinity)
```

```
norm(A, Maximum)
```

```
norm(v, Infinity)
```

```
norm(v, Maximum)
```

```
norm(A, Frobenius)
```

```
norm(A, 1)
```

`norm(v, Euclidean)`

`norm(v, k)`

`norm(A, Maximum)` computes the maximum norm of the matrix `A`, which is the maximum row sum (the row sum is the sum of norms of each component in a row).

If the domain `R` does not implement the methods `"max"` and `"norm"`, `FAIL` is returned.

Using `norm(v, Infinity)` for a vector `v` the maximum norm of all elements is returned.

If the domain `R` does not implement the methods `"max"` and `"norm"`, `FAIL` is returned.

Using `norm(v, Maximum)` for a vector `v` the maximum norm of all elements is returned.

If the domain `R` does not implement the methods `"max"` and `"norm"`, `FAIL` is returned.

`norm(A, Frobenius)` computes the Frobenius norm of `A`, which is the square root of the sum of the squares of the norms of each component.

If the result is no longer an element of the domain `R`, or if `R` does not implement the method `"norm"`, `FAIL` is returned.

`norm(A, 1)` computes the 1-norm of the matrix `A`, which is the maximum sum of the norms of the elements of each column. If `R` does not implement the methods `"max"` and `"norm"`, `FAIL` is returned.

`norm(v, Euclidean)` computes the Euclidean norm (2-norm) of the vector `v`, which is defined to be the square root of the sum of the norms of the elements of `v` raised to the square.

`FAIL` is returned if the result is no longer an element of the domain `R`. The function linalg::scalarProduct is used to compute the Euclidean norm of the vector `v`.

If `R` does not implement the method `"norm"`, `FAIL` is returned.

`norm(v, k)` computes the k-norm of the vector `v`, which is defined to be the kth root of the sum of the norms of the elements of `v` raised to the kth power.

`FAIL` is returned if the result is no longer an element of the domain `R`. For k = 2, the function linalg::scalarProduct is used to compute the 2-norm of `v`.

If `R` does not implement the method `"norm"`, `FAIL` is returned.

The method `norm` overloads the function norm for matrices, i.e., one may use it in the form `norm(A k )`, where `k` is either `Infinity`, `Frobenius`, or a positive integer. The default value of `k` is `Infinity`.
normalSimplification of matrix components

`normal(A)`

If `R` does not implement the method `"normal"`, but the elements of `R` are represented by kernel domains, i.e., `R` has the axiom Ax::systemRep, then the system function normal is applied to the components of `A`. Otherwise `normal(A)` returns `A` without any changes.

This method overloads the function normal for matrices, i.e., one may use it in the form `normal(A)`.
nonZerosNumber of non-zero components of a matrix

`nonZeros(A)`
nonZeroesNumber of non-zero components of a matrix

`nonZeroes(A)`
nonZeroOperandsReturn a sequence of all non-zero operands

`nonZeroOperands(A)`

This method is useful for retrieving information on the non-zero entries. For example, to find out the types of the entries in the matrix, one should not consider all operands `op(A)`, because this would also involve the zero entries. For large matrices with few entries, it is much more efficient to use this method to extract the entries.
randomRandom matrix generation

`random()`

This method only exists if `R` implements the method `"random"`.

The dimension of the matrix is also chosen randomly, but it is limited by the values given in `"randomDimen"` (see “Entries” above).

To change the value of the entry `"randomDimen"` for a domain `MatR` created with `Dom::DenseMatrix`, one must first unprotect the domain `Dom` (see unprotect for details).
sinSine of a matrix

```
sin(A)
```

If `A` is not square, an error message is issued. If the component domain of `A` does not allow the computation of `sin(elem)` for an arbitrary element `elem` of the component ring, `FAIL` is returned.

This method uses the function numeric::expMatrix for a floating-point approximation of the exponential of `A` if `A` is defined over the domain Dom::Float.

If some eigenvalues of `A` do not exist in `R` or cannot be computed, then `FAIL` is returned.

In the symbolic case the functions exp and linalg::jordanForm are called. The latter may not be able to compute the Jordan form of `A`. In this case `FAIL` is returned. Increasing the level of information (see setuserinfo) can yield useful information.

This method only exists if `R` is a domain of category Cat::Field.

This method overloads the function sin for matrices, i.e., one may use it in the form `sin(A)`.
sqrtSquare root of a matrix

```
sqrt(A, <sqrtfunc>)
```

Returned is a matrix B with $B^2 = A$ such that the eigenvalues of B are the square roots of the eigenvalues of A or FAIL if the square root of the matrix does not exist. For computing the square roots of the eigenvalues a function satisfying $sqrtfunc(a)^2 = a$ for every element a of the coefficient ring of A can be given as optional second argument.

For details we refer to the help page of the function linalg::sqrtMatrix.
testeqTesting for equality of two matrices

`testeq(A, B)`
trTrace of a square matrix

`tr(A)`

If `A` is not square, then an error message is issued.
transposeTranspose of a matrix

`transpose(A)`
Access Methods
_concatHorizontal concatenation of matrices

`_concat(A, B,  )`

An error message is issued if the given matrices do not have the same number of rows.

This method overloads the function _concat for matrices, i.e., one may use it in the form `A . B . ...`, or in functional notation: `_concat(A, B, ...)`.
_indexMatrix indexing

`_index(A, i, j)`

`_index(A, r1 ..  r2, c1 ..  c2)`

`_index(v, i)`

`_index(v, i1 ..  i2)`

If `i` and `j` are not integers, then the call of this method returns in its symbolic form (of type `"_index"`) with evaluated arguments.

Otherwise an error message is given, if `i` and `j` are not valid row and column indices, respectively.

Note Note that this method uses the system function context to evaluate the entry in the context of the calling environment.

`_index(A,r1..r2,c1..c2)` returns the submatrix of `A` created by the rows of `A` with indices from `r1` to `r2` and the columns of `A` with indices from `c1` to `c2`.

`_index(v,i)` returns the *i*th entry of the vector `v`.

An error message is issued if `v` is not a vector.

If `i` is not an integer, then the call of this method returns in its symbolic form (of type `"_index"`) with evaluated arguments.

Otherwise an error message is given, if `i` is less than one or greater than the dimension of `v`.

Note Note that this method uses the system function context to evaluate the entry in the context of the calling environment.

`_index(v,i1..i2)` returns the subvector of `v`, formed by the entries with index `i1` to `i2`. See also the method `"op"`.

An error message is issued if `v` is not a vector.

This method overloads the function _index for matrices, i.e., one may use it in the form `A[i, j]`, `A[r1..r2, c1..c2]`, `v[i]` and `v[i1..i2]`, respectively, or in functional notation: `_index(A, ...)`.

concatMatrixHorizontal concatenation of matrices

```
concatMatrix(A, B,  )
```

colExtracting a column

```
col(A, c)
```

An error message is issued if `c` is less than one or greater than the number of columns of `A`.

delColDeleting a column

```
delCol(A, c)
```

`NIL` is returned if `A` consists of only one column.

An error message is issued if `c` is less than one or greater than the number of columns of `A`.

delRowDeleting a row

```
delRow(A, r)
```

NIL is returned if A consists of only one row.

An error message is issued if r is less than one or greater than the number of rows of A.

evalpEvaluating matrices of polynomials at a certain point

```
evalp(A, x = a,  )
```

This method is only defined if R is a polynomial ring of category Cat::Polynomial.

This method overloads the function evalp for matrices, i.e., one may use it in the form evalp(A, x = a).

lengthLength of a matrix

```
length(A)
```

This method overloads the function length for matrices, i.e., one may use it in the form length(A).

mapApply a function to matrix components

```
map(A, func, <expr,  >)
```

Note Note that the function values are converted into elements of the domain R only if testargs returns TRUE (e.g., if one calls this method from the interactive level of MuPAD).

If testargs returns FALSE, then one must guarantee that the function calls return elements of the domain type R, otherwise the resulting matrix, which is of domain type Dom::DenseMatrix(R), would have components which are not elements of the domain R!

This method overloads the function map for matrices, i.e., one may use it in the form map(A, func, ...).

mapNonZeroesApply a function to the non-zero components of a matrix

```
mapNonZeroes(A, f, <p1, p2,  >)
```

nopsNumber of components of a matrix

```
nops(A)
```

This method overloads the function nops for matrices, i.e., one may use it in the form `nops(A)`.

opComponent of a matrix

```
op(A, i)
```

```
op(A)
```

This method returns an expression sequence of all components of `A`.

See also the method `"_index"`.

This method overloads the function op for matrices, i.e., one may use it in the form `op(A, i)` and `op(A)`, respectively.

rowExtracting a row

```
row(A, r)
```

An error message is issued if `r` is less than one or greater than the number of rows of `A`.

setColReplacing a column

```
setCol(A, c, v)
```

An error message is issued if `c` is less than one or greater than the number of rows of `A`.

setRowReplacing a row

```
setRow(A, r, v)
```

An error message is issued if `r` is less than one or greater than the number of rows of `A`.

stackMatrixVertical concatenation of matrices

```
stackMatrix(A, B,  )
```

An error message is issued if the given matrices do not have the same number of columns.

subsSubstitution of matrix components

```
subs(A,  )
```

Note Note that the function values are converted into elements of the domain `R` only if testargs returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If testargs returns `FALSE`, then one must guarantee that the function calls return elements of the domain type `R`, otherwise the resulting matrix, which is of domain type `Dom::DenseMatrix(R)`, would have components which are not elements of the domain `R`!

This method overloads the function `subs` for matrices, i.e., one may use it in the form `subs(A, ...)`.

subsexExtended substitution of matrix components

```
subsex(A,  )
```

Note Note that the results of the substitutions are converted into elements of the domain `R` only if testargs returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If testargs returns `FALSE`, then one must guarantee that the results of the substitutions are of the domain type `R`, otherwise the resulting matrix, which is of domain type `Dom::DenseMatrix(R)`, would have components which are not elements of the domain `R`!

This method overloads the function `subsex` for matrices, i.e., one may use it in the form `subsex(A, ...)`.

subsopOperand substitution of matrix components

```
subsop(A, i = x,  )
```

Note Note that x is converted into the domain R only if testargs returns TRUE (e.g., if one calls this method from the interactive level of MuPAD).

If testargs returns FALSE, then x must be an element of R, otherwise the resulting matrix, which is of domain type Dom::DenseMatrix(R), would have components which are not elements of the domain R!

See also the method "set_index".

This method overloads the function subsop for matrices, i.e., one may use it in the form subsop(A, ...).

swapColSwapping matrix columns

```
swapCol(A, c1, c2)
```

```
swapCol(A, c1, c2, r1 ..  r2)
```

An error message is issued if one of the column indices is less than one or greater than the number of columns of A.

swapCol(A,c1,c2,r1..r2) swaps the column with index c1 and the column with index c2 of A, but by taking only those column components which lie in the rows with indices r1 to r2.

An error message is issued if one of the column indices is less than one or greater than the number of columns of A, or if one of the row indices is less than one or greater than the number of rows of A.

swapRowSwapping matrix rows

```
swapRow(A, r1, r2)
```

```
swapRow(A, r1, r2, c1 ..  c2)
```

An error message is issued if one of the row indices is less than one or greater than the number of rows of A.

swapCol(A,r1,r2,c1..c2) swaps the row with index r1 and the row with index r2 of A, but by taking only those row components which lie in the columns with indices c1 to c2.

An error message is issued if one of the row indices is less than one or greater than the number of rows of A, or if one of the column indices is less than one or greater than the number of columns of A.

set_indexSetting matrix components

```
set_index(A, i, j, x)
```

```
set_index(v, i, x)
```

Note Note that x is converted into an element of the domain R only if testargs returns TRUE and i and j are integers (e.g., if one calls this method from the interactive level of MuPAD). If x is a matrix of the same type as A or can be converted into a matrix of the same type as A and the indices i or j are ranges corresponding to a submatrix of A, then x replaces the corresponding submatrix in A.

Otherwise one has to take care that x is of domain type R.

See also the method "subsop".

set_index(v,i,x) replaces the *i*th entry of the vector v by x.

set_index on vectors overloads the function set_index for matrices, i.e., one may use it in the form A[i, j] := x and v[i] := x, respectively, or in functional notation: A := set_index(A, i, j, x) or v := set_index(v, i, x).

zipCombine matrices component-wise

```
zip(A, B, func, <expr,  >)
```

The row number of the matrix returned is the minimum of the row numbers of A and B, and its column number is the minimum of the column numbers of A and B.

Note Note that the function values are converted into elements of the domain `R` only if testargs returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If testargs returns `FALSE`, then one must guarantee that the function calls return elements of the domain type `R`, otherwise the resulting matrix, which is of domain type `Dom::DenseMatrix(R)`, would have components which are not elements of the domain `R`!

This method overloads the function zip for matrices, i.e., one may use it in the form `zip(A, B, ...)`.

Conversion Methods

convertConversion to a matrix

```
convert(x)
```

`FAIL` is returned if the conversion fails.

`x` may either be an array, a matrix, or a list (of sublists, see the parameter `ListOfRows` in "Creating Elements" above). Their entries must then be convertible into elements of the domain `R`.

convert_toMatrix conversion

```
convert_to(A, T)
```

`T` may either be DOM_ARRAY, DOM_LIST, or a domain constructed by `Dom::DenseMatrix` or Dom::SquareMatrix. The elements of `A` must be convertible into elements of the domain `R`.

Use the function expr to convert `A` into an object of a kernel domain (see below).

createDefining matrices without component conversions

```
create(x,  )
```

This method works more efficient than if one creates matrices by calling the method `"new"` of the domain, because it avoids any conversion of the components. One must guarantee that the components have the correct domain type, otherwise run-time errors can be caused.

If x is a list of sublists, it might be a good idea first to create a two-dimensional array from that list before calling this method. This is due to the fact that creating a matrix from an array is the fastest way one can achieve.

Please note that when creating a two-dimensional array from a list of sublists, the sublists must have the same number of elements.

exprMatrix conversion into an object of a kernel domain

```
expr(A)
```

The result is an array representing the matrix A where each entry is an object of a kernel domain.

This method overloads the function expr for matrices, i.e., one may use it in the form expr(A).

expr2textMatrix conversion to a string

```
expr2text(A)
```

This method overloads the function expr2text for matrices, i.e., one may use it in the form expr2text(A).

TeXTeX formatting of a matrix

```
TeX(A)
```

Note that in the case of very large matrices the output will not be useful. For printing large matrices use the function "doprint".

The method "TeX" of the component ring R is used to get the TeX-representation of each component of A.

This method is used by the function generate::TeX.

Technical Methods

assignElementsMultiple assignment to matrices

```
assignElements(A,  )
```

The assigned components must have the domain type R, an implicit conversion of the components into elements of domain type R is not performed.

This method overloads the function assignElements for matrices, i.e., one may use it in the form assignElements(A, ...).

mkDenseConversion of a matrix to an array

```
mkDense(Array)
```

```
mkDense(List)
```

```
mkDense(r, c, List)
```

`mkDense(List)` tries to convert the list `List` into an array `a`. The result is either `FAIL` if this is not possible, or the list `[r, c, a]`, where the positive integers `r` and `c` give the dimension of `a`. See the parameters `List` and `ListOfRows` in "Creating Elements" above for admissible formats of `List`.

The array `a` has dimension one if `r` or `c` is equal to one. The entries of `a` have been converted into elements of the domain `R`.

`mkDense(r,c,List)` tries to convert the list `List` into an array `a` of the dimension `r` times `c`.

The result is either `FAIL` if this is not possible, or the list `[r, c, a]`.

The array `a` has dimension one if `r` or `c` is equal to one. The entries of `a` have been converted into elements of the domain `R`.

printPrinting matrices

```
print(A)
```

Note Note that in general it is not useful to print very large matrices. Hence, a warning message is be displayed if the size of the matrix oversteps a certain dimension – printing such matrices can be done by using the function `"doprint"`.

---

doprintPrinting very large matrices

```
doprint(A)
```

unapplyCreate a procedure from a matrix

```
unapply(A, <x,  >)
```

This method overloads the function `fp::unapply` for matrices, i.e., one may use it in the form `fp::unapply(A)`.

See Also Dom::MatrixDom::MatrixGroupDom::SquareMatrix

Dom::DihedralGroup

Purpose

Dihedral groups

Syntax

Domain Creation

```
Dom::DihedralGroup(n)
```

Element Creation

```
Dom::DihedralGroupn(l)
```

Description

Domain Creation

`Dom::DihedralGroup(n)` creates the dihedral group of size n, i.e., the group of symmetries of a regular polygon with n edges.

`Dom::DihedralGroup(n)` creates the group of all congruent mappings of the plane that induce a bijective mapping of the set of corners of a regular n-angle to itself.

Element Creation

`Dom::DihedralGroup(n)([a,b])` represents the group element "t^a carried out after r^b", where r is a rotation that maps each corner to its left neighbor, and t is a reflection w.r.t. some fixed central diagonal.

Superdomain

Dom::BaseDomain

Axioms

Ax::canonicalRep

Categories

Cat::Group

Examples

Example 1

Define the group D_6, i.e., the group of congruence mappings of the hexagon:
G := Dom::DihedralGroup(6)Dom::DihedralGroup(6)

```
Dom::DihedralGroup(6)
```

Then elements may be created as follows:
a := G([7, 19]);[1, 1]

```
[1, 1]
```

This means that 19 rotations—mapping each corner to its left neighbor—and 7 reflections have the same effect as one operation of either type.

Parameters

n

Positive integer

l

List or array of two integers

Entries

"size"	the number of elements, which equals $2n$.
"one"	the mapping leaving each point fixed.

Methods

Mathematical Methods

_multFunctional composition of elements

```
_mult(a,  )
```

This method overloads the kernel function _mult.

_invertInverse of an element

```
_invert(a)
```

This method overloads the kernel function _invert.

_powerPower of an element

```
_power(a, n)
```

It overloads the kernel function _power.

orderOrder of a group element

```
order(a)
```

randomRandom element

```
random()
```

Conversion Methods

exprConvert group element to list

```
expr(a)
```

TeXTeX output of a group element

```
TeX(a)
```

Dom::DistributedPolynomial

Purpose

Domains of distributed polynomials

Syntax

Domain Creation

```
Dom::DistributedPolynomial(<Vars, <R, <Order>>>)
```

Element Creation

```
Dom::DistributedPolynomial(Vars, R, Order)(p)
Dom::DistributedPolynomial(Vars, R, Order)(lm)
Dom::DistributedPolynomial(Vars, R, Order)(lm, v)
```

Description

`Dom::DistributedPolynomial(Vars, R, ..)` creates the domain of polynomials in the variables of the list `Vars` over the commutative ring `R` in distributed representation.

`Dom::DistributedPolynomial(Vars, R, Order)` creates a domain of polynomials in the variables of the list `Vars` over a domain of category Cat::CommutativeRing in sparse distributed representation with respect to the monomial ordering `Order`.

If `Dom::DistributedPolynomial` is called without any argument, a polynomial domain in arbitrarily many indeterminates over the domain Dom::ExpressionField(`normal`) with respect to the lexicographic monomial ordering is created.

If `Dom::DistributedPolynomial` is called only with the variable list `Vars` as argument, the polynomial domain in the variable list `Vars` over the domain Dom::ExpressionField(`normal`) with respect to the lexicographic monomial ordering is created.

Note Only commutative coefficient rings of type DOM_DOMAIN are allowed which inherit from Dom::BaseDomain. If `R` is of type DOM_DOMAIN but does not inherit from Dom::BaseDomain, the domain Dom::ExpressionField(`normal`) will be used instead.

`Dom::DistributedPolynomial` accepts expressions as indeterminates, similar to the kernel domain DOM_POLY. Hence, for example, `[x,cos(x)]` is a valid variable list.

If the variable list `Vars` is the empty list (`[]`), a polynomial domain in arbitrarily many indeterminates is created. In this case, when creating new elements from polynomials or polynomial expressions, the system function indets is first called to get the variables and then the polynomial is created with respect to these variables. Hence, in this case only identifiers can be valid indeterminates, because indets returns only identifiers.

It is not allowed to create polynomial domains in arbitrarily many indeterminates over another polynomial domain of category Cat::Polynomial, but it is possible to create multivariate polynomial domains with a given list of variables over any polynomial domain.

`Dom::DistributedPolynomial` represents polynomials over arbitrary commutative rings. It is intended as a basic domain for distributed polynomials from which it is easy to create new distributed polynomial domains.

All usual algebraic and arithmetical polynomial operations are implemented, including Gröbner basis computation.

Note It is highly recommended to use only coefficient rings with unique zero representation. Otherwise it can happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

Please note that for reasons of efficiency not all methods check their arguments, not even at the interactive level. In particular this is true for many access methods, converting methods and technical methods.

Superdomain

Dom::BaseDomain

Axioms

If `R` has Ax::normalRep, then Ax::normalRep.

If R has Ax::canonicalRep, then Ax::canonicalRep.

Categories

If Vars has exactly one variable, then Cat::UnivariatePolynomial(R), else Cat::Polynomial(R).

Examples

Example 1

The following call creates a polynomial domain in *x*, *y* and *z*.
DP := Dom::DistributedPolynomial([x, y, z])Dom::DistributedPolynomial([x, y, z], Dom::ExpressionField(normal, iszero@normal), LexOrder)

$$\text{Dom::DistributedPolynomial}([x, y, z], \text{Dom::ExpressionField(norma}$$

Since neither the coefficient ring nor the monomial ordering was specified, this domain is created with the default values for these parameters.

It is rather easy to create elements of this domain, as e.g.
a := DP(x + 2*y*z + 3)x + 2*y*z + 3

$$x + 2\,y\,z + 3$$

b := DP(z^4 - 2*y^2*x^2)- 2*x^2*y^2 + z^4

$$-2\,x^2\,y^2 + z^4$$

In contrast to expressions all elements of this domain have a representation which is fixed by the chosen Order, the representation of the coefficient ring R and the way of representing monomials.

With these elements one can now perform usual arithmetic operations as, e.g., (scalar) multiplication, multiplication with integers and adding polynomials and ring elements:
4*b^2 + a/3 + 1/216*x^4*y^4 - 16*x^2*y^2*z^4 + x/3 + (2*y*z)/3 + 4*z^8 + 3/2

$$16\,x^4\,y^4 - 16\,x^2\,y^2\,z^4 + \frac{x}{3} + \frac{2\,y\,z}{3} + 4\,z^8 + \frac{3}{2}$$

There are a lot of methods for manipulating polynomials and to get access to all parts of a polynomial. For example one has access to the leading monomial of a as follows:
lmonomial(a)x

$$x$$

The leading monomial of a polynomial depends on the monomial ordering, so with respect to the degree order one gets a different result:
lmonomial(a, DegreeOrder)2*y*z

$$2\,y\,z$$

To get a minus its leading monomial one may call:
DP::reductum(a)2*y*z + 3

$$2\,y\,z + 3$$

Obviously the following identity holds:
a - lmonomial(a) - DP::reductum(a)0

$$0$$

There are also methods for converting elements of this domain into other domains, like a basic polynomial domain or the domain of arbitrary expressions:
poly(a), domtype(poly(a))poly(x + 2*y*z + 3, [x, y, z], Dom::ExpressionField(normal, iszero@normal)), DOM_POLY

poly($x + 2\ y\ z + 3$, [x, y, z], Dom::ExpressionField(normal, iszero ∘ r
expr(b), domtype(expr(b))z^4 - 2*x^2*y^2, DOM_EXPR

$z^4 - 2\ x^2\ y^2$, DOM_EXPR

Parameters

Vars

A list of indeterminates. Default is `[]` (the empty list, indicating "arbitrary indeterminates").

R

A commutative ring, i.e., a domain of category Cat::CommutativeRing. Default is `Dom::ExpressionField(normal)`.

Order

A monomial ordering, i.e., one of the predefined orderings `LexOrder`, `DegreeOrder` or `DegInvLexOrder` or any object of type Dom::MonomOrdering. Default is `LexOrder`.

p

A polynomial or a polynomial expression.

lm

List of monomials, which are represented as lists containing the coefficients together with the exponents or exponent vectors.

v

List of indeterminates. This parameter is only valid for `Vars = []`.

Entries

"characteristic"	The characteristic of this domain.
"coeffRing"	The coefficient ring of this domain as defined by the parameter `R`.
"key"	The name of the created domain.
"one"	The neutral element w.r.t. `"_mult"`.
"ordering"	The monomial order as defined by the parameter `Order`.
"variables"	The list of variables as defined by the parameter `Vars`.
"zero"	The neutral element w.r.t. `"_plus"`.

Methods

Mathematical Methods

_divideExact polynomial division

```
_divide(a, b)
```

```
_divide(a, b)
```

```
_divide(a, b)
```

It overloads the function `_divide` for polynomials, i.e., one may use it either in the form `a / b`, or in functional form `_divide(a, b)`.

Note This method only exists if `R` is an integral domain, i.e., a domain of category Cat::IntegralDomain.

_invertInverse of an element

```
_invert(a)
```

_multMultiplie polynomials and coefficient ring elements

```
_mult(<a, b,  >)
```

This method overloads the function _mult for polynomials, i.e., one may use it either in the form `a * b * ...` or in functional notation `_mult(a, b, ...)`.
_negateNegate a polynomial

```
_negate(a)
```

This method overloads the function _negate for polynomials, i.e., one may use it either in the form `-a` or in functional notation `_negate(a)`.
_plusAdd polynomials and coefficent ring elements

```
_plus(<a, b,  >)
```

This method overloads the function _plus for polynomials, i.e., one may use it either in the form `a + b + ...` or in functional notation `_plus(a, b, ...)`.
_powerNth power of a polynomial

```
_power(a, n)
```

This method overloads the function _power for polynomials, i.e., one may use it either in the form `a^n` or in functional notation `_power(a,n)`.
_subtractSubtract a polynomial or a coefficient ring element

```
_subtract(a, b)
```

This method overloads the function _subtract for polynomials, i.e., one may use it either in the form `a - b` or in functional notation `_subtract(a, b)`.
associatesTest if elements are associates

Inherited from Cat::IntegralDomain.
contentContent of a polynomial

```
content(a)
```

Note This method only exists if `R` is a domain of category Cat::GcdDomain.

DDifferential operator for polynomials

```
D(a)
```

```
D(1, a)
```

DpolyDifferential operator for polynomials

```
Dpoly(a)
```

```
Dpoly(l, a)
```

`Dpoly(l,a)` computes the partial derivative of `a` with respect to `l`. For details see polylib::Dpoly.

This method overloads the function polylib::Dpoly for polynomials.
decomposeFunctional decomposition of a polynomial

```
decompose(a, <var>)
```

If `a` is a polynomial in only one variable, the second argument is not necessary.

This method overloads the function polylib::decompose for polynomials.
diffDifferentiate a polynomial

```
diff(a, varseq)
```

If `varseq` is an empty sequence, `a` is returned unchanged.

If in `varseq` an expression occurs which is not a variable of `a`, the zero polynomial is returned.

This method overloads the function diff for polynomials.
dimensionDimension of affine variety

```
dimension(ais, <ord>)
```

```
dimension(ais, <ord>)
```

This method is merely an interface for the function groebner::dimension.

Note This method only exists if `R` is a field, i.e., a domain of category Cat::Field and `Vars` is not the empty list.

---

divideDivide polynomials

```
divide(a, b, <Quo | Rem | Exact>)
```

```
divide(a, b, var, <Quo | Rem | Exact>)
```

If no option is given, the quotient `s` and the remainder `r` are computed such that `a = s*b + r` and the degree of `r` in the relevant indeterminate is smaller than that of `b`. The sequence consisting of `s, r` is returned, otherwise `FAIL`.

If the option `Quo` is given, only the quotient `s` is returned.

If the option `Rem` is given, only the remainder `r` is returned.

If the option `Exact` is given, only the quotient `s` is returned, in case the remainder is zero, otherwise `FAIL`.

`divide(a,b,Exact)` divides the multivariate polynomial `a` by `b`. If `a` cannot be divided by `b`, the method returns FAIL.

This method overloads the function divide for polynomials.

Note This method only exists if `R` is a field, i.e., a domain of category Cat::Field and either this domain is of category `Cat::UnivariatePolynomial(R)` or `R` has characteristic zero (`R::characteristic = 0`). If the first pair of conditions is true then the first call is valid otherwise the second one.

---

dividesTest if elements divides another

Inherited from Cat::IntegralDomain.
equalTest for mathematical equality

Inherited from Dom::BaseDomain.
equivTest for equivalence

Inherited from Cat::BaseCategory.
evalpEvaluate a polynomial

```
evalp(a, var = e)
```

This method overloads the function evalp for polynomials.
factorFactor a polynomial

```
factor(a)
```

This method overloads the function factor for polynomials.

Note This method only exists if R is a domain of category Cat::Field or if R is the domain Dom::Integer.

func_callApplie expressions to a polynomial

```
func_call(a, e1,  , en, <Expr>)
```

```
func_call(a, e1,  , en, <Expr>)
```

```
func_call(a, e1,  , en, <Expr>)
```

`a(e1,...,en)` applies the sequence `e1,...,en` of either elements of this domain or elements of `R` with respect to `Vars` (where `n` is the number of variables) to the polynomial `a`. An element of this domain or an element of the coefficient ring respectively is returned.

`a(e1,...,en, Expr)` applies the sequence of expressions or of elements of this domain or of elements of `R` to the polynomial `a`. With this call `a` is first converted into an expression. Afterwards `e1,...,en` is substituted into this expression with respect to `Vars`. The return value may be any object.

The number of variables must be equal to the number of applied expressions.

Note This method only exists if `Vars` has at least one indeterminate.

gcdGreatest common divisor of polynomials

```
gcd(a, b,  )
```

This method overloads the function gcd for polynomials.

Note This method only exists if `R` is a domain of category Cat::GcdDomain.

gcdexExtended Euclidean algorithm for polynomials

```
gcdex(a, b)
```

This method overloads the function gcdex for polynomials. Especially, it only works for coefficient rings described there.

Note This method only exists if `R` is a domain of category Cat::GcdDomain.

---

groebnerReduced Gröbner basis

```
groebner(ais, <ord>, <Reorder>)
```

```
groebner(ais, <ord>, <Reorder>)
```

If the option `Reorder` is given, the lexicographical order of variables may change to another one that is likely to decrease the running time.

Note Note that this may also cause a change of the returned list, which may now have polynomials over the same coefficient ring `R` but with a possibly re-ordered variable list. Thus, it may contain elements *not* belonging to this domain.

This method is merely an interface for the function groebner::gbasis.

Note This method only exists if `R` is a field, i.e., a domain of category Cat::Field, and `Vars` is not the empty list.

---

idealGeneratorGenerator of finitely generated ideal

Inherited from Cat::EuclideanDomain.
intDefinite and indefinite integration of a polynomial

```
int(a, <x>)
```

```
int(a, <x = x0 ..  x1>)
```

`int(a,x=x0..x1)` returns the definite integral int(a, x = x0..x1) $\int_{x0}^{x1} a \, dx$ or `FAIL`, if the result is not an element of this domain or an element of a polynomial domain over `Dom::Fraction(R)`.

This method overloads the function int for polynomials.
intmultMultiplie a polynomial with an integer

```
intmult(a, z)
```

This method is more efficient than using polynomial multiplication and is, e.g., necessary for the method `"Dpoly"`.
irreducibleTest if element is irreducible

Inherited from Cat::FactorialDomain.
isUnitTest if element is a unit

Inherited from Cat::Polynomial.
isoneTest for one

```
isone(a)
```

Note The result can only be valid if the coefficients of `a` are in normal form (i.e., if zero has a unique representation in `R`). Thus, `R` should have at least Ax::normalRep.

---

iszeroTest for zero

```
iszero(a)
```

Note The result can only be valid, if the coefficients of `a` are in normal form (i.e., if zero has a unique representation in `R`). Thus, the coefficient ring `R` should have at least Ax::normalRep.

---

lcmLeast common multiple of polynomials

```
lcm(a, b,  )
```

This method overloads the function lcm for polynomials.

Note This method only exists if `R` is a domain of category Cat::GcdDomain.

---

makeIntegralMake the coefficients fraction free

```
makeIntegral(a)
```

Note This method only exists if `R` is a domain of category Cat::GcdDomain and `R` has the method `"denom"`.

---

monicNormalize a polynomial

```
monic(a)
```

The zero polynomial returns itself.

Note This method only exists if `R` is a field, i.e., a domain of category Cat::Field.

---

normalFormComplete reduction modulo an ideal

```
normalForm(a, ais, <ord>)
```

```
normalForm(a, ais, <ord>)
```

This method is merely an interface for the function groebner::normalf.

Note This method only exists if `R` is a field, i.e., a domain of category Cat::Field, and `Vars` is not the empty list.

---

numericSolveNumerical zeros of polynomials

```
numericSolve(a, <var>, <options>)
```

```
numericSolve(a, <vars>, options)
```

```
numericSolve(ais, <var>, options)
```

```
numericSolve(ais, <vars>, options)
```

`numericSolve(ais, ..)` tries to find the zeros of the polynomial system `ais` numerically, with the exact behavior depending on further arguments. For details see the function numeric::solve).

All coefficients must be convertible into the basic domain DOM_EXPR, since in a precomputation step all polynomials of this domain are converted into the basic polynomial domain DOM_POLY over DOM_EXPR.

For a detailed description of possible return values and options see function numeric::solve.

This method overloads the function numeric::solve.
pdioeSolve polynomial Diophantine equations

```
pdioe(a, b, c)
```

This method overloads the function solvelib::pdioe.

Note This method only exists if `R` is a field, i.e., a domain of category Cat::Field and `Vars` consists of a single variable.

---

pdivide Pseudo-division of polynomials

```
pdivide(a, b, <Quo | Rem>)
```

If the option `Quo` is given, only the pseudo-quotient `q` is returned.

If the option `Rem` is given, only the pseudo-remainder `r` is returned.

This method overloads the function pdivide for polynomials.

Note This method only exists if `Vars` consists of a single variable.

pquoPseudo-quotient of polynomials

```
pquo(a, b)
```

Note This method only exists if `Vars` consists of a single variable.

premPseudo-remainder of polynomials

```
prem(a, b)
```

Note This method only exists if `Vars` consists of a single variable.

primpartReturn primitive part

Inherited from Cat::Polynomial.
quoEuclidean quotient

Inherited from Cat::EuclideanDomain.
randomCreate a random polynomial

```
random()
```

With every call the global variable `SEED` is changed by a call of `random()`. Thus it is hard to create the same random sequence twice, see random.

If the parameter `Vars` is the empty list, first a list of 1 to 4 variables is generated randomly and the random polynomial is generated in these indeterminates afterwards.

This method overloads the function polylib::randpoly for polynomials.
realSolveIsolate all real roots of a real univariate polynomial

```
realSolve(a, <eps>)
```

`realSolve(a, eps)` returns refined intervals approximating the real roots of `a` to the relative precision given by `eps`.

For a detailed description see function polylib::realroots.

All coefficients must be convertible into either integers, rational numbers or (real) floating-point numbers.

This method overloads the function polylib::realroots for polynomials.

Note This method only exists if `Vars` consists of a single variable.

---

remEuclidean remainder

Inherited from Cat::EuclideanDomain.
resultantResultant of two polynomials

`resultant(a, b, <var>)`

`resultant(a, b, var)` returns the resultant of `a` and `b` with respect to the variable `var`.

The value returned is a polynomial of this domain or `FAIL`.

This method overloads the function polylib::resultant for polynomials.

Note This method only exists if `R` has the method `"_divide"`.

---

ringmultMultiplie a polynomial with a coefficient ring element

`ringmult(a, c)`
solveZero of polynomials

`solve(a, <var>, <options>)`

`solve(a, <vars>, <options>)`

`solve(ais, <var>, <options>)`

```
solve(ais, <vars>, <options>)
```

`solve(ais, ..)` tries to find the zeros of the polynomial system `ais`. The exact behavior depends on further arguments.

For a detailed description of possible return values and options see function solve.

This method overloads the function solve.
SPolynomialCompute the S-polynomial of two polynomials

```
SPolynomial(a, b, <ord>)
```

This method is merely an interface for the function groebner::spoly.

Note This method only exists if `R` is a field, i.e., a domain of category Cat::Field, and `Vars` is not the empty list.

---

sqrfreeSquare-free factorization of polynomials

```
sqrfree(a)
```

The `ai` are primitive and pairwise different square-free divisors of `a` and represented as elements of this domain. `u` is a unit of the coefficient ring and represented as an element of this domain. The `ei` are integers.

This method overloads the function polylib::sqrfree for polynomials.

Note This method only exists if `R` is a field, i.e., a domain of category Cat::Field, or if `R` is Dom::Integer.

---

unitNormalReturn unit normal

Inherited from Cat::Polynomial.
unitNormalRepReturn unit normal representation

Inherited from Cat::Polynomial.

Access Methods

coeffCoefficient of a polynomial

```
coeff(a)
```

```
coeff(a, var, n)
```

```
coeff(a, n)
```

`coeff(a,var,n)` returns the coefficient of the term `var^n`—as an element of this domain if it is of category `Cat::Polynomial(R)`, or as an element of the coefficient ring `R` if it is of `Cat::UnivariatePolynomial(R)`, where `a` is considered as a univariate polynomial in a valid variable `var`.

`coeff(a,n)` returns the coefficient of the term `var^n`—as an element of this domain if it is of category `Cat::Polynomial(R)`, or as an element of the coefficient ring `R` if it is of `Cat::UnivariatePolynomial(R)`, where `a` is considered as a univariate polynomial in `var` and `var` is the main variable of `a`, i.e., the variable returned by `dom::mainvar(a)`.

This method overloads the function coeff for polynomials.

degreeDegree of a polynomial

```
degree(a)
```

```
degree(a, var)
```

`degree(a, var)` returns the degree of `a` with respect to `var`.

The degree of the zero polynomial is defined as zero.

This method overloads the function degree for polynomials.

degreevecVector of exponents of the leading term of a polynomial

```
degreevec(a, <ord>)
```

The degree vector of the zero polynomial is defined as a list of zeros.

This method overloads the function degreevec for polynomials.

euclideanDegreeEuclidean degree function

```
euclideanDegree(a)
```

Note This method only exists if `Vars` consists of a single variable.

groundGround term of a polynomial

```
ground(a)
```

This method overloads the function ground for polynomials.

hasExistence of an object in a polynomial

```
has(a, obj)
```

This method overloads the function has.

indetsIndeterminate of a polynomial

```
indets(<a>)
```

In case `Vars` is not the empty list, `indets` can be called without argument.

Since this domain allows expressions as indeterminates, the returned set may contain expressions, too.

This method overloads the function indets for polynomials.

lcoeffLeading coefficient of a polynomial

```
lcoeff(a)
```

```
lcoeff(a, <vars>, <ord>)
```

`lcoeff(a, ord)` returns the leading coefficient of `a` with respect to the monomial ordering `ord` as an element of the coefficient ring `R`.

`lcoeff(a, vars, ord)` returns the leading coefficient of `a` with respect to the variable list `vars` and the monomial ordering `ord` as an element of this domain if it is of category `Cat::Polynomial(R)`, or as an element of the coefficient ring `R` if it is of `Cat::UnivariatePolynomial(R)`.

- If `ord` is not explicitly given, the lexicographical order `LexOrder` will be used instead.
- It tries to convert `a` into a polynomial in the specified list of indeterminates `vars` over the coefficient ring `R` and returns FAIL if this conversions fails.

This method overloads the function lcoeff for polynomials.

ldegreeLowest degree of a polynomial

```
ldegree(a)
```

```
ldegree(a, x)
```

`ldegree(a, x)` returns the lowest degree of the variable `x` in `a`.

This method overloads the function ldegree for polynomials.

lmonomialLeading monomial of a polynomial

```
lmonomial(a, <ord>)
```

```
lmonomial(a, <vars>, <ord>, <Rem>)
```

`lmonomial(a, vars, ord)` returns the leading monomial of `a` with respect to the variable list `vars` and the monomial ordering `ord` as an element of this domain.

- If `ord` is not explicitly given, the lexicographical order `LexOrder` will be used instead.
- It tries to convert `a` into a polynomial in the specified list of indeterminates `vars` over the coefficient ring `R` and returns FAIL if this conversions fails.

`lmonomial(a, vars, ord, Rem)` returns the list consisting of the leading monomial and the reductum of `a` with respect to the variable list `vars` and the monomial ordering `ord` as a list of elements of this domain.

- If `ord` is not explicitly given, the lexicographical order `LexOrder` will be used instead.
- It tries to convert `a` into a polynomial in the specified list of indeterminates `vars` over the coefficient ring `R` and returns FAIL if this conversions fails.

Note In MuPAD a monomial denotes a coefficient together with a power product as, e.g., $3x^2$.

This method overloads the function lmonomial for polynomials.

ltermLeading term of a polynomial

```
lterm(a)
```

```
lterm(a, <vars>, <ord>)
```

`lterm(a, ord)` returns the leading coefficient of `a` with respect to the monomial ordering `ord` as an element of this domain.

`lterm(a, vars, ord)` returns the leading term of `a` with respect to the variable list `vars` and the monomial ordering `ord` as an element of this domain.

- If `ord` is not explicitly given, the lexicographical order `LexOrder` will be used instead.
- It tries to convert `a` into a polynomial in the specified list of indeterminates `vars` over the coefficient ring `R` and returns FAIL if this conversions fails.

Note In MuPAD a term denotes a power product without a coefficient as, e.g., x^2y^3z.

This method overloads the function lterm for polynomials.

mainvarMain variable of a polynomial

```
mainvar(<a>)
```

If `Vars` is not the empty list, `mainvar` can be called without argument.

mapcoeffsApplie a function to the coefficients of a polynomial

```
mapcoeffs(a, f, <e1,  >)
```

This method overloads the function mapcoeffs for polynomials.

multcoeffsMultiplie the coefficients of a polynomial with a factor

```
multcoeffs(a, c)
```

This method overloads the function multcoeffs for polynomials.

ntermsNumber of terms of a polynomial

```
nterms(a)
```

This method overloads the function nterms for polynomials.

nthcoeffN-th coefficient of a polynomial

```
nthcoeff(a, n, <ord>)
```

If `n` is larger than the number of monomials of the polynomial then the function returns `FAIL`.

The zero polynomial has no monomials. `nthcoeff` returns `FAIL` when invoked on the zero polynomial.

This method overloads the function nthcoeff for polynomials.

nthmonomialN-th monomial of a polynomial

```
nthmonomial(a, n, <ord>)
```

If `n` is larger than the number of monomials of the polynomial then the function returns `FAIL`.

The zero polynomial has no monomials. `nthmonomial` returns `FAIL` for the zero polynomial.

This method overloads the function nthmonomial for polynomials.

nthtermN-th term of a polynomial

```
nthterm(a, n, <ord>)
```

If `n` is larger than the number of monomials of the polynomial then the function returns `FAIL`.

The zero polynomial has no monomials. `nthterm` returns `FAIL` when called with the zero polynomial.

This method overloads the function nthterm for polynomials.

orderedVariableListOrdered list of indeterminates of a polynomial

```
orderedVariableList(<a>)
```

In case `Vars` is not the empty list, `orderedVariableList` can be called without an argument.

pivotSizeSize of a pivot element

```
pivotSize(a)
```

This method is called if this domain is used as the component ring of a matrix domain to perform Gaussian elimination.

reductumReductum of a polynomial

```
reductum(a, <ord>)
```

subsAvoid substitution

Inherited from Dom::BaseDomain.

subsexAvoid extended substitution

Inherited from Dom::BaseDomain.

tcoeffLowest coefficient of a polynomial

```
tcoeff(a, <ord>)
```

This method overloads the function tcoeff for polynomials.

Conversion Methods

coerceCoerce into this domain

`isNeg(a)`

multMultiplie polynomials

```
mult(a, b,  )
```

newCreate a new element

```
new(p)
```

```
new(lm)
```

```
new(lm, v)
```

`dom(p)` creates an element of this domain from a polynomial or a polynomial expression `p` and returns that element. If this is not possible, an error message is given.

If `Vars` is chosen as the empty list (`[]`) then in creating new elements from a polynomial or polynomial expression the function indets is first called to get the identifiers. Afterwards the element is created with this list of identifiers. For creating an element from a constant the dummy variable `_dummy` is introduced. The drawback of this approach is that two mathematically equal polynomials may have variable lists which differ by the dummy variable.

`dom(lm)` creates, if `Vars` is not the empty list `[]`, a polynomial from the list `lm` of the form `[[c1, [e11,... e1n]],... [cm,[em1,... emn]]]` where the `ci` are coefficients and the `eij` are the exponents with respect to `Vars`. For a univariate polynomial this list can be simplified to `[[c1,e1],... [cm,em]]`.

`dom(lm,v)` creates, if `Vars = []`, a polynomial from the list `lm` of the form `[[c1, [e11,... e1n]],... [cm,[em1,... emn]]]` where the `ci` are coefficients and the `eij` are the exponents with respect to `v`. For a univariate polynomial this list can be simplified to `[[c1,e1],... [cm,em]]`. The list of indeterminates `v` must contain valid indeterminates.

plusAdd polynomials

```
plus(a, b,  )
```

printPrint polynomials

```
print(a)
```

This method overloads the function print.

printMethodsPrint out methods

Inherited from Dom::BaseDomain.

printMonomialPrint a monomial in defined order

`printMonomial(c, d, v)`
printTermPrint a term in defined order

`printTerm(d)`

`printTerm(d, v)`

`printTerm(d,v)` returns an ordered sequence of the indeterminates together with their powers as given in the variable list `v` and the degree vector `d` respectively.

Note that this call is only valid if `nops(v)=nops(d)`.

Dom::Expression

Purpose

Domain of all objects of basic type

Syntax

```
Dom::Expression(x)
```

Description

`Dom::Expression` comprises all objects only consisting of operands of built-in types.

`Dom::Expression` is a façade domain: it has no domain elements, but uses system representation.

Unlike Dom::ExpressionField, `Dom::Expression` does not belong to any arithmetical category, and its elements need not be arithmetical expressions.

`Dom::Expression` mainly serves as a super-domain to Dom::ArithmeticalExpression; it rarely makes sense to use it directly.

Superdomain

Dom::BaseDomain

Axioms

Ax::systemRep, Ax::efficientOperation(`"_divide"`), Ax::efficientOperation(`"_mult"`), Ax::efficientOperation(`"_invert"`)

Categories

Cat::BaseCategory

Examples

Example 1

Almost every MuPAD object can be converted to an expression. Objects of basic type *are* expressions.
Dom::Expression([3, array(1..2), rectform(exp(I))])[3, array(1..2, [NIL, NIL]), cos(1) + sin(1)*I]

```
[3, ( NIL  NIL ), cos(1) + sin(1) i]
```

The `convert` method flattens its argument: hence expression sequences are *not* allowed.

Dom::Expression((3, x)) Error: The number of arguments is incorrect.
[expr] Evaluating: Dom::Expression::new

Parameters

x

An object of basic type consisting only of operands of built-in types, or any other object convertible to such using expr.

Entries

"randomIdent"	an identifier used for creating random elements

Methods

Conversion Methods

convertConversion of objects

```
convert(x)
```

convert_toConversion to other domains

```
convert_to(x, T)
```

exprJust return the argument

```
expr(x)
```

testtypeTest whether its argument is an expression

```
testtype(x, Dom::Expression)
```

This method overloads testtype; since `Dom::Expression` has no domain elements, the overloading can only be caused by the second argument.
floatConvert numbers to floats

```
float(x)
```

See Also Dom::ExpressionField

Dom::ExpressionField

Purpose

Domains of expressions forming a field

Syntax

Domain Creation

```
Dom::ExpressionField(<Normal, <IsZero>>)
```

Element Creation

```
Dom::ExpressionField(Normal, IsZero)(e)
```

Description

Domain Creation

`Dom::ExpressionField(Normal, IsZero)` creates a domain of expressions forming a field, where the functions `Normal` and `IsZero` are used to normalize expressions and test for zero.

The function `Normal` is used to normalize the expressions representing the elements, the function `IsZero` is used to test the expressions for zero. It is assumed that the field has characteristic 0.

The domain cannot decide if the element expressions—given the normalizing function and zero test—actually form a field. It is up to the user to choose correct functions for normalizing and zero test and to enter only valid expressions as domains elements.

One should view this domain constructor as a pragmatic way to create a field of characteristic 0 in an ad-hoc fashion. Note that the default of using id and iszero does not yield a field really, but it is often convenient and sensible to use the resulting structure as a field.

`Normal` must be a function which takes an expression representing a domain element and returns the normalized expression. `Normal` should return FAIL if the expression is not valid.

If `Normal` is not given, then the system function id is used, i.e., only the kernel simplifier is used to normalize expressions.

If a normalizing function other than id is given, it is assumed that this functions returns a normal form where the zero element is uniquely represented by the constant `0`.

`IsZero` must be a function which takes an expression representing a domain element and returns TRUE if the expression represents zero and FALSE otherwise.

If `IsZero` is not given, then `iszero @ Normal` is used for zero testing. If `Normal` is equal to id this functional expression is simplified to iszero.

If `Normal` is equal to id and `IsZero` is equal to iszero, a façade domain is created, i.e., the domain elements are simply expressions and are not explicitly created by new.

Otherwise the elements of the domain are explicitly created by new. Each such element has one operand, which is the expression representing the domain element. The element expressions are normalized after each operation using the function `Normal`.

Element Creation

`Dom::ExpressionField(Normal, IsZero)(e)` creates a field element represented by the expression `e`. The expression is normalized using the function `Normal`.

If `Normal` returns FAIL, it is assumed that the expression does not represent a valid field element. If this test is not fully implemented the domain cannot decide if the expression represents a valid field element. In this case it is up to the user to enter only valid expressions as field elements.

If `Normal` is equal to id and `IsZero` is equal to iszero, the domain is only a façade domain. In this case the expression `e` is returned after being simplified by the built-in kernel simplifier.

Superdomain

If `Normal = id` and `IsZero = iszero`, then Dom::ArithmeticalExpression, else Dom::BaseDomain.

Axioms

Ax::indetElements

If `Normal = id` and `IsZero = iszero`, then `Ax::efficientOperation ("_divide"), Ax::efficientOperation ("_mult"), Ax::efficientOperation("_invert")`, else Ax::normalRep.

If `Normal = id` and `IsZero = iszero` and `IsZero = iszero`, then Ax::systemRep.

Categories

Cat::Field, Cat::DifferentialRing

Examples

Example 1

`Dom::ExpressionField(normal)` creates a field of rational expressions over the rationals. The expressions representing the field elements are allways normalized by normal:
Fn := Dom::ExpressionField(normal): a := Fn((x^2 - 1)/(x - 1))x + 1

$$x + 1$$

The field elements are explicit elements of the domain:
domtype(a)Dom::ExpressionField(normal, iszero@normal)

$$\text{Dom::ExpressionField(normal, iszero} \circ \text{normal)}$$

Example 2

In the domain `Dom::ExpressionField(id, iszero@normal)` the expressions representing the elements are normalized by the kernel simplifier only:
Fi := Dom::ExpressionField(id, iszero@normal): a := Fi((x^2 - 1)/(x - 1))(x^2 - 1)/(x - 1)

$$\frac{x^2 - 1}{x - 1}$$

The elements of this domain are not normalized (when viewed as rational expressions over the rationals), thus the domain does not have the axiom Ax::normalRep:
b := a/Fi(x + 1) - Fi(1)(x^2 - 1)/((x - 1)*(x + 1)) - 1

$$\frac{x^2 - 1}{(x-1)(x+1)} - 1$$

But nevertheless this domain also represents the field of rational expressions over the rationals, because zero is detected correctly by the function `iszero @ normal`:

```
iszero(b)TRUE
```

$$\mathrm{TRUE}$$

Parameters

Normal

A function used to normalize the expressions of the domain; default is id.

IsZero

A function used to test the expressions of the domain for zero; default is `iszero @ Normal`.

e

An expression representing a field element.

Entries

"characteristic"	The characteristic of the fields created by this constructor is assumed to be `0`.
"one"	The element represented by the expression `1` is assumed to be a neutral element w.r.t. `"_mult"`.
"zero"	The element represented by the expression `0` is assumed to be a neutral element w.r.t. `"_plus"`.

Methods

Mathematical Methods

absAbsolute value

```
abs(x)
```

Overloads the function abs, thus may be called via `abs(x)`.

combineCombine terms of the same algebraic structure

```
combine(x, <a>)
```

Overloads the function combine, thus may be called via `combine(x,...)`.

conjugateComplex conjugate

```
conjugate(x)
```

Overloads the function conjugate, thus may be called via `conjugate(x)`.

DDifferential operator

```
D(<l>, x)
```

Overloads the function D, thus may be called via `D(x)` or `D(l, x)`.

denomDenominator

```
denom(x)
```

Overloads the function denom, thus may be called via `denom(x)`.

diffDifferentiate an element

```
diff(x, <v, ,  >)
```

Overloads the function diff, thus may be called via `diff(x,...)`.

_divideDivide elements

```
_divide(x, y)
```

Overloads the function _divide, thus may be called via `x/y` or `_divide(x, y)`.

equalTest for mathematical equality

```
equal(x, y)
```

expandExpand an element

```
expand(x)
```

Overloads the function expand, thus may be called via `expand(x)`.

factorFactorize an element

```
factor(x)
```

Overloads the function factor, thus may be called via `factor(x)`.
floatFloating-point approximation

```
float(x)
```

Overloads the function float, thus may be called via `float(x)`.
gcdGreatest common divisor

```
gcd(x,  )
```

Overloads the function gcd, thus may be called via `gcd(x,...)`.
ImImaginary part of an element

```
Im(x)
```

Overloads the function Im, thus may be called via `Im(x)`.
intDefinite and indefinite integration

```
int(x, <v>)
```

Overloads the function int, thus may be called via `int(x,...)`.
intmultInteger mutiple

```
intmult(x, n)
```

_invertInvert an element

```
_invert(x)
```

Overloads the function _invert, thus may be called via `1/x` or `_invert(x)`.
iszeroTest for zero

```
iszero(x)
```

Overloads the function iszero, thus may be called via `iszero(x)`.
lcmLeast common multiple

```
lcm(x,  )
```

Overloads the function lcm, thus may be called via `lcm(x, ...)`.
_leequalTest if less or equal

```
_leequal(x, y)
```

Please note that the function _leequal can only test numbers (in a syntactical sense), but not constant expressions like PI or `sqrt(2)`.

Overloads the function _leequal, thus may be called via `x <= y`, `y >= x` or `_leequal(x, y)`.
_lessTest if element is less

```
_less(x, y)
```

Please note that the function _less can only test numbers (in a syntactical sense), but not constant expressions like PI or `sqrt(2)`.

Overloads the function _less, thus may be called via `x < y`, `y > x` or `_less(x, y)`.
limitLimit computation

```
limit(x, <v,  >)
```

Overloads the function limit, thus may be called via `limit(x,...)`.
maxMaximum of arguments

```
max(x,  )
```

Overloads the function max, thus may be called via `max(x,...)`.
minMinimum of arguments

```
min(x,  )
```

Overloads the function min, thus may be called via `min(x,...)`.
_multMultiplie elements

```
_mult(x,  )
```

If all arguments are of this domain or can be coerced to this domain (using the method coerce), the product of the expressions representing the arguments is calculated using the function _mult.

If one of the arguments cannot be coerced, the arguments up to the offending one are multiplied and then the method `"_mult"` of the domain of the offending argument is called to multiply the remaining arguments.

Overloads the function _mult, thus may be called via `x*...` or `_mult(x,...)`.
_negateNegate an element

```
_negate(x)
```

Overloads the function _negate, thus may be called via `-x` or `_negate(x)`.
normNorm of an element

```
norm(x)
```

Overloads the function norm, thus may be called via `norm(x)`.

Please note that the system function norm, applied to an expression, computes the norm of that expression interpreted as a polynomial expression and *not* the absolute value of the expression. This may be regarded as an inconsistency.
normalNormal form

```
normal(x)
```

Overloads the function normal, thus may be called via `normal(x)`.
numerNumerator

```
numer(x)
```

Overloads the function numer, thus may be called via `numer(x)`.
_plusAdd elements

```
_plus(x,  )
```

If all arguments are of this domain or can be coerced to this domain (using the method coerce) the sum of the expressions representing the arguments is calculated using the function _plus.

If one of the arguments cannot be coerced the arguments up to the offending one are added and then the method `"_plus"` of the domain of the offending argument is called to add the remaining arguments.

Overloads the function _plus, thus may be called via `x+...` or `_plus(x,...)`.
_powerExponentiate arguments

```
_power(x, y)
```

```
_power(x, y)
```

If both arguments are of this domain the power is calculated by mapping the function _power to the expressions representing the arguments.

If one of the arguments is not of this domain it is coerced to this domain, then the power is computed. If the coercion fails an error is raised.

Note that it is assumed that at least one of the arguments is of this domain.

Overloads the function _power, thus may be called via `x^y` or `_power(x, y)`.
radsimpSimplifie radicals

```
radsimp(x)
```

Overloads the function radsimp, thus may be called via `radsimp(x)`.
randomCreate a random element

```
random()
```

See polylib::randpoly for details about creating random polynomials.
ReReal part of an element

```
Re(x)
```

Overloads the function Re, thus may be called via `Re(x)`.
signSign of an element

```
sign(x)
```

Overloads the function sign, thus may be called via `sign(x)`.
simplifyGeneral simplification of an element

```
simplify(x, <a>)
```

Overloads the function simplify, thus may be called via `simplify(x,...)`.
solveSolve an equation

```
solve(x, <a,  >)
```

Note that this method will never return an element of this domain. See solve for details about results and optional additional arguments.

Overloads the function solve, thus may be called via `solve(x,...)`.
sqrfreeSquare-free factorization

```
sqrfree(x)
```

Overloads the function polylib::sqrfree, thus may be called via `polylib::sqrfree(x)`.

_subtractSubtract elements

```
_subtract(x, y)
```

Overloads the function _subtract, thus may be called via `x-y` or `_subtract(x, y)`.

Conversion Methods

convertConvert to this domain

```
convert(x)
```

convert_toConvert to other domain

```
convert_to(x, T)
```

exprConvert to basic type

```
expr(x)
```

This method is called by the function expr if a subexpression of the argument is an element of this domain.

newCreating an element

```
new(x)
```

Overloads the function call operator for this domain, thus may be called via `F(x)` where `F` is this domain.

Access Methods

nopsNumber of operands

```
nops(x)
```

Overloads the function nops, thus may be called via `nops(x)`.

opGet operands

```
op(x)
```

```
op(x, i)
```

Returns the operand with index `i` of the expression representing `x`. If `i` is `0` then the operator of the expression is returned, which usually is not an element of this domain. The other operands are converted to elements of this domain.

This method is called by the function op when an element of this domain is contained, as a subexpression, in the first argument of op. Operand ranges

and paths are handled by op and need not be handled by this method. See op for details.

subsSubstitute subexpressions

```
subs(x, e,  )
```

Maps subs to the expression representing `x`. The resulting expression is converted to an element of this domain.

This method is called by the function subs when an element of this domain is contained, as a subexpression, in the first argument of subs. See subs for details.

subsexExtended substitution

```
subsex(x, e, ,  )
```

Maps subsex to the expression representing `x`. The resulting expression is converted to an element of this domain.

This method is called by the function subsex when an element of this domain is contained, as a subexpression, in the first argument of subsex. See subsex for details.

subsopSubstitute operand

```
subsop(x, e, ,  )
```

This method is called by the function subsop when an element of this domain is contained, as a subexpression, in the first argument of subsop. Operand ranges and pathes are handled by subsop and need not be handled by this method. See subsop for details.

Technical Methods

indetsIdentifier of an element

```
indets(x, <optionName>)
```

Overloads the function indets, thus may be called via `indets(x)` and `indets(x, optionName)`, respectively.

lengthSize of an element

```
length(x)
```

Overloads the function length, thus may be called via `length(x)`.

mapApplie function to operands

```
map(x, f, <a,  >)
```

Overloads the function map, thus may be called via `map(x, f,...)`.

rationalizeApproximate floating-point numbers by rationals

```
rationalize(x, <a,  >)
```

Note that this method does *not* overload the function rationalize from the standard library package, but the function numeric::rationalize from the `numeric` package instead. Thus the method may be called via `numeric::rationalize(x,...)`.

pivotSizePivot size

```
pivotSize(x)
```

Dom::Float

Purpose

Real floating-point numbers

Syntax

```
Dom::Float(x)
```

Description

`Dom::Float` is the set of real floating-point numbers represented by elements of the domain DOM_FLOAT.

`Dom::Float` is the domain of real floating point numbers represented by expressions of type `DOM_FLOAT`.

`Dom::Float` has category Cat::Field out of pragmatism. This domain actually is not a field because `bool(1.0 = float(3) / float(3))` returns `FALSE` for example.

Elements of `Dom::Float` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input expression may be converted to a floating point number. This means `Dom::Float` is a facade domain which creates elements of domain type `DOM_FLOAT`.

Viewed as a differential ring `Dom::Float` is trivial, it contains constants only.

`Dom::Float` has the domain Dom::Numerical as its super domain, i.e., it inherits each method which is defined by `Dom::Numerical` and not implemented by `Dom::Float`. Methods described below are re-implemented by `Dom::Float`.

Superdomain

Dom::Numerical

Axioms

Ax::canonicalRep, Ax::systemRep, Ax::canonicalOrder, Ax::efficientOperation(`"_divide"`), Ax::efficientOperation(`"_mult"`), Ax::efficientOperation(`"_invert"`)

Categories

Cat::DifferentialRing, Cat::Field, Cat::OrderedSet

Examples

Example 1

Creating some floating-point numbers using `Dom::Float`. This example also shows that `Dom::Float` is a facade domain.
Dom::Float(2.3); domtype(%)2.3

2.3
DOM_FLOAT

DOM_FLOAT
Dom::Float(sin(2/3*PI) + 3)3.866025404

3.866025404
Dom::Float(sin(x)) Error: The arguments are invalid. [Dom::Float::new]

Example 2

By tracing the method `Dom::Float::testtypeDom` we can see the interaction between testtype and `Dom::Float::testtypeDom`.
prog::trace(Dom::Float::testtypeDom): delete x: testtype(x, Dom::Float); testtype(3.4, Dom::Float); prog::untrace(Dom::Float::testtypeDom):enter Dom::Float::testtypeDom(x, Dom::Float) computed FAIL FALSE

FALSE
enter Dom::Float::testtypeDom(3.4, Dom::Float) computed TRUE
TRUE

TRUE

Parameters

x

An expression which can be converted to a `DOM_FLOAT` by the function float.

Entries

"one"	the unit element; it equals `1.0`.
"zero"	The zero element; it equals `0.0`.

Methods

Mathematical Methods

pivotSizeSize of a pivot element

```
pivotSize(x)
```

This method is called if this domain is used as the component ring of a matrix domain to perform Gaussian elimination.

randomRandom number generation

```
random()
```

Conversion Methods

convertConversion of objects

```
convert(x)
```

In general, if `float(x)` evaluates to a real floating-point number of type `DOM_FLOAT`, this number is the result of the conversion.

convert_toConversion to other domains

```
convert_to(x, T)
```

The following domains are allowed for `T`: DOM_FLOAT, `Dom::Float` and Dom::Numerical.

testtypeType checking

```
testtype(x, T)
```

In general this method is called from the function testtype and not directly by the user. “Example 2” on page 6-159 demonstrates this behavior.

See Also

Dom::ComplexDom::IntegerDom::NumericalDom::RationalDom::Real

Dom::FloatIV

Purpose

The “field” of Floating Point Intervals

Syntax

```
Dom::FloatIV(x,  )
```

Description

`Dom::FloatIV` is the inclusion algebra of (finite unions of) rectangular intervals in the complex plane.

`Dom::FloatIV` is the domain of kernel intervals of type DOM_INTERVAL.

`Dom::FloatIV` has category Cat::Field out of pragmatism. This domain actually is not a field because, for example, there is no additive inverse of `1...2`.

Elements of `Dom::FloatIV` are usually not created explicitly. The syntax given above is equivalent to an interval call, with no check to ensure that the result is in fact an interval, it could, for example, also be an expression with all numerical coefficients replaced by intervals. Apart from this behavior of the constructor and the `"convert"` slot, `Dom::FloatIV` is a façade domain for elements of domain type `DOM_INTERVAL`.

Viewed as a differential ring `Dom::FloatIV` is trivial, it contains constants only.

`Dom::FloatIV` has the domain Dom::Numerical as its super domain, i.e., it inherits each method which is defined by `Dom::Numerical` and not re-implemented by `Dom::FloatIV`. Methods described below are those implemented by `Dom::FloatIV`.

Superdomain

Dom::Fraction

Purpose

Field of fractions of an integral domain

Syntax

Domain Creation

```
Dom::Fraction(R)
```

Element Creation

```
Dom::Fraction(R)(r)
```

Description

Domain Creation

`Dom::Fraction(R)` creates a domain which represents the field of fractions F=ImageSet(x/y, x in R_, y in R_ minus {0}) $F = \left\{ \frac{x}{y} \;\middle|\; x \in \mathbb{R},\ y \in \mathbb{R} \setminus \{0\} \right\}$ of the integral domain R.

An element of the domain `Dom::Fraction(R)` has two operands, the numerator and denominator.

If `Dom::Fraction(R)` has the axiom Ax::canonicalRep (see below), the denominators have unit normal form and the gcds of numerators and denominators cancel.

The domain `Dom::Fraction(Dom::Integer)` represents the field of rational numbers. But the created domain is not the domain Dom::Rational, because it uses a different representation of its elements. Arithmetic in `Dom::Rational` is much more efficient than it is in `Dom::Fraction(Dom::Integer)`.

Element Creation

If `r` is a rational expression, then an element of the field of fractions `Dom::Fraction(R)` is created by going through the operands of `r` and converting each operand into an element of `R`. The result of this process is `r` in the form (x)/(y) $\frac{x}{y}$, where x and y are elements of `R`. If `R` has Cat::GcdDomain, then x and y are coprime.

If one of the operands can not be converted into the domain `R`, an error message is issued.

Superdomain Dom::BaseDomain

Axioms Ax::normalRep

Categories Cat::QuotientField(R)

Examples

Example 1

We define the field of rational functions over the rationals:
F := Dom::Fraction(Dom::Polynomial(Dom::Rational))Dom::Fraction(Dom::Polynomial(D
LexOrder))

$$\text{Dom::Fraction(Dom::Polynomial(Dom::Rational, LexOrder))}$$

and create an element of F:
a := F(y/(x - 1) + 1/(x + 1))(x + y + x*y - 1)/(x^2 - 1)

$$\frac{x + y + x\,y - 1}{x^2 - 1}$$

To calculate with such elements use the standard arithmetical operators:
2*a, 1/a, a*a(2*x + 2*y + 2*x*y - 2)/(x^2 - 1), (x^2 - 1)/(x + y + x*y - 1), (x^2*y^2 + 2*x^2*y + x^2 + 2*x*y^2 - 2*x + y^2 - 2*y + 1)/(x^4 - 2*x^2 + 1)

$$\frac{2\,x + 2\,y + 2\,x\,y - 2}{x^2 - 1},\quad \frac{x^2 - 1}{x + y + x\,y - 1},\quad \frac{x^2\,y^2 + 2\,x^2\,y + x^2 + 2\,x\,y^2 - 2}{x^4 - 2\,x^2 + 1}$$

Some system functions are overloaded for elements of domains generated by Dom::Fraction, such as diff, numer or denom (see the

description of the corresponding methods `"diff"`, `"numer"` and `"denom"` above).

For example, to differentiate the fraction `a` with respect to `x` enter:
diff(a, x)-(y - 2*x + 2*x*y + x^2*y + x^2 + 1)/(x^4 - 2*x^2 + 1)

$$-\frac{y - 2\,x + 2\,x\,y + x^2\,y + x^2 + 1}{x^4 - 2\,x^2 + 1}$$

If one knows the variables in advance, then using the domain Dom::DistributedPolynomial yields a more efficient arithmetic of rational functions:
Fxy := Dom::Fraction(Dom::DistributedPolynomial([x, y], Dom::Rational))Dom::Fraction(Dom::DistributedPolynomial([x, y], Dom::Rational, LexOrder))

Dom::Fraction(Dom::DistributedPolynomial([x, y], Dom::Rational, Lex(
b := Fxy(y/(x - 1) + 1/(x + 1)): b^3(x^3*y^3 + 3*x^3*y^2 + 3*x^3*y + x^3 + 3*x^2*y^3 + 3*x^2*y^2 - 3*x^2*y - 3*x^2 + 3*x*y^3 - 3*x*y^2 - 3*x*y + 3*x + y^3 - 3*y^2 + 3*y - 1)/(x^6 - 3*x^4 + 3*x^2 - 1)

$$\left(x^3\,y^3 + 3\,x^3\,y^2 + 3\,x^3\,y + x^3 + 3\,x^2\,y^3 + 3\,x^2\,y^2 - 3\,x^2\,y - 3\,x^2 + 3\,x\,y^3 - 3\,x\,y^2 - 3\,x\,y + 3\,x + y^3 - 3\,y^2 + 3\,y - 1\right)\Big/\left(x^6 - 3\,x^4 + 3\,x^2 - 1\right)$$

Example 2

We create the field of rational numbers as the field of fractions of the integers, i.e., Symbol::Qopf =ImageSet(x/y, x in Z_, y in Z_ minus {0})

$$\mathbb{Q} = \left\{ \frac{x}{y} \;\middle|\; x \in \mathbb{Z},\ y \in \mathbb{Z} \setminus \{0\} \right\}:$$

Q := Dom::Fraction(Dom::Integer): Q(1/3)1/3

$\frac{1}{3}$ domtype(%)Dom::Fraction(Dom::Integer)

Dom::Fraction(Dom::Integer)

Another representation of in MuPAD is the domain Dom::Rational where the rationals are of the kernel domains DOM_INT and DOM_RAT. Therefore it is much more efficient to work with `Dom::Rational` than with `Dom::Fraction(Dom::Integer)`.

Parameters

`R`

An integral domain, i.e., a domain of category Cat::IntegralDomain

`r`

A rational expression, or an element of `R`

Entries

"characteristic"	is the characteristic of `R`.
"coeffRing"	is the integral domain `R`.
"one"	is the one of the field of fractions of `R`, i.e., the fraction 1.
"zero"	is the zero of the field of fractions of `R`, i.e., the fraction 0.

Methods

Mathematical Methods

_divideDivide two fractions

`_divide(x, y)`

This method overloads the function `_divide` for fractions, i.e., one may use it in the form `x / y` or in functional notation: `_divide(x, y)`.

_invertInvert a fraction

`_invert(r)`

This method overloads the function `_invert` for fractions, i.e., one may use it in the form `1/r` or `r^(-1)`, or in functional notation: `_invert(r)`.
_lessLess-than relation

`_less(q, r)`

An implementation is provided only if `R` is an ordered set, i.e., a domain of category Cat::OrderedSet.

This method overloads the function `_less` for fractions, i.e., one may use it in the form `q < r`, or in functional notation: `_less(q, r)`.
_multMultiplie fractions by fractions or rational expressions

`_mult(q, r)`

If `q` is not of the domain type `Dom::Fraction(R)`, it is considered as a rational expression which is converted into a fraction over `R` and multiplied with `q`. If the conversion fails, `FAIL` is returned.

The same applies to `r`.

This method also handles more than two arguments. In this case, the argument list is splitted into two parts of the same length which both are multiplied with the function _mult. The two results are multiplied again with `_mult` whose result then is returned.

This method overloads the function _mult for fractions, i.e., one may use it in the form `q * r` or in functional notation: `_mult(q, r)`.
_negateNegate a fraction

`_negate(r)`

This method overloads the function _negate for fractions, i.e., one may use it in the form `-r` or in functional notation: `_negate(r)`.
_powerInteger power of a fraction

`_power(r, n)`

This method overloads the function _power for fractions, i.e., one may use it in the form `r^n` or in functional notation: `_power(r, n)`.
_plusAdd fractions

```
_plus(q, r,  )
```

If one of the arguments is not of the domain type `Dom::Fraction(R)`, then `FAIL` is returned.

This method overloads the function _plus for fractions, i.e., one may use it in the form `q + r` or in functional notation: `_plus(q, r)`.
DDifferential operator

```
D(r)
```

An implementation is provided only if `R` is a partial differential ring, i.e., a domain of category Cat::PartialDifferentialRing.

This method overloads the operator D for fractions, i.e., one may use it in the form `D(r)`.
denomDenominator of a fraction

```
denom(r)
```

This method overloads the function denom for fractions, i.e., one may use it in the form `denom(r)`.
diffDifferentiation of fractions

```
diff(r, u)
```

This method overloads the function diff for fractions, i.e., one may use it in the form `diff(r, u)`.

An implementation is provided only if `R` is a partial differential ring, i.e., a domain of category Cat::PartialDifferentialRing.
equalTest on equality of fractions

```
equal(q, r)
```

factorFactorize the numerator and denominator of a fraction

```
factor(r)
```

The factors u, r_1, ..., r_n are fractions of type `Dom::Fraction(R)`, the exponents e_1, ..., e_n are integers.

The system function factor is used to perform the factorization of the numerator and denominator of `r`.

This method overloads the function factor for fractions, i.e., one may use it in the form `factor(r)`.
intmultInteger multiple of a fraction

```
intmult(r, n)
```

iszeroTest for zero

```
iszero(r)
```

An element of the field `Dom::Fraction(R)` is zero if its numerator is the zero element of `R`. Note that there may be more than one representation of the zero element if `R` does not have Ax::canonicalRep.

This method overloads the function iszero for fractions, i.e., one may use it in the form `iszero(r)`.
numerNumerator of a fraction

```
numer(r)
```

This method overloads the function numer for fractions, i.e., one may use it in the form `numer(r)`.
randomRandom fraction generation

```
random()
```

The returning fraction is normalized (see the methods `"normalize"` and `"normalizePrime"`.

Conversion Methods

convert_toFraction conversion

```
convert_to(r, T)
```

If the conversion fails, `FAIL` is returned.

The conversion succeeds if `T` is one of the following domains: Dom::Expression or Dom::ArithmeticalExpression.

Use the function expr to convert `r` into an object of a kernel domain (see below).

exprConvert a fraction into an object of a kernel domain

```
expr(r)
```

The result is an object of a kernel domain (e.g., DOM_RAT or DOM_EXPR).

This method overloads the function expr for fractions, i.e., one may use it in the form `expr(r)`.

TeXTeX formatting of a fraction

```
TeX(r)
```

The method `TeX` of the component ring `R` is used to get the TeX-representations of the numerator and denominator of `r`, respectively.

retractRetraction to base domain

```
retract(r)
```

Technical Methods

normalizeNormalizing fractions

```
normalize(x, y)
```

Normalization means to remove the gcd of `x` and `y`. Hence, `R` needs to be of category Cat::GcdDomain. Otherwise, normalization cannot be performed and the result of this method is the fraction (x)/(y) $\frac{x}{y}$.

normalizePrimeNormalizing fractions over integral domains with a gcd

```
normalizePrime(x, y)
```

In rings of category Cat::GcdDomain, elements are assumed to be relatively prime. Hence, there is no need to normalize the fraction (x)/(y) $\frac{x}{y}$.

In rings not of category Cat::GcdDomain, normalization of elements can not be performed and the result of this method is the fraction (x)/(y) $\frac{x}{y}$.

Dom::Rational

Dom::GaloisField

Purpose

Finite fields

Syntax

Domain Creation

```
Dom::GaloisField(q)
Dom::GaloisField(p, n)
Dom::GaloisField(p, n, f)
Dom::GaloisField(F, n)
Dom::GaloisField(F, n, f)
```

Element Creation

```
Dom::GaloisField(p, n, f)(g)
```

Description

Domain Creation

`Dom::GaloisField(p, n, f)` creates the residue class field

_outputSequence(Z_p,'[X]/<f>')$Z_p[X]/<f>$, a finite field with p^n elements. If `f` is not given, it is chosen at random among all irreducible polynomials of degree n.

`Dom::GaloisField(q)` (where $q = p^n$) is equivalent to `Dom::GaloisField(p,n)`.

`Dom::GaloisField(F, n, f)` creates the residue class field *F[X]/<f>*, a finite field with $|F|^n$ elements.

If `f` is not given, a random irreducible polynomial of appropriate degree is used; some free identifier is chosen as its variable, and this one must also be used when creating domain elements.

Although $n = 1$ is allowed, Dom::IntegerMod should be used for representing prime fields.

If `F` is of type `Dom::GaloisField`, consisting of residue classes of polynomials, the variable of these polynomials must be distinct from the variable of `f`. If a tower several of Galois fields is constructed, the variable used in the uppermost Galois field must not equal any of those used in the tower. A special entry `"VariablesInUse"` serves to keep track of all variables appearing somewhere in the tower.

Element Creation

`Dom::GaloisField(p,n,f)(g)` (or, respectively, `Dom::GaloisField(F,n,f)(g)`) creates the residue class of `g` modulo `f`. It is represented by the unique polynomial in that class that has smaller degree than `f`.

Dom::ImageSet

Purpose

Domain of images of sets under mappings

Syntax

Domain Creation

```
Dom::ImageSet()
```

Element Creation

```
Dom::ImageSet(f, x, S)
Dom::ImageSet(f, [x1,  ], [S1,  ])
```

Description

Domain Creation

`Dom::ImageSet` is the domain of all sets of complex numbers that can be written as the set of all values taken on by some mapping, i.e., sets of the form ImageSet(f(x[1], Symbol::hellip, x[n]), x[i] in S[i])$\{f(x_1, \ldots, x_n) \mid x_i \in S_i\}$ for some function *f* and some sets $S_1, \ldots, S_n$.

Image sets are mainly used by solve to express sets like ImageSet(k*PI, k in Z_)$\{k\ \pi \mid k \in \mathbb{Z}\}$.

`Dom::ImageSet` belongs to the category Cat::Set—arithmetical and set-theoretic operations are inherited from there.

Element Creation

`Dom::ImageSet(f, x, S)` represents the set of all values that can be obtained by substituting some element of `S` for `x` in the expression `f`.

`Dom::ImageSet(f, [x1, ...], [S1, ...])` represents the set of all values that can be obtained by substituting, for each *i*, the identifier x_i by some element of S_i in the expression `f`.

`Dom::ImageSet(f, x, S)` represents the set ImageSet(f, x in S)$\{f \mid x \in S\}$. `Dom::ImageSet(f, [x1, ..., xn], [S1, ..., Sn])` represents the set ImageSet(f, x[i] in S[i]), i = 1...n$\{f \mid x_i \in S_i\},\ i = 1 \ldots n$.

`f` need not contain `x`; on the other hand, it may contain other identifiers (free variables).

If a list of several identifiers is given, the identifiers must be distinct.

`S` must be a set; see solve for an overview of the different kinds of sets in MuPAD.

`Dom::ImageSet` carries out some automatical simplifications that may produce a result of a type different from `Dom::ImageSet`.

`Dom::ImageSet` renames the variables `x1, ..., xn`, in order to avoid naming conflicts as well as producing a nicer output.

Superdomain

Dom::BaseDomain

Categories

Cat::Set

Examples

Example 1

We define S to be the set of all integer multiples of π.
S:= Dom::ImageSet(ugly*PI, ugly, Z_)Dom::ImageSet(PI*k, k, Z_)

$$\{\pi\ k \mid k \in \mathbb{Z}\}$$

Our ugly variable name has been replaced by a nicer one which suggests that it represents an integer.

We may now apply the usual set-theoretic operations.
S intersect Dom::Interval(3..7){PI, 2*PI}

$$\{\pi, 2\ \pi\}$$

Example 2

An element of an image set may be obtained by substituting all parameters by some values:
S:= Dom::ImageSet(a^7 + b^3 + C, [a, b], [Z_, Z_])Dom::ImageSet(k^7 + l^3 + C, [k, l], [Z_, Z_])

$$\{k^7 + l^3 + C \mid k \in \mathbb{Z}, l \in \mathbb{Z}\}$$

On calling the `evalParam` method, we have to take care that the variable names have been replaced.
Dom::ImageSet::evalParam(S, k = 3, l = 5)C + 2312

$$C + 2312$$

The same may be achieved using the index operator:
S[3, 5]C + 2312

$$C + 2312$$

Substituting only for one parameter, we obtain an image set in the other parameter:
Dom::ImageSet::evalParam(S, k = 3)Dom::ImageSet(l^3 + C + 2187, l, Z_)

$$\{l^3 + C + 2187 \mid l \in \mathbb{Z}\}$$

A parameter may be substituted by itself, meaning that it becomes a free variable:
Dom::ImageSet::evalParam(S, k = k)Dom::ImageSet(k^7 + l^3 + C, l, Z_)

$$\{k^7 + l^3 + C \mid l \in \mathbb{Z}\}$$

The `evalParam` method cannot be used to substitute a free variable:
Dom::ImageSet::evalParam(S, C = 3)Dom::ImageSet(k^7 + l^3 + C, [k, l], [Z_, Z_])

$$\{k^7 + l^3 + C \mid k \in \mathbb{Z}, l \in \mathbb{Z}\}$$

delete S:

Parameters

f

Arithmetical expression

x

Identifier or indexed identifier

S

Set of any type

Methods

Mathematical Methods

changevarChange the name of a variable

```
changevar(A, oldvar, newvar)
```

The new variable `newvar` must not equal any element of the list of variables; this is not checked!

setvarSet the name of the variable

```
setvar(A, newvar)
```

```
setvar(A, newvar)
```

For an argument `A` that is not an image set, the method `"setvar"` is applied to all image sets contained in the expression `A`. `A` might be, for example, a union, intersection, etc. of image sets and other sets.

homogpointwiseDefine an n-ary pointwise operator for image sets

```
homogpointwise(Op)
```

`Op` must accept arithmetical expressions as arguments.

isEmptyTest whether a set is empty

```
isEmpty(A)
```

substituteBySetSubstitute an ImageSet for a variable

```
substituteBySet(a, x, A)
```

freeIndetsFree parameters of a set

```
freeIndets(A)
```

If A=ImageSet(f(x[1], Symbol::hellip, x[n], y[1], Symbol::hellip * y[k]), x[i] in S[i])$A = \{f(x_1, \ldots, x_n, y_1, \ldots y_k) \mid x_i \in S_i\}$, the x_i are called bound and the y_i are called free parameters.

Use the slot `"variables"` to obtain the bound parameters.
evalParamInsert values for bound parameters

```
evalParam(A(x = value,  ))
```

If `x` is not a parameter, but a free variable of `A`, it is not substituted by `value`.

`value` may be an identifier or contain identifiers; in particular, it may contain `x` and/or some of the remaining parameters. This may be used to convert parameters into free variables.

Several parameters may be replaced in a single call.

See “Example 2” on page 6-180.
_indexExtract element by inserting values for bound parameters

```
_index(A, value1,  )
```

The number of values passed must match the number of variables of `A`.

It is not checked whether for each i, the value for the ith parameter belongs to the ith set.

See “Example 2” on page 6-180.

Dom::Integer

Purpose

Ring of integer numbers

Syntax

```
Dom::Integer(x)
```

Description

`Dom::Integer` is the ring of integer numbers represented by elements of the domain DOM_INT.

Elements of `Dom::Integer` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input is an integer number. This means that `Dom::Integer` is a façade domain which creates elements of domain type `DOM_INT`.

Viewed as a differential ring `Dom::Integer` is trivial, it contains constants only.

`Dom::Integer` has the domain Dom::Numerical as its super domain, i.e., it inherits each method which is defined by `Dom::Numerical` and not re-implemented by `Dom::Integer`. Methods described below are those implemented by `Dom::Integer`.

The following domains are allowed for `T`: DOM_INT, `Dom::Integer`, Dom::Rational, DOM_FLOAT, Dom::Float and Dom::Numerical.

testtypeType checking

`testtype(x, T)`

Usually, this method is called from the function testtype and not directly by the user. “Example 2” on page 6-186 demonstrates this behavior.

Dom::IntegerMod

Purpose

Residue class rings modulo integers

Syntax

Domain Creation

```
Dom::IntegerMod(n)
```

Element Creation

```
Dom::IntegerMod(n)(a)
```

Description

Domain Creation

`Dom::IntegerMod(n)` creates the residue class ring of integers modulo `n`.

`Dom::IntegerMod(n)` creates the integer residue class rings _outputSequence(Z_,'/',n,Z_)$\mathbb{Z}/n\mathbb{Z}$.

Element Creation

`Dom::IntegerMod(n)(a)` creates the residue class of `a` modulo `n`.

Superdomain

Dom::BaseDomain

Axioms

Ax::normalRep, Ax::canonicalRep, Ax::noZeroDivisors, Ax::closedUnitNormals, Ax::canonicalUnitNormal, Ax::efficientOperation(`"_invert"`), Ax::efficientOperation(`"_divide"`), Ax::efficientOperation(`"_mult"`)

Categories

If `n` is prime, then Cat::Field, else Cat::CommutativeRing.

Examples

Example 1

We define the residue class ring of the integers `mod 7`:
Z7:= Dom::IntegerMod(7)Dom::IntegerMod(7)

Dom::IntegerMod(7)

Next, we create some elements:
a:= Z7(1); b:= Z7(2); c:= Z7(3)1 mod 7

1 mod 7
2 mod 7

2 mod 7
3 mod 7

3 mod 7

We may use infix notation for arithmetical operations since the operators have been overloaded:
a + b, a*b*c, 1/c, b/c/a/c3 mod 7, 6 mod 7, 5 mod 7, 1 mod 7

3 mod 7, 6 mod 7, 5 mod 7, 1 mod 7

`a` and `b` are squares while `c` is not:
Z7::isSquare(a), Z7::isSquare(b), Z7::isSquare(c)TRUE, TRUE, FALSE

TRUE, TRUE, FALSE

Indeed, `c` is a generator of the group of units:
Z7::order(a), Z7::order(b), Z7::order(c)1, 3, 6

1, 3, 6

Parameters

`n`

Positive integer greater than 1

`a`

Any integer or a rational number whose denominator is coprime to `n`

Entries

"characteristic"	the characteristic of the residue class ring, `n`
"one"	the unit element, `1 mod n`
"zero"	the zero element, `0 mod n`

Methods

Mathematical Methods

_divideDivision of two elements

`_divide(element1, element2)`

_invertInvert elements

`_invert(element)`

_multMultiply elements

`_mult(element, )`

_negateNegate elements

`_negate(element)`

_plusAdd elements

`_plus(element, )`

_powerPower of elements

`_power(element, power)`

_subtractSubtraction of two elements

`_subtract(element1, element2)`

Dom::Interval

Purpose

Intervals of real numbers

Syntax

```
Dom::Interval(l, r)
Dom::Interval([l], r)
Dom::Interval(l, [r])
Dom::Interval([l], [r])
Dom::Interval([l, r])
```

Description

`Dom::Interval` represents the set of all intervals of real numbers.

`Dom::Interval(l, r)` creates the interval of all real numbers between `l` and `r`. If a border is given as a list with `l` or `r` as the sole element, this border will be regarded as a closed border, otherwise the interval does not contain `l` and `r`.

A border can be any arithmetical expression that could represent a real number, e.g., `sqrt(2*x)` and `a + I`. Properties are ignored.

The domain `Dom::Interval` provides fundamental operations to combine intervals with intervals and other mathematical objects.

The return value can be either an interval of type `Dom::Interval` or the empty set of type DOM_SET, if the interval is empty.

Most mathematical operations are overloaded to work with intervals (such as sin). If *f* is a function of *n* real variables, its extension to intervals is defined to be f(J[1], Symbol::hellip, J[n]) = ImageSet(f(j[1], Symbol::hellip, j[n]), j[i] in J[i])$f(J_1, \ldots, J_n) = \{f(j_1, \ldots, j_n) \mid j_i \in J_i\}$. The return value of such an operation is in most cases an interval, a union of intervals, a Dom::ImageSet or a set. For example, the sine of an interval `[a, b]` is the interval `{sin(x), x in [a, b]}` that contains all sine values of the given interval. In general, you should expect the return value to be an interval larger than strictly necessary. Also note that, when using the same interval twice in one formula, the uses are regarded as independent, so `interval1/interval1` does not return the interval `[1, 1]` as you might expect.

The functions overloaded in this way are:

- _mult, _divide, _invert, _power
- _plus, _negate, _subtract
- abs
- cos, arccos, cosh, arccosh, cot, arccot, coth, arccoth, csc, arccsc, csch, arccsch, sec, arcsec, sech, arcsech, sin, arcsin, sinh, arcsinh, tan, arctan, tanh, arctanh
- dirac, heaviside
- exp, ln
- sign

Furthermore, an interval is a special type of set. This is reflected by `Dom::Interval` having the category Cat::Set. Among the methods inherited from Cat::Set, the following are especially important: intersect, minus and union.

An interval can be open or closed. If one border is given as a list with one element `[x]`, then this element `x` is taken as border and the interval will be created as closed at this side. If the interval should be closed at both sides, one list with the both borders as arguments can be given.

Superdomain

Dom::BaseDomain

Categories

Cat::Set, Cat::AbelianMonoid

Examples

Example 1

First create a closed interval between `0` and `1`.
A:= Dom::Interval([0], [1])Dom::Interval([0], [1])

```
[0, 1]
```

Now another open interval between `-1` and `1`.

B:= Dom::Interval(-1, 1)Dom::Interval(-1, 1)

$$(-1, 1)$$

Intervals can be handled like other objects.
A + B, A - B, A*B, A/BDom::Interval(-1, 2), Dom::Interval(-1, 2), Dom::Interval(-1, 1), R_

$$(-1, 2), (-1, 2), (-1, 1), \mathbb{R}$$

2*A, 1 - A, (A - 1)^2Dom::Interval([0], [2]), Dom::Interval([0], [1]), Dom::Interval([0], [1])

$$[0, 2], [0, 1], [0, 1]$$

Example 2

Standard functions are overloaded to work with intervals.
sin(B), float(sin(B))Dom::Interval(-sin(1), sin(1)), Dom::Interval(-0.8414709848, 0.8414709848)

$$(-\sin(1), \sin(1)), (-0.8414709848, 0.8414709848)$$

Example 3

The next examples shows some technical methods to access and manipulate intervals.

Get the borders and open/closed information about intervals.
A:= Dom::Interval([0], [1]): Dom::Interval::left(A), Dom::Interval::leftB(A)0, [0]

$$0, [0]$$

Dom::Interval::isleftopen(A), Dom::Interval::subsleft(A, -1)FALSE, Dom::Interval([-1], [1])

```
FALSE, [-1, 1]
```

Parameters

I

The left border. If given as a list of one element (the left border), the interval will be created as left closed.

r

The right border. If given as a list of one element (the right border), the interval will be created as right closed.

Entries

"one"	the unit element; it equals the one-point interval [1, 1].
"zero"	the zero element; it equals the one-point interval [0, 0].

Methods

Mathematical Methods

ImImaginary part of an interval (this always equals zero)

```
Im(interval)
```

ReReal part of an interval (this is the interval)

```
Re(interval)
```

_divideDivide intervals

```
_divide(interval1, interval2)
```

_intersectIntersection of sets

Inherited from Cat::Set.

_invertInvert intervals

```
_invert(interval)
```

_minusSet of subtractions

Inherited from Cat::Set.
_multSet of product of set elements

Inherited from Cat::Set.
_negateNegate intervals

`_negate(interval)`
_plusSet of sums of set elements

Inherited from Cat::Set.
_powerPointwise power

Inherited from Cat::Set.
_subtractSubtract intervals

`_subtract(interval1, interval2)`
_unionUnion of sets

Inherited from Cat::Set.
absAbsolute value of intervals

`abs(interval)`
arccosInverse cosine of intervals

`arccos(interval)`
arccoshArea cosine of intervals

`arccosh(interval)`
arccotInverse cotangent of intervals

`arccot(interval)`
arccothArea cotangent of intervals

`arccoth(interval)`
arcsinInverse sine of intervals

`arcsin(interval)`
arcsinhArea sine of intervals

`arcsinh(interval)`
arctanInverse tangent of intervals

`arctan(interval)`
arctanhArea tangent of intervals

```
arctanh(interval)
```
coerceCoerce into this domain

Inherited from Cat::BaseCategory.
containsContaining an element

```
contains(interval, element)
```
cosCosinu of intervals

```
cos(interval)
```
coshHyperbolic cosinus of intervals

```
cosh(interval)
```
cotCotangent of intervals

```
cot(interval)
```
cothHyperbolic cotangent of intervals

```
coth(interval)
```
diracDirac distribution of an interval

```
dirac(interval)
```
equivTest for equivalence

Inherited from Cat::BaseCategory.
expExponential function of an interval

```
exp(interval)
```
heavisideHeaviside function

```
heaviside(interval)
```
intmultReturn integer multiple

Inherited from Cat::AbelianMonoid.
lnNatural logarithm of an interval

```
ln(interval)
```
maxMaximum of an interval

```
max(interval,  )
```

The maximum of intervals is the set of all possible results of the function max when applied to a sequence of arguments consisting of exactly one element of each interval.

minMinimum of an interval

```
min(interval,  )
```

The minimum of intervals is defined analogously to their maximum.
newCreate an interval

```
new(left, right)
```

```
new([left], right)
```

```
new(left, [right])
```

```

Type::Interval

Dom::LinearOrdinaryDifferentialOperator

Purpose

Domain of linear ordinary differential operators

Syntax

Domain Creation

```
Dom::LinearOrdinaryDifferentialOperator(<Var,
<DVar, <Ring>>>)
```

Element Creation

```
Dom::LinearOrdinaryDifferentialOperator(Var, DVar, Ring)(p)
Dom::LinearOrdinaryDifferentialOperator(Var, DVar, Ring)(l)
Dom::LinearOrdinaryDifferentialOperator(Var,
DVar, Ring)(eq, yx)
```

Description

`Dom::LinearOrdinaryDifferentialOperator(Var, DVar, Ring)` creates the domain of linear ordinary differential operators with coefficients in the differential ring `Ring` and with derivation `Var` where `DVar` is the differential indeterminate. Elements of this domain are also called Ore polynomials and the multiplication of two elements is completely determined by the prescribed rule Var * r = r * Var + diff(r,DVar) $\mathrm{Var}\ r = r\ \mathrm{Var} + \frac{\partial}{\partial \mathrm{DVar}} r$ for every element `r` in `Ring`. And so `Dom::LinearOrdinaryDifferentialOperator` is a noncommutative ring.

Note Nevertheless, for some reasons, for every element `r` in `Ring`, `Var*r` is automatically rewritten as `r*Var`. See “Example 1” on page 6-207.

If `Dom::LinearOrdinaryDifferentialOperator` is called without any argument, a domain with coefficients in Dom::ExpressionField(`normal`) with derivation `Df` and differential indeterminate `x` is created.

Note Only commutative differential rings of type DOM_DOMAIN are allowed which inherit from Dom::BaseDomain. If `Ring` is of type DOM_DOMAIN but does not inherit from Dom::BaseDomain, the domain Dom::ExpressionField(`normal`) will be used instead.

Note It is highly recommend to use only coefficient rings with unique zero representation. Otherwise it can happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

Examples

Example 1

First we create the domain of linear ordinary differential operators:
lodo := Dom::LinearOrdinaryDifferentialOperator()Dom::LinearOrdinaryDifferentialOpera
x, Dom::ExpressionField(normal, iszero@normal))

Dom::LinearOrdinaryDifferentialOperator(Df, x, Dom::ExpressionF

by default the above domain has coefficients in the field Dom::ExpressionField(`normal`) with derivation `Df` and differential indeterminate `x`.

We can create elements of `lodo` in 3 ways: polynomials in `Df`, list of elements of Dom::ExpressionField and with a linear ordinary homogeneous differential equation:
lodo(Df^2 + (x + 1)*Df + 2*x), lodo([2*x, x + 1, 1]), lodo(diff(y(x),x,x) + (x + 1)*diff(y(x),x) + 2*x*y(x), y(x))Df^2 + (x + 1)*Df + 2*x, Df^2 + (x + 1)*Df + 2*x, Df^2 + (x + 1)*Df + 2*x

$$Df^2 + (x + 1)\,Df + 2\,x,\ Df^2 + (x + 1)\,Df + 2\,x,\ Df^2 + (x + 1)\,Df + 2\,x$$

It's easy to obtain the linear differential equation associated to a linear differential operator:
L := lodo((x + x^3)*Df^3 + (6*x^2 + 3)*Df^2 - 12): L(y(x))6*x^2*diff(y(x), x, x) - 12*y(x) + x*diff(y(x), x, x, x) + x^3*diff(y(x), x, x, x) + 3*diff(y(x), x, x)

$$6\,x^2\,\frac{\partial^2}{\partial x^2}\,y(x) - 12\,y(x) + x\,\frac{\partial^3}{\partial x^3}\,y(x) + x^3\,\frac{\partial^3}{\partial x^3}\,y(x) + 3\,\frac{\partial^2}{\partial x^2}\,y(x)$$

and one can also evaluates a differential operator at an expression:
L(2*x^2 + 1), L(ln(x)), L(ln(x), Unsimplified)0, -(12*x^2*ln(x) + 4*x^2 + 1)/x^2, (2*(x^3 + x))/x^3 - (6*x^2 + 3)/x^2 - 12*ln(x)

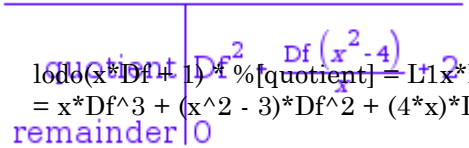
$$0,\ -\frac{12\,x^2\,\ln(x) + 4\,x^2 + 1}{x^2},\ \frac{2\,(x^3 + x)}{x^3} - \frac{6\,x^2 + 3}{x^2} - 12\,\ln(x)$$

Multiplication of elements of `lodo` is noncommutative but for every element `r` of the coefficients ring one has `Df*r = r*Df`:
lodo(x^2*Df), lodo(Df*x^2), lodo(Df)*lodo(x^2)x^2*Df, x^2*Df, x^2*Df + 2*x

$$x^2\,\mathrm{Df},\ x^2\,\mathrm{Df},\ x^2\,\mathrm{Df} + 2\,x$$

Example 2

`Dom::LinearOrdinaryDifferentialOperator` is a domain where the Euclidean division exists but one has to precise if the multiplication of 2 elements of this domain is made on the right or on the left side:
L1 := lodo(x*Df^3 + (x^2 - 3)*Df^2 + 4*x*Df + 2):
lodo::leftDivide(L1,lodo(x*Df + 1))table(remainder = 0, quotient = Df^2 + ((x^2 - 4)/x)*Df + 2)



lodo(x*Df + 1) * %[quotient] = L1x*Df^3 + (x^2 - 3)*Df^2 + (4*x)*Df + 2
= x*Df^3 + (x^2 - 3)*Df^2 + (4*x)*Df + 2

$$x\,Df^3 + (x^2 - 3)\,Df^2 + (4\,x)\,Df + 2 = x\,Df^3 + (x^2 - 3)\,Df^2 + (4\,x)\,Df + 2$$

Hence one has the notions of greatest common divisor, least common multiple on the right and on the left, and a modified version of the extended Euclidean algorithm:
L2 := lodo(x*Df + 1): ree := lodo::rightExtendedEuclid(L1,L2)[[-12/x^2, 1, - Df^2 - ((x^2 - 6)/x)*Df - (2*(x^2 + 6))/x^2], [(x^3/12)*Df + x^2/4, -(x^3/12)*Df^3 + (x^2/4 - x^4/12)*Df^2 - (x^3/2)*Df - x^2/2]]

$$\left[\left[-\frac{12}{x^2},\ 1,\ -Df^2 - \frac{x^2 - 6}{x}\,Df - \frac{2\,(x^2 + 6)}{x^2}\right],\ \left[\frac{x^3}{12}\,Df + \frac{x^2}{4},\ -\frac{x^3}{12}\,Df^3 + \left(\right.\right.\right.$$

The right greatest common divisor and the left least common multiple can be read from the above list:
iszero(lodo::rightGcd(L1,L2) - ree[1][1]), iszero(ree[1][1] - (ree[1][2]*L1 + ree[1][3]*L2)), iszero(lodo::leftLcm(L1,L2) - (-ree[2][1]*L1)), iszero(-ree[2][1]*L1 - ree[2][2]*L2)TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE

Example 3

One can compute polynomial, rational and exponential zeros of linear differential operators of any degree provided the ring `Ring` is the field of rational functions of `x`

```
L3 := lodo((x^2 + 1)*x*Df^3 + 3*(2*x^2 + 1)*Df^2 - 12):
lodo::rationalZeros(L3), lodo::exponentialZeros(L3){x^2 + 1/2}, {x^2 +
1/2, x*sqrt(x^2 + 1)}
```

$$\left\{x^2 + \frac{1}{2}\right\}, \left\{x^2 + \frac{1}{2}, x\sqrt{x^2 + 1}\right\}$$

even when the operator contains some parameters rationally:

```
lodo::exponentialZeros( lodo(Df^4 + (b*l - 2*a^2 - a*l*x)*Df^2 +
a^4-a^2*b*l + a^3*l*x)){exp(a*x), exp(-a*x)}
```

$$\left\{e^{a\,x}, e^{-a\,x}\right\}$$

Example 4

One can factorize linear differential operators into irreducible factors when the ring `Ring` is the field of rational functions of `x`. Nevertheless, the algorithm is complete only for operators of degree at most 3; for higher degree only left and right factors of degree 1 are found:

```
factor(lodo((x^2 + 1)*x*Df^3 + 3*(2*x^2 + 1)*Df^2 - 12)),
factor(lodo(Df^3 + a*x*Df + a + b^3 + a*b*x))((x*(x^2 + 1))*Df + 5*x^2
+ 3)*(Df + (x*(6*x^2 + 5))/((x^2 + 1)*(2*x^2 + 1)))*(Df - (4*x)/(2*x^2 +
1)), (- Df - b)*(- Df^2 + b*Df - a*x - b^2)
```

$$\left((x^2 + 1)\,Df + 5\,x^2 + 3\right)\left(Df + \frac{x\,(6\,x^2 + 5)}{(x^2 + 1)\,(2\,x^2 + 1)}\right)\left(Df - \frac{4\,x}{2\,x^2 + 1}\right),$$

Here the operator factors into two factors of degree 2 which cannot be found by MuPAD:

$$(-Df - b)\left(-Df^2 + b\,Df - a\,x - b^2\right)$$

```
factor(lodo(Df^2 + x^3 + 1/x^3) * lodo(Df^2 + x^2 - 1/x^3))Df^4 + (x^2
+ x^3)*Df^2 + ((2*(2*x^5 + 3))/x^4)*Df + (- 12*x + x^5 + x^6 + x^11
- 1)/x^6
```

$$Df^4 + (x^2 + x^3)\,Df^2 + \frac{2\,(2\,x^5 + 3)}{x^4}\,Df + \frac{-12\,x + x^5 + x^6 + x^{11} - 1}{x^6}$$

Example 5

Solving linear differential operators using the command solve is also possible:

```
solve(lodo(Df^2 + (3 - x)/(16*x^2))){x^(1/4)*exp(-sqrt(x)/2),
x^(1/4)*exp(sqrt(x)/2)}
```

$$\left\{x^{1/4}\,e^{-\frac{\sqrt{x}}{2}},\ x^{1/4}\,e^{\frac{\sqrt{x}}{2}}\right\}$$

For certain cases, where the groups associated to the dfferential operators are finite primitive groups of degree 2, a polynomial is returned corresponding to the minimal polynomial of all zeros of the differential operator (they are algebraic over the base field):

```
solve(lodo(Df^2 + (-27*x + 32*x^2 + 27)/(144*x^2 - 288*x^3 +
144*x^4))){RootOf(_Y1^24 + (-4320*x^2*(x - 1)^3)*_Y1^16 +
((51840*sqrt(3)*I)*x^3*(x - 2)*(x - 1)^4)*_Y1^12 + (-2799360*x^4*(x
- 1)^6)*_Y1^8 + ((4478976*sqrt(3)*I)*x^5*(x - 2)*(x - 1)^7)*_Y1^4 +
2985984*x^8*(x - 1)^8, _Y1)}
```

$$\{\mathrm{RootOf}(_{Y1}^{24} + (-4320\,x^2\,(x-1)^3)\,_{Y1}^{16} + ((51840\,\sqrt{3}\,i)\,x^3\,(x-2)\,(x$$
$$+ (-2799360\,x^4\,(x-1)^6)\,_{Y1}^{8} + ((4478976\,\sqrt{3}\,i)\,x^5\,(x-2)\,(x-1)^7)$$

For linear differential operators of degree greater than 3 only exponential zeros will be found:

```
solve(lodo(x*Df^4 + (-x + 4)*Df^3 + 3*Df^2 - x + x^2)){exp(x)/x}
```

$$\left\{\frac{e^{x}}{x}\right\}$$

Certain second degree linear differential operator can be solved in terms of some special functions (nonliouvillian functions) such as airyAi, besselI and whittakerM:
solve(lodo(Df^2 - (x + 1)/(x - 1)^5)){airyAi(-(2*2^(1/3)*sqrt(3)*I + 2*2^(1/3)*x + 2*2^(1/3) + 2*2^(1/3)*sqrt(3)*x*I)/(8*x - 8), 0)*(x - 1), airyBi(-(2*2^(1/3)*sqrt(3)*I + 2*2^(1/3)*x + 2*2^(1/3) + 2*2^(1/3)*sqrt(3)*x*I)/(8*x - 8), 0)*(x - 1)}

solve(lodo(Df^2 - (243 + 4*x^8 + 162*x^2 + 19*x^4)/36/x^2/(x^2 + 3)^2)){whittakerM(1/2, -2/3, x^2/3 + 1)/sqrt(x), whittakerW(1/2, -2/3, x^2/3 + 1)/sqrt(x)}

$$\left\{airyAi\left(-\frac{2\,2^{1/3}\sqrt{3}\,i + 2\,2^{1/3}\,x + 2\,2^{1/3} + 2\,2^{1/3}\sqrt{3}\,x\,i}{8\,x - 8}, 0\right)(x-1),\ airyBi\left(-\frac{2\,2^{1/3}\sqrt{3}\,i + 2\,2^{1/3}\,x + 2\,2^{1/3} + 2\,2^{1/3}\sqrt{3}\,x\,i}{8\,x - 8}, 0\right)(x-1)\right\}$$

$$\left\{\frac{M_{\frac{1}{2},-\frac{2}{3}}\left(\frac{x^2}{3}+1\right)}{\sqrt{x}}, \frac{W_{\frac{1}{2},-\frac{2}{3}}\left(\frac{x^2}{3}+1\right)}{\sqrt{x}}\right\}$$

Parameters

Var

An indeterminate of type DOM_IDENT. Default is `Df`.

DVar

A differential indeterminate of type DOM_IDENT. Default is `x`.

Ring

An arbitrary commutative differential ring of characteristic zero. Default is Dom::ExpressionField(normal).

p

A polynomial expression in Var.

l

A list corresponding to the coefficients of the differential operator. If n is the length of l then the result returned is l[1] + l[2]*Var + ... + l[n]*Var^(n-1).

eq

A linear homogeneous differential equation.

yx

A function of DVar representing the dependent variable of the above linear differential equation.

Methods

Mathematical Methods

_multMultiplie linear differential operators

```
_mult(<a, b, >)
```

This method overloads the function _mult of the system kernel, i.e. one may use it either in the form a * b * ... or in functional notation _mult(a, b, ...).

_negateNegate a linear differential operator

```
_negate(a)
```

This method overloads the function _negate of the system kernel, i.e. one may use it either in the form -a or in functional notation _negate(a).

_plusAdd linear differential operators and coefficient ring elements

```
_plus(<a, b, >)
```

This method overloads the function _plus of the system kernel, i.e. one may use it either in the form a + b + ... or in functional notation _plus(a, b, ...).

_powerNth power of a linear differential operator

```
_power(a, n)
```

This method overloads the function _power of the system kernel, i.e., one may use it either in the form `a^n` or in functional notation `_power(a,n)`.
_subtractSubtract a linear differential operator

```
_subtract(a, b)
```

This method overloads the function _subtract of the system kernel, i.e. one may use it either in the form `a - b` or in functional notation `_subtract(a, b)`.
adjointAdjoint of a linear differential operator

```
adjoint(a)
```

companionSystemCompanion matrix of a linear differential operator

```
companionSystem(a)
```

If `a` is not of positive degree, an error message is issued.
DDerivative of a linear differential operator

```
D(<l>, a)
```

DpolyDerivative of a linear differential operator

```
Dpoly(<l>, a)
```

`Dpoly(l,a)` computes the partial derivative of `a` with respect to `l`. If `l = [1,...,1]` with `length(l) = n` then the method computes the `n`-th derivative `a`. If `l = []` then the result returned is `a`.
evalLODOApplie an expression to a linear differential operator

```
evalLODO(a, f)
```

This method may be used either in the form `a(f)` or in functional notation `evalLODO(a,f)`.
exponentialZerosExponential zeros of a linear differential operator

```
exponentialZeros(a)
```

Note This method only works when `Ring` is the field of rational functions in `DVar`.

---

factorFactor a linear differential operator

```
factor(a)
```

Note This method is only available when the base field `Ring` is the field of rational functions in `DVar`. If `a` is of degree greater than or equal to 4 then only left and right factors of degree 1 of `a` will be found. Otherwise, a complete factorization is returned.

This method overloads the function factor of the system kernel.
factorsList of irreducible factors of a linear differential operator

```
factors(a)
```

func_callApplie an expression to a linear differential operator

```
func_call(a, f, <Unsimplified>)
```

This method may be used either in the form `a(f)` or in functional notation `func_call(a,f)`.
leftDivideLeft division of 2 linear differential operators

```
leftDivide(a, b)
```

leftExtendedEuclidLeft extended Euclidean algorithm for linear differential operators

```
leftExtendedEuclid(a, b)
```

leftExtendedGcdCoefficient in the left extended Euclidean algorithm

```
leftExtendedGcd(a, b)
```

leftGcdLeft greatest common divisor of linear differential operators

```
leftGcd(a, b)
```

leftLcmLeft least common multiple of linear differential operators

```
leftLcm(a, b)
```

leftQuotientLeft quotient of linear differential operators

```
leftQuotient(a, b)
```

leftRemainderLeft remainder of linear differential operators

`leftRemainder(a, b)`
makeIntegralIntegral form of a linear differential operator

`makeIntegral(a)`
monicNormalize a linear differential operator

`monic(a)`
polynomialZerosPolynomial zeros of a linear differential operator

`polynomialZeros(a)`

Note This method only works when `Ring` is the field of rational functions in `DVar`.

---

rationalZerosRational zeros of a linear differential operator

`rationalZeros(a)`

Note This method only works when `Ring` is the field of rational functions in `DVar`.

---

rightDivideRight division of 2 linear differential operators

`rightDivide(a, b)`
rightExtendedEuclidRight extended Euclidean algorithm for linear differential operators

`rightExtendedEuclid(a, b)`
rightExtendedGcdCoefficient in the right extended Euclidean algorithm

`rightExtendedGcd(a, b)`
rightGcdRight greatest common divisor of linear differential operators

`rightGcd(a, b)`
rightLcmRight least common multiple of linear differential operators

`rightLcm(a, b)`

rightQuotientRight quotient of linear differential operators

```
rightQuotient(a, b)
```

rightRemainderRight remainder of linear differential operators

```
rightRemainder(a, b)
```

solveZero of a linear differential operator

```
solve(a, <Transform>, <Irreducible>)
```

The algorithm for finding liouvillian solutions is complete for operators of degree at most 2 and enables to solve partially operators of higher degree (i.e. it finds all exponential solutions). The algorithm for finding solutions in terms of special functions (nonliouvillian solutions) is not complete even for the degree 2.

When option `Transform` is given the unimodular transformation is performed unconditionally and when option `Irreducible` is given, `a` is assumed to be irreducible.

Note This method only works when `Ring` is the field of rational functions in `DVar`.

This method overloads the function solve of the system kernel.
symmetricPowerSymmetric power of a linear differential operator

```
symmetricPower(a, m)
```

unimodularUnimodular transformation of a linear differential operator

```
unimodular(a, <Transform>)
```

If the option `Transform` is given then `a` is transformed unconditionally even if `a` has yet a unimodular Galois group.

Access Methods

coeffCoefficient of a linear differential operator

```
coeff(a)
```

```
coeff(a, Var, n)
```

`coeff(a, n)`

`coeff(a,Var,n)` returns the coefficient of the term `Var^n` as an element of the coefficient ring `Ring`, where `a` is a linear differential operator in the variable `Var`.

`coeff(a,n)` returns the coefficient of the term `Var^n` as an element of the coefficient ring `Ring`, where `a` is a linear differential operator in the variable `Var`.

This method overloads the function coeff of the system kernel.

degreeDegree of a linear differential operator

`degree(a)`

The degree of the zero polynomial is defined as zero.

This method overloads the function degree for polynomials.

vectorizeList of coefficients of a linear differential operator

`vectorize(a)`

Conversion Methods

convertConversion to a linear differential operator

`convert(a)`

`FAIL` is returned if the conversion fails.

exprConversion into an object of a kernel domain

`expr(a)`

This method overloads the function expr of the system kernel.

TeXTeX formatting of a linear differential operator

`TeX(a)`

This method is used by the function generate::TeX.

Description

Domain Creation

`Dom::Matrix(R)` creates domains of matrices over a component domain `R` of category Cat::Rng (a ring, possibly without unit).

If the optional parameter `R` is not given, `Dom::ExpressionField()` is used as component domain. Matrices of this type accept arbitrary

MuPAD expressions (numbers, symbols etc.) as entries. The name matrix is an alias for this default matrix domain `Dom::Matrix()`.

A vector with n entries is either an n 1 matrix (a column vector), or a 1 n matrix (a row vector).

Arithmetical operations with matrices can be performed by using the standard arithmetical operators of MuPAD.

E.g., if `A` and `B` are two matrices defined by `Dom::Matrix(R)`, `A + B` computes the sum, and `A * B` computes the product of the two matrices, provided that the dimensions are appropriate.

Similarly, `A^(-1)` or `1/A` computes the inverse of a square matrix `A` if it exists. Otherwise, FAIL is returned. See "Example 1" on page 6-225.

Many system functions are overloaded for matrices, such as map, subs, has, zip, E.g., use conjugate to compute the complex conjugate of a matrix, norm to compute matrix norms, or exp to compute the exponential of a matrix.

Most of the functions in the MuPAD linear algebra package linalg work with matrices. For example, to compute the determinant of a square matrix `A`, call `linalg::det(A)`. The command `linalg::gaussJordan(A)` performs Gauss-Jordan elimination on `A` to transform `A` to its reduced row echelon form.

See the documentation of linalg for a list of available functions of this package.

The domain `Dom::Matrix(R)` represents matrices over `R` of arbitrary size. Therefore, it does not have any algebraic structure (other than being a *set* of matrices).

In this help page, we use the following notations for a matrix A (an element of `Dom::Matrix(R)`):

- *nrows*(A) denotes the number of rows of A.
- *ncols*(A) denotes the number of columns of A.
- A *row index* is an integer in the range from 1 to *nrows*(A).

- A *column index* is an integer in the range from 1 to *ncols*(*A*).

Note The number of rows and columns, respectively, of a matrix must be less than 2^{31}.

Note The components of a matrix are no longer evaluated after the creation of the matrix, i.e., if they contain free identifiers they will not be replaced by their values.

Element Creation

`Dom::Matrix(R)(Array)` and `Dom::Matrix(R)(Matrix)` create a new matrix with the dimension and the components of `Array` and `Matrix`, respectively.

The components of `Array` or `Matrix` are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

The creation of (sparse) matrices via arrays is useful for matrices of moderate size. Note that indexed assignments to arrays are much faster than the corresponding indexed assignments to matrices. However, since all elements of the array (including the zeroes) need to be filled in before conversion to a (sparse) matrix, memory is wasted for very large and very sparse matrices. In such a situation, one should define a table containing only the non-zero elements and convert the table to a matrix (see below).

`Dom::Matrix(R)(List)` creates an m 1 column vector with components taken from the nonempty list, where m is the number of entries of `List`.

One may also use a list of equations to create an object of `Dom::Matrix`. In this case the entries of the list must be of the form `(i, j) = value`, where `i` and `j` denote the row and column index and `value` the coefficient of the matrix. `i` and `j` need to be positive integers.

`Dom::Matrix(R)(ListOfRows)` creates an m n matrix with components taken from the nested list `ListOfRows`, where m is the number of inner lists of `ListOfRows`, and n is the maximal number of elements of an inner list. Each inner list corresponds to a row of the matrix. Both m and n must be non-zero.

If an inner list has less than n entries, the remaining components in the corresponding row of the matrix are set to zero.

The entries of the inner lists are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

The call `Dom::Matrix(R)(m, n)` returns the m n zero matrix.

Use the method `"identity"` to create the n n identity matrix.

The call `Dom::Matrix(R)(m, n, Array)` creates an m n matrix with components taken from `Array`, which must be an array or an hfarray. `Array` must have mn operands. The first m operands define the first row, the next m operands define the second row, etc. The formatting of the array is irrelevant. E.g., any array with 6 elements can be used to create a matrix of dimension 1 6, or 2 3, or 3 2, or 6 1.

`Dom::Matrix(R)(m, n, List)` creates an m n matrix with components taken row after row from the non-empty list. The list must contain mn entries.

`Dom::Matrix(R)(m, n, ListOfRows)` creates an m n matrix with components taken from the list `ListOfRows`.

If $m \geq 2$ and $n \geq 2$, then `ListOfRows` must consist of at most `m` inner lists, each having at most `n` entries. The inner lists correspond to the rows of the returned matrix.

If an inner list has less than `n` entries, the remaining components of the corresponding row of the matrix are set to zero. If there are less than `m` inner lists, the remaining lower rows of the matrix are filled with zeroes.

`Dom::Matrix(R)(m, n, Table)` creates an m n matrix with components taken from the table `Table`.

By defining the entries of the table first, one can easily create large and sparse matrices. The entry `Table[i, j]` of the table will be the entry in the `i`-th row and the `j`-th column of the matrix. Therefore, the table needs to be indexed by positive integers `i` and `j`.

`Dom::Matrix(R)(m, n, [(i1, j1) = value1, (i2, j2) = value2, ...])` is a further way to create a matrix specifying only the non-zero entries `A[i1, j1] = value1`, `A[i2, j2] = value2` etc. The ordering of the entries in the input list is irrelevant.

`Dom::Matrix(R)(m, n, f)` returns the matrix whose (*i*, *j*)-th component is the value of the function call `f(i, j)`. The row index *i* ranges from 1 to *m* and the column index *j* from 1 to *n*.

The function values are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(1, n, Array)` returns the 1 *n* row vector with components taken from `Array`. The array or hfarray `Array` must have `n` entries.

The entries of the array are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(1, n, List)` returns the 1 *n* row vector with components taken from `List`. The list `List` must have at most `n` entries. If there are fewer entries, the remaining vector components are set to zero.

The entries of the list are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(1, n, Table)` returns the 1 *n* row vector with components taken from `Table`. The table `Table` must not have more than `n` entries. If there are fewer entries, the remaining vector components are regarded as zero.

`Dom::Matrix(R)(m, 1, Array)` returns the *m* 1 column vector with components taken from `Array`. The array or hfarray `Array` must have `m` entries.

The entries of the array are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(m, 1, List)` returns the m 1 column vector with components taken from `List`. The list `List` must have at most `m` entries. If there are fewer entries, the remaining vector components are set to zero.

The entries of the list are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(m, 1, Table)` returns the m 1 column vector with components taken from `Table`. The table `Table` must have no more than `m` entries. If there are fewer entries, the remaining vector components are regarded as zero.

Cat::Matrix`(R)`

Examples

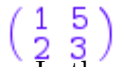
Example 1

Whenever possible, one should use Dom::ExpressionField`()` as the coefficient domain of matrices – therefore Dom::ExpressionField`()` is the default coefficient domain of matrices.

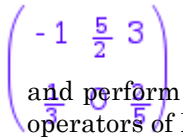
The components of matrices over Dom::ExpressionField`()` can be arbitrary arithmetical expressions. Consider
Mat := Dom::Matrix()Dom::Matrix()

Dom::Matrix()

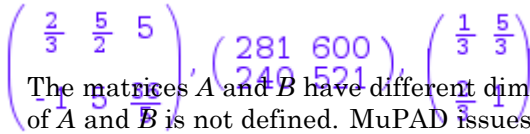
We assigned the domain to the identifier `Mat` and now we can define a matrix A of two rows, where each row is a list of two elements by the following line:
A := Mat([[1, 5], [2, 3]])matrix([[1, 5], [2, 3]])



In the same way, we define the following 2 3 matrix:
B := Mat([[-1, 5/2, 3], [1/3, 0, 2/5]])matrix([[-1, 5/2, 3], [1/3, 0, 2/5]])

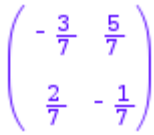


and perform matrix arithmetic using the standard arithmetical operators of MuPAD, e.g., the matrix product AB, the fourth power of A as well as the scalar multiplication of A times (1)/(3) $\frac{1}{3}$:
A * B, A ^ 4, 1/3 * Amatrix([[2/3, 5/2, 5], [-1, 5, 36/5]]), matrix([[281, 600], [240, 521]]), matrix([[1/3, 5/3], [2/3, 1]])



The matrices A and B have different dimensions, and therefore the sum of A and B is not defined. MuPAD issues an error message:
A + B Error: The dimensions do not match.
[(Dom::Matrix(Dom::ExpressionField())::_plus]

To compute the inverse of A, just enter:
1/Amatrix([[-3/7, 5/7], [2/7, -1/7]])



If a matrix is not invertible, `FAIL` is the result of this operation. For example, the matrix:
C := Mat(2, 2, [[2]])matrix([[2, 0], [0, 0]])

$$\begin{pmatrix} 2 & 0 \\ 0 & 0 \end{pmatrix}$$

is not invertible, hence:
C^(-1)FAIL

FAIL

delete A, B, C:

Example 2

We create the domain of matrices over the coeffcient ring `Dom::ExpressionField()`:
Mat := Dom::Matrix()Dom::Matrix()

Dom::Matrix()

Beside standard matrix arithmetic, the library linalg offers many functions dealing with matrices. For example, if one wants to compute the rank of a matrix, use linalg::rank:
A := Mat([[1, 2], [2, 4]])matrix([[1, 2], [2, 4]])

$$\begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix}$$

linalg::rank(A)1

1

Use linalg::eigenvectors to compute eigenvalues and eigenvectors of the matrix *A*:

linalg::eigenvectors(A)[[0, 1, [matrix([[-2], [1]])]], [5, 1, [matrix([[1/2], [1]])]]]

$$\left[\left[0,\ 1,\ \left[\begin{pmatrix} -2 \\ 1 \end{pmatrix}\right]\right],\ \left[5,\ 1,\ \left[\begin{pmatrix} \frac{1}{2} \\ 1 \end{pmatrix}\right]\right]\right]$$

Try `info(linalg)` for a list of available functions, or enter `help(linalg)` for details about the library linalg.

Some of the functions in the `linalg` package simply serve as "interface" functions for methods of a matrix domain described above. For example, linalg::transpose uses the method `"transpose"` to get the transposed matrix. The function linalg::gaussElim applies Gaussian elimination to a matrix by calling the method `"gaussElim"`:
linalg::gaussElim(A) = A::dom::gaussElim(A)[1]matrix([[1, 2], [0, 0]]) = matrix([[1, 2], [0, 0]])

$$\begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix}$$

In contrast to the methods of the domain `Dom::Matrix(R)`, the corresponding functions of the `linalg` packages do extended checking of their input parameters. Note that there might be minor differences in the functionality of the `linalg` functions and the matrix methods. E.g., the option `ColumnElimination` is not available in `linalg::gaussElim`, but only in the `"gaussElim"` method of the matrix domain:
A::dom::gaussElim(A, ColumnElimination)[matrix([[1, 0], [2, 0]]), 1, 0, {1}]

$$\left[\begin{pmatrix} 1 & 0 \\ 2 & 0 \end{pmatrix},\ 1,\ 0,\ \{1\}\right]$$

delete A:

Example 3

We create the default matrix domain `Dom::Matrix()`. As a shortcut, this domain can also be created via matrix:
A := matrix([[1, 2, 3, 4], [2, 0, 4, 1], [-1, 0, 5, 2]])matrix([[1, 2, 3, 4], [2, 0, 4, 1], [-1, 0, 5, 2]])

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 0 & 4 & 1 \\ -1 & 0 & 5 & 2 \end{pmatrix}$$

domtype(A)Dom::Matrix()

Dom::Matrix()

Matrix components can be extracted by the index operator `[]`:
A[2, 1] * A[1, 2] - A[3, 1] * A[1, 3]7

7

If one of the indices is not in its valid range, an error message is issued.
Assignments to matrix components are performed similarly:
delete a: A[1, 2] := a^2: Amatrix([[1, a^2, 3, 4], [2, 0, 4, 1], [-1, 0, 5, 2]])

$$\begin{pmatrix} 1 & a^2 & 3 & 4 \\ 2 & 0 & 4 & 1 \\ -1 & 0 & 5 & 2 \end{pmatrix}$$

Beside the usual indexing of matrix components, it is also possible to extract submatrices from a given matrix. The following call creates the submatrix of *A* which consists of the rows 2 to 3 and columns 1 to 3 of *A*:
A[2..3, 1..3]matrix([[2, 0, 4], [-1, 0, 5]])

$$\begin{pmatrix} 2 & 0 & 4 \\ -1 & 0 & 5 \end{pmatrix}$$

The index operator does not allow to insert submatrices into a given matrix. This is implemented by the function linalg::substitute.
delete A:

Example 4

In the following examples, we demonstrate the different ways of creating matrices. We work with matrices defined over the field $_{19}$, i.e., the field of integers modulo 19. This component ring can be created with the domain constructor Dom::IntegerMod.

We start by giving a list of rows, where each row is a list of row entries:
MatZ19 := Dom::Matrix(Dom::IntegerMod(19)): MatZ19([[1, 2], [2]])Dom::Matrix(Dom::IntegerMod(19))([[1, 2], [2, 0]])

$$\begin{pmatrix} 1 \bmod 19 & 2 \bmod 19 \\ 2 \bmod 19 & 0 \bmod 19 \end{pmatrix}$$

The elements of the two inner lists, the row entries, were converted to elements of the domain `Dom::IntegerMod(19)`.

The number of rows is the number of sublists of the argument, i.e., $m = 2$. The number of columns is determined by the length of the inner list with the most entries, which is the first inner list with two entries. Missing entries in the other inner lists are treated as zero components.
The call:
MatZ19(4, 4, [[1, 2], [2]])Dom::Matrix(Dom::IntegerMod(19))([[1, 2, 0, 0], [2, 0, 0, 0], [0, 0, 0, 0], [0, 0, 0, 0]])

$$\begin{pmatrix} 1 \bmod 19 & 2 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 2 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \end{pmatrix}$$

fixes the dimension of the matrix. Missing entries and inner lists are treated as zero components and zero rows, respectively.

An error message is issued if one of the given entries cannot be converted to an element over $_{19}$:

MatZ19([[2, 3], [-1, I]]) Error: Cannot define a matrix over 'Dom::IntegerMod(19)'. [(Dom::Matrix(Dom::IntegerMod(19)))::new]

delete MatZ19:

Example 5

This example illustrates how to create a matrix with components given as values of an index function. First we create the 2 2 Hilbert matrix (see also the functions linalg::hilbert and linalg::invhilbert):

Dom::Matrix()(2, 2, (i, j) -> 1/(i + j - 1))matrix([[1, 1/2], [1/2, 1/3]])

$$\begin{pmatrix} 1 & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{3} \end{pmatrix}$$

Note the difference when working with expressions and functions. If you give an expression it is treated as a function in the row and column indices:

delete x: Dom::Matrix()(2, 2, x), Dom::Matrix()(2, 2, (i, j) -> x)matrix([[x(1, 1), x(1, 2)], [x(2, 1), x(2, 2)]]), matrix([[x, x], [x, x]])

$$\begin{pmatrix} x(1,1) & x(1,2) \\ x(2,1) & x(2,2) \end{pmatrix}, \begin{pmatrix} x & x \\ x & x \end{pmatrix}$$

Example 6

Diagonal matrices can be created with the option `Diagonal` and a list of diagonal components:

```
Mat := Dom::Matrix(): Mat(3, 4, [1, 2, 3], Diagonal)matrix([[1, 0, 0, 0], [0, 2, 0, 0], [0, 0, 3, 0]])
```

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 3 & 0 \end{pmatrix}$$

Hence, to define the n n identity matrix, you can enter:

```
Mat(3, 3, [1 $ 3], Diagonal)matrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

or call:

```
Mat(3, 3, x -> 1, Diagonal)matrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

The easiest way to create the identity matrix, however, is to use the method `"identity"`:

```
Mat::identity(3)matrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

delete Mat:

Example 7

Toeplitz matrices can be defined with the option `Banded`. The following call defines a three-banded matrix with the component 2 on the main diagonal and the component - 1 on the first subdiagonal and superdiagonal:
Dom::Matrix()(4, 4, [-1, 2, -1], Banded)matrix([[2, -1, 0, 0], [-1, 2, -1, 0], [0, -1, 2, -1], [0, 0, -1, 2]])

$$\begin{pmatrix} 2 & -1 & 0 & 0 \\ -1 & 2 & -1 & 0 \\ 0 & -1 & 2 & -1 \\ 0 & 0 & -1 & 2 \end{pmatrix}$$

Example 8

Some system functions can be applied to matrices, such as norm, expand, diff, conjugate, or exp.

For example, to expand the components of the matrix:
delete a, b: A := Dom::Matrix()([[(a - b)^2, a^2 + b^2], [a^2 + b^2, (a - b)*(a + b)]])matrix([[(a - b)^2, a^2 + b^2], [a^2 + b^2, (a + b)*(a - b)]])

$$\begin{pmatrix} (a-b)^2 & a^2+b^2 \\ a^2+b^2 & (a+b)(a-b) \end{pmatrix}$$

enter:
expand(A)matrix([[a^2 - 2*a*b + b^2, a^2 + b^2], [a^2 + b^2, a^2 - b^2]])

$$\begin{pmatrix} a^2 - 2\,a\,b + b^2 & a^2 + b^2 \\ a^2 + b^2 & a^2 - b^2 \end{pmatrix}$$

If you want to differentiate the matrix components, then call for example:
diff(A, a)matrix([[2*a - 2*b, 2*a], [2*a, 2*a]])

$$\begin{pmatrix} 2\,a - 2\,b & 2\,a \\ 2\,a & 2\,a \end{pmatrix}$$

To substitute matrix components by some values, enter:
subs(A, a = 1, b = -1)matrix([[4, 2], [2, 0]])

$$\begin{pmatrix} 4 & 2 \\ 2 & 0 \end{pmatrix}$$

The function zip can also be applied to matrices. The following call combines two matrices *A* and *B* by dividing each component of *A* by the corresponding component of *B*:
A := Dom::Matrix()([[4, 2], [9, 3]]): B := Dom::Matrix()([[2, 1], [3,-1]]):
zip(A, B, `/`)matrix([[2, 2], [3, -3]])

$$\begin{pmatrix} 2 & 2 \\ 3 & -3 \end{pmatrix}$$

The quoted character `` `/` `` is another notation for the function `_divide`, the functional form of the division operator `/`.

If one needs to apply a function to the components of a matrix, then use the function map. For example, to simplify the components of the matrix:

```
C := Dom::Matrix()( [[sin(x)^2 + cos(x)^2, cos(x)*tan(x)], [(a^2 - b^2)/(a
+ b), 1]] )matrix([[cos(x)^2 + sin(x)^2, cos(x)*tan(x)], [(a^2 - b^2)/(a +
b), 1]])
```

$$\begin{pmatrix} \cos(x)^2 + \sin(x)^2 & \cos(x)\,\tan(x) \\ a^2 - b^2 & 1 \\ a + b & \end{pmatrix}$$

call:
`map(C, Simplify)matrix([[1, sin(x)], [a - b, 1]])`

$$\begin{pmatrix} 1 & \sin(x) \\ a - b & 1 \end{pmatrix}$$

delete A, B, C:

Example 9

However, there may appear some unexpected results using the function diff in the context of matrices. The derivative of the following unspecified function `f` of a matrix is computed due to the chain rule:
`diff(f(matrix([[a*x^2, b], [c, d]])), x)matrix([[2*a*x*D(f)(matrix([[a*x^2, b], [c, d]])), 0], [0, 0]])`

$$\begin{pmatrix} 2\,a\,x\,f'\left(\begin{pmatrix} a\,x^2 & b \\ c & d \end{pmatrix}\right) & 0 \\ 0 & 0 \end{pmatrix}$$

Usually, the function `f` would implicitly be assumed to be scalar. Hence, the derivative of `f` should be scalar as well. In the above situation the chain rule is applied for differentiation: the inner function is the matrix containing the symbolic components `a*x^2`, `b`, `c` and `d`. Its derivative is computed by simply applying diff to each component of the matrix:

```
diff(matrix([[a*x^2, b], [c, d]]), x)matrix([[2*a*x, 0], [0, 0]])
```

$$\begin{pmatrix} 2\,a\,x & 0 \\ 0 & 0 \end{pmatrix}$$

Finally, the exterior unspecified function `f` is implicitly assumed to be scalar, such that each component of the derivative of the inner function is multiplied by the exterior differentiation.

Example 10

A column vector is represented by a 2 1 matrix:

```
Mat := Dom::Matrix(): v := Mat(2, 1, [1, 2])matrix([[1], [2]])
```

$$\begin{pmatrix} 1 \\ 2 \end{pmatrix}$$

The dimension of this vector is:

```
Mat::matdim(v)[2, 1]
```

$$[2,\ 1]$$

The length of a vector may also be queried by linalg::vecdim or `nops(v)`:

```
linalg::vecdim(v)2
```

$$2$$

The *i*th component of this vector can be extracted in two ways: either by `v[i, 1]` or by `v[i]`:

```
v[1], v[2]1, 2
```

$$1,\ 2$$

We compute the 2-norm of `v` by the following call:

norm(v, 2)sqrt(5)

$$\sqrt{5}$$

delete Mat, v:

Example 11

We create random matrices over the field of the rational numbers. Consider a random matrix `A1` with 3 rows and 3 columns:
Mat := Dom::Matrix(Dom::Rational): A1 := Mat::random(3, 3)Dom::Matrix(Dom::Rational)([[-65/824, 221/72, -245/597], [741/814, 229/220, 747/79], [764/979, -535/617, -535/477]])

$$\begin{pmatrix} -\frac{65}{824} & \frac{221}{72} & -\frac{245}{597} \\ \frac{741}{814} & \frac{229}{220} & \frac{747}{79} \\ \frac{764}{979} & -\frac{535}{617} & -\frac{535}{477} \end{pmatrix}$$

A second matrix A2 should contain at most 2 non-zero entries. We can create such a matrix by using 2 as the third argument for `random`:
A2 := Mat::random(3, 3, 2)Dom::Matrix(Dom::Rational)([[0, 0, 905/906], [0, 0, 0], [0, 4/133, 0]])

$$\begin{pmatrix} 0 & 0 & \frac{905}{906} \\ 0 & 0 & 0 \\ 0 & \frac{4}{133} & 0 \end{pmatrix}$$

The product of these matrices is given by
C := A1 * A2Dom::Matrix(Dom::Rational)([[0, -140/11343, -58825/746544], [0, 2988/10507, 223535/245828], [0, -2140/63441, 345710/443487]])

$$\begin{pmatrix} 0 & -\frac{140}{11343} & -\frac{58825}{746544} \\ 0 & \frac{2988}{10507} & \frac{223535}{245828} \\ 0 & -\frac{2140}{63441} & \frac{345710}{443487} \end{pmatrix}$$

By default, matrices are displayed like 'dense' arrays with zeroes in the empty places. For sparse matrices of large column and/or row dimension, such a 'dense' print mode is not appropriate: formatting of the print output would be very time consuming. Further, a 'dense' print output is not very informative for sparse matrices. For this reason, the `"doprint"` method provides a sparse output mode printing only the non-zero entries:

C::dom::doprint(C)Dom::Matrix(Dom::Rational)(3, 3, [(1, 2) = -140/11343, (1, 3) = -58825/746544, (2, 2) = 2988/10507, (2, 3) = 223535/245828, (3, 2) = -2140/63441, (3, 3) = 345710/443487])'Dom::Matrix(Dom::Rational)(3, 3, [(1, 2) = -140/11343, (1, 3) = -58825/746544, (2, 2) = 2988/10507, (2, 3) = 223535/245828, (3, 2) = -2140/63441, (3, 3) = 345710/443487])'

```
Dom::Matrix(Dom::Rational)(3, 3, [(1, 2) = -140/11343, (1, 3) = -5882
```

With this method, one can also print large sparse matrices. We create a random sparse matrix with 100 rows, 200 columns and at most 6 non-zero entries:

X := Mat::random(100, 200, 6): print(X) Warning: This matrix is too large for display. To see all nonzero entries of a matrix A, use 'A::dom::doprint(A)'. [(Dom::Matrix(Dom::Rational))::print] 'Dom::Matrix(Dom::Rational)(100, 200, ["..."])'

```
Dom::Matrix(Dom::Rational)(100, 200, ["..."])
```

Warning: This matrix is too large for display. If you want to see all nonzero entries of a matrix, say A, then call 'A::dom::doprint(A)'.

[(Dom::Matrix(Dom::Rational))::print] Warning: This matrix is too large for display. If you want to see all nonzero entries of a matrix, say A, then call 'A::dom::doprint(A)'. [(Dom::Matrix(Dom::Rational))::print] 'Dom::Matrix(Dom::Rational)(100, 200, ["..."])'

```
Dom::Matrix(Dom::Rational)(100, 200, ["..."])
```

The warning speaks for itself. `X` is regarded as 'too large for display' since, with the default 'dense' output mode, the sparse matrix would be printed as a huge array-like structure of dimension 100 200 with (integer) zeroes in the empty places. The sparse print mode should be used:
X::dom::doprint(X)Dom::Matrix(Dom::Rational)(100, 200, [(16, 64) = 448/765, (19, 4) = -61/702, (27, 126) = 343/304, (46, 42) = 433/49, (68, 176) = 451/483, (100, 97) = -235/174])'Dom::Matrix(Dom::Rational)(100, 200, [(16, 64) = 448/765, (19, 4) = -61/702, (27, 126) = 343/304, (46, 42) = 433/49, (68, 176) = 451/483, (100, 97) = -235/174])'

```
Dom::Matrix(Dom::Rational)(100, 200, [(16, 64) = 448/765, (19, 4
304, (46, 42) = 433/49, (68, 176) = 451/483, (100, 97) = -235/1
```

For convenience, there is a function doprint that calls this method by just entering:
doprint(X)Dom::Matrix(Dom::Rational)(100, 200, [(16, 64) = 448/765, (19, 4) = -61/702, (27, 126) = 343/304, (46, 42) = 433/49, (68, 176) = 451/483, (100, 97) = -235/174])'Dom::Matrix(Dom::Rational)(100, 200, [(16, 64) = 448/765, (19, 4) = -61/702, (27, 126) = 343/304, (46, 42) = 433/49, (68, 176) = 451/483, (100, 97) = -235/174])'

```
Dom::Matrix(Dom::Rational)(100, 200, [(16, 64) = 448/765, (19, 4
304, (46, 42) = 433/49, (68, 176) = 451/483, (100, 97) = -235/1
```

delete Mat, A1, A2, C, X:

Parameters

R

A ring, i.e., a domain of category Cat::Rng. The default ring is `Dom::ExpressionField()`.

Array

A one- or two-dimensional array or hfarray

Matrix

A matrix, i.e., an element of a domain of category Cat::Matrix

m

n

Matrix dimension (positive integers)

List

A list of matrix components

ListOfRows

A list of at most `m` rows; each row given as a list of at most `n` matrix components

Table

A table of coefficients of the matrix for sparse input

f

A function or a functional expression with two parameters (the row and column index)

g

A function or a functional expression with one parameter (the row index)

Options

Diagonal

Create a diagonal matrix

With the option `Diagonal`, diagonal matrices can be created with diagonal elements taken from a list, or computed by a function or a functional expression.

`Dom::Matrix(R)(m, n, List, Diagonal)` creates the m n diagonal matrix, whose diagonal elements are the entries of `List`.

`List` must have at most $min(m, n)$ entries. If it has fewer elements, the remaining diagonal elements are set to zero.

The entries of `List` are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(m, n, g, Diagonal)` returns the sparse matrix whose ith diagonal element is `g(i, i)`, where the index i runs from 1 to $min(m, n)$.

The function values are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

Banded

Create a Toeplitz matrix

`Dom::Matrix(R)(m, n, List, Banded)` creates an m n Toeplitz matrix with the elements of `List` as entries. The number of entries of `List` must be odd, say $2h + 1$, and must not exceed $2min(m, n) - 1$. The bandwidth of the resulting matrix is at most $2h + 1$.

A Toeplitz matrix is a matrix where the elements of each band are identical. See also “Example 7” on page 6-233.

All elements of the main diagonal of the created matrix are initialized with the middle element of `List`. All elements of the i-th subdiagonal are initialized with the $(h + 1 - i)$-th element of `List`. All elements of the i-th superdiagonal are initialized with the $(h + 1 + i)$-th element of `List`. All entries on the remaining sub- and superdiagonals are set to zero.

The entries of `List` are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

Entries

"isSparse"	is always `TRUE`.
"randomDimen"	is set to `[10, 10]`. See the method `"random"` below for details.

Methods

Mathematical Methods

_divideDivide matrices

```
_divide(A, B)
```

An error message is issued if the dimensions of `A` and `B` do not match.

This method only exists if `R` is a commutative ring with a unit, i.e., a domain of category Cat::Ring.

This method overloads the system function _divide for matrices, i.e., one may use it in the form `A / B`, or in functional notation: `_divide(A, B)`.

_invertCompute the inverse of a matrix

```
_invert(A, Normal = b)
```

This method only exists if `R` is a domain of category Cat::Ring.

This method overloads the system function _invert for matrices, i.e., one may use it in the form `1/A` or `A^(-1)`, or in functional notation: `_invert(A)`.

If `Normal = TRUE`, then the matrix inverse is always returned in a normalized form. For details about normalization, see normal. If `Normal = FALSE`, then the matrix inverse can appear in a normalized form, but normalization is not guaranteed. By default `Normal = TRUE`.

`Normal` affects the results only if a matrix contains variables or exact expressions, such as `sqrt(5)` or `sin(PI/7))`.

_modMap the modulo operator to the elements of a matrix

```
_mod(A, n)
```

`n` must be non-zero, and `a mod n` must be defined for every entry `a` of `A`.

This method overloads the function _mod for matrices; one may use it in the form `A mod n`, or in functional notation: `_mod(A, n)`.

_multMultiplie matrices by matrices, vectors and scalars

```
_mult(x, y)
```

```
_mult(x, y)
```

If `y` is of the domain type `R` or can be converted to such an element, the corresponding scalar multiplication is computed.

Otherwise, `y` is converted to a matrix of the domain type of `x`. If this conversion fails, this method calls the method `"_mult"` of the domain of `y` giving all arguments in the same order.

If `x` is a matrix of the same domain type as `y`, the matrix product *xy* is computed. An error message is issued if the dimensions of the matrices do not match.

If `x` is of the domain type `R` or can be converted to such an element, the corresponding scalar multiplication is computed.

Otherwise, `x` is converted to a matrix of the domain type of `y`. If this conversion fails, `FAIL` is returned.

This method handles more than two arguments by calling itself recursively with the first half of all arguments and the last half of all arguments. Then the product of these two results is computed with the system function _mult.

This method overloads the system function _mult for matrices, i.e., one may use it in the form `x * y`, or in functional notation: `_mult(x, y)`.
_negateNegate a matrix

```
_negate(A)
```

This method overloads the system function _negate for matrices, i.e., one may use it in the form `-A`, or in functional notation: `_negate(A)`.
_plusAdd matrices

```
_plus(A, B,  )
```

The arguments `A, B , ...` are converted to matrices of the domain type `Dom::Matrix(R)`. `FAIL` is returned if one of these conversions fails.

This method overloads the system function _plus for matrices, i.e., one may use it in the form `A + B`, or in functional notation: `_plus(A, B)`.

_powerInteger power of a matrix

```
_power(A, n)
```

If the power `n` is a negative integer then `A` must be nonsingular and `R` must be a domain of category Cat::IntegralDomain. Otherwise `FAIL` is returned.

If `n` is zero and the component ring `R` is a ring with no unit (i.e., of category Cat::Rng, but not of category Cat::Ring), `FAIL` is returned.

This method overloads the system function _power for matrices, i.e., one may use it in the form `A^n`, or in functional notation: `_power(A, n)`.
conjugateComplex conjugate of a matrix

```
conjugate(A)
```

This method only exists if `R` implements the method `"conjugate"`, which computes the complex conjugate of an element of the domain `R`.

This method overloads the system function conjugate for matrices, i.e., one may use it in the form `conjugate(A)`.
cosCosine of a matrix

```
cos(A)
```

If `A` is not square, an error message is issued. If the component domain of `A` does not allow the computation of `cos(elem)` for an arbitrary element `elem` of the component ring, `FAIL` is returned.

This method uses the function numeric::expMatrix for a floating-point approximation of the exponential of `A` if `A` is defined over the domain Dom::Float.

If some eigenvalues of `A` do not exist in `R` or cannot be computed, then `FAIL` is returned.

In the symbolic case the functions exp and linalg::jordanForm are called. The latter may not be able to compute the Jordan form of `A`. In this case `FAIL` is returned. Increasing the level of information (see setuserinfo) can yield useful information.

This method only exists if `R` is a domain of category Cat::Field.

This method overloads the function cos for matrices, i.e., one may use it in the form `cos(A)`.
diffDifferentiation of matrix components

```
diff(A,  )
```

This method only exists if `R` implements the method `"diff"`.

This method overloads the system function `diff` for matrices, i.e., one may use it in the form `diff(A, ...)`. See “Example 8” on page 6-233 and “Example 9” on page 6-235.
equalEquality test of matrices

```
equal(A, B)
```

Note that if `R` has the axiom Ax::systemRep then normal is used to simplify the components of `A` and `B` before testing their equality.
expExponential of a matrix

```
exp(A, <t>)
```

If `A` is not square, an error message is issued. If the component domain of `A` does not allow the computation of `exp(elem)` for an arbitrary element `elem` of the component ring, `FAIL` is returned.

This method uses the function numeric::expMatrix for a floating-point approximation of the exponential of `A` if `A*t` contains at least one floating-point number and all entries can be converted to floating-point numbers.

If some eigenvalues of `A` do not exist in `R` or cannot be computed, then `FAIL` is returned.

In the symbolic case, the function linalg::jordanForm is called, which may not be able to compute the Jordan form of `A`. In this case `FAIL` is returned. Increasing the level of information (see setuserinfo) can yield useful information.

This method only exists if `R` is a domain of category Cat::Field.

This method overloads the system function exp for matrices, i.e., one may use it in the form `exp(A, ...)`.
expandExpand matrix components

```
expand(A)
```

This method only exists if `R` implements the method `"expand"`, or if `R` has the axiom Ax::systemRep (in this case, the system function expand is used).

This method overloads the system function expand for matrices, i.e., one may use it in the form `expand(A)`.
factorScalar-matrix factorization

```
factor(A)
```

The factor *s* is the gcd of all components of the matrix `A`. Hence, this method only exists if `R` is of category Cat::GcdDomain.

This method overloads the system function factor for matrices, i.e., one may use it in the form `factor(A)`.
floatFloating-point approximation of the matrix components

```
float(A)
```

This method only exists if `R` implements the method `"float"`.

Note Usually the floating-point approximations are not elements of `R`! For example, Dom::Integer implements such a method, but the floating-point approximation of an integer cannot be re-converted to an integer.

This method checks whether the resulting matrix can be converted to the domain type of `A` only if `testargs()` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

Otherwise, one has to take care that the matrix returned is compatible with its component ring.

---

fourierFourier transform of the matrix components

```
fourier(A, t, s)
```

This method overloads the function transform::fourier for matrices, i.e., one may call it by `transform::fourier(A, t, s)`.

gaussElimGaussian elimination for matrices

```
gaussElim(A, <ColumnElimination>)
```

With the option `ColumnElimination`, the matrix *A* is reduced to a lower triangular echelon form via elementary *column* operations (without `ColumnElimination`, the Gauss algorithm uses elementray *row* operations to obtain the upper echelon form). The following relation holds: `transpose(gaussElim(A, ColumnElimination)[1]) = gaussElim(transpose(A))[1]`. With `ColumnElimination`, the last entry of the returned list is the set of characteristic *column* indices of *A*.

For very large *m n* matrices *A* with *m* much greater *n*, the column elimination is faster than the row elimination.

If the matrix is not square, i.e., the determinant of `A` is not defined, then the third entry of the returned list is the value `FAIL`.

This method only exists if the component ring `R` is an integral domain, i.e., a domain of category Cat::IntegralDomain.

If `R` has the method `"pivotSize"`, the pivot element of smallest size is chosen at every pivoting step, whereby `pivotSize` must return a positive integer representing the “size” of an element.

If no such method is defined, Gaussian elimination without a pivot strategy is applied to `A`.

If `R` has the axiom Ax::efficientOperation`("_invert")` and is of category Cat::Field, ordinary Gaussian elimination is used. Otherwise, fraction-free elimination is performed on `A`.

If `R` implements the method `"normal"`, it is used to simplify subsequent computations of the Gaussian elimination process.

Note that if `R` does not implement the method `"normal"`, but the elements of `R` are represented by kernel domains, i.e., `R` has the axiom Ax::systemRep, the system function normal is used instead.
identityIdentity matrix

```
identity(n)
```

This method only exists if the component ring `R` is of category Cat::Ring, i.e., a ring with unit.
intIntegration of matrix components

```
int(A,  )
```

This method only exists if `R` implements the method `"int"`.

This method overloads the system function `int` for matrices, i.e., one may use it in the form `int(A, ...)`.
invfourierInverse Fourier transform of the matrix components

```
invfourier(A, s, t)
```

This method overloads the function transform::invfourier for matrices, i.e., one may call it by `transform::invfourier(A, t, s)`.
invlaplaceInverse Laplace transform of the matrix components

```
invlaplace(A, s, t)
```

This method overloads the function transform::invlaplace for matrices, i.e., one may call it by `transform::invlaplace(A, t, s)`.
iszeroTest for zero matrices

```
iszero(A)
```

Note that there may exist more than one representation of the zero matrix of a given dimension if `R` does not have Ax::canonicalRep.

If `R` implements the method `"normal"`, it is used to simplify the components of `A` for the zero-test.

Note that if `R` does not implement such a method, but the elements of `R` are represented by kernel domains, i.e., `R` has the axiom Ax::systemRep, the system function normal is used instead.

This method overloads the system function iszero for matrices, i.e., one may use it in the form `iszero(A)`.
laplaceLaplace transform of the matrix components

```
laplace(A, t, s)
```

This method overloads the function transform::laplace for matrices, i.e., one may call it by `transform::laplace(A, t, s)`.

matdimMatrix dimension

`matdim(A)`
normNorm of matrices and vectors

`norm(A, Infinity)`

`norm(A, Maximum)`

`norm(v, Infinity)`

`norm(v, Maximum)`

`norm(A, Frobenius)`

`norm(A, 1)`

`norm(v, Euclidean)`

`norm(v, k)`

`norm(A, Maximum)` computes the maximum norm of the matrix `A`, which is the maximum row sum (the row sum is the sum of norms of each component in a row).

If the domain `R` does not implement the methods `"max"` and `"norm"`, `FAIL` is returned.

Using `norm(v, Infinity)` for a vector `v` the maximum norm of all elements is returned.

If the domain `R` does not implement the methods `"max"` and `"norm"`, `FAIL` is returned.

Using `norm(v, Maximum)` for a vector `v` the maximum norm of all elements is returned.

If the domain `R` does not implement the methods `"max"` and `"norm"`, `FAIL` is returned.

`norm(A, Frobenius)` computes the Frobenius norm of `A`, which is the square root of the sum of the squares of the norms of each component.

If the result is no longer an element of the domain `R`, or if `R` does not implement the method `"norm"`, `FAIL` is returned.

`norm(A, 1)` computes the 1-norm of the matrix `A`, which is the maximum sum of the norms of the elements of each column. If `R` does not implement the methods `"max"` and `"norm"`, `FAIL` is returned.

`norm(v, Euclidean)` computes the Euclidean norm (2-norm) of the vector `v`, which is defined to be the square root of the sum of the norms of the elements of `v` raised to the square.

`FAIL` is returned if the result is no longer an element of the domain `R`. The function linalg::scalarProduct is used to compute the Euclidean norm of the vector `v`.

If `R` does not implement the method `"norm"`, `FAIL` is returned.

`norm(v, k)` computes the *k*-norm of the vector `v`, which is defined to be the *k*th root of the sum of the norms of the elements of `v` raised to the *k*th power.

`FAIL` is returned if the result is no longer an element of the domain `R`. For $k = 2$, the function linalg::scalarProduct is used to compute the 2-norm of `v`.

If `R` does not implement the method `"norm"`, `FAIL` is returned.

The method `norm` overloads the function norm for matrices, i.e., one may use it in the form `norm(A k )`, where `k` is either `Infinity`, `Frobenius`, or a positive integer. The default value of `k` is `Infinity`.
normalSimplification of matrix components

`normal(A)`

If `R` does not implement the method `"normal"`, but the elements of `R` are represented by kernel domains, i.e., `R` has the axiom Ax::systemRep, the system function normal is applied to the components of `A`. Otherwise `normal(A)` returns `A` without any changes.

This method overloads the system function normal for matrices, i.e., one may use it in the form `normal(A)`.
nonZerosNumber of non-zero components of a matrix

`nonZeros(A)`
nonZeroesNumber of non-zero components of a matrix

`nonZeroes(A)`
nonZeroOperandsReturn a sequence of all non-zero operands

```
nonZeroOperands(A)
```

This method is useful for retrieving information on the non-zero entries. For example, to find out the types of the entries in the matrix, one should not consider all operands `op(A)`, because this would also involve the zero entries. For large matrices with few entries, it is much more efficient to use this method to extract the entries.
randomRandom matrix generation

```
random()

random(g)

random(m, n)

random(m, n, g)

random(m, n, p)

random(m, n, p, g)
```

The dimension of the matrix is also chosen randomly. The matrix size is limited by the values `"randomDimen"` (see “Entries” above). To change the value of the entry `"randomDimen"`, one must first unprotect the domain `Dom` (see unprotect for details).

When calling the `"random"` method with one parameter `g`, this parameter is regarded as a random generator. The matrix entries are created by the calls `g()` which must return elements of the coefficient ring `R`.

The dimension of the matrix is chosen randomly as above.

When calling the `"random"` method with two positive integers `m` and `n`, a random matrix with `m` rows and `n` columns is created. Its elements are generated by the method `"random"` of the component ring `R`. If `R::random` does not exist, FAIL is returned.

`random(m,n,g)` creates a matrix with `m` rows and `n` columns. The third parameter `g` is regarded as a random generator. The matrix entries are created by the calls `g()` which must return elements of the coefficient ring `R`.

When calling the `"random"` method with positive integers `m`, `n` and a nonnegative integer `p`, a sparse matrix with `m` rows, `n` columns and at most

p non-zero entries is created. These entries are generated by the function "random" of the component ring R. If R::random does not exist, FAIL is returned.

The integer p must satisfy $0 \le p \le mn$.

When calling the "random" method with four parameters, a sparse matrix with m rows, n columns and at most p non-zero entries is created. The fourth parameter g is regarded as a random generator. The matrix entries are created by the calls g() which must return elements of the coefficient ring R.

The integer p must satisfy $0 \le p \le mn$.
sinSine of a matrix

```
sin(A)
```

If A is not square, an error message is issued. If the component domain of A does not allow the computation of sin(elem) for an arbitrary element elem of the component ring, FAIL is returned.

This method uses the function numeric::expMatrix for a floating-point approximation of the exponential of A if A is defined over the domain Dom::Float.

If some eigenvalues of A do not exist in R or cannot be computed, then FAIL is returned.

In the symbolic case the functions exp and linalg::jordanForm are called. The latter may not be able to compute the Jordan form of A. In this case FAIL is returned. Increasing the level of information (see setuserinfo) can yield useful information.

This method only exists if R is a domain of category Cat::Field.

This method overloads the function sin for matrices, i.e., one may use it in the form sin(A).
sqrtSquare root of a matrix

```
sqrt(A, <sqrtfunc>)
```

Returned is a matrix B with $B^2 = A$ such that the eigenvalues of B are the square roots of the eigenvalues of A or FAIL if the square root of the matrix does not exist. For computing the square roots of the eigenvalues a function

satisfying *sqrtfunc*(*a*)^2 = *a* for every element *a* of the coefficient ring of *A* can be given as optional second argument.

For details we refer to the help page of the function linalg::sqrtMatrix.
testeqTesting for equality of two matrices

```
testeq(A, B)
```

trTrace of a square matrix

```
tr(A)
```

If `A` is not square, an error message is issued.
transposeTranspose of a matrix

```
transpose(A)
```

Access Methods

_concatHorizontal concatenation of matrices

```
_concat(A, B,  )
```

This method overloads the system function _concat for matrices, i.e., one may use it in the form `A . B . ...`, or in functional notation: `_concat(A, B, ...)`.

_indexMatrix indexing

```
_index(A, i, j)
```

```
_index(A, r1 ..  r2, c1 ..  c2)
```

```
_index(v, i)
```

```
_index(v, i1 ..  i2)
```

If `i` and `j` are not integers, the call of this method returns in its symbolic form (of type `"_index"`) with evaluated arguments.

Otherwise an error message is given, if `i` and `j` are not valid row and column indices, respectively.

Note Note that this method uses the system function context to evaluate the entry in the context of the calling environment.

`_index(A,r1..r2,c1..c2)` returns the submatrix of `A` created by the rows of `A` with indices from `r1` to `r2` and the columns of `A` with indices from `c1` to `c2`.

This method returns the *i*th entry of the vector `v`.

An error message is issued if `v` is not a vector.

If `i` is not an integer, the call of `_index(v,i)` returns in its symbolic form (of type `"_index"`) with evaluated arguments.

Otherwise an error message is given, if `i` is less than one or greater than the dimension of `v`.

Note Note that this method uses the system function context to evaluate the entry in the context of the calling environment.

`_index(v,i1..i2)` returns the subvector of `v`, formed by the entries with index `i1` to `i2`. See also the method `"op"`.

An error message is issued if `v` is not a vector.

`_index` overloads the system function _index for matrices, i.e., one may use it in the form `A[i, j]`, `A[r1..r2, c1..c2]`, `v[i]` and `v[i1..i2]`, respectively, or in functional notation: `_index(A, ...)`.

addColAddition of a multiple of one column to the multiple of another column

```
addCol(A, i, j, f, <g>)
```

`i` and `j` must be positive integers smaller than or equal to the number of columns of the matrix `A`.

If `f` and `g` are not elements of the coefficient domain `R` of the matrix `A` and cannot be converted to `R`, `FAIL` is returned.

addRowAddition of a multiple of one row to the multiple of another row

```
addRow(A, i, j, f, g)
```

`i` and `j` must be positive integers smaller than or equal to the number of rows of the matrix `A`.

If f and g are not elements of the coefficient domain R of the matrix A and cannot be converted to R, FAIL is returned.

concatMatrixHorizontal concatenation of matrices

```
concatMatrix(A, B,  )
```

colExtracting a column of a matrix

```
col(A, c)
```

An error message is issued if c is less than one or greater than the number of columns of A.

delColDeleting a column of a matrix

```
delCol(A, c)
```

NIL is returned if A consists of only one column.

An error message is issued if c is less than one or greater than the number of columns of A.

delRowDeleting a row of a matrix

```
delRow(A, r)
```

NIL is returned if A consists of only one row.

An error message is issued if r is less than one or greater than the number of rows of A.

evalpEvaluating matrices of polynomials at a certain point

```
evalp(A, x = a,  )
```

This method is only defined if R is a polynomial ring of category Cat::Polynomial.

This method overloads the system function evalp for matrices, i.e., one may use it in the form evalp(A, x = a).

lengthLength of a matrix

```
length(A)
```

This method overloads the system function length for matrices, i.e., one may use it in the form length(A).

mapApply a function to matrix components

```
map(A, f, <p1, p2,  >)
```

Note Note that values returned by `f` are converted to elements of the domain `R` only if `testargs()` returns `TRUE` (i.e., if one calls this method from the interactive level of MuPAD).

If `testargs()` returns `FALSE`, one must guarantee that `f` returns elements of the domain type `R`. Otherwise, the resulting matrix will have components which are not elements of the component ring `R`!

Note If the function `f` does not map the zero element of the component ring to the zero element, a sparse matrix will change into a dense matrix. This may lead to memory problems when dealing with very large (sparse) matrices.

Note that there is the method `"mapNonZeroes"` which maps a function to the non-zero entries of the matrix only.

This method overloads the system function `map` for matrices, i.e., one may use it in the form `map(A, f p1 , p2 , , )`.

mapNonZeroesApply a function to the non-zero components of a (sparse) matrix

```
mapNonZeroes(A, f, <p1, p2,  >)
```

multColMultiplication of one column by a scalar factor

```
multCol(A, i, f)
```

`i` must be a positive integer smaller than or equal to the number of columns of the matrix `A`.

If `f` is not an element of the coefficient domain `R` of the matrix `A` and cannot be converted to `R`, `FAIL` is returned.

multRowMultiplication of one row by a scalar factor

```
multRow(A, i, f)
```

`i` must be a positive integer smaller than or equal to the number of rows of the matrix `A`.

If `f` is not an element of the coefficient domain `R` of the matrix `A` and cannot be converted to `R`, `FAIL` is returned.

nopsNumber of components of a matrix

```
nops(A)
```

This method overloads the system function nops for matrices, i.e., one may use it in the form `nops(A)`.

opComponent of a matrix

```
op(A, i)
```

```
op(A)
```

This method returns an expression sequence of all components of `A`.

See also the method `"_index"`.

This method overloads the system function op for matrices, i.e., one may use it in the form `op(A, i)` and `op(A)`, respectively.

rowExtracting a row from a matrix

```
row(A, r)
```

An error message is issued if `r` is less than one or greater than the number of rows of `A`.

setColReplacing a column of a matrix

```
setCol(A, c, v)
```

An error message is issued if `c` is less than one or greater than the number of rows of `A`.

setRowReplacing a row of a matrix

```
setRow(A, r, v)
```

An error message is issued if `r` is less than one or greater than the number of rows of `A`.

stackMatrixVertical concatenation of matrices

```
stackMatrix(A, B,  )
```

An error message is issued if the given matrices do not have the same number of columns.

subsSubstitution of matrix components

```
subs(A,  )
```

Note Note that the function values are converted to elements of the domain `R` only if `testargs()` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs()` returns `FALSE`, one must guarantee that `f` returns elements of the domain type `R`. Otherwise, the resulting matrix, which is of domain type `Dom::Matrix(R)`, would have components which are not elements of the domain `R`!

This method overloads the system function `subs` for matrices, i.e., one may use it in the form `subs(A, ...)`.

subsexExtended substitution of matrix components

```
subsex(A,  )
```

Note Note that the results of the substitutions are converted to elements of the domain `R` only if `testargs()` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs()` returns `FALSE`, one must guarantee that the results of the substitutions are of the domain type `R`, otherwise the resulting matrix, which is of domain type `Dom::Matrix(R)`, would have components which are not elements of the domain `R`!

This method overloads the system function `subsex` for matrices, i.e., one may use it in the form `subsex(A, ...)`.

subsopOperand substitution of matrix components

```
subsop(A, i = x,  )
```

Note Note that `x` is converted to the domain `R` only if `testargs()` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs()` returns `FALSE`, `x` must be an element of `R`, otherwise the resulting matrix, which is of domain type `Dom::Matrix(R)`, would have components which are not elements of the domain `R`!

See also the method `"set_index"`.

This method overloads the system function `subsop` for matrices, i.e., one may use it in the form `subsop(A, ...)`.

swapColSwapping matrix columns

```
swapCol(A, c1, c2)
```

```
swapCol(A, c1, c2, r1 ..  r2)
```

An error message is issued if one of the column indices is less than one or greater than the number of columns of `A`.

`swapCol(A,c1,c2,r1..r2)` swaps the column with index `c1` and the column with index `c2` of `A`, but by taking only those column components which lie in the rows with indices `r1` to `r2`.

An error message is issued if one of the column indices is less than one or greater than the number of columns of `A`, or if one of the row indices is less than one or greater than the number of rows of `A`.

swapRowSwapping matrix rows

```
swapRow(A, r1, r2)
```

```
swapRow(A, r1, r2, c1 ..  c2)
```

An error message is issued if one of the row indices is less than one or greater than the number of rows of `A`.

`swapCol(A,r1,r2,c1..c2)` swaps the row with index `r1` and the row with index `r2` of `A`, but by taking only those row components which lie in the columns with indices `c1` to `c2`.

An error message is issued if one of the row indices is less than one or greater than the number of rows of `A`, or if one of the column indices is less than one or greater than the number of columns of `A`.

set_indexSetting matrix components

```
set_index(A, i, j, x)
```

```
set_index(v, i, x)
```

Note Note that `x` is converted into an element of the domain `R` only if testargs returns `TRUE` and `i` and `j` are integers (e.g., if one calls this method from the interactive level of MuPAD). If `x` is a matrix of the same type as `A` or can be converted into a matrix of the same type as `A` and the indices `i` or `j` are ranges corresponding to a submatrix of `A`, then `x` replaces the corresponding submatrix in `A`.

Otherwise one has to take care that `x` is of domain type `R`.

See also the method `"subsop"`.

`set_index(v,i,x)` replaces the *i*th entry of the vector `v` by `x`.

`set_index` on vectors overloads the function `set_index` for matrices, i.e., one may use it in the form `A[i, j] := x` and `v[i] := x`, respectively, or in functional notation: `A := set_index(A, i, j, x)` or `v := set_index(v, i, x)`.

zipCombine matrices component-wise

```
zip(A, B, f, <p1, p2,  >)
```

The row number of the matrix returned is the minimum of the row numbers of `A` and `B`. Its column number is the minimum of the column numbers of `A` and `B`.

Note Note that the values returned by `f` are converted to elements of the domain `R` only if `testargs()` returns `TRUE` (i.e., if one calls this method from the interactive level of MuPAD).

If `testargs()` returns `FALSE`, one must guarantee that `f` returns elements of the domain type `R`. Otherwise, the resulting matrix will have components which are not elements of the component ring `R`!

This method overloads the system function zip for matrices, i.e., one may use it in the form `zip(A, B, f p1 , p2 , , )`.

Conversion Methods

convertConversion to a matrix

```
convert(x)
```

`FAIL` is returned if the conversion fails.

`x` may either be an array, a matrix, or a list (of sublists, see the parameter `ListOfRows` in "Creating Elements" above). Their entries must then be convertible into elements of the domain `R`.

convert_toMatrix conversion

```
convert_to(A, T)
```

`T` may either be DOM_ARRAY, DOM_LIST, or a domain constructed by `Dom::Matrix` or Dom::SquareMatrix. The elements of `A` must be convertible into elements of the domain `R`.

Use the function expr to convert `A` into an object of a kernel domain (see below).

createDefining matrices without component conversions

```
create(x, )
```

This method works more efficiently than if one creates matrices by calling the method `"new"` of the domain, because it avoids any conversion of the components. One must guarantee that the components have the correct domain type, otherwise run-time errors can be caused.

exprConversion of a matrix to an object of a kernel domain

```
expr(A)
```

The result is an array representing the matrix A where each entry is an object of a kernel domain.

This method overloads the system function expr for matrices, i.e., one may use it in the form `expr(A)`.

expr2textConversion of a mtrix to a string

```
expr2text(A)
```

This method overloads the system function expr2text for matrices, i.e., one may use it in the form `expr2text(A)`.

TeXTeX formatting of a matrix

```
TeX(A)
```

Note that in the case of very large matrices the output will not be useful. For printing large matrices use the function `"doprint"` to obtain a sparse matrix output displaying all non-zero entries. Alternatively, use the matrix slot `"setPrintMaxSize"` to set the maximal size of matrices that will be printed like “dense” arrays with zero entries displayed as the integer 0.

The method `"TeX"` of the component ring `R` is used to get the TeX-representation of each component of `A`.

This method is used by the function generate::TeX.

Technical Methods

assignElementsMultiple assignment to matrices

```
assignElements(A,  )
```

The assigned components must have the domain type `R`, an implicit conversion of the components into elements of domain type `R` is not performed.

This method overloads the system function assignElements for matrices, i.e., one may use it in the form `assignElements(A, ...)`.

mkSparseConversion of an array or a list of lists to a sparse structure

```
mkSparse(Array)
```

```
mkSparse(List)
```

```
mkSparse(r, c, List)
```

The 'sparse structure' `s` is a list of `c` univariate polynomials that is used to store the non-trivial elements of the columns of matrices.

`mkSparse(List)` tries to convert the list `List` into a a sparse structure. The result is either `FAIL` if this is not possible, or the list `[s, [r, c]]`, where the positive integers `r` and `c` are the dimension of the corresponding matrix. The 'sparse structure' `s` is a list of univariate polynomials that is used to store the non-trivial elements of the columns of matrices.

See the parameters `List` and `ListOfRows` in "Creating Elements" above for admissible formats of `List`.

The matrix is regarded as a column or a row vector, if `r` or `c` is equal to one. T

`mkSparse(r,c,List)` tries to convert the list `List` into a sparse structure representing a matrix of dimension `r` times `c`.

The result is either `FAIL` if this is not possible, or the list `[s, [r, c]]`. The 'sparse structure' `s` is a list of univariate polynomials that is used to store the non-trivial elements of the columns of matrices.

The matrix is regarded as a column or a row vector, if `r` or `c` is equal to one. T

printPrinting matrices

`print(A)`

Note Note that it will not be useful to print very large sparse matrices with lots of zero coefficients in this way – printing such matrices can be done by using the function `"doprint"`.

Use the matrix slot `"setPrintMaxSize"` to set the maximal size of matrices that will be printed like "dense" arrays with zero entries displayed as the integer 0.

doprintPrinting large sparse matrices

`doprint(A)`

setPrintMaxSizeSet the maximal size of matrices that will be printed like "dense" arrays

```
setPrintMaxSize(printMaxSize)
```

The value of the parameter `printMaxSize` may also be infinity. In this case, matrices of arbitrary size are printed like “dense” arrays.

This method returns the previous value of `printMaxSize`.

The default value is `printMaxSize` = 500.

unapplyCreate a procedure from a matrix

```
unapply(A, <x,  >)
```

This method overloads the system function `fp::unapply` for matrices, i.e., one may use it in the form `fp::unapply(A)`.

```

Description

Domain Creation

`Dom::MatrixGroup(m, n, R)` creates a domain which represents the Abelian group of m n matrices over the component ring `R`, i.e., it is a domain of category Cat::AbelianGroup.

The domain `Dom::ExpressionField()` is used as the component ring for the matrices if the optional parameter `R` is not given.

For matrices of a domain created by `Dom::MatrixGroup(m, n, R)`, matrix arithmetic is implemented by overloading the standard arithmetical operators `+`, `-`, `*`, `/` and `^`. All functions of the linalg package dealing with matrices can be applied.

`Dom::MatrixGroup(m, n, R)` has the domain `Dom::Matrix(R)` as its super domain, i.e., it inherits each method which is defined by `Dom::Matrix(R)` and not re-implemented by `Dom::MatrixGroup(m, n, R)`.

Methods described below are implemented by `Dom::MatrixGroup`.

The domain `Dom::Matrix(R)` represents matrices over `R` of arbitrary size, and it therefore does not have any algebraic structure (except of being a *set* of matrices).

The domain `Dom::SquareMatrix(n, R)` represents the *ring* of n n matrices over R.

Element Creation

`Dom::MatrixGroup(m, n, R)(Array)` and `Dom::MatrixGroup(m, n, R)(Matrix)` create a new matrix formed by the entries of `Array` and `Matrix`, respectively.

The components of `Array` and `Matrix`, respectively, are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

The call `Dom::MatrixGroup(m, n, R)( m , n )` returns the m n zero matrix. Note that the m n zero matrix can also be found in the entry `"zero"` (see below).

`Dom::MatrixGroup(m, n, R)( m , n List)` creates an m n matrix with components taken from the list `List`.

This call is only allowed for m 1 or 1 n matrices, i.e., if either `m` or `n` is equal to one.

If the list has too few entries, the remaining components of the matrix are set to zero.

The entries of the list are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::MatrixGroup(m, n, R)( m , n ListOfRows)` creates an m n matrix with components taken from the nested list `ListOfRows`. Each inner list corresponds to a row of the matrix.

If an inner list has less than `n` entries, the remaining components in the corresponding row of the matrix are set to zero. If there are less than `m` inner lists, the remaining lower rows of the matrix are filled with zeroes.

The entries of the inner lists are coerced into elements of the domain `R`. An error message is issued if one of these conversions fails.

It might be a good idea first to create a two-dimensional array from that list before calling `Dom::MatrixGroup(m, n, R)`. This is due to the fact that creating a matrix from an array is the fastest way one can achieve. However, in this case the sublists must have the same number of elements.

`Dom::MatrixGroup(m, n, R)( m , n f)` returns the matrix whose (*i*, *j*)th component is the value of the function call `f(i, j)`. The row index *i* ranges from 1 to `m` and the column index *j* from 1 to `n`.

The function values are coerced into elements of the domain `R`. An error message is issued if one of these conversions fails.

Superdomain

Dom::Matrix(`R`)

Axioms

If `R` has Ax::canonicalRep, then Ax::canonicalRep.

Categories

Cat::Matrix(`R`), Cat::AbelianGroup

Examples

Example 1

A lot of examples can be found on the help page of the domain constructor Dom::Matrix, and most of them are also examples for working with domains created by `Dom::MatrixGroup`. This example only highlights some differences with respect to working with matrices of the domain `Dom::Matrix(R)`.

The following command defines the abelian group of 3 4 matrices over the rationals:
MatGQ := Dom::MatrixGroup(3, 4, Dom::Rational)Dom::MatrixGroup(3, 4, Dom::Rational)

Dom::MatrixGroup(3, 4, Dom::Rational)
MatGQ::hasProp(Cat::AbelianGroup),
MatGQ::hasProp(Cat::Ring)TRUE, FALSE

TRUE, FALSE

`MatGQ` is a commutative group with respect to the addition of matrices. The unit of this group is the 3 4 zero matrix:
MatGQ::zeroDom::MatrixGroup(3, 4, Dom::Rational)([[0, 0, 0, 0], [0, 0, 0, 0], [0, 0, 0, 0]])

$$\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

Note that some operations defined by the domain `MatGQ` return matrices which are no longer elements of the matrix group. They return matrices of the domain `Dom::Matrix(Dom::Rational)`, the super-domain of `MatGQ`.

For example, if we define the matrix:
A := MatGQ([[1, 2, 1, 2], [-5, 3], [2, 1/3, 0, 1]])Dom::MatrixGroup(3, 4, Dom::Rational)([[1, 2, 1, 2], [-5, 3, 0, 0], [2, 1/3, 0, 1]])

$$\begin{pmatrix} 1 & 2 & 1 & 2 \\ -5 & 3 & 0 & 0 \\ 2 & \frac{1}{3} & 0 & 1 \end{pmatrix}$$

and delete its third column, we get the matrix:
MatGQ::delCol(A, 3)Dom::Matrix(Dom::Rational)([[1, 2, 2], [-5, 3, 0], [2, 1/3, 1]])

$$\begin{pmatrix} 1 & 2 & 2 \\ -5 & 3 & 0 \\ 2 & \frac{1}{3} & 1 \end{pmatrix}$$

which is of the domain type:
domtype(%)Dom::Matrix(Dom::Rational)

Dom::Matrix(Dom::Rational)

As another example we create the 3 3 identity matrix using the method `"identity"` of our domain:
E3 := MatGQ::identity(3)Dom::Matrix(Dom::Rational)([[1, 0, 0], [0, 1, 0], [0, 0, 1]])

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

This is also a matrix of the domain `Dom::Matrix(Dom::Rational)`:
domtype(E3)Dom::Matrix(Dom::Rational)

Dom::Matrix(Dom::Rational)

If we concatenate `E3` to the right of the matrix `A` defined above, we get the 3 7 matrix:
B := A . E3Dom::Matrix(Dom::Rational)([[1, 2, 1, 2, 1, 0, 0], [-5, 3, 0, 0, 0, 1, 0], [2, 1/3, 0, 1, 0, 0, 1]])

$$\begin{pmatrix} 1 & 2 & 1 & 2 & 1 & 0 & 0 \\ -5 & 3 & 0 & 0 & 0 & 1 & 0 \\ 2 & \frac{1}{3} & 0 & 1 & 0 & 0 & 1 \end{pmatrix}$$

which is of the domain type `Dom::Matrix(Dom::Rational)`:
domtype(B)Dom::Matrix(Dom::Rational)

Dom::Matrix(Dom::Rational)

Example 2

We can convert a matrix from a domain created with `Dom::MatrixGroup` into or from another matrix domain, as shown next:

```
MatGR := Dom::MatrixGroup(2, 3, Dom::Real): MatC
:= Dom::Matrix(Dom::Complex):A := MatGR((i, j) ->
i*j)Dom::MatrixGroup(2, 3, Dom::Real)([[1, 2, 3], [2, 4,
6]])
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 4 & 6 \end{pmatrix}$$

To convert `A` into a matrix of the domain `MatC`, enter:

```
coerce(A, MatC)Dom::Matrix(Dom::Complex)([[1, 2, 3], [2, 4, 6]])
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 4 & 6 \end{pmatrix}$$

```
domtype(%)Dom::Matrix(Dom::Complex)
```

Dom::Matrix(Dom::Complex)

The conversion is done component-wise. For example, we define the following matrix:

```
B := MatC([[0, 1, 0], [exp(I), 0, 1]])Dom::Matrix(Dom::Complex)([[0, 1,
0], [exp(I), 0, 1]])
```

$$\begin{pmatrix} 0 & 1 & 0 \\ e^{i} & 0 & 1 \end{pmatrix}$$

The matrix *B* has one complex component and therefore cannot be converted into the domain `MatGR`:

```
coerce(B, MatGR)FAIL
```

FAIL

Note: The system function coerce uses the methods `"convert"` and `"convert_to"` implemented by any domain created with `Dom::MatrixGroup` and `Dom::Matrix`.

Parameters

m

n

Positive integers (matrix dimension)

R

A commutative ring, i.e., a domain of category Cat::CommutativeRing; the default is `Dom::ExpressionField()`

Array

An *m n* array

Matrix

An *m n* matrix, i.e., an element of a domain of category Cat::Matrix

List

A list of matrix components

ListOfRows

A list of at most `m` rows; each row is a list of at most `n` matrix components

f

A function or a functional expression with two parameters (the row and column index)

g

A function or a functional expression with one parameter (the row index)

Options

Diagonal

Create a diagonal matrix

With the option `Diagonal`, diagonal matrices can be created with diagonal elements taken from a list, or computed by a function.

`Dom::MatrixGroup(m, n, R)( m , n List, Diagonal)` creates the m n diagonal matrix whose diagonal elements are the entries of `List`.

`List` must have at most $min(m, n)$ entries. If it has fewer elements, then the remaining diagonal elements are set to zero.

The entries of `List` are coerced into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::MatrixGroup(m, n, R)( m , n g, Diagonal)` returns the matrix whose ith diagonal element is `g(i, i)`, where the index i runs from 1 to $min(m, n)$.

The function values are coerced into elements of the domain `R`. An error message is issued if one of these conversions fails.

Banded

Create a banded Toeplitz matrix

With the option `Banded`, banded matrices can be created.

A *banded matrix* has all entries zero outside the main diagonal and some of the adjacent sub- and superdiagonals.

`Dom::MatrixGroup(m, n, R)( m , n List, Banded)` creates an m n banded Toeplitz matrix with the elements of `List` as entries. The number of entries of `List` must be odd, say $2h + 1$, and must not exceed `n`. The resulting matrix has bandwidth at most $2h + 1$.

All elements of the main diagonal of the created matrix are initialized with the middle element of `List`. All elements of the ith subdiagonal are initialized with the $(h + 1 - i)$th element of `List`. All elements of the ith superdiagonal are initialized with

the $(h + 1 + i)$th element of `List`. All entries on the remaining sub- and superdiagonals are set to zero.

The entries of `List` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

Entries

"one"	is only defined if `m` is equal to `n`; in that case it defines the n n identity matrix.
"randomDimen"	is set to `[m, n]`.
"zero"	is the m n zero matrix.

Methods

Mathematical Methods

evalpEvaluating matrices of polynomials at a certain point

```
evalp(A, x = a,  )
```

This method is only defined if `R` is a polynomial ring of category Cat::Polynomial.

This method overloads the function `evalp` for matrices, i.e., one may use it in the form `evalp(A, x = a)`.

identityIdentity matrix

```
identity(k)
```

Note The matrix returned is of the domain `Dom::Matrix(R)`, if _outputSequence(m, Symbol::ne, n) $m \neq n$ or if _outputSequence(k, Symbol::ne, n) $k \neq n$.

---

matdimMatrix dimension

```
matdim(A)
```

randomRandom matrix generation

```
random()
```

The components of the random matrix are randomly generated with the method `"random"` of the component ring `R`.

Access Methods

_concatHorizontally concatenation of matrices

```
_concat(A, B,  )
```

An error message is issued if the given matrices do not have the same number of rows.

Note The returned matrix is of the domain `Dom::Matrix(R)`.

This method overloads the function _concat for matrices, i.e., one may use it in the form `A . B . ...`, or in functional notation: `_concat(A, B, ...)`.

_indexMatrix indexing

```
_index(A, i, j)
```

```
_index(A, r1 ..  r2, c1 ..  c2)
```

```
_index(A, i)
```

```
_index(A, i1 ..  i2)
```

If `i` and `j` are not integers, then the call of this method returns in its symbolic form (of type `"_index"`) with evaluated arguments.

Otherwise an error message is given, if `i` and `j` are not valid row and column indices, respectively.

Note Note that the system function context is used to evaluate the entry in the context of the calling environment.

This method overloads the function _index for matrices, i.e., one may use it in the form `A[i, j]` or in functional notation: `_index(A, i, j)`.

Returns the submatrix of A, created by the rows of A with indices from r1 to r2 and the columns of A with indices from c1 to c2.

Note The submatrix is of the domain Dom::Matrix(R).

This method returns the *i*th entry of A.

If i is not an integer, then the call of this method returns in its symbolic form (of type "_index") with evaluated arguments.

Otherwise an error message is given, if i is less than one or greater than the dimension of v.

This call is only allowed for 1 *n* or *m* 1 matrices, i.e., either m or n must be equal to one. Otherwise an error message is issued.

Note Note that the system function context is used to evaluate the entry in the context of the calling environment.

This method returns the subvector of A, formed by the entries with index i1 to i2 (see also the method "op").

This call is only allowed for 1 *n* or *m* 1 matrices, i.e., either m or n must be equal to one. Otherwise an error message is issued.

This method overloads the function _index for matrices, i.e., one may use it in the form A[i,j], A[r1..r2,c1..c2], A[i] or A[i1..i2], respectively, or in functional notation: _index(A, ...).

concatMatrixHorizontally concatenation of matrices

```
concatMatrix(A, B,  )
```

colExtracting a column

```
col(A, c)
```

An error message is issued if c is less than one or greater than n.

delColDeleting a column

```
delCol(A, c)
```

`NIL` is returned if `A` only consists of one column.

Note The returned matrix is of the domain `Dom::Matrix(R)`.

An error message is issued if `c` is less than one or greater than `n`.

delRowDeleting a row

```
delRow(A, r)
```

`NIL` is returned if `A` only consists of one row.

Note The returned matrix is of the domain `Dom::Matrix(R)`.

An error message is issued if `r` is less than one or greater than `m`.

rowExtracting a row

```
row(A, r)
```

An error message is issued if `r` is less than one or greater than `m`.

stackMatrixConcatenating of matrices vertically

```
stackMatrix(A, B,  )
```

An error message is issued if the given matrices do not have the same number of columns.

Note The matrix returned is of the domain `Dom::Matrix(R)`.

Conversion Methods

convertConversion into a matrix

```
convert(x)
```

FAIL is returned if the conversion fails.

x may either be an m n array, or an m n matrix of category Cat::Matrix.

x can also be a list. See the parameter List and ListOfRows in "Creating Elements" above for admissible values of x.

The entries of x must be convertable into elements of the domain R, otherwise FAIL is returned.

Dom::MonomOrdering

Purpose

Monomial orderings

Syntax

```
Dom::MonomOrdering(Lex(n))
Dom::MonomOrdering(RevLex(n))
Dom::MonomOrdering(DegLex(n))
Dom::MonomOrdering(DegRevLex(n))
Dom::MonomOrdering(DegInvLex(n))
Dom::MonomOrdering(WeightedLex(w_1,  ,w_n))
Dom::MonomOrdering(WeightedDegLex(w_1,  ,w_n))
Dom::MonomOrdering(WeightedDegRevLex(w_1,  ,w_n))
Dom::MonomOrdering(WeightedRevLex(w_1,  ,w_n))
Dom::MonomOrdering(Block(o_1,  ))
Dom::MonomOrdering(Matrix(params))
```

Description

`Dom::MonomOrdering` represents the set of all possible monomial orderings. A monomial ordering is a well-ordering of the set of all k-tuples of nonnegative integers for some k.

In MuPAD, a monomial ordering is implemented as a function that, when applied to two lists of nonnegative integers, returns `-1`, `0`, or `1` if the first list is respectively smaller than, equal to, or greater than the second list. Each ordering can only compare lists of one fixed length, called its its *order length*. Since the lists under consideration will be exponent vectors in most cases, their length is also referred to as the number of indeterminates.

Monomial orderings are used in algebraic geometry for comparing terms product(X[i]^(Symbol::alpha[i]), i=1..n)$\prod_{i=1}^{n} X_i^{\alpha_i}$ and product(X[i]^(Symbol::beta[i]), i=1..n)$\prod_{i=1}^{n} X_i^{\beta_i}$ in a polynomial ring. Since `Dom::MonomOrdering` works on the exponent vectors $[\alpha_1, \ldots, \alpha_n]$ and $[\beta_1, \ldots, \beta_n]$, degreevec must be applied to the terms to be compared before applying `Dom::MonomOrdering`.

Elements of `Dom::MonomOrdering` can be used as arguments for lcoeff, lmonomial, lterm, and tcoeff as well as for the functions of the groebner package in order to specify the monomial ordering to be considered.

Monomial orderings are created by calling `Dom::MonomOrdering(someIdentifier(parameters))`, where `someIdentifier` is one of a certain set of predefined identifiers, as stated below. Converting `someIdentifier` into a string gives the *order type* of the monomial ordering.

`Dom::MonomOrdering(Lex(n))` creates the lexicographical order on n indeterminates.

`Dom::MonomOrdering(RevLex(n))` creates the reverse lexicographical order on n indeterminates, i.e., `Dom::MonomOrdering(RevLex(n))([a1,...,an])= Dom::MonomOrdering(Lex(n))([an,...,a1])`.

`Dom::MonomOrdering(DegLex(n))` creates the degree order on n indeterminates with the lexicographical order used for tie-break.

`Dom::MonomOrdering(DegRevLex(n))` creates the degree order on n indeterminates with the reverse lexicographical order used for tie-break .

`Dom::MonomOrdering(DegInvLex(n))` creates the degree order on n indeterminates, with the tie break being the opposite to the lexicographical order.

`Dom::MonomOrdering(Weighted...(w1,...,wn))` returns a weighted degree order with weights w_1 through w_n. The word following the word `Weighted` specifies the tie-break used. Note that MuPAD uses the ordinary degree order as the first tie-break.

`Dom::MonomOrdering(Matrix(params))` creates a matrix order, with the order matrix defined by Dom::Matrix`()(params)`.

`Dom::MonomOrdering(Block(o1, ..., on))` or, equivalently, `Dom::MonomOrdering([o1, ..., on])`, creates a block order such that `Dom::MonomOrdering(o1)` is used on the first indeterminates,

then `Dom::MonomOrdering(o2)` is used as a tie-break on the following indeterminates etc.

Block orders may be nested, i.e., the blocks may be block orders, too.

Weight vectors with negative entries and order matrices do not define well-orderings in general. You may enter such orderings, but it may cause trouble, e.g., to use them with the groebner package.

Superdomain

Dom::BaseDomain

Categories

Cat::BaseCategory

Examples

Example 1

We define `ORD` by prescribing that lists $[a, b, c]$ are ordered according to their weighted degrees $5a + 2b + \pi c$. For lists with equal weighted degree, the non-weighted degree $a + b + c$ is used as a tie-break. Finally, the lexicographical order decides (in fact, this last step is not necessary because π is irrational).

```
ORD:=Dom::MonomOrdering(WeightedDegLex(5, 2,
PI))WeightedDegLex(5, 2, PI)
```

$$\text{WeightedDegLex}(5, 2, \pi)$$

With respect to `ORD`, `[1, 6, 1]` is smaller than `[2, 1, 3]`:

```
ORD([1,6,1], [2,1,3])-1
```

$$-1$$

Parameters

n

Positive integer

w_1, ...

Numerical expressions

o_1, ...

Valid arguments to `Dom::MonomOrdering`

params

A sequence valid as the sequence of arguments to Dom::Matrix().

Methods

Mathematical Methods

func_callCompare two lists of integers

```
func_call(o, l1, l2)
```

The lengths of `l1` and `l2` must not exceed the order length of `o`. If `l1` or `l2` is too short, the necessary number of zeroes is appended.

Access Methods

ordertypeReturn the type of an order

```
ordertype(o)
```

If `o` equals `Dom::MonomOrdering(someIdentifier(params))`, then converting `someIdentifier` into a string gives the order type of `o`.

orderlengthReturn the length of an order

```
orderlength(o)
```

nopsNumber of blocks

```
nops(o)
```

blockGet a particular block

```
block(o, i)
```

blocktypeGet the order type of a particular block

```
blocktype(o, i)
```

blocklengthGet the order length of a particular block

```
blocklength(o, i)
```

Conversion Methods

exprReturn an expression from which the order can be restored

```
expr(o)
```

groebner::gbasis

Dom::Multiset

Purpose

Multisets

Syntax

```
Dom::Multiset(<s1, s2,  >)
```

Description

`Dom::Multiset` is the domain of multisets, i.e., sets with possibly multiple identical elements.

A multiset is represented by a set of lists of the form [*s*, *m*], where *s* is an element of the multiset and *m* its multiplicity.

Multisets can be returned by the system solver solve. For example, the input `solve(x^3 - 4*x^2 + 5*x - 2, x, Multiple)` gives all roots of the polynomial $x^3 - 4x^2 + 5x - 2$ in form of the multiset `{[1, 2], [2, 1]}`.

The standard set operations such as union, intersection and subtraction of sets have been extended to deal with multisets.

These operations can handle different types of sets, such as sets of type DOM_SET and multisets. One may, for example, compute the union of the multiset `{[a, 2], [b, 1]}` and the set `{c}`, which results in the multiset `{[a, 2], [b, 1], [c, 1]}`.

The elements of the multiset are sorted at the time where the multiset is created. The system function sort is used in order to guarantee that exactly one representation exists for a multiset, independent of the sequence in which the arguments appear.

`Dom::Multiset(s1, s2, ...)` creates the multiset consisting of the elements `s1, s2, ...`

Multiple identical elements in `s1, s2`, ... are collected. For example, the call `Dom::Multiset(a, b, a, c)` creates a multiset with the elements `a, b, c`. The element `a` has multiplicity two, the other two elements `b` and `c` both have multiplicity one.

Superdomain

Dom::BaseDomain

Categories

Cat::Set

Examples

Example 1

The multiset $\{a, a, b\}$ consists of the two different elements a and b, where a has multiplicity two and b has multiplicity one:
delete a, b, c: set1 := Dom::Multiset(a, a, b){[a, 2], [b, 1]}

$$\{[a, 2], [b, 1]\}$$

We create another multiset:
set2 := Dom::Multiset(a, c, c){[a, 1], [c, 2]}

$$\{[a, 1], [c, 2]\}$$

Standard set operations such as disjoint union, intersection or subtraction are implemented for multisets and can be performed using the standard set operators of MuPAD:
set1 union set2{[a, 3], [b, 1], [c, 2]}

$$\{[a, 3], [b, 1], [c, 2]\}$$

set1 intersect set2{[a, 1]}

$$\{[a, 1]\}$$

contains(set1, a), contains(set1, d)TRUE, FALSE

$$\text{TRUE, FALSE}$$

Example 2

Some system functions were overloaded for multisets, such as expand, normal or split.

If we apply `expand` to a multiset, for example, we get an expression sequence of all elements of the multiset (appearing in correspondence to their multiplicity):
delete a, b, c, d, e: set := Dom::Multiset(a, b, c, a, c, d, c, e, c){[a, 2], [b, 1], [c, 4], [d, 1], [e, 1]}

$$\{[a, 2], [b, 1], [c, 4], [d, 1], [e, 1]\}$$

expand(set)a, a, b, c, c, c, c, d, e

$$a, a, b, c, c, c, c, d, e$$

If you want to convert a multiset into an ordinary set of the domain type DOM_SET, use coerce:
coerce(set, DOM_SET){a, b, c, d, e}

$$\{a, b, c, d, e\}$$

Note: The system function `coerce` uses the methods `"convert"` and `"convert_to"` of the domain `Dom::Multiset`.

Compare the last result with the return value of the function expr, when it is applied for multisets:
expr(set){[a, 2], [b, 1], [c, 4], [d, 1], [e, 1]}

$$\{[a, 2], [b, 1], [c, 4], [d, 1], [e, 1]\}$$

The result is a set of the domain type `DOM_SET`, consisting of lists of the domain type DOM_LIST with two entries, an element of the multiset and the corresponding multiplicity of that element.

Parameters

`s1, s2, ...`

Objects of any type

Entries

"isFinite"	is `TRUE` because `Dom::Multiset` represents finite sets.
"inhomog_intersect"	a table of the form `T = Proc(multiset, setoftypeT)`. This entry is used internally by the implementation, and thus should not be touched.
"inhomog_union"	a table of the form `T = Proc(multiset, setoftypeT)`. This entry is used internally by the implementation, and thus should not be touched.

Methods

Mathematical Methods

normalNormalization of multisets

```
normal(set)
```

This method overloads the function `normal` for multisets, i.e., one may use it in the form `normal(set)`.

powersetPower set of a multiset

```
powerset(set)
```

The power set of `set` is returned as a set of multisets.

randomRandom multiset generation

```
random()
```

The number of elements created, including their multiplicities, is restricted to 20.

Access Methods

_indexMultiset indexing

```
_index(set, i)
```

See the method `"op"`.

This method overloads the function _index for multisets, i.e., one may use it in the form `set[i]`, or in functional notation: `_index(set, i)`.

containsCheck on existence of set elements

```
contains(set, s)
```

This method overloads the function contains for multisets, i.e., one may use it in the form `contains(set, s)`.

equalTest on equality of multisets

```
equal(set1, set2)
```

The system function _equal is used for the test.

expandExpand a multiset to a sequence of its elements

```
expand(set)
```

This method overloads the function expand for multisets, i.e., one may use it in the form `expand(set)`.

getElementExtract one element from a multiset

```
getElement(set)
```

Note that the elements of the multiset are sorted with the use of the system function sort, and thus the order of a multiset depends on the sorting criteria specified by this function.

This method overloads the function solvelib::getElement, i.e., one may use it in the form `solvelib::getElement(set)`.

hasCheck on existence of (sub-)expressions

```
has(set, expr)
```

To check whether `expr` is contained as an element of `set` and not as a subexpression of the elements of `set`, the function contains must be used.

This method overloads the function has for multisets, i.e., one may use it in the form `has(set, expr)`.

mapApply a function to multiset elements

```
map(set, func, <expr,  >)
```

It overloads the function `map` for multisets, i.e., one may use it in the form `map(set, func, ...)`.

multiplicityMultiplicity of an element

```
multiplicity(set, s)
```

Elements which are not contained in `set` have multiplicity zero.

cardNumber of elements in a multiset

```
card(set)
```

This method overloads the function card.

nopsNumber of different elements in a multiset

```
nops(set)
```

This method overloads the function nops for multisets, i.e., one may use it in the form `nops(set)`.

opElement of a multiset

```
op(set)
```

```
op(set, i)
```

Returns the *i*-th element *s* of the multiset `set` and its multiplicity *m* in form of the list [*s*, *m*].

See also the method `"_index"`.

Note that the elements of the multiset are sorted with the use of the system function sort, and thus the order of a multiset depends on the sorting criteria specified by this function.

This method overloads the function op for multisets, i.e., one may use it in the form `op(s, i)`.

selectSelecting of multiset elements

```
select(set, func, <expr,  >)
```

This method overloads the function select for multisets, i.e., one may use it in the form `select(set, func, ...)`. See select for details.

splitSplitting a multiset

```
split(set, func, <expr,  >)
```

This method overloads the function split for multisets, i.e., one may use it in the form `split(set, func, ...)`. See split for details.

subsSubstitution of elements in multisets

```
subs(set,  )
```

This method overloads the function `subs` for multisets, i.e., one may use it in the form `subs(set, ...)`.

Conversion Methods

convertConversion into a multiset

```
convert(x)
```

`FAIL` is returned if the conversion fails.

Currently only sets of type DOM_SET can be converted into multisets.

convert_toMultiset conversion

```
convert_to(set, T)
```

`FAIL` is returned if the conversion fails.

Currently `T` may either be DOM_SET to convert the multiset `set` into a set (loosing the multiplicities and the order of the elements of `set`), or DOM_EXPR or `"_exprseq"` to convert `set` into an expression sequence (see the method `"expand"` for details).

See also the method `"expr"`.

exprMultiset conversion into an object of a kernel domain

```
expr(set)
```

This method overloads the function expr for multisets, i.e., one may use it in the form `expr(set)`.

sortSorting of multisets

```
sort(set)
```

This method overloads the function sort for multisets, i.e., one may use it in the form `sort(set)`.

Technical Methods

bin_intersectIntersection of two multisets

```
bin_intersect(set1, set2)
```

This method is called from routines defined in the category Cat::Set, which implements among others the overloading of the function intersect for multisets. One may intersect two multisets directly by `set1 intersect set2`, or in functional notation by `_intersect(set1, set2)`.

bin_minusSubtraction of two multisets

```
bin_minus(set1, set2)
```

This method is called from routines defined in the category Cat::Set, which implements among others the overloading of the function minus for multisets. One may subtract two multisets directly by `set1 minus set2`, or in functional notation by `_minus(set1, set2)`.

homog_unionUnion of multisets

```
homog_union(set,  )
```

This method is called from routines defined in the category Cat::Set, which implements among others the overloading of the function union for multisets. One may compute the union of two multisets directly by `set1 union set2`, or in functional notation by `_union(set1, set2)`.

nested_unionUnion of nested sets

```
nested_union(setofsets)
```

This method is called from routines defined in the category Cat::Set, which implements among others the overloading of the function union for multisets and sets. One may compute the union of multisets and sets directly by `set1 union set2`, or in functional notation by `_union(set1, set2)`.

Element Creation

```
Dom::MultivariatePolynomial(Vars, R, Order)(p)
Dom::MultivariatePolynomial(Vars, R, Order)(lm)
```

Description

`Dom::MultivariatePolynomial(Vars, R, ..)` creates the domain of multivariate polynomials in the variable list `Vars` over the commutative ring `R` in distributed representation.

`Dom::MultivariatePolynomial` represents multivariate polynomials over arbitrary commutative rings.

All usual algebraic and arithmetical polynomial operations are implemented, including Gröbner basis computation and some classical construction tools used in invariant theory.

Note It is highly recommend to use only coefficient rings with unique zero representation. Otherwise it may happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

`Dom::MultivariatePolynomial(Vars, R, Order)` creates a domain of multivariate polynomials in the variable list `Vars` over a domain `R` of category Cat::CommutativeRing in sparse distributed representation with respect to the monomial ordering `Order`.

`Dom::MultivariatePolynomial()` creates a polynomial domain in the variable list `[x,y,z]` over the domain Dom::ExpressionField`(normal)` with respect to the lexicographic monomial ordering.

`Dom::MultivariatePolynomial(Vars)` generates the polynomial domain in the variable list `Vars` over the domain

`Dom::ExpressionField(normal)` with respect to the lexicographic monomial ordering is created.

Note Only commutative coefficient rings of type DOM_DOMAIN which inherit from Dom::BaseDomain are allowed. If `R` is of type DOM_DOMAIN but does not inherit from Dom::BaseDomain, the domain Dom::ExpressionField`(normal)` will be used instead.

In contrast to the domain Dom::DistributedPolynomial, `Dom::MultivariatePolynomial` accepts only identifiers (DOM_IDENT) as indeterminates. This restriction enables some further methods described below.

Please note: For reasons of efficiency not all methods check their arguments, not even at the interactive level. In particular this is true for many access methods, converting methods and technical methods. This may cause strange error messages.

Superdomain

Dom::DistributedPolynomial

Axioms

If `R` has Ax::normalRep, then Ax::normalRep.

If `R` has Ax::canonicalRep, then Ax::canonicalRep.

Categories

If `Vars` has a single variable, then `Cat::UnivariatePolynomial(R)`, else `Cat::Polynomial(R)`.

Examples

Example 1

To create the ring of multivariate polynomials in `x`, `y` and `z` over the rationals one may define
MP := Dom::MultivariatePolynomial([x, y, z], Dom::Rational)Dom::MultivariatePolynomial([x, y, z], Dom::Rational, LexOrder)

Dom::MultivariatePolynomial([x, y, z], Dom::Rational, LexOrder)

The elementary symmetric polynomials of this domain are
s1 := MP(x + y + z)x + y + z

$$x + y + z$$

s2 := MP(x*y + x*z + y*z)x*y + x*z + y*z

$$x\,y + x\,z + y\,z$$

s3:=MP(x*y*z)x*y*z

$$x\,y\,z$$

A polynomial is called symmetric if it remains unchanged under every possible permutation of variables as, e.g.:
s3=s3(MP(y), MP(z), MP(x))x*y*z = x*y*z

$$x\,y\,z = x\,y\,z$$

These polynomials arise naturally in studying the roots of a polynomial. To show this, we first have to create an univariate polynomial, e.g., in `U` over `MP`, and generate a polynomial in `U` with roots in `x`, `y` and `z`.
UP:=Dom::UnivariatePolynomial(U, MP)Dom::UnivariatePolynomial(U, Dom::MultivariatePolynomial([x, y, z], Dom::Rational, LexOrder), LexOrder)

Dom::UnivariatePolynomial(U, Dom::MultivariatePolynomial([x, y, z], Dom::Rational, LexOrder), LexOrder)

f := UP((U - x)*(U - y)*(U - z))U^3 + (- x - y - z)*U^2 + (x*y + x*z + y*z)*U - x*y*z

$$U^3 + (-x - y - z)\,U^2 + (x\,y + x\,z + y\,z)\,U - x\,y\,z$$

UP(U^3)-s1*UP(U^2)+s2*UP(U)+(-1)^3*s3U^3 + (- x - y - z)*U^2 + (x*y + x*z + y*z)*U - x*y*z

$$U^3 + (-x - y - z)\,U^2 + (x\,y + x\,z + y\,z)\,U - x\,y\,z$$

This exemplifies that the coefficients of `f` are (elementary) symmetric polynomials in its roots.

From the fundamental theorem of symmetric polynomials we know that every symmetric polynomial can be written uniquely as a polynomial in the elementary symmetric polynomials. Thus we can rewrite the following symmetric polynomial `s` in the elementary symmetric polynomials `s1`, `s2` and `s3`,

s:=MP(x^3*y+x^3*z+x*y^3+x*z^3+y^3*z+y*z^3)x^3*y + x^3*z + x*y^3 + x*z^3 + y^3*z + y*z^3

$$x^3\,y + x^3\,z + x\,y^3 + x\,z^3 + y^3\,z + y\,z^3$$

S:=MP::rewritePoly(s,[s1=S1,s2=S2,s3=S3])S1^2*S2 - S1*S3 - 2*S2^2

$$S1^2\,S2 - S1\,S3 - 2\,S2^2$$

where these polynomials are represented by the three new variables `S1`, `S2` and `S3` respectively. To see that this new polynomial `S` in the new variables indeed represents the old original polynomial `s`, we simply have to plug in the three elementary symmetric polynomials into `S`:

poly(S, Expr)(s1,s2,s3)x^3*y + x^3*z + x*y^3 + x*z^3 + y^3*z + y*z^3

$$x^3\,y + x^3\,z + x\,y^3 + x\,z^3 + y^3\,z + y\,z^3$$

When one has a given list of polynomials, e.g., like:

l:=[3*s1,2*s1,s1,s3][3*x + 3*y + 3*z, 2*x + 2*y + 2*z, x + y + z, x*y*z]

$$[3\,x + 3\,y + 3\,z,\ 2\,x + 2\,y + 2\,z,\ x + y + z,\ x\,y\,z]$$

and one wants to sort them in an appropriate order, one may use one of the following two methods.
MP::sortList(l,Dom::MonomOrdering(DegLex(3)))[x*y*z, 2*x + 2*y + 2*z, x + y + z, 3*x + 3*y + 3*z]

$$[x\,y\,z,\ 2\,x + 2\,y + 2\,z,\ x + y + z,\ 3\,x + 3\,y + 3\,z]$$

MP::stableSort(l,Dom::MonomOrdering(DegLex(3)))[x*y*z, 3*x + 3*y + 3*z, 2*x + 2*y + 2*z, x + y + z]

$$[x\,y\,z,\ 3\,x + 3\,y + 3\,z,\ 2\,x + 2\,y + 2\,z,\ x + y + z]$$

In the first sorted list the order of the three polynomials of the same degree has changed, while with the second method this order remains stable.

Example 2

Let _outputSequence(G,Symbol::Subset,GL(n,k)) $G \subset \mathrm{GL}(n,\ k)$ be a finite (matrix) subgroup of the general linear group. Then a polynomial _outputSequence(f, Symbol::epsi, k,[x[1], Symbol::hellip, x[(n)]]) $f \in k[x_1,\ \ldots,\ x_n]$ is called *invariant under* G, if for all A G

f(x) = f(A*x)

$$f(x) = f(A\ x)$$

where x=matrix([[x[1],Symbol::hellip,x[n]]]) $x = (\ x_1\ \ldots\ x_n\ )$. The symmetric polynomials `s1`, `s2` and `s3` from the previous example are invariants under the symmetric group S_3. In fact, these three fundamental invariants yet generate the whole ring of invariants of S_3.

Now let us examine the invariants of the famous icosahedral group. One may find a representation of this group on page 73 of H. F. Blichfeldt: Finite collineation groups, University of Chicago Press, 1917.

S' = matrix([[Symbol::epsiv^3,0], [0,Symbol::epsiv^2]]), U' = matrix([[0,1],[-1,0]]), T' = matrix([[Symbol::alpha, Symbol::beta], [Symbol::beta, -Symbol::alpha]]), Symbol::epsiv^5 = 1, Symbol::alpha = (Symbol::epsiv^4 - Symbol::epsiv)/sqrt(5), Symbol::beta = (Symbol::epsiv^2 - Symbol::epsiv^3)/sqrt(5)

$$S' = \begin{pmatrix} \varepsilon^3 & 0 \\ 0 & \varepsilon^2 \end{pmatrix},\ U' = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix},\ T' = \begin{pmatrix} \alpha & \beta \\ \beta & -\alpha \end{pmatrix},\ \varepsilon^5 = 1,\ \alpha = \frac{\varepsilon^4 - \varepsilon}{\sqrt{5}},\ \beta = \varepsilon$$

The group is generated from these three matrices, has 120 elements and is thus a finite subgroup, even of the special linear group $SL(2, (\varepsilon))$. It is also well known that

i[1] = x[1]*x[2]^11 - 1*x[1]^6*x[2]^6 - x[1]^11*x[2]

$$i_1 = x_1 x_2^{11} - x_1^6 x_2^6 - x_1^{11} x_2$$

is a fundamental invariant of degree 12 of this group. To declare i_1 in MuPAD one has first to define the polynomial domain.
MP:=Dom::MultivariatePolynomial([x1,x2],Dom::Rational)Dom::MultivariatePolyno
x2], Dom::Rational, LexOrder)

Dom::MultivariatePolynomial([x1, x2], Dom::Rational, LexOrder)

i1:=MP(x1*x2^(11)-11*x1^6*x2^6-x1^(11)*x2)- x1^11*x2 -
11*x1^6*x2^6 + x1*x2^11

$$-x1^{11}\,x2 - 11\,x1^6\,x2^6 + x1\,x2^{11}$$

From the invariant i_1 one can compute a further fundamental invariant i_2 with
i2:=MP::hessianDet(i1)- 121*x1^20 + 27588*x1^15*x2^5 - 59774*x1^10*x2^10 - 27588*x1^5*x2^15 - 121*x2^20

$$-121\,x1^{20}+27588\,x1^{15}x2^{5}-59774\,x1^{10}x2^{10}-27588\,x1^{5}x2^{15}-121\,x2^{2}$$

But to get more simple coefficients we choose i_2 as
i2:=-1/121*MP::hessianDet(i1)x1^20 - 228*x1^15*x2^5 + 494*x1^10*x2^10 + 228*x1^5*x2^15 + x2^20

$$x1^{20}-228\,x1^{15}x2^{5}+494\,x1^{10}x2^{10}+228\,x1^{5}x2^{15}+x2^{20}$$

instead. Similar we obtain a third fundamental invariant i_3 with
i3:=1/20*MP::jacobianDet([i1,i2])x1^30 + 522*x1^25*x2^5 - 10005*x1^20*x2^10 - 10005*x1^10*x2^20 - 522*x1^5*x2^25 + x2^30

$$x1^{30}+522\,x1^{25}x2^{5}-10005\,x1^{20}x2^{10}-10005\,x1^{10}x2^{20}-522\,x1^{5}x2^{25}+x$$

In contrast to the symmetric groups, where all invariants can be uniquely represented by the fundamental invariants, the fundamental invariants of this group have an algebraic relation, a so-called syzygy between them. It is possible to represent i_3^2 in two ways:
MP::rewritePoly(i3^2,[i1=I1,i2=I2,i3=I3])- 1728*I1^5 + I2^3

$$-1728\,I1^{5}+I2^{3}$$

MP::rewritePoly(i3^2,[i1=I1,i2=I2,i3=I3],Unsorted)I3^2

$$I3^{2}$$

And hence we get the syzygy:

MP::rewritePoly(i3^2,[i1=I1,i2=I2,i3=I3],Unsorted)-
MP::rewritePoly(i3^2,[i1=I1,i2=I2,i3=I3]) = 01728*I1^5 - I2^3
+ I3^2 = 0

$$1728\,I1^{5} - I2^{3} + I3^{2} = 0$$

Parameters

Vars

A list of indeterminates. Default: `[x,y,z]`.

R

A commutative ring, i.e., a domain of category Cat::CommutativeRing. Default: `Dom::ExpressionField(normal)`.

Order

A monomial ordering, i.e., one of the predefined orderings `LexOrder`, `DegreeOrder`, or `DegInvLexOrder` or any object of type Dom::MonomOrdering. Default: `LexOrder`.

p

A polynomial or a polynomial expression.

lm

List of monomials, which are represented as lists containing the coefficients together with the exponents or exponent vectors.

Entries

"characteristic"	The characteristic of this domain.
"coeffRing"	The coefficient ring of this domain as defined by the parameter `R`.
"key"	The name of the domain created.
"one"	The neutral element w.r.t. `"_mult"`.

"ordering"	The monomial ordering defined by the parameter `Order`.
"variables"	The list of variables defined by the parameter `Vars`.
"zero"	The neutral element w.r.t. `"_plus"`.

Dom::Natural

Purpose

Semi-ring of natural integer numbers

Syntax

```
Dom::Natural(x)
```

Description

`Dom::Natural` is the semi-ring of integer numbers represented by elements of the domain DOM_INT.

`Dom::Natural` is the domain of natural integer numbers represented by expressions of type `DOM_INT`.

Elements of `Dom::Natural` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input is an integer number. This means that `Dom::Natural` is a façade domain which creates elements of domain type `DOM_INT`.

Viewed as a differential ring `Dom::Natural` is trivial, it contains constants only.

`Dom::Natural` has the domain Dom::Numerical as its super domain, i.e., it inherits each method which is defined by `Dom::Numerical` and not re-implemented by `Dom::Natural`. Methods described below are those implemented by `Dom::Natural`.

Superdomain

Dom::Numerical

Axioms

Ax::canonicalRep, Ax::systemRep, Ax::canonicalOrder, Ax::canonicalUnitNormal, Ax::closedUnitNormals, Ax::efficientOperation(`"_divide"`), Ax::efficientOperation(`"_mult"`)

Categories

Dom::ComplexDom::FloatDom::NumericalDom::RationalDom::Integer

Dom::Numerical

Purpose

Field of numbers

Syntax

```
Dom::Numerical(x)
```

Description

`Dom::Numerical` is the field of numbers.

`Dom::Numerical` is the domain of numbers represented by one of the kernel domains DOM_INT, DOM_RAT, DOM_FLOAT, or DOM_COMPLEX.

`Dom::Numerical` is of category Cat::Field due to pragmatism. This domain actually is not a field because `bool(1.0 = float(3) / float(3))` returns `FALSE`, for example.

Elements of `Dom::Numerical` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input expression can be converted into a number (see below).

This means that `Dom::Numerical` is a façade domain which creates elements of domain type `DOM_INT`, `DOM_RAT`, `DOM_FLOAT` or `DOM_COMPLEX`. Every system function dealing with numbers can be applied, and computations in this domain are performed efficiently.

`Dom::Numerical` has no normal representation, because `0` and `0.0` both represent zero.

Viewed as a differential ring, `Dom::Numerical` is trivial. It only contains constants.

If `x` is a constant arithmetical expression such as `sin(2)` or `PI + 2`, the system function float is applied to convert `x` into a floating-point approximation.

An error message is issued if the result of this conversion is not of domain type DOM_FLOAT or DOM_COMPLEX.

Superdomain

Dom::ArithmeticalExpression

Axioms

Ax::canonicalRep, Ax::systemRep, Ax::efficientOperation("_divide"), Ax::efficientOperation("_mult"), Ax::efficientOperation("_invert")

Categories

Cat::DifferentialRing, Cat::Field

Examples

Example 1

`Dom::Numerical` contains numbers of the domains DOM_INT, DOM_RAT, DOM_FLOAT and DOM_COMPLEX:
Dom::Numerical(2), Dom::Numerical(2/3), Dom::Numerical(3.141), Dom::Numerical(2 + 3*I)2, 2/3, 3.141, 2 + 3*I

$$2,\ \frac{2}{3},\ 3.141,\ 2 + 3\,i$$

Constant arithmetical expressions are converted into a real and complex floating-point number, respectively, i.e., into an element of the domain DOM_FLOAT or DOM_COMPLEX (see the function float for details):
Dom::Numerical(exp(5)), Dom::Numerical(sin(2/3*I) + 3)148.4131591, 3.0 + 0.717158461*I

$$148.4131591,\ 3.0 + 0.717158461\,i$$

Note that the elements of this domain are elements of kernel domains, there are no elements of the domain type `Dom::Numerical`!

An error message is issued for non-constant arithmetical expressions:
Dom::Numerical(sin(x)) Error: The arguments are invalid. [Dom::Numerical::new]

Example 2

`Dom::Numerical` is regarded as a field, and it therefore can be used as a coefficient ring of polynomials or as a component ring of matrices, for example.

We create the domain of matrices of arbitrary size (see Dom::Matrix) with numerical components:

MatN := Dom::Matrix(Dom::Numerical)Dom::Matrix(Dom::Numerical)

Dom::Matrix(Dom::Numerical)

Next we create a banded matrix, such as:
A := MatN(4, 4, [-PI, 0, PI], Banded)Dom::Matrix(Dom::Numerical)([[0, 3.141592654, 0, 0], [-3.141592654, 0, 3.141592654, 0], [0, -3.141592654, 0, 3.141592654], [0, 0, -3.141592654, 0]])

$$\begin{pmatrix} 0 & 3.141592654 & 0 & 0 \\ -3.141592654 & 0 & 3.141592654 & 0 \\ 0 & -3.141592654 & 0 & 3.141592654 \\ 0 & 0 & -3.141592654 & 0 \end{pmatrix}$$

and a row vector with four components as a 1 4 matrix:
v := MatN([[2, 3, -1, 0]])Dom::Matrix(Dom::Numerical)([[2, 3, -1, 0]])

$$\begin{pmatrix} 2 & 3 & -1 & 0 \end{pmatrix}$$

Vector-matrix multiplication can be performed with the standard operator * for multiplication:
v * ADom::Matrix(Dom::Numerical)([[-9.424777961, 9.424777961, 9.424777961, -3.141592654]])

$$\begin{pmatrix} -9.424777961 & 9.424777961 & 9.424777961 & -3.141592654 \end{pmatrix}$$

Finally we compute the determinant of the matrix A, using the function linalg::det of the linalg package:
linalg::det(A)97.40909103

97.40909103

Parameters

`x`

An arithmetical expression

Entries

"characteristic" is zero.

Methods

Mathematical Methods

DDifferential operator for numbers

`D(a)`

See the function D for details and further calling sequences.

diffDifferentiation of numbers

`diff(a, x)`

See the function diff for details and further calling sequences.

normAbsolute value of numbers

`norm(a)`

randomRandom number generation

`random()`

Conversion Methods

convertConversion of objects into numbers

`convert(x)`

If `x` is of the domain type DOM_INT, DOM_RAT, DOM_FLOAT or DOM_COMPLEX, `x` is returned.

Otherwise `float(x)` is computed and the result is returned, if it is of the domain type `DOM_FLOAT` or DOM_COMPLEX. If it is not, `FAIL` is returned.

convert_toConversion into other domains

`convert_to(a, T)`

If the conversion fails, `FAIL` is returned.

It currently handles the following domains for `T`: DOM_INT, Dom::Integer, DOM_RAT, Dom::Rational, DOM_FLOAT, Dom::Float and DOM_COMPLEX.

testtypeType checking

`testtype(a, T)`

This method is called from the function testtype.

See Also

Dom::ComplexDom::FloatDom::IntegerDom::RationalDom::Real

Dom::Polynomial

Purpose

Domains of polynomials in arbitrarily many indeterminates

Syntax

Domain Creation

```
Dom::Polynomial(<R, <Order>>)
```

Element Creation

```
Dom::PolynomialRorder(p)
Dom::PolynomialRorder(lm, v)
```

Description

`Dom::Polynomial(R, ..)` creates the domain of polynomials in arbitrarily many indeterminates over the commutative ring `R` in distributed representation.

`Dom::Polynomial` represents polynomials in arbitrarily many indeterminates over arbitrary commutative rings.

It is simply a front end to the domain `Dom::DistributedPolynomial([],R,Order)` and thus all usual algebraic and arithmetical polynomial operations are implemented. Please see the documentation for Dom::DistributedPolynomial for a list of methods.

`Dom::Polynomial(R, Order)` creates a domain of polynomials in arbitrarily many indeterminates over a domain of category Cat::CommutativeRing in sparse distributed representation with respect to the monomial ordering `Order`.

If `Dom::Polynomial` is called without any argument, a polynomial domain over the domain `Dom::ExpressionField(normal)` with respect to the lexicographic monomial ordering is created.

Note Only commutative coefficient rings of type DOM_DOMAIN which inherit from Dom::BaseDomain are allowed. If `R` is of type DOM_DOMAIN but does not inherit from Dom::BaseDomain, the domain Dom::ExpressionField`(normal)` will be used instead.

Only identifiers should be used as polynomial indeterminates, since when creating a new element from a polynomial or a polynomial expression the function indets is first called to get the identifiers and then the polynomial is created with respect to these identifiers.

Note It is highly recommend to use only coefficient rings with unique zero representation. Otherwise it may happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

Please note that for reasons of efficiency not all methods check their arguments, not even at the interactive level. In particular, this is true for many access methods, converting methods and technical methods. Thus, improper use of these methods may result in confusing error messages.

Superdomain

Dom::DistributedPolynomial

Axioms

Ax::indetElements

Categories

Cat::Polynomial(R)

Examples

Example 1

The following call creates the polynomial domain over the rationals.
PR:=Dom::Polynomial(Dom::Rational)Dom::Polynomial(Dom::Rational, LexOrder)

Dom::Polynomial(Dom::Rational, LexOrder)

Since the monomial ordering was not specified, this domain is created with the default value for this parameter.

It is rather easy to create elements of this domain, as, e.g.,
a := PR(x*(2*x + y^3) - 7/2)2*x^2 + x*y^3 - 7/2

$$2x^2 + xy^3 - \frac{7}{2}$$

b := PR(x*(2*t*x + z^3) - 6)2*t*x + x*z^3 - 6

$$2txz^3 - 6$$

c := a^2-b/3+3- (2*t*x)/3 + 4*x^4 + 4*x^3*y^3 + x^2*y^6 - 14*x^2 - 7*x*y^3 - (x*z^3)/3 + 69/4

$$-\frac{2tx}{3} + 4x^4 + 4x^3y^3 + x^2y^6 - 14x^2 - 7xy^3 - \frac{xz^3}{3} + \frac{69}{4}$$

Parameters

R

A commutative ring, i.e., a domain of category Cat::CommutativeRing. Default: `Dom::ExpressionField(normal)`.

Order

A monomial ordering, i.e., one of the predefined orderings `LexOrder`, `DegreeOrder`, or `DegInvLexOrder` or an element of the domain Dom::MonomOrdering. Default: `LexOrder`.

p

A polynomial or a polynomial expression.

lm

List of monomials, which are represented as lists containing the coefficients together with the exponents or exponent vectors.

v

List of indeterminates.

Entries

"characteristic"	The characteristic of this domain, which is the characteristic of `R`.
"coeffRing"	The coefficient ring of this domain as defined by the parameter `R`.
"key"	The name of the domain created.
"one"	The neutral element w.r.t. `"_mult"`, which is `R::one`.
"ordering"	The monomial order as defined by the parameter `Order`.
"zero"	The neutral element w.r.t. `"_plus"`, which is `R::zero`.

Algorithms

To create polynomials from expressions with no suitable indeterminates the dummy variable `_dummy` is introduced. With this variable it is possible to create elements from constants which otherwise would fail. The drawback of this approach is that two mathematically equal polynomials may have variable lists which differ by this dummy variable.

See Also

Dom::DistributedPolynomialDom::MultivariatePolynomialDom::UnivariatePolynomial

Dom::Product

Purpose

Homogeneous direct products

Syntax

Domain Creation

```
Dom::Product(Set, <n>)
Dom::ProductSetn(e1, e2,  , en)
Dom::ProductSetn(List)
```

Description

`Dom::Product(Set, n)` is an `n`-fold direct product of the domain *Set*.

`Dom::Product(Set, n)(e1, e2, ..., en)` creates the `n`-tuple (e_1, e_2, ..., e_n).

The objects `e1`, `e2`, ..., `en` must be convertible into elements of the domain `Set`, otherwise an error message is issued.

`Dom::Product(Set, n)(List)` creates the `n`-tuple (l_1, l_2, ..., l_n).

The `n` elements l_i of `List` must be convertible into elements of the domain `Set`, otherwise an error message is issued.

The list must consist of exactly `n` elements, otherwise an error message is issued.

Following to the definition of a direct product many of the methods such as `"D"` and `"_negate"` just map the operation to all the components of the tuple.

Most `n`-ary methods like `"_plus"` and `"_mult"` apply the operation component-wise to the tuples.

Superdomain

Dom::BaseDomain

Axioms

If `Set` has Ax::canonicalRep, then Ax::canonicalRep.

If `Set` has Cat::AbelianMonoid, then Ax::normalRep.

Categories

Cat::HomogeneousFiniteProduct(`Set`)

Examples

Example 1

Define the 3-fold direct product of the rational numbers:
P3 := Dom::Product(Dom::Rational, 3)Dom::Product(Dom::Rational, 3)

Dom::Product(Dom::Rational, 3)

and create elements:
a := P3([1, 2/3, 0])[1, 2/3, 0]

$$\left[1, \frac{2}{3}, 0\right]$$

b := P3(2/3, 4, 1/2)[2/3, 4, 1/2]

$$\left[\frac{2}{3}, 4, \frac{1}{2}\right]$$

We use the standard arithmetical operators to calculate with such tuples:
a + b, a*b, 2*a[5/3, 14/3, 1/2], [2/3, 8/3, 0], [2, 4/3, 0]

$$\left[\frac{5}{3}, \frac{14}{3}, \frac{1}{2}\right], \left[\frac{2}{3}, \frac{8}{3}, 0\right], \left[2, \frac{4}{3}, 0\right]$$

Some system functions were overloaded for such elements, such as diff, map or zip (see the description of the corresponding methods `"diff"`, `"map"` and `"zip"` above).

For example, to divide each component of `a` by 2 we enter:
map(a, '/', 2)[1/2, 1/3, 0]

$$\left[\frac{1}{2}, \frac{1}{3}, 0\right]$$

The quoted character `` `/` `` is another notation for the function `_divide`, the functional form of the division operator `/`.

Be careful that the mapping function returns elements of the domain the product is defined over. This is not checked by the function `map` (for efficiency reasons) and may lead to "invalid" tuples. For example:
b := map(a, sin); domtype(b)[sin(1), sin(2/3), 0]

Dom::Product(Dom::Rational, 3)

But the components of `b` are no longer rational numbers!

Parameters

Set

An arbitrary domain of elements, i.e., a domain of category Cat::BaseCategory

n

The dimension of the product (a positive integer); default is `1`

e1e2, en, ...

Elements of `Set` or objects convertible into such

List

A list of `n` elements of `Set` or objects convertible into such

Entries

"dimen"	is the dimension of `Dom::Product(Set, n)`, which is equal to `n`.
"coeffRing"	is the domain `S`.

"one"	is the n-tuple `(Set::one, Set::one, ..., Set::one)`. This entry only exists if `Set` is a monoid, i.e., a domain of category Cat::Monoid.
"zero"	is the n-tuple `(Set::zero, Set::zero, ..., Set::zero)`. This entry only exists if `Set` is an Abelian group, i.e., a domain of category Cat::AbelianGroup.

Methods

Mathematical Methods

_divideDivide tuples

```
_divide(x, y)
```

This method only exists if `Set` is a (multiplicative) group, i.e., a domain of category Cat::Group.

This method overloads the function _divide for n-tuples, i.e., one may use it in the form `x / y`, or in functional notation: `_divide(x, y)`.

_invertCompute the inverse of a tuple

```
_invert(x)
```

This method only exists if `Set` is a (multiplicative) group, i.e., a domain of category Cat::Group.

This method overloads the function _invert for n-tuples, i.e., one may use it in the form `1/x` or `x^(-1)`, or in functional notation: `_inverse(x)`.

_lessLess-than relation

```
_less(x, y)
```

An implementation is provided only if `Set` is an ordered set, i.e., a domain of category Cat::OrderedSet.

This method overloads the function _less for n-tuples, i.e., one may use it in the form `x < y`, or in functional notation: `_less(x, y)`.

_multMultiplie tuples by tuples and scalars

```
_mult(x, y,  )
```

If `x` is not of the type `Dom::Product(Set,n)`, it is considered as a scalar which is multiplied to each component of the `n`-tuple `y` (and vice versa).

This method only exists if `Set` is a semigroup, i.e., a domain of category Cat::SemiGroup.

This method also handles more than two arguments. In this case, the argument list is split into two parts of the same length which both are multiplied with the function _mult. These two result are multiplied again with `_mult` whose result then is returned.

This method overloads the function _mult for `n`-tuples, i.e., one may use it in the form `x * y`, or in functional notation: `_mult(x, y)`.
_negateNegate an `n`-tuple

```
_negate(x)
```

This method overloads the function _negate for `n`-tuples, i.e., one may use it in the form `-x`, or in functional notation: `_negate(x)`.
_powerith power of a tuple

```
_power(x, i)
```

An implementation is provided only if `Set` is a semigroup, i.e., a domain of category Cat::SemiGroup.

This method overloads the function _power for `n`-tuples, i.e., one may use it in the form `x^i`, or in functional notation: `_power(x, i)`.
_plusAdd tuples

```
_plus(x, y,  )
```

The sum of two `n`-tuples x and y is defined component-wise as $(x_1 + y_1, \ldots, x_n + y_n)$.

This method overloads the function _plus for `n`-tuples, i.e., one may use it in the form `x + y`, or in functional notation: `_plus(x, y)`.
DDifferential operator

```
D(x)
```

An implementation is provided only if `Set` is a partial differential ring, i.e., a domain of category Cat::PartialDifferentialRing.

This method overloads the operator D for `n`-tuples, i.e., one may use it in the form `D(x)`.
diffDifferentiation of `n`-tuples

```
diff(a, x)
```

This method overloads the function diff for `n`-tuples, i.e., one may use it in the form `diff(a, x)`.

An implementation is provided only if `Set` is a partial differential ring, i.e., a domain of category Cat::PartialDifferentialRing.
equalTest on equality of `n`-tuples

```
equal(x, y)
```
intmultMultiple of a tuple

```
intmult(x, k)
```

An implementation is provided only if `Set` is an Abelian semigroup, i.e., a domain of category Cat::AbelianSemiGroup.
iszeroTest on zero

```
iszero(x)
```

Note that there may be more than one representation of the zero `n`-tuple if `R` does not have Ax::canonicalRep.

This method overloads the function iszero for `n`-tuples, i.e., one may use it in the form `iszero(x)`.
randomRandom tuple generation

```
random()
```
Access Methods

_indexTuple indexing

```
_index(x, i)
```

See also the method `"op"`.

This method overloads the function _index for `n`-tuples, i.e., one may use it in the form `x[i]`, or in functional notation: `_index(x, i)`.

mapApply a function to tuple components

```
map(x, func, <expr,  >)
```

Note Note that the function values will *not* be implicitly converted into elements of the domain `Set`. One has to take care that the function calls return elements of the domain type `Set`.

This method overloads the function `map` for `n`-tuples, i.e., one may use it in the form `map(x, func, ...)`.

mapCanFailApply a function to tuple components

```
mapCanFail(x, func, <expr,  >)
```

opComponent of a tuple

```
op(x, i)
```

```
op(x)
```

See also the method `"_index"`.

This method overloads the function op for `n`-tuples, i.e., one may use it in the form `op(x, i)`.

Returns a sequence of all components of `x`.

set_indexAssigning tuple components

```
set_index(x, i, e)
```

See also the method `"subsop"`.

Note This method does not check whether `e` has the correct type.

This method overloads the indexed assignment _assign for `n`-tuples, i.e., one may use it in the form `x[i] := e`, or in functional notation: `_assign(x[i], e)`.

sortSorting the components of a tuple

```
sort(x)
```

This method overloads function sort for tuples, i.e. one may use it in the form `sort(x)`.

subsSubstitution of tuple components

```
subs(x,  )
```

Note The objects obtained by the substitutions will not be implicitly converted into elements of the domain `Set`. One has to take care that the substitutions return elements of the domain `Set`.

This method overloads the function `subs` for `n`-tuples, i.e., one may use it in the form `subs(x, ...)`. See subs for details and calling sequences.

testEachCheck every component for a certain condition

```
testEach(x, func, <expr,  >)
```

`func` must return either `TRUE` or `FALSE`, otherwise a runtime error is raised.

testOneCheck an component for a certain condition

```
testOne(x, func, <expr,  >)
```

`func` must return either `TRUE` or `FALSE`, otherwise a runtime error is raised.

zipCombine tuples component-wise

```
zip(x, y, func, <expr,  >)
```

Note The function values will not be implicitly converted into elements of the domain `Set`. One has to take care that the function calls return elements of the domain `Set`.

This method overloads the function `zip` for `n`-tuples, i.e., one may use it in the form `zip(x, y, func, ...)`.

zipCanFailCombine tuples component-wise

```
zipCanFail(x, y, func, <expr,  >)
```

Conversion Methods

convertConversion into an n-tuple

```
convert(List)
```

```
convert(e1, <e2,  >)
```

FAIL is returned if this conversion fails.

Tries to convert the arguments into an element of the domain `Dom::Product(Set, n)`. This can be done if exactly `n` arguments are given where each argument can be converted into an element of the domain `Set`.

FAIL is returned if this conversion fails.

exprConversion into an object of a kernel domain

```
expr(x)
```

This method overloads the function `expr` for `n`-tuples, i.e., one may use it in the form `expr(x)`.

Dom::Quaternion

Purpose

Skew field of quaternions

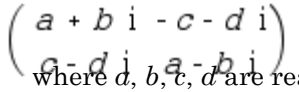
Syntax

```
Dom::Quaternion(listi)
Dom::Quaternion(ex)
Dom::Quaternion(M)
```

Description

Domain `Dom::Quaternion` represents the skew field of quaternions.

Quaternions are usually defined to be complex 2 2 matrices of the special form
matrix([[a+b*I, -c-d*I],[c-d*I, a-b*I]])



where a, b, c, d are real numbers. Another usual notation is $a + bi + cj + dk$; the subfield of those quaternions for which $c = d = 0$ is isomorphic to the field of complex numbers.

The domain `Dom::Quaternion` regards these fields as being identical, and it allows both notations that have been mentioned, as well as simply `[a,b,c,d]`.

If you enter a quaternion as an arithmetical expression `ex`, the identifiers `i`, `j`, and `k` are understood in the way mentioned above; `I`, `J`, and `K` may be used alternatively, and you may also mix small and capital letters. Every subexpression of `ex` not containing one of these must be real and constant.

Note Be sure that you have not assigned a value to one of the identifiers mentioned.

`Dom::Quaternion` has the domain Dom::BaseDomain as its super domain, i.e., it inherits each method which is defined by

`Dom::BaseDomain` and not re-implemented by `Dom::Quaternion`. Methods described below are re-implemented by `Dom::Quaternion`.

Superdomain

Dom::BaseDomain

Axioms

Ax::canonicalRep

Categories

Cat::SkewField

Examples

Example 1

Creating some quaternions.

```
Dom::Quaternion([1,2,3,4]), Dom::Quaternion(11+12*i+13*j+14*k);
M := Dom::Matrix(Dom::Complex)([[3+4*I,-6-2*I],[6-2*I,3-4*I]]): M,
Dom::Quaternion(M)1 + 2*I + 3*j + 4*k, 11 + 12*I + 13*j + 14*k
```

$$1 + 2\,i + 3\,j + 4\,k,\ 11 + 12\,i + 13\,j + 14\,k$$

```
Dom::Matrix(Dom::Complex)([[3 + 4*I, - 6 + (- 2*I)], [6 + (- 2*I), 3 + (-
4*I)]]), 3 + 4*I + 6*j + 2*k
```

$$\begin{pmatrix} 3 + 4\,i & -6 - 2\,i \\ 6 - 2\,i & 3 - 4\,i \end{pmatrix},\ 3 + 4\,i + 6\,j + 2\,k$$

Example 2

Doing some standard arithmetic.

```
a:=Dom::Quaternion([1,2,3,4]): b:=Dom::Quaternion([11,2,33.3,2/3]):
a*b, a+b, a^2/3, b^3;- 95.56666667 + (- 107.2*I) + 72.96666667*j +
105.2666667*k, 12 + 4*I + 36.3*j + (14*k)/3, - 28/3 + (4/3)*I + 2*j +
(8*k)/3, - 35409.03667 + (- 1500.668889*I) - 24986.137*j - 500.222963*k
```

$- 95.56666667 - 107.2\, i + 72.96666667\, j + 105.2666667\, k, 12 + 4\, i + 3$

Example 3

More mathematical operations:
a:=Dom::Quaternion([1,2,3,4]): b:=Dom::Quaternion([11,2,33,3,2/3]):
Dom::Quaternion::nthroot(b,3); abs(a), sign(b)2.993953193 +
0.07959236197*I + 1.325212827*j + 0.02653078732*k

$- \frac{28}{3} + \frac{4\, i}{3} + 2\, j + \frac{8\, k}{3}, - 35409.03667 - 1500.668889\, i - 24986.137\, j$

$2.993953193 + 0.07959236197\, i + 1.325212827\, j + 0.02653078732\, k$

sqrt(30), 0.3130950929 + 0.05692638053*I + 0.9478242358*j +
0.01897546018*k

$\sqrt{30}, 0.3130950929 + 0.05692638053\, i + 0.9478242358\, j + 0.018975$

Example 4

Some miscellaneous operations.
a:=Dom::Quaternion([1,2,3,4]): Dom::Quaternion::matrixform(a);
map(a, sqrt), map(a, _plus, 1);Dom::Matrix(Dom::Complex)([[1 + 2*I, - 3
+ (- 4*I)], [3 + (- 4*I), 1 + (- 2*I)]])

$$\begin{pmatrix} 1 + 2\, i & -3 - 4\, i \\ 3 - 4\, i & 1 - 2\, i \end{pmatrix}$$

1 + sqrt(2)*I + sqrt(3)*j + 2*k, 2 + 3*I + 4*j + 5*k

$1 + \sqrt{2}\, i + \sqrt{3}\, j + 2\, k, 2 + 3\, i + 4\, j + 5\, k$

Parameters

listi

A list containing four elements of type Type::Real

ex

Arithmetical expression

M

A matrix of type `Dom::Matrix(Dom::Complex)`. It has to be of a special form described in the Details section.

Entries

"characteristic"	the characteristic of this domain is 0
"one"	the unit element; it equals `Dom::Quaternion([1,0,0,0])`.
"size"	the number of quaternions is `infinity`.
"zero"	The zero element; it equals `Dom::Quaternion([0,0,0,0])`.

Methods

Mathematical Methods

_multMultiplie quaternions

```
_mult(x, y,  )
```

_plusAdd quaternions

```
_plus(x, y,  )
```

_powern-th power of a quaternion

```
_power(x, n)
```

ImReturn the imaginary (vectorial) part of a quaternion.

```
Im(x)
```

The result is still a quaternion.

ReReturn the real part of a quaternion.

`Re(x)`

The result is of type Type::Real.
absAbsolute value of a quaternion

`abs(x)`

The result is of type Type::Real.
conjugateConjugate element

`conjugate(x)`
intpowerMultiplie quaternions

`intpower(x, {DOM_INT})`

The implementation uses “repeated squaring”.

`Dom::Quaternion` is used by `"_power"`.
nthrootN-th root of a quaternion

`nthroot(x, n)`

The implementation uses “repeated squaring”.

`Dom::Quaternion` is used by `"_power"`.
normNorm of a quaternion

`norm(x)`

The result is of type Type::Real.
randomRandom number generation

`random()`
scalarmultScalar multiplication

`scalarmult(s, x)`
scalarprodInner product

`scalarprod(x, y)`
signSign of a quaternion

`sign(x)`

The result is of type Type::Real.

Conversion Methods

convertConversion of objects

```
convert(x)
```

convert_toConversion to other domains

```
convert_to(x, T)
```

It currently handles the following domains for `T`: DOM_EXPR, DOM_LIST, Dom::Matrix`(Dom::Complex)`.

exprConvert a quaternion to an object of a kernel domain

```
expr(x)
```

The result is an object of the kernel domain `DOM_EXPR`.

This method overloads the function expr for quaternions, i.e., you may use it in the form `expr(x)`.

matrixformConvert a quaternion to a 2 x 2 matrix with complex entries.

```
matrixform(x)
```

The result is an object of the domain `Dom::Matrix(Dom::Complex)`.

Technical Methods

TeXGenerate TeX-formatted string

```
TeX(x)
```

mapApply a function to all components of a quaternion

```
map(x, f, arg,  )
```

If optional arguments are present, then each component `co` of `x` is replaced by f(co, arg...). So for the quaternion $x := a + bi + cj + dk$, `Dom::Quaternion(x, f, arg, ...)` returns the quaternion $f(a, arg, \ldots) + f(b, arg, \ldots)i + f(c, arg, \ldots)j + f(d, arg, \ldots)k$.

simplifySimplification of a quaternion

```
simplify(x)
```

See Also

Dom::Complex

Dom::Rational

Purpose

Field of rational numbers

Syntax

```
Dom::Rational(x)
```

Description

`Dom::Rational` is the domain of rational numbers represented by elements of the domains DOM_INT or DOM_RAT. `Dom::Rational` represents the field of rational numbers.

Elements of `Dom::Rational` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input is of type `DOM_INT` or `DOM_RAT`. This means `Dom::Rational` is a façade domain which creates elements of domain type `DOM_INT` or `DOM_RAT`.

Viewed as a differential ring `Dom::Rational` is trivial, it contains constants only.

`Dom::Rational` has the domain Dom::Numerical as its super domain, i.e., it inherits each method which is defined by `Dom::Numerical` and not re-implemented by `Dom::Rational`. Methods described below are re-implemented by `Dom::Rational`.

Superdomain

Dom::Numerical

Axioms

Ax::canonicalRep, Ax::systemRep, Ax::canonicalOrder, Ax::efficientOperation(`"_divide"`), Ax::efficientOperation(`"_mult"`), Ax::efficientOperation(`"_invert"`)

Categories

Cat::QuotientField(`Dom::Integer`), Cat::DifferentialRing, Cat::OrderedSet

Examples

Example 1

Creating some rational numbers using `Dom::Rational`. This example also shows that `Dom::Rational` is a façade domain.

```
Dom::Rational(2/3) ; domtype(%)2/3
```

$\frac{2}{3}$ DOM_RAT

DOM_RAT
Dom::Rational(2.0) Error: The arguments are invalid.
[Dom::Rational::new]

Example 2

By tracing the method `Dom::Rational::testtypeDom` we can see the interaction between testtype and `Dom::Rational::testtypeDom`.
prog::trace(Dom::Rational::testtypeDom): delete x:
testtype(x, Dom::Rational); testtype(3/4, Dom::Rational);
prog::untrace(Dom::Rational::testtypeDom):enter
Dom::Rational::testtypeDom(x, Dom::Rational) computed FAIL FALSE

FALSE
enter Dom::Rational::testtypeDom(3/4, Dom::Rational) computed
TRUE TRUE

TRUE

Parameters

x

An integer or a rational number

Methods

Mathematical Methods
denomDenominator of a rational number

`denom(x)`
diffDifferentiates

`diff(z, <x, >)`

numerNumerator of the rational number

`numer(x)`
randomRandom number generation

`random()`
retractRetract to an integer element

`retract(x)`
Conversion Methods
convertConversion of objects

`convert(x)`
convert_toConversion to other domains

`convert_to(x, T)`

The following domains are allowed for `T`: DOM_INT, Dom::Integer, `Dom::Rational`, DOM_RAT, DOM_FLOAT, Dom::Float and Dom::Numerical.
testtypeType checking

`testtype(x, T)`

In general this method is called from the function testtype and not directly by the user. “Example 2” on page 6-335 demonstrates this behaviour.

See Also

Dom::ComplexDom::FloatDom::NumericalDom::RationalDom::Real

Dom::Real

Purpose

Field of real numbers

Syntax

```
Dom::Real(x)
```

Description

`Dom::Real` is the field of real numbers represented by elements of the kernel domains DOM_INT, DOM_RAT, DOM_FLOAT, and DOM_EXPR.

`Dom::Real` is the domain of real numbers represented by expressions of type `DOM_INT`, `DOM_RAT` or `DOM_FLOAT`. An expression of type `DOM_EXPR` is considered as a real number if it is of type Type::Arithmetical and if it contains no indeterminates which are not of type Type::ConstantIdents and if it contains no imaginary part. See “Example 2” on page 6-338.

`Dom::Real` has category Cat::Field due to practical reasons. This domain actually is not a field because `bool(1.0 = 1e100 + 1.0 - 1e100)` returns FALSE for example.

Elements may not have an unique representation, for example `bool(0 = sin(2)^2 + cos(2)^2 - 1)` returns FALSE.

Elements of `Dom::Real` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input expression can be converted to a number. This means `Dom::Real` is a façade domain which creates elements of domain type `DOM_INT`, `DOM_RAT`, `DOM_FLOAT`, or `DOM_EXPR`.

`Dom::Real` has no normal representation, because `0` and `0.0` both represent zero.

Viewed as a differential ring, `Dom::Real` is trivial, it contains constants only.

`Dom::Real` has the domain Dom::Complex as its super domain, i.e., it inherits each method which is defined by `Dom::Complex` and not re-implemented by `Dom::Real`. Methods described below are re-implemented by `Dom::Real`.

Superdomain

Dom::Complex

Axioms

Ax::systemRep, Ax::canonicalOrder, Ax::efficientOperation("_divide"), Ax::efficientOperation("_mult"), Ax::efficientOperation("_invert")

Categories

Cat::DifferentialRing, Cat::Field, Cat::OrderedSet

Examples

Example 1

The following lines demonstrate how to generate elements of `Dom::Real`. The rational and the floating-point numbers are elements of the real numbers:

```
Dom::Real(2/3)2/3
```

$$\frac{2}{3}$$

```
Dom::Real(0.5666)0.5666
```

$$0.5666$$

Example 2

The numbers `PI` and `sin(2)` are real numbers whereas `sin(2/3 * I) + 3` and `sin(x)` for general symbolic `x` are not real numbers. If we try to create the elements `Dom::Real(sin(2/3 * I) + 3)` and `Dom::Real(sin(x))` an error message is produced.

```
Dom::Real(PI)PI
```

$$\pi$$

```
Dom::Real(sin(2))sin(2)
```

$$\sin(2)$$

Dom::Real(sin(2/3 * I) + 3) Error: The arguments are invalid.
[Dom::Real::new] Dom::Real(sin(x)) Error: The arguments are invalid.
[Dom::Real::new]

Parameters

x

An expression of type DOM_INT, DOM_RAT, or DOM_FLOAT. An expression of type DOM_EXPR is also allowed if it is of type Type::Arithmetical and if it contains no indeterminates which are not of type Type::ConstantIdents and if it contains no imaginary part.

Methods

Mathematical Methods

_lessBoolean operator “less”

```
_less(x, y)
```

_leequalBoolean operator “less or equal”

```
_leequal(x, y)
```

_powerPower operator

```

Dom::ComplexDom::FloatDom::IntegerDom::NumericalDom::Rational

Dom::SparseMatrixF2

Purpose

Domain of sparse matrices over the field with two elements

Description

`Dom::SparseMatrixF2` represents the set of all matrices over the finite field with two elements.

`Dom::SparseMatrixF2(m, n, [s1, ..., sm])` creates the m times n matrix (a_{ij}) such that, for each i, the set of all j with $a_{ij} = 1$ equals the set (or list) s_i.

The internal representation of `Dom::SparseMatrixF2` guarantees that both storage and computing time required for the arithmetical operations depend on the number of non-zero entries. Therefore, `Dom::SparseMatrixF2` is suitable for representing large matrices with few nonzero entries.

The matrices generated by `Dom::SparseMatrixF2` are mathematically equivalent to the matrices generated by `Dom::Matrix(Dom::IntegerMod(2))`. We recommend to use `Dom::Matrix(Dom::IntegerMod(2))`.

Superdomain

Dom::BaseDomain

Axioms

Ax::canonicalRep

Categories

Cat::Matrix(Dom::IntegerMod(2))

Examples

Example 1

We create a sparse matrix with three non-zero entries:

```
A := Dom::SparseMatrixF2(3, 3, [{2}, {1}, {3}])[{2}, {1}, {3}]
```

```
[{2}, {1}, {3}]
```

Conversion to a Dom::Matrix yields a nicer output:

A::dom::convert_to(A, Dom::Matrix(Dom::IntegerMod(2)))Dom::Matrix(Dom::IntegerMod(2))([[0, 1, 0], [1, 0, 0], [0, 0, 1]])

$$\begin{pmatrix} 0 \bmod 2 & 1 \bmod 2 & 0 \bmod 2 \\ 1 \bmod 2 & 0 \bmod 2 & 0 \bmod 2 \\ 0 \bmod 2 & 0 \bmod 2 & 1 \bmod 2 \end{pmatrix}$$

We create a large sparse matrix and a vector as well as the equivalent matrix/vector of type `Dom::Matrix(Dom::IntegerMod(2))`:
A := Dom::SparseMatrixF2::randmatrix(1000, 1000): x := Dom::SparseMatrixF2::randmatrix(1000, 1): B := A::dom::convert_to(A, Dom::Matrix(Dom::IntegerMod(2))): y := x::dom::convert_to(x, Dom::Matrix(Dom::IntegerMod(2))):

The timings both for the multiplication `A*x` using `Dom::SparseMatrixF2` as well as for the multiplication `B*y` using Dom::Matrix show that both data structures have a similiar efficiency:
time(A*x)*msec, time(B*y)*msec; 80 msec, 100 msec

Compared to `Dom::SparseMatrixF2`, the matrix domain Dom::Matrix provides much more functionality. For instance, matrices can be multiplied:
time(B^2)*msec; 480 msec delete A, x, B, y:

Parameters

`m`

`n`

Positive integers

`s1, ...`

Sets or lists of integers between 1 and `n`

`f`

A procedure or another object that, when called with an integer between 1 and m and another integer between 1 and n, returns an element of `Dom::IntegerMod(2)`.

Entries

"coeffRing"	The coefficient ring always equals `Dom::IntegerMod(2)`.
"isSparse"	This entry is always set to `TRUE`.

Methods

Mathematical Methods

zeroMatrixMatrix of a given dimension, consisting of zeros

```
zeroMatrix(m, n)
```

_plusAdd matrices

```
_plus(A,  )
```

This method overloads the function _plus.

_negateNegate a matrix

```
_negate(A)
```

matrixvectorproductMultiply a matrix and a vector

```
matrixvectorproduct(A, b)
```

_multMultiply a matrix and a vector

```
_mult(A, b)
```

It overloads the function _mult.

Note The product of arbitrary sparse matrices (where `b` is not a vector) has *not* been implemented.

---

randmatrixGenerate random matrix

```
randmatrix(m, n, <s>)
```

Access Methods

nrowsNumber of rows

`nrows(A)`
ncolsNumber of rows

`ncols(A)`
dimenNumber of rows and columns

`dimen(A)`
bodyBody of the matrix

`body(A)`
rowRow of a matrix

`row(A, i)`
colColumn of a matrix

`col(A, i)`
_indexRow or single entry of a matrix

`_index(A, i)`

`_index(A, i, j)`

This method overloads the _index operator; `A[i]` may be entered equivalently.

returns the entry of `A` in the *i*-th row, *j*-th column.

Equivalently, `A[i,j]` may be entered.
set_indexAssignment to a matrix entry

`set_index(A, i, j, v)`

This method can be used for indexed assignments using the syntax `A[i,j]:=v`. In this case, the value of the identifier or local variable `A` is changed as a side effect; `v` (but not the result of converting it to a field element!) is returned.

Note If the assignment stops with an error, the domain element stored in `A` is destroyed, and the new value of `A` is FAIL.

See _assign for more information about indexed assignments.
Conversion Methods
convert_toConversion of a sparse matrix into another type

```
convert_to(A, T)
```

Dom::SquareMatrix(n, R)(<n, n>, List, <Diagonal>)
Dom::SquareMatrix(n, R)(<n, n>, g, <Diagonal>)
Dom::SquareMatrix(n, R)(<n, n>, List, <Banded>)
```

Description

Domain Creation

`Dom::SquareMatrix(n, R)` creates a domain which represents the ring of n n matrices over a component domain `R`. The domain `R` must be of category Cat::Rng (a ring, possibly without unit).

If the optional parameter `R` is not given, the domain `Dom::ExpressionField()` is used as the component ring for the square matrices.

For matrices of a domain created by `Dom::SquareMatrix(n, R)`, standard matrix arithmetic is implemented by overloading the standard arithmetical operators `+`, `-`, `*`, `/` and `^`. All functions of the `linalg` package dealing with matrices can also be applied.

`Dom::SquareMatrix(n, R)` has the domain `Dom::Matrix(R)` as its super domain, i.e., it inherits each method which is defined by `Dom::Matrix(R)` and not re-implemented by `Dom::SquareMatrix(n, R)`.

Methods described below are re-implemented by `Dom::SquareMatrix`.

The domain `Dom::Matrix(R)` represents matrices over `R` of arbitrary size, and it therefore does not have any algebraic structure (except of being a *set* of matrices).

The domain `Dom::MatrixGroup(m, n, R)` represents the Abelian group of m n matrices over R.

Element Creation

`Dom::SquareMatrix(n, R)(Array)` and `Dom::SquareMatrix(n, R)(Matrix)` create a new matrix formed by the entries of `Array` and `Matrix`, respectively.

The components of `Array` and `Matrix`, respectively, are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

The call `Dom::SquareMatrix(n, R)( n , n )` returns the n n zero matrix. Note that the n n zero matrix is also defined by the entry `"zero"` (see below).

`Dom::SquareMatrix(n, R)( n , n ListOfRows)` creates an n n matrix with components taken from the nested list `ListOfRows`. Each inner list corresponds to a row of the matrix.

If an inner list has less than `n` entries, the remaining components in the corresponding row of the matrix are set to zero. If there are less than `n` inner lists, the remaining lower rows of the matrix are filled with zeroes.

The entries of the inner lists are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

It might be a good idea first to create a two-dimensional array from that list before calling `Dom::SquareMatrix(n, R)`. This is due to the fact that creating a matrix from an array is the fastest way one can achieve. However, in this case the sublists must have the same number of elements.

`Dom::SquareMatrix(n, R)( n , n f)` returns the matrix whose (i, j)th component is the value of the function call `f(i, j)`. The row and column indices i and j range from 1 to `n`.

The function values are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

Superdomain

Dom::Matrix(`R`)

Axioms

If `R` has Ax::canonicalRep, then Ax::canonicalRep.

Categories

Cat::SquareMatrix(`R`)

Examples

Example 1

A lot of examples can be found on the help page of the domain constructor Dom::Matrix, and most of them are also examples for working with domains created by `Dom::SquareMatrix`.

These examples only concentrate on some differences with respect to working with matrices of the domain `Dom::Matrix(R)`.

The following command defines the ring of two-dimensional matrices over the rationals:
SqMatQ := Dom::SquareMatrix(2, Dom::Rational)Dom::SquareMatrix(2, Dom::Rational)

```
Dom::SquareMatrix(2, Dom::Rational)
```

SqMatQ::hasProp(Cat::Ring)TRUE

```
TRUE
```

The unit is defined by the entry `"one"`, which is the 2 2 identity matrix:
SqMatQ::oneDom::SquareMatrix(2, Dom::Rational)([[1, 0], [0, 1]])

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

Note that some operations defined by the domain `SqMatQ` return matrices which are no longer square. They return therefore matrices of the domain `Dom::Matrix(Dom::Rational)`, the super-domain of `SqMatQ`. For example, if we delete the first row of the matrix:
A := SqMatQ([[1, 2], [-5, 3]])Dom::SquareMatrix(2, Dom::Rational)([[1, 2], [-5, 3]])

$$\begin{pmatrix} 1 & 2 \\ -5 & 3 \end{pmatrix}$$

we get the matrix:
SqMatQ::delRow(A, 1)Dom::Matrix(Dom::Rational)([[-5, 3]])

$$\begin{pmatrix} -5 & 3 \end{pmatrix}$$

which is of the domain type:
domtype(%)Dom::Matrix(Dom::Rational)

$$\mathrm{Dom::Matrix(Dom::Rational)}$$

Example 2

We can convert a square matrix into or from another matrix domain, as shown next:
SqMatR := Dom::SquareMatrix(3, Dom::Real): MatC := Dom::Matrix(Dom::Complex):A := SqMatR((i, j) -> sin(i*j))Dom::SquareMatrix(3, Dom::Real)([[sin(1), sin(2), sin(3)], [sin(2), sin(4), sin(6)], [sin(3), sin(6), sin(9)]])

$$\begin{pmatrix} \sin(1) & \sin(2) & \sin(3) \\ \sin(2) & \sin(4) & \sin(6) \\ \sin(3) & \sin(6) & \sin(9) \end{pmatrix}$$

To convert `A` into a matrix of the domain `MatC`, enter:
coerce(A, MatC)Dom::Matrix(Dom::Complex)([[sin(1), sin(2), sin(3)], [sin(2), sin(4), sin(6)], [sin(3), sin(6), sin(9)]])

$$\begin{pmatrix} \sin(1) & \sin(2) & \sin(3) \\ \sin(2) & \sin(4) & \sin(6) \\ \sin(3) & \sin(6) & \sin(9) \end{pmatrix}$$

domtype(%)Dom::Matrix(Dom::Complex)

Dom::Matrix(Dom::Complex)

The conversion is done component-wise, as the following examples shows:
B := MatC([[0, 1], [exp(I), 0]])Dom::Matrix(Dom::Complex)([[0, 1], [exp(I), 0]])

$$\begin{pmatrix} 0 & 1 \\ e^{i} & 0 \end{pmatrix}$$

The matrix B is square but has one complex component and therefore cannot be converted into the domain `SqMatR`:
coerce(B, SqMatR)FAIL

FAIL

Parameters

n

A positive integer

R

A ring, i.e., a domain of category Cat::Rng; default is `Dom::ExpressionField()`

Array

An n n array

Matrix

An n n matrix, i.e., an element of a domain of category Cat::Matrix

List

A list of matrix components

ListOfRows

A list of at most `n` rows; each row is a list of at most `n` matrix components

f

A function or a functional expression with two parameters (the row and column index)

g

A function or a functional expression with one parameter (the row index)

Options

Diagonal

Create a diagonal matrix

With the option `Diagonal`, diagonal matrices can be created with diagonal elements taken from a list, or computed by a function.

`Dom::SquareMatrix(n, R)( n , n List, Diagonal)` creates the n n diagonal matrix whose diagonal elements are the entries of `List`.

`List` must have at most `n` entries. If it has fewer elements, the remaining diagonal elements are set to zero.

The entries of `List` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::SquareMatrix(n, R)( n , n g, Diagonal)` returns the matrix whose ith diagonal element is `g(i)`, where the index i runs from 1 to `n`.

The function values are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

Banded

Create a banded Toeplitz matrix

`Dom::SquareMatrix(n, R)( n , n List, Banded)` creates an n n banded Toeplitz matrix with the elements of `List` as entries. The number of entries of `List` must be odd, say $2h + 1$, and must not exceed `n`. The resulting matrix has bandwidth at most $2h + 1$.

All elements of the main diagonal of the created matrix are initialized with the middle element of `List`. All elements of the ith subdiagonal are initialized with the $(h + 1 - i)$th element of `List`. All elements of the ith superdiagonal are initialized with the $(h + 1 + i)$th element of `List`. All entries on the remaining sub- and superdiagonals are set to zero.

The entries of `List` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

Entries

"one"	is the n n identity matrix. This entry exists if the component ring `R` is a domain of category Cat::Ring, i.e., a ring with unit.
"randomDimen"	is set to `[n, n]`.
"zero"	is the n n zero matrix.

Methods

Mathematical Methods

evalpEvaluating matrices of polynomials at a certain point

```
evalp(A, x = a,  )
```

This method is only defined if `R` is a polynomial ring of category Cat::Polynomial.

This method overloads the function `evalp` for matrices, i.e., one may use it in the form `evalp(A, x = a)`.
identityIdentity matrix

```
identity(k)
```

Note The matrix returned is of the domain `Dom::Matrix(R)` if _outputSequence(k, Symbol::ne, n)$k \neq n$.

This method only exists if the component ring `R` is of category Cat::Ring, i.e., a ring with unit.
matdimMatrix dimension

```
matdim(A)
```

randomRandom matrix generation

```
random()
```

The components of the random matrix are generated with the method `"random"` of the component ring `R`.

Access Methods

_concatHorizontal concatenation of matrices

```
_concat(A, B,  )
```

An error message is issued if the given matrices do not have the same number of rows.

Note The matrix returned is of the domain `Dom::Matrix(R)`!

This method overloads the function _concat for matrices, i.e., one may use it in the form `A . B . ...`, or in functional notation: `_concat(A, B, ...)`.

_indexMatrix indexing

```
_index(A, i, j)
```

```
_index(A, r1 ..  r2, c1 ..  c2)
```

If `i` and `j` are not integers, then the call of this method returns in its symbolic form (of type `"_index"`) with evaluated arguments.

Otherwise an error message is given, if `i` and `j` are not valid row and column indices, respectively.

Note Note that the system function context is used to evaluate the entry in the context of the calling environment.

Returns the submatrix of `A`, created by the rows of `A` with indices from `r1` to `r2` and the columns of `A` with indices from `c1` to `c2`.

Note The submatrix returned is of the domain `Dom::Matrix(R)`!

This method overloads the function _index for matrices, i.e., one may use it in the form `A[i, j]` and `A[r1..r2, c1..c2]`, respectively, or in functional notation: `_index(A, ...)`.

concatMatrixHorizontal concatenation of matrices

```
concatMatrix(A, B,  )
```

colExtracting a column

```
col(A, c)
```

An error message is issued if `c` is less than one or greater than `n`.

delColDeleting a column

```
delCol(A, c)
```

`NIL` is returned if `A` only consists of one column.

Note The matrix returned is of the domain `Dom::Matrix(R)`.

An error message is issued if `c` is less than one or greater than `n`.

delRowDeleting a row

```
delRow(A, r)
```

`NIL` is returned if `A` only consists of one row.

Note The matrix returned is of the domain `Dom::Matrix(R)`.

An error message is issued if `r` is less than one or greater than `n`.

rowExtracting a row

```
row(A, r)
```

An error message is issued if `r` is less than one or greater than `n`.

stackMatrixVertical concatenation of matrices

```
stackMatrix(A, B,  )
```

An error message is issued if the given matrices do not have the same number of columns.

Note The matrix returned is of the domain `Dom::Matrix(R)`!

Conversion Methods

createDefining matrices without component conversions

```
create(x,  )
```

This method should be used if the elements of the parameters `x`, ... are elements of the domain type `R`. This is often the case if a matrix is to be created whose components come from preceding matrix and scalar operations.

See Also Dom::MatrixDom::MatrixGroup

Dom::SymmetricGroup

Purpose

Symmetric groups

Syntax

```
Dom::SymmetricGroup(n)
Dom::SymmetricGroup(n)(l)
```

Description

`Dom::SymmetricGroup(n)` creates the symmetric group of order n, that is, the domain of all the permutations of $\{1, \ldots, n\}$ elements.

A permutation of n elements is a bijective mapping of the set $\{1, \ldots, n\}$ onto itself.

The domain element `Dom::SymmetricGroup(n)(l)` represents the bijective mapping of the first n positive integers that maps the integer i to `l[i]`, for $1 \le i \le n$.

Superdomain

Dom::BaseDomain

Axioms

Ax::canonicalRep

Categories

Cat::Group

Examples

Example 1

Consider the group of permutations of the first seven positive integers:
G := Dom::SymmetricGroup(7)Dom::SymmetricGroup(7)

```
Dom::SymmetricGroup(7)
```

We create an element of `G` by providing the image of 1, 2, etc.:
a:=G([2,4,6,1,3,5,7])[2, 4, 6, 1, 3, 5, 7]

```
[2, 4, 6, 1, 3, 5, 7]
```

a(3)6

6

Parameters

n

Positive integer

l

List or array consisting of the first n integers in some order.

Entries

"one"	the identical mapping of the set {1, …, n} to itself.

Methods

Mathematical Methods

_multProduct of permutations

```
_mult(a1,  )
```

This method overloads the function _mult.

_invertInverse of a permutation

```
_invert(a)
```

This method overloads the function _invert.

func_callFunction value of a permutation at a point

```
func_call(a, i)
```

It computes the function value of `a` at `i`, i.e., the integer that `i` is mapped to by the permutation `a`; `i` must be an integer between 1 and n.

cyclesCycle representation of a permutation

Dom::UnivariatePolynomial

Purpose

Domains of univariate polynomials

Syntax

Domain Creation

```
Dom::UnivariatePolynomial(<Var, <R, <Order>>>)
```

Element Creation

```
Dom::UnivariatePolynomial(Var, R, Order)(p)
Dom::UnivariatePolynomial(Var, R, Order)(lm)
```

Description

`Dom::UnivariatePolynomial(Var, R, ..)` creates the domain of univariate polynomials in the variable `Var` over the commutative ring `R`.

`Dom::UnivariatePolynomial` represents univariate polynomials over arbitrary commutative rings.

All usual algebraic and arithmetical polynomial operations are implemented, including Gröbner basis computations.

`Dom::UnivariatePolynomial(Var, R, Order)` creates a domain of univariate polynomials in the variable `Var` over a domain of category Cat::CommutativeRing in sparse representation with respect to the monomial ordering `Order`.

`Dom::UnivariatePolynomial()` creates the univariate polynomial domain in the variable `x` over the domain Dom::ExpressionField`(normal)` with respect to the lexicographic monomial ordering.

`Dom::UnivariatePolynomial(Var)` creates the univariate polynomial domain in the variable `Var` over the domain Dom::ExpressionField`(normal)` with respect to the lexicographic monomial ordering.

Note Only commutative coefficient rings of type DOM_DOMAIN which inherit from Dom::BaseDomain are allowed. If `R` is of type DOM_DOMAIN but inherits not from Dom::BaseDomain, the domain Dom::ExpressionField(`normal`) will be used instead.

For this domain only identifiers are valid variables.

Note It is highly recommend to use only coefficient rings with unique zero representation. Otherwise it may happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

Please note that for reasons of efficiency not all methods check their arguments, not even at the interactive level. In particular this is true for many access methods, converting methods and technical methods. Therefore, using these methods inappropriately may result in strange error messages.

Superdomain

Dom::MultivariatePolynomial

Axioms

If `R` has Ax::normalRep, then Ax::normalRep.

If `R` has Ax::canonicalRep, then Ax::canonicalRep.

Categories

Cat::UnivariatePolynomial(`R`)

Examples

Example 1

To create the ring of univariate polynomials in `x` over the integers one may define
UP:=Dom::UnivariatePolynomial(x,Dom::Integer)Dom::UnivariatePolynomial(x, Dom::Integer, LexOrder)

Dom::UnivariatePolynomial(x, Dom::Integer, LexOrder)

Now, let us create two univariate polynomials.
a:=UP((2*x-1)^2*(3*x+1))12*x^3 - 8*x^2 - x + 1

$$12\,x^3 - 8\,x^2 - x + 1$$

b:=UP(((2*x-1)*(3*x+1))^2)36*x^4 - 12*x^3 - 11*x^2 + 2*x + 1

$$36\,x^4 - 12\,x^3 - 11\,x^2 + 2\,x + 1$$

The usual arithmetical operations for polynomials are available:
a^2+a*b432*x^7 - 288*x^6 - 264*x^5 + 200*x^4 + 35*x^3 - 36*x^2 - x + 2

$$432\,x^7 - 288\,x^6 - 264\,x^5 + 200\,x^4 + 35\,x^3 - 36\,x^2 - x + 2$$

The leading coefficient, leading term, leading monomial and reductum of a are
lcoeff(a),lterm(a),lmonomial(a),UP::reductum(a)12, x^3, 12*x^3, - 8*x^2 - x + 1

$$12,\ x^3,\ 12\,x^3,\ -8\,x^2 - x + 1$$

and a is of degree
degree(a)3

3

The method gcd computes the greatest common divisor of two polynomials
gcd(a,b)12*x^3 - 8*x^2 - x + 1

$$12 x^3 - 8 x^2 - x + 1$$

and `lcm` the least common multiple:
lcm(a,b)36*x^4 - 12*x^3 - 11*x^2 + 2*x + 1

$$36 x^4 - 12 x^3 - 11 x^2 + 2 x + 1$$

Computing the definite and indefinite integral of a polynomial is also possible,
int(a)3*x^4 - (8*x^3)/3 - x^2/2 + x

$$3 x^4 - \frac{8 x^3}{3} - \frac{x^2}{2} + x$$

which is in the case of indefinite integration simply the antiderivative of the polynomial.
D(int(a)), domtype(D(int(a)))12*x^3 - 8*x^2 - x + 1, Dom::UnivariatePolynomial(x, Dom::Fraction(Dom::Integer), LexOrder)

$$12 x^3 - 8 x^2 - x + 1,\ \mathrm{Dom::UnivariatePolynomial}(x,\ \mathrm{Dom::Fraction}(\mathrm{Do}$$

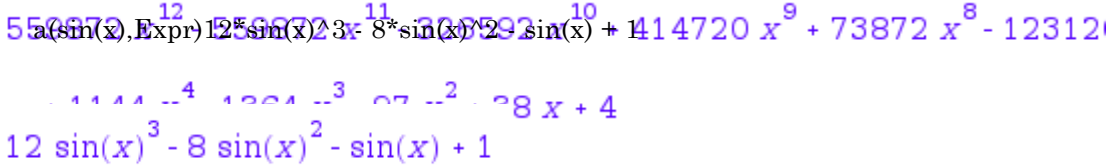
But, since for representing the indefinite integral of `a` the coefficient ring chosen as the integers is not appropriate, the polynomial ring over its quotient field is used instead.

Furthermore, interpreting the polynomials as polynomial functions is also allowed in applying coefficient ring elements, polynomials of this domain or arbitrary expressions with option `Expr` to them:
a(5)1296

$$1296$$

a(b)559872*x^12 - 559872*x^11 - 326592*x^10 + 414720*x^9 + 73872*x^8 - 123120*x^7 - 9924*x^6 + 18408*x^5 + 1144*x^4 - 1364*x^3 - 97*x^2 + 38*x + 4

a(sin(x),Expr)12*sin(x)^3 - 8*sin(x)^2 - sin(x) + 1



To get a vector of coefficients of a polynomial, which gives the dense representation of it, one may use the method `vectorize`.
UP::vectorize(a), UP::vectorize(a,6)[1, -1, -8, 12], [1, -1, -8, 12, 0, 0]

Parameters

Var

An indeterminate given by an identifier; default is `x`.

R

A commutative ring, i.e. a domain of category Cat::CommutativeRing; default is `Dom::ExpressionField(normal)`.

Order

A monomial ordering, i.e. one of the predefined orderings `LexOrder`, `DegreeOrder` or `DegInvLexOrder` or an element of domain Dom::MonomOrdering; default is `LexOrder`.

P

A polynomial or a polynomial expression.

lm

List of monomials, which are represented as lists containing the coefficients together with the exponents or exponent vectors.

Entries

"characteristic"	The characteristic of this domain.
"coeffRing"	The coefficient ring of this domain as defined by the parameter `R`.
"key"	The name of the domain created.
"one"	The neutral element w.r.t. `"_mult"`.
"ordering"	The monomial order as defined by the parameter `Order`.
"variables"	The list of the variable as defined by the parameter `Var`.
"zero"	The neutral element w.r.t. `"_plus"`.

Methods

Access Methods

coeffCoefficient of a polynomial

```
coeff(a)
```

```
coeff(a, Var, n)
```

```
coeff(a, n)
```

`coeff(a, Var, n)` returns the coefficient of the term `Var^n` as an element of `R`.

`coeff(a, n)` returns the coefficient of the term `Var^n` as an element of `R`.

This method overloads the function coeff for polynomials.

Factored

Purpose

Objects kept in factored form

Syntax

```
Factored(list, <type>, <ring>)
Factored(f, <type>, <ring>)
```

Description

`Factored` is the domain of objects kept in factored form, such as prime factorization of integers, square-free factorization of polynomials, or the factorization of polynomials in irreducible factors.

The argument `list` must be a list of odd length and of the form `[u, f1, e1, f2, e2, ..., fr, er]`, where the entries u and f_i are elements of the domain `ring`, or can be converted into such elements. The e_i must be integers. Here, i ranges from 1 to r.

See section "Operands" below for the meaning of the entries of that list.

An error message is reported, if one of the list entries is of wrong type.

An arithmetical expression `f` given as the first argument is the same as giving the list `[ring::one, f, 1]`.

See section "Operands" below for the meaning of the entries of that list.

`f` must be an element of the domain `ring`, or must be convertible into such an element, otherwise an error message would be given.

The argument `type` indicates what is known about the factorization. Currently, the following types are known:

- `"unknown"` – nothing is known about the factorization.
- `"irreducible"` – the f_i are irreducible over the domain `ring`.
- `"squarefree"` – the f_i are square-free over the domain `ring`.

If this argument is missing, then the type of the created factored object is set to `"unknown"`.

The type of factorization is known to any element of `Factored`. Use the methods `"getType"` and `"setType"` (see below) to read and set the type of factorization of a given factored object.

The argument `ring` is the ring of factorization. It must be an integral domain, i.e., a domain of category Cat::IntegralDomain.

If this argument is missing, then the domain `Dom::ExpressionField()` is used.

The ring of factorization is known to any element of `Factored`. Use the methods `"getRing"` and `"setRing"` (see below) to read and set the ring of factorization of a given factored object.

You can use the index operator [ ] to extract the factors of an element `f` of the domain `Factored`. E.g., for $f = uf_1^{e_1}f_2^{e_2}\ldots$, you have $f[1] = u$, $f[2] = f_1^{e_1}$, $f[3] = f_2^{e_2}$ etc.

You can also use the methods `"factors"` and `"exponents"` (see below) to access the operands, i.e., the call `Factored::factors(f)` returns a list of the factors f_i, and `Factored::exponents(g)` returns a list of the exponents e_i ($1 \le i \le r$).

The system functions ifactor, factor and polylib::sqrfree are the main application of this domain, they return their result in form of such factored objects (see their help pages for information about the type and ring of factorization).

There may be no need to explicitly create factored objects, but to work with the results of the mentioned system functions.

Note that an element of `Factored` is printed like an expression and behaves like that. As an example, the result of `f := factor(x^2 + 2*x + 1)` is an element of `Factored` and printed as `(x + 1)^2`. The call `type(f)` returns `"_power"` as the expression type of `f`.

For an element `f` of `Factored`, the call `Factored::convert(f, DOM_LIST)` gives a list of all operands of `f`.

Examples

Example 1

The following computes the prime factorization of the integer 20:

f := ifactor(20)2^2*5

$2^2\ 5$

The result is an element of the domain `Factored`:
domtype(f)Factored

Factored

which consists of the following five operands:
op(f)1, 2, 2, 5, 1

1, 2, 2, 5, 1

They represent the integer 20 in the following form: $20 = 12^25$. The factors are prime numbers and can be extracted via `Factor::factors`:
Factored::factors(f)[2, 5]

[2, 5]

ifactor kept the information that the factorization ring is the ring of integers (represented by the domain Dom::Integer), and that the factors of `f` are prime (and therefore irreducible, because is an integral domain):
Factored::getRing(f), Factored::getType(f)Dom::Integer, "irreducible"

Dom::Integer, "irreducible"

We can convert such an object into different forms, such as into a list of its operands:
Factored::convert_to(f, DOM_LIST)[1, 2, 2, 5, 1]

$$[1, 2, 2, 5, 1]$$

or into an unevaluated expression, keeping the factored form:
Factored::convert_to(f, DOM_EXPR)2^2*5

$$2^2\,5$$

or back into an integer:
Factored::convert_to(f, Dom::Integer)20

$$20$$

You may also use the system function coerce here, which has the same effect.

Example 2

We compute the factorization of the integers 108 and 512:
n1 := ifactor(108); n2 := ifactor(512)2^2*3^3

$$2^2\,3^3$$

2^9

$$2^9$$

The multiplication of these two integers gives the prime factorization of 55296 = 108512:
n1*n22^11*3^3

$$2^{11}\,3^3$$

Note that the most operations on such objects lead to an un-factored form, such as adding these two integers:
n1 + n2620

620

You may apply the function ifactor to the result, if you are interested in its prime factorization:
ifactor(%)2^2*5*31

2^2 5 31

You an apply (almost) each function to factored objects, functions that mainly expect arithmetical expressions as their input. Note that, before the operation is applied, the factored object is converted into an arithmetical expression in un-factored form:
Re(n1)108

108

Example 3

The second system function which deals with elements of `Factored`, is factor, which computes all irreducible factors of a polynomial.

For example, if we define the following polynomial of $_{101}$:
p := poly(x^12 + x + 1, [x], Dom::IntegerMod(101)):

and compute its factorization into irreducible factors, we get:
f := factor(p)poly(x^2 + 73*x + 29, [x], Dom::IntegerMod(101))*poly(x^5 + 62*x^4 + 64*x^3 + 63*x^2 + 58*x + 100, [x], Dom::IntegerMod(101))*poly(x^5 + 67*x^4 + 72*x^3 + 100*x^2 + 33*x + 94, [x], Dom::IntegerMod(101))

If we multiply the factored object with an element that can be converted into an element of the ring of factorization, then we get a new factored object, which then is of the factorization type "unknown":

```
x*fpoly(x^2 + 73*x + 29, [x], Dom::IntegerMod(101))*poly(x^5 + 62*x^4
+ 64*x^3 + 63*x^2 + 58*x + 100, [x], Dom::IntegerMod(101))*poly(x^5 +
67*x^4 + 72*x^3 + 100*x^2 + 33*x + 94, [x], Dom::IntegerMod(101))*x
```

```
Factored::getType(%)"unknown"
```

$$\text{poly}(x^2 + 73\,x + 29, [x], \text{Dom::IntegerMod}(101))$$

$$\text{"unknown"} \quad 62\,x^4 + 64\,x^3 + 63\,x^2 + 58\,x + 100, [x], \text{Dom::IntegerMod}$$

You may use the function expand which returns the factored object in expanded form as an element of the factorization ring:

```
expand(f)poly(x^12 + x + 1, [x], Dom::IntegerMod(101))
```

$$\text{poly}(x^{12} + x + 1, [x], \text{Dom::IntegerMod}(101))$$

Example 4

The third system function which return elements of `Factored` is polylib::sqrfree, which computes the square-free factorization of polynomials. For example:
f := polylib::sqrfree(x^2 + 2*x + 1)(x + 1)^2

$$(x + 1)^2$$

The factorization type, of course, is `"squarefree"`:
Factored::getType(f)"squarefree"

```
"squarefree"
```

Parameters

list

A list of odd length

f

An arithmetical expression

type

A string (default: `"unknown"`)

ring

A domain of category Cat::IntegralDomain (default: `Dom::ExpressionField()`)

Function Calls

Calling a factored object as a function yields the object itself, regardless of the arguments. The arguments are *not* evaluated.

Operations

You can apply (almost) every function to factored objects, functions that mainly expect arithmetical expressions as their input.

For example, one may add or multiply those objects, or apply functions such as expand and diff to them. But the result of such an operation then is usually not any longer of the domain `Factored`, as the factored form could be lost due to the operation (see examples below).

Call `expr(f)` to convert the factored object `f` into an arithmetical expression (as an element of a kernel domain).

The call `coerce(f, DOM_LIST)` returns a list of operands of the factored object `f` (see method `"convert_to"` below).

Operands

An element f of `Factored` consists of the $r + 1$ operands u, f_1, e_1, f_2, e_2, …, f_r, e_r, such that $f = u f_1^{e_1} f_2^{e_2} \ldots f_r^{e_r}$.

The first operand u and the factors f_i are elements of the domain `ring`. The exponents e_i are integers.

Methods

Mathematical Methods

_multMultiply factored objects

```
_mult(f, g,  )
```

Suppose that `g` is an element of the domain `ring` (or can be converted into such an element).

If `g` is a unit of `ring` or a factor of `f`, then the result is a factored object of the same factorization type as `f`. Otherwise, the result is an element of `Factored` with the factorization type `"unknown"`.

If both `f` and `g` are factored objects with factorization type `"irreducible"`, then the result is again a factored object of this type, i.e., the result is still in factored form.

Otherwise, the factored form of `f` is lost, and the result of this method is an element of `ring`.

This method overloads the function _mult for factored objects, i.e., one may use it in the form `f*g*...`, or in functional notation: `_mult(f, g, ...)`.

_powerRaise a factored object to a certain power

```
_power(f, n)
```

If `n` is a positive integer and `f` a factored object with factorization type `"irreducible"` or `"squarefree"`, then the result is still a factored object of this type.

Otherwise, the factored form of `f` is lost, and the result of this method is an element of `ring`.

This method overloads the function _power for factored objects, i.e., one may use it in the form `f^n`, or in functional notation: `_power(f, n)`.
expandExpand a factored object

```
expand(f)
```

exponentsGet the exponents of a factored object

```
exponents(f)
```

factorFactor a factored object

```
factor(f)
```

If `f` already is of the factorization type `"irreducible"`, then this method just return `f`.

Otherwise, this method converts `f` into an element of the domain `ring` and calls the method `"factor"` of `ring`.

This method returns a factored object of the domain `Factored` with factorization type `"irreducible"`, if the factorization of `f` can be computed (otherwise, `FAIL` is returned).

This method overloads the function factor for factored objects, i.e., one may use it in the form `factor(f)`.
factorsGet the factors of a factored object

```
factors(f)
```

irreducibleTest if a factored object is irreducible

```
irreducible(f)
```

The test on irreducible is trivial, if `f` has the factorization type `"irreducible"`.

Otherwise, this method converts `f` into an element of `ring` and calls the method `"irreducible"` of `ring`. The value `FAIL` is returned, if the domain `ring` cannot test if `f` is irreducible.

iszeroTest on zero for factored objects

```
iszero(f)
```

This method overloads the function iszero for factored objects, i.e., one may use it in the form `iszero(f)`.
sqrfreeCompute a square-free factorization of a factored object

```
sqrfree(f)
```

If `f` already is of the factorization type `"squarefree"`, then this method just return `f`.

Otherwise, this method converts `f` into an element of the domain `ring` and calls the method `"squarefree"` of `ring`.

This method returns a factored object of the domain `Factored` with factorization type `"squarefree"`, if the square-free factorization of `f` can be computed (otherwise, `FAIL` is returned).

This method overloads the function polylib::sqrfree for factored objects, i.e., one may use it in the form `polylib::sqrfree(f)`.

Access Methods

_indexExtract a term of a factored object

```
_index(f, i)
```

Responds with an error message, if `i` is greater than the number of terms of `f`.

This method overloads the index operator [ ] for factored objects, i.e., one may use it in the form `f[i]`.

getRingGet the ring of factorization

```
getRing(f)
```

getTypeGet the type of factorization

```
getType(f)
```

hasExistence of an object in a factored object

```
has(f, x,  )
```

This method overloads the function has for factored objects, i.e., one may use it in the form `has(f, x, ...)`.

mapMap a function to the operands of factored objects

```
map(f, func,  )
```

See the system function map for details.

This method overloads the function map for factored objects, i.e., one may use it in the form `map(f, func, ...)`.

nopsNumber of operands of a factored object

```
nops(f)
```

This method overloads the function nops for factored objects, i.e., one may use it in the form `nops(f)`.

opExtract an operand of a factored object

```
op(f, i)
```

Returns `FAIL`, if `i` is greater than the number of operands of `f`.

This method overloads the function op for factored objects, i.e., one may use it in the form `op(f, i)`.

selectSelect operands of a factored object

```
select(f, func,  )
```

This method overloads the function select for factored objects, i.e., one may use it in the form `select(f, func, ...)`.

set_indexSet/change a term of a factored object

```
set_index(f, i, x)
```

Responds with an error message, if `i` is greater than the number of terms of `f`.

Note Make sure that `x` either is an element of the domain `ring`, or an integer.

This method overloads the index operator [ ] for factored objects, i.e., one may use it in the form `f[i] := x`.

setRingSet the ring of factorization

```
setRing(f, ring)
```

Note Use this method with caution! Make sure that the factorization of `f` is still valid over the new ring, and that the operands of `f` have the correct domain type.

`ring` must be a domain of category Cat::IntegralDomain, which is not checked by this method.

setTypeSet the type of factorization

```
setType(f, type)
```

Note Use this method with caution! Make sure that the factorization type corresponds with the factorization of `f`.

subsSubstitute subexpressions in the operands of a factored object

```
subs(f, x = a,  )
```

This method overloads the function subs for factored objects, i.e., one may use it in the form `subs(f, x = a, ...)`.

subsopSubstitute operands of a factored object

```
subsop(f, i = a,  )
```

This method overloads the function subsop for factored objects, i.e., one may use it in the form `subsop(f, i = a, ...)`.

typeExpression type of factored objects

```
type(f)
```

Conversion Methods

convertConvert an object into a factored object

```
convert(x)
```

If the conversion fails, then `FAIL` is returned.

`x` may either be a list of the form `[u, f1, e1, ..., fr, er]` of odd length (where `u, f1, ..., fr` are of the domain type `ring`, or can be converted into such elements, and `e1, ..., er` are integers), or an element that can be converted into the domain `ring`. The latter case corresponds to the list `[ring::one,x,1]`.

convert_toConvert factored objects into other domains

```
convert_to(f, T)
```

If the conversion fails, then `FAIL` is returned.

If `T` is the domain DOM_LIST, then the list of operands of `f` is returned.

If `T` is the domain DOM_EXPR, then the unevaluated expression `u*f1^e1*f2^e2*...*fr^er` is returned, where `u, f1, e1, ...` are the operands of `f`.

Otherwise, the method `"convert"` of the domain `T` is called to convert `f` into an element of the domain `T` (which could return `FAIL`).

Use the function expr to convert `f` into an object of a kernel domain (see below).

createCreate simple and fast a factored objects

```
create(list)
```

```
create(x)
```

This method creates a new factored object with the operands `ring::one, x, 1`.

exprConvert a factored object into a kernel domain

```
expr(f)
```

Note Note that the factored form of `f` may be lost due to this conversion.

---

expr2textConvert a factored object into a string

```
expr2text(f)
```

testtypeType testing for factored objects

```
testtype(f, T)
```

This method is called from the system function testtype.

TeXLaTeX formatting of a factored object

```
TeX(f)
```

The method `"TeX"` of the domain `ring` is used to get the LaTeX-representation of the corresponding operands of `f`.

This method is called from the system function generate::TeX.

Technical Methods

_concatConcatenate operands of factored objects

```
_concat(f, g)
```

`f` and `g` must have the same factorization type and factorization ring, otherwise an error message is given.

maprecAllow recursive mapping for factored objects

```
maprec(f, x,  )
```

First `f` is converted into the unevaluated expression `u*f1^e1*f2^e2*...*fr^er`, where `u, f1, e1, ...` are the operands of `f`. Then the function `misc::maprec` is called with this expression as its first parameter.

Note that the result of this method is not longer an object of `Factored`!

printPretty-print routine for factored objects

```
print(f)
```

unapplyCreate a procedure from a factored object

```
unapply(f, <x>)
```

This method overloads the function `fp::unapply` for factored objects, i.e., one may use it in the form `fp::unapply(f)`. See fp::unapply for details.

Series::Puiseux

Purpose

Truncated Puiseux series expansions

Syntax

```
Series::Puiseux(f, x, <order>, <dir>)
Series::Puiseux(f, x = x0, <order>, <dir>)
```

Description

`Series::Puiseux` is a domain for truncated series expansions. Elements of this domain represent initial segments of Taylor, Laurent, or Puiseux series expansions, as well as slightly more general types of series expansions.

The system function series is the main application of this domain. It tries to compute a Taylor, Laurent, or Puiseux series or a more general series expansion of a given arithmetical expression, and the result is returned as an element of `Series::Puiseux` or, possibly, of the more general domain Series::gseries.

There is usually no need for you to explicitly create elements of this domain. The methods described on this help page apply if you want to process a result returned by series further.

Note If you create elements explicitly as described above, then any special mathematical function, such as sin or exp, involving the series variable is considered as a coefficient. Use series to expand such functions as well, and use the constructor only if `f` does not contain any special mathematical functions. Cf. “Example 1” on page 6-383.

Use the type specifier Type::Series to determine for an element of this domain, which kind of series expansion it is.

Note The coefficients are allowed to depend sublinearly on the variable of the series expansion. For example, logarithmic terms in the series variable may appear as coefficients. Be aware that this is no Puiseux series in the mathematical sense. Cf. “Example 4” on page 6-392 and the help page for series.

Environment Interactions

The function is sensitive to the global variable ORDER, which determines the default number of terms of the expansion.

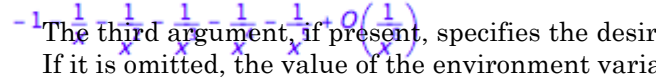
Examples

Example 1

You can create objects of `Series::Puiseux` in various ways. The standard method is to use the constructor. The second argument specifies the series variable and the expansion point, with default 0 if omitted:
Series::Puiseux(x/(1 - x), x); Series::Puiseux(x/(1 - x), x = 2); Series::Puiseux(x/(1 - x), x = complexInfinity);x + x^2 + x^3 + x^4 + x^5 + x^6 + O(x^7)

- 2 + x - 2 - (x - 2)^2 + (x - 2)^3 - (x - 2)^4 + (x - 2)^5 + O((x - 2)^6)

- 1 - 1/x - 1/x^2 - 1/x^3 - 1/x^4 - 1/x^5 + O(1/x^6)



The third argument, if present, specifies the desired number of terms. If it is omitted, the value of the environment variable ORDER is used:
Series::Puiseux(x/(1 - x), x = 2, 4); ORDER := 2: Series::Puiseux(x/(1 - x), x); delete ORDER:- 2 + x - 2 - (x - 2)^2 + (x - 2)^3 + O((x - 2)^4)

$-2 + x - 2 - (x-2)^2 + (x-2)^3 + O((x-2)^4)$

x + x^2 + O(x^3)

$x + x^2 + O(x^3)$

The methods `const`, `one`, and `zero` provide shortcuts for creating series expansions with only a constant term or no non-zero term at all. Specifying the order of the error term is mandatory:
Series::Puiseux::const(PI, x, 4); Series::Puiseux::one(x = 2, 3); Series::Puiseux::zero(x = 0, 3/2); Series::Puiseux::zero(x = complexInfinity, 5);PI + O(x^4)

$\pi + O(x^4)$

1 + O((x - 2)^3)

$1 + O((x-2)^3)$

O(x^(3/2))

$O\left(x^{3/2}\right)$

O(1/x^5)

$O\left(\frac{1}{x^5}\right)$

Note that, e.g., `O(x^(3/2))` is not an element of `Series::Puiseux`, but can be converted by the constructor:
f := O(x^(3/2)); g := Series::Puiseux(f, x); domtype(f), domtype(g)O(x^(3/2))

$O\left(x^{3/2}\right)$

O(x^(3/2))

$O\left(x^{3/2}\right)$
O, ‘Series::Puiseux‘

O, Series::Puiseux
Both the constructor `Series::Puiseux` and the method `const` regard special mathematical functions, such as `exp` or `sin`, as coefficients:
Series::Puiseux(sin(x)/(1 - x), x, 4); Series::Puiseux::const(cos(x), x = 1, 3);sin(x) + x*sin(x) + x^2*sin(x) + x^3*sin(x) + O(x^4)

$\sin(x) + x\sin(x) + x^2\sin(x) + x^3\sin(x) + O\left(x^4\right)$
cos(x) + O((x - 1)^3)

$\cos(x) + O\left((x-1)^3\right)$
Use the system function series if you want to have special functions expanded as well:
series(sin(x)/(1 - x), x, 4);x + x^2 + (5*x^3)/6 + (5*x^4)/6 + O(x^5)

$x + x^2 + \frac{5\,x^3}{6} + \frac{5\,x^4}{6} + O\left(x^5\right)$
The constructor returns `FAIL`, if it cannot convert the input into an element of `Series::Puiseux`. Then series may be able to produce a more general expansion:
delete a: Series::Puiseux(x^a/(1 - x), x); f := series(x^a/(1 - x), x); domtype(f);FAIL

FAIL
x^a + x*x^a + x^2*x^a + x^3*x^a + x^4*x^a + x^5*x^a + O(x^6*x^a)

$$x^a + x\,x^a + x^2\,x^a + x^3\,x^a + x^4\,x^a + x^5\,x^a + O\left(x^6\,x^a\right)$$

'Series::gseries'

Series::gseries

The method `create` is a purely syntactical constructor, where the operands are specified explicitly. The sixth and seventh arguments are optional and default to 0 and `Undirected`, respectively:
Series::Puiseux::create(3, 1, 5, [1/2, 5], x) = Series::Puiseux::create(3, 1, 5, [1/2, 5], x, 0, Undirected)x^(1/3)/2 + 5*x^(2/3) + O(x^(5/3)) = x^(1/3)/2 + 5*x^(2/3) + O(x^(5/3))

$$\frac{x^{1/3}}{2} + 5\,x^{2/3} + O\left(x^{5/3}\right) = \frac{x^{1/3}}{2} + 5\,x^{2/3} + O\left(x^{5/3}\right)$$

Series::Puiseux::create(1, -2, 1, [ln(x), 0, 3], x, complexInfinity);x^2*ln(x) + 3 + O(1/x)

$$x^2 \ln(x) + 3 + O\left(\frac{1}{x}\right)$$

Example 2

We demonstrate the internal structure of objects of type `Series::Puiseux`:
f := series(exp(x), x = 1); g := series(sin(sqrt(1/x)), x = infinity); h := series(sin(sqrt(-x))/x, x = 0)exp(1) + exp(1)*(x - 1) + (exp(1)*(x - 1)^2)/2 + (exp(1)*(x - 1)^3)/6 + (exp(1)*(x - 1)^4)/24 + (exp(1)*(x - 1)^5)/120 + O((x - 1)^6)

$$e + e\,(x-1) + \frac{e\,(x-1)^2}{2} + \frac{e\,(x-1)^3}{6} + \frac{e\,(x-1)^4}{24} + \frac{e\,(x-1)^5}{120} + O\left((x-1)^6\right)$$

1/sqrt(x) - 1/(6*x^(3/2)) + 1/(120*x^(5/2)) + O(1/x^(7/2))

$$\frac{1}{\sqrt{x}} - 1/\mathrm{sqrt}(-x) + \mathrm{sqrt}(-x)/6 - (-x)^{(3/2)}/120 + O(x^{(5/2)})$$

op(f); op(g); op(h)0, 1, 0, 6, [exp(1), exp(1), exp(1)/2, exp(1)/6, exp(1)/24, exp(1)/120], x = 1, Undirected

0, 1, 0, 6, [1, 0, 1/6, 0, 1/120], x = complexInfinity, Left

1, 2, -1, 5, [-1/sqrt(-x), 0, sqrt(-x)/6, 0, -(-x)^(3/2)/120], x = 0, Undirected

The series `f` and `g` are of type 0, while `h` is of type 1:
op(f, 1), op(g, 1), op(h, 1)0, 0, 1

0, 0, 1

The branching order of `f` is 1, and the branching order of both `g` and `h` is 2:
op(f, 2), op(g, 2), op(h, 2)1, 2, 2

1, 2, 2

The third and the fourth operand determine the order of the leading term and the error term, respectively:

ldegree(f) = op(f, 3)/op(f, 2), ldegree(g) = op(g, 3)/op(g, 2), ldegree(h) = op(h, 3)/op(h, 2); Series::Puiseux::order(f) = op(f, 4)/op(f, 2), Series::Puiseux::order(g) = op(g, 4)/op(g, 2), Series::Puiseux::order(h) = op(h, 4)/op(h, 2);0 = 0, 1/2 = 1/2, -1/2 = -1/2

$$0 = 0, \frac{1}{2} = \frac{1}{2}, -\frac{1}{2} = -\frac{1}{2}$$

6 = 6, 7/2 = 7/2, 5/2 = 5/2

$$6 = 6, \frac{7}{2} = \frac{7}{2}, \frac{5}{2} = \frac{5}{2}$$

For series expansions of type 0, the fifth operand contains the coefficients of the expansion:
op(f, 5) = [coeff(f)]; op(g, 5) = [coeff(g)];[exp(1), exp(1), exp(1)/2, exp(1)/6, exp(1)/24, exp(1)/120] = [exp(1), exp(1), exp(1)/2, exp(1)/6, exp(1)/24, exp(1)/120]

$$\left[e, \frac{e}{2}, \frac{e}{6}, \frac{e}{24}, \frac{e}{120}\right] = \left[e, \frac{e}{2}, \frac{e}{6}, \frac{e}{24}, \frac{e}{120}\right]$$

[1, 0, -1/6, 0, 1/120] = [1, 0, -1/6, 0, 1/120]

$$\left[1, 0, -\frac{1}{6}, 0, \frac{1}{120}\right] = \left[1, 0, -\frac{1}{6}, 0, \frac{1}{120}\right]$$

However, h is an expansion of type 1, and then the fifth operand stores the summands:
op(h, 5); [coeff(h)];[-1/sqrt(-x), 0, sqrt(-x)/6, 0, -(-x)^(3/2)/120]

$$\left[-\frac{1}{\sqrt{-x}}, 0, \frac{\sqrt{-x}}{6}, 0, -\frac{(-x)^{3/2}}{120}\right]$$

[-sqrt(x)/sqrt(-x), 0, sqrt(-x)/(6*sqrt(x)), 0, -(-x)^(3/2)/(120*x^(3/2))]

$$\left[-\frac{\sqrt{x}}{\sqrt{-x}},\ 0,\ \frac{\sqrt{-x}}{6\,\sqrt{x}},\ 0,\ -\frac{(-x)^{3/2}}{120\,x^{3/2}}\right]$$

The sixth operand contains the series variable and the expansion point: op(f, 6), Series::Puiseux::indet(f), Series::Puiseux::point(f); op(g, 6), Series::Puiseux::indet(g), Series::Puiseux::point(g); op(h, 6), Series::Puiseux::indet(h), Series::Puiseux::point(h);x = 1, x, 1

$x = 1, x, 1$

x = complexInfinity, x, complexInfinity

$x = \text{complexInfinity}, x, \text{complexInfinity}$

x = 0, x, 0

$x = 0, x, 0$

The expansions `f` and `h` are undirected, while `g` is a directed expansion from the left along the real line to the positive infinity: op(f, 7) = Series::Puiseux::direction(f), op(g, 7) = Series::Puiseux::direction(g), op(h, 7) = Series::Puiseux::direction(h);Undirected = Undirected, Left = Left, Undirected = Undirected

Undirected = Undirected, Left = Left, Undirected = Undirected

Note Since the internal structure may be subject to changes, accessing the operands of and element of `Series::Puiseux` via op should be avoided. Use the corresponding access methods instead.

Example 3

Around branch points, the series expansions of type 1 can approximate a function in a wider range than those of type 0:
f := x -> arcsin(x + 1): g := series(f(x), x, 2); h := series(f(x), x, 2, Right);PI/2 - sqrt(2)*sqrt(-x) - (sqrt(2)*(-x)^(3/2))/12 + O(x^(5/2))

$$\frac{\pi}{2} - \sqrt{2}\sqrt{-x} - \frac{\sqrt{2}(-x)^{3/2}}{12} + O\left(x^{5/2}\right)$$

PI/2 - sqrt(2)*sqrt(x)*I + (sqrt(2)*x^(3/2)*I)/12 + O(x^(5/2))

$$\frac{\pi}{2} - \sqrt{2}\sqrt{x}\,i + \frac{\sqrt{2}\,x^{3/2}\,i}{12} + O\left(x^{5/2}\right)$$

The expansion g, of type 1, approximates f well in an open disc centered at the origin. However, the expansion h, of type 0, was requested for positive real values of x only, and in fact it does not approximate f on the negative real axis and in the upper half plane:
op(g); op(h);1, 2, 0, 5, [PI/2, -sqrt(2)*sqrt(-x), 0, -(sqrt(2)*(-x)^(3/2))/12], x = 0, Undirected

$$1, 2, 0, 5, \left[\frac{\pi}{2}, -\sqrt{2}\sqrt{-x}, 0, \frac{\sqrt{2}(-x)^{3/2}}{12}\right], x = 0, \text{Undirected}$$

0, 2, 0, 5, [PI/2, -sqrt(2)*I, 0, (sqrt(2)*I)/12], x = 0, Right

$$0, 2, 0, 5, \left[\frac{\pi}{2}, -\sqrt{2}\,i, 0, \frac{\sqrt{2}\,i}{12}\right], x = 0, \text{Right}$$

DIGITS:= 4: [f(0.01), f(0.01*I), f(-0.01), f(-0.01*I)]; map([g(0.01), g(0.01*I), g(-0.01), g(-0.01*I)], float); map([h(0.01), h(0.01*I), h(-0.01), h(-0.01*I)], float); delete DIGITS:[1.571 + (- 0.1413*I), 1.471 + 0.1001*I, 1.429, 1.471 + (- 0.1001*I)]

$$[1.571 - 0.1413\,i,\ 1.471 + 0.1001\,i,\ 1.429,\ 1.471 - 0.1001\,i]$$

[1.571 + (- 0.1413*I), 1.471 + 0.1001*I, 1.429, 1.471 + (- 0.1001*I)]

[1.571 – 0.1413 i, 1.471 + 0.1001 i, 1.429, 1.471 – 0.1001 i]

[1.571 + (- 0.1413*I), 1.671 + (- 0.1001*I), 1.712, 1.471 + (- 0.1001*I)]

[1.571 – 0.1413 i, 1.671 – 0.1001 i, 1.712, 1.471 – 0.1001 i]

The method `convert01` converts a series expansion of type 0 into one of type 1:
h1 := Series::Puiseux::convert01(h); op(h1);PI/2 - sqrt(2)*sqrt(x)*I + (sqrt(2)*x^(3/2)*I)/12 + O(x^(5/2))

$\frac{\pi}{2} - \sqrt{2}\sqrt{x}\,i + \frac{\sqrt{2}\,x^{3/2}\,i}{12} + O\left(x^{5/2}\right)$

1, 2, 0, 5, [PI/2, -sqrt(2)*sqrt(x)*I, 0, (sqrt(2)*x^(3/2)*I)/12], x = 0, Right

$1, 2, 0, 5, \left[\frac{\pi}{2}, -\sqrt{2}\sqrt{x}\,i, 0, \frac{\sqrt{2}\,x^{3/2}\,i}{12}\right], x = 0, \text{Right}$

The reverse conversion, using the method `convert10`, is in not always possible:
op(Series::Puiseux::convert10(h1)); op(Series::Puiseux::convert10(g));0, 2, 0, 5, [PI/2, -sqrt(2)*I, 0, (sqrt(2)*I)/12], x = 0, Right

$0, 2, 0, 5, \left[\frac{\pi}{2}, -\sqrt{2}\,i, 0, \frac{\sqrt{2}\,i}{12}\right], x = 0, \text{Right}$

1, 2, 0, 5, [PI/2, -sqrt(2)*sqrt(-x), 0, -(sqrt(2)*(-x)^(3/2))/12], x = 0, Undirected

$1, 2, 0, 5, \left[\frac{\pi}{2}, -\sqrt{2}\sqrt{-x}, 0, -\frac{\sqrt{2}\,(-x)^{3/2}}{12}\right], x = 0, \text{Undirected}$

You can enforce a conversion by using properties:
assume(x > 0): op(Series::Puiseux::convert10(g)); unassume(x):0, 2, 0, 5, [PI/2, -sqrt(2)*I, 0, (sqrt(2)*I)/12], x = 0, Undirected

$$0,\ 2,\ 0,\ 5,\ \left[\frac{\pi}{2},\ -\sqrt{2}\ i,\ 0,\ \frac{\sqrt{2}\ i}{12}\right],\ x = 0,\ \text{Undirected}$$

Example 4

Despite the name, elements of `Series::Puiseux` may contain coefficient functions depending on the series variable:
f := series(psi(x), x = infinity, 4); domtype(f), coeff(f, 0)ln(x) - 1/(2*x) - 1/(12*x^2) + O(1/x^4)

$$\ln(x) - \frac{1}{2\,x} - \frac{1}{12\,x^2} + O\left(\frac{1}{x^4}\right)$$

'Series::Puiseux', ln(x)

Series::Puiseux, ln(x)

With respect to differentiation, integration, and composition, such expansions behave like functions of the series variable and not like formal series:
diff(f, x) = series(diff(psi(x), x), x = infinity, 4)1/x + 1/(2*x^2) + 1/(6*x^3) + O(1/x^5) = 1/x + 1/(2*x^2) + 1/(6*x^3) + O(1/x^5)

$$\frac{1}{x} + \frac{1}{2\,x^2} + \frac{1}{6\,x^3} + O\left(\frac{1}{x^5}\right) = \frac{1}{x} + \frac{1}{2\,x^2} + \frac{1}{6\,x^3} + O\left(\frac{1}{x^5}\right)$$

int(f, x) = series(int(psi(x), x), x = infinity, 4)x*(ln(x) - 1) - ln(x)/2 + 1/(12*x) + O(1/x^3) = x*(ln(x) - 1) + ln(2)/2 + ln(PI)/2 - ln(x)/2 + 1/(12*x) + O(1/x^3)

$$x\,(\ln(x) - 1) - \frac{\ln(x)}{2} + \frac{1}{12\,x} + O\left(\frac{1}{x^3}\right) = x\,(\ln(x) - 1) + \frac{\ln(2)}{2} + \frac{\ln(\pi)}{2} - \ln($$

f @ series(2*x, x = infinity) = series(psi(2*x), x = infinity, 4)ln(2) + ln(x) - 1/(4*x) - 1/(48*x^2) + O(1/x^4) = ln(2) + ln(x) - 1/(4*x) - 1/(48*x^2) + O(1/x^4)

$$\ln(2) + \ln(x) - \frac{1}{4\,x} - \frac{1}{48\,x^2} + O\left(\frac{1}{x^4}\right) = \ln(2) + \ln(x) - \frac{1}{4\,x} - \frac{1}{48\,x^2} + O$$

Example 5

The basic arithmetical operations are implemented for elements of `Series::Puiseux`:

f := series(exp(x), x, 4); g := series(sqrt(x)/(1 - x), x, 4); h := series(cot(x), x, 4);1 + x + x^2/2 + x^3/6 + O(x^4)

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + O(x^4)$$

sqrt(x) + x^(3/2) + x^(5/2) + x^(7/2) + O(x^(9/2))

$$\sqrt{x} + x^{3/2} + x^{5/2} + x^{7/2} + O\left(x^{9/2}\right)$$

1/x - x/3 + O(x^3)

$$\frac{1}{x} - \frac{x}{3} + O(x^3)$$

f + g + h;_plus(f, g, h)1/x + 1 + sqrt(x) + (2*x)/3 + x^(3/2) + x^2/2 + x^(5/2) + O(x^3)

$$\frac{1}{x} + 1 + \sqrt{x} + \frac{2\,x}{3} + x^{3/2} + \frac{x^2}{2} + x^{5/2} + O(x^3)$$

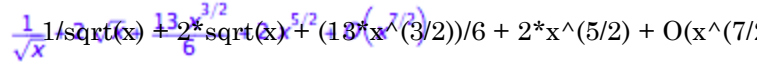
1/x + 1 + sqrt(x) + (2*x)/3 + x^(3/2) + x^2/2 + x^(5/2) + O(x^3)

$$\frac{1}{x} + 1 + \sqrt{x} + \frac{2\,x}{3} + x^{3/2} + \frac{x^2}{2} + x^{5/2} + O(x^3)$$

f - h = _subtract(f, h); -g = _negate(g);- 1/x + 1 + (4*x)/3 + x^2/2 + O(x^3) = - 1/x + 1 + (4*x)/3 + x^2/2 + O(x^3)

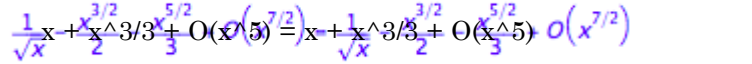
- sqrt(x) - x^(3/2) - x^(5/2) - x^(7/2) + O(x^(9/2)) = - sqrt(x) - x^(3/2) - x^(5/2) - x^(7/2) + O(x^(9/2))

f*g*h; _mult(f, g, h)1/sqrt(x) + 2*sqrt(x) + (13*x^(3/2))/6 + 2*x^(5/2) + O(x^(7/2))



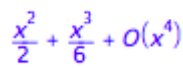
1/sqrt(x) + 2*sqrt(x) + (13*x^(3/2))/6 + 2*x^(5/2) + O(x^(7/2))

f/g2 = _divide(f, g);1/h = _invert(h);1/sqrt(x) - x^(3/2)/2 - x^(5/2)/3 + O(x^(7/2)) = 1/sqrt(x) - x^(3/2)/2 - x^(5/2)/3 + O(x^(7/2))



x + x^3/3 + O(x^5) = x + x^3/3 + O(x^5)

Operands that are not of type `Series::Puiseux` are implicitly converted into series expansions with the same expansion point via the constructor before the arithmetical operation is performed:
f - 1 - x; h * (sin(x) + x);x^2/2 + x^3/6 + O(x^4)



sin(x)/x + 1 - (x*sin(x))/3 - x^2/3 + O(x^3)

$$\frac{\sin(x)}{x} + 1 - \frac{x\sin(x)}{3} - \frac{x^2}{3} + O(x^3)$$

An error occurs when the expansion points differ or the directions of expansion are incompatible:
f := series(arccot(x), x = 0, Left); g := series(sqrt(sin(x)), x = 0, Right); f + g- PI/2 - x + x^3/3 - x^5/5 + O(x^7)

$$-\frac{\pi}{2} - x + \frac{x^3}{3} - \frac{x^5}{5} + O(x^7)$$

sqrt(x)- x^(5/2)/12 + x^(9/2)/1440 + O(x^(13/2))

$$\sqrt{x} - \frac{x^{5/2}}{12} + \frac{x^{9/2}}{1440} + O(x^{13/2})$$

Error: Inconsistent direction. [Series::Puiseux::plus] h := series(1/x, x = 2, 4); f * h1/2 - (x - 2)/4 + (x - 2)^2/8 - (x - 2)^3/16 + O((x - 2)^4)

$$\frac{1}{2} - \frac{x-2}{4} + \frac{(x-2)^2}{8} - \frac{(x-2)^3}{16} + O((x-2)^4)$$

Error: Both series must use the same variables and expansion points. [Series::Puiseux::mult]

If the directions are compatible, then the direction of the result specifies the minimal range where all operands are defined:
s := series(tanh(x), x, Real);x - x^3/3 + (2*x^5)/15 + O(x^7)

$$x - \frac{x^3}{3} + \frac{2x^5}{15} + O(x^7)$$

f + s; Series::Puiseux::direction(%)- PI/2 - x^5/15 + O(x^7)

$$-\frac{\pi}{2} - \frac{x^5}{15} + O(x^7)$$

Left

Left

Example 6

The method `scalmult` implements multiplication by a constant or a single term:
f := series(1 + 2*x^3, x); Series::Puiseux::scalmult(f, 5) = 5*f; Series::Puiseux::scalmult(f, 5, 3) = 5*x^3*f;1 + 2*x^3 + O(x^6)

$$1 + 2\,x^3 + O(x^6)$$

5 + 10*x^3 + O(x^6) = 5 + 10*x^3 + O(x^6)

$$5 + 10\,x^3 + O(x^6) = 5 + 10\,x^3 + O(x^6)$$

5*x^3 + 10*x^6 + O(x^9) = 5*x^3 + 10*x^6 + O(x^9)

$$5\,x^3 + 10\,x^6 + O(x^9) = 5\,x^3 + 10\,x^6 + O(x^9)$$

g := series(1 + 2*x^3, x = 2, 3); Series::Puiseux::scalmult(g, 1, 3) = (x - 2)^3*g17 + 24*(x - 2) + 12*(x - 2)^2 + O((x - 2)^3)

$$17 + 24\,(x-2) + 12\,(x-2)^2 + O((x-2)^3)$$

17*(x - 2)^3 + 24*(x - 2)^4 + 12*(x - 2)^5 + O((x - 2)^6) = 17*(x - 2)^3 + 24*(x - 2)^4 + 12*(x - 2)^5 + O((x - 2)^6)

$$17\,(x-2)^3 + 24\,(x-2)^4 + 12\,(x-2)^5 + O((x-2)^6) = 17\,(x-2)^3 + 24\,(x-2)^4 + 12\,(x-2)^5 + O((x-2)^6)$$

h := series(1 + 2*x^3, x = complexInfinity); Series::Puiseux::scalmult(h, 1, 1/2) = x^(-1/2)*h2*x^3 + 1 + O(1/x^3)

$$2\,x^3 + 1 + O\left(\frac{1}{x^3}\right)$$

2*x^(5/2) + 1/sqrt(x) + O(1/x^(7/2)) = 2*x^(5/2) + 1/sqrt(x) + O(1/x^(7/2))

$$2\,x^{5/2} + \frac{1}{\sqrt{x}} + O\left(\frac{1}{x^{7/2}}\right) = 2\,x^{5/2} + \frac{1}{\sqrt{x}} + O\left(\frac{1}{x^{7/2}}\right)$$

Example 7

Exponentiation is implemented for integral and rational exponents:
f := series(exp(x), x, 3); f^2 = _power(f, 2); f^(1/3) = _power(f, 1/3)1 + x + x^2/2 + O(x^3)

$$1 + x + \frac{x^2}{2} + O(x^3)$$

1 + 2*x + 2*x^2 + O(x^3) = 1 + 2*x + 2*x^2 + O(x^3)

$$1 + 2\,x + 2\,x^2 + O(x^3) = 1 + 2\,x + 2\,x^2 + O(x^3)$$

1 + x/3 + x^2/18 + O(x^3) = 1 + x/3 + x^2/18 + O(x^3)

$$1 + \frac{x}{3} + \frac{x^2}{18} + O(x^3) = 1 + \frac{x}{3} + \frac{x^2}{18} + O(x^3)$$

Exponents are allowed to be non-rational, if the series expansion starts with a constant summand independent of the series variable:
f^I = series(exp(I*x), x, 3);1 + x*I - x^2/2 + O(x^3) = 1 + x*I - x^2/2 + O(x^3)

$$1 + x\,i - \frac{x^2}{2} + O(x^3) = 1 + x\,i - \frac{x^2}{2} + O(x^3)$$

g := series(sin(-x), x); g^I- x + x^3/6 - x^5/120 + O(x^7)

$$-x + \frac{x^3}{6} - \frac{x^5}{120} + O(x^7)$$

Error: The exponent must be a rational number.
[Series::Puiseux::_power]

If the exponent contains the series variable, then an error occurs:

f^x Error: The exponent must not contain the series variable. [Series::Puiseux::_power]

For undirected expansions and rational exponents that are not integral, the result has type 1 in general:
g^(1/2); op(%, 1);sqrt(-x) - (-x)^(5/2)/12 + (-x)^(9/2)/1440 + O(x^(13/2))

$$\sqrt{-x} - \frac{(-x)^{5/2}}{12} + \frac{(-x)^{9/2}}{1440} + O\left(x^{13/2}\right)$$

1

1

The result simplifies when you specify one of the directions `Left` or `Right`:
g := series(sin(-x), x, Left): g^(1/2); op(%, 1);- sqrt(x)*I + (x^(5/2)*I)/12 - (x^(9/2)*I)/1440 + O(x^(13/2))

$$-\sqrt{x}\,i + \frac{x^{5/2}\,i}{12} - \frac{x^{9/2}\,i}{1440} + O\left(x^{13/2}\right)$$

0

0

g := series(sin(-x), x, Right): g^(1/2);sqrt(x)*I - (x^(5/2)*I)/12 + (x^(9/2)*I)/1440 + O(x^(13/2))

$$\sqrt{x}\,i - \frac{x^{5/2}\,i}{12} + \frac{x^{9/2}\,i}{1440} + O\left(x^{13/2}\right)$$

Example 8

Functional composition of elements of `Series::Puiseux` is implemented by the method `_fconcat`:

```
f := series(ln(x), x = 1, 4); g := series(cos(y), y = 0); f@g = _fconcat(f, g);
series(ln(cos(y)), y = 0, 4);x - 1 - (x - 1)^2/2 + (x - 1)^3/3 - (x - 1)^4/4 +
O((x - 1)^5)
```

$$x - 1 - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{3} - \frac{(x-1)^4}{4} + O((x-1)^5)$$

```
1 - y^2/2 + y^4/24 + O(y^6)
```

$$1 - \frac{y^2}{2} + \frac{y^4}{24} + O(y^6)$$

```
- y^2/2 - y^4/12 + O(y^6) = - y^2/2 - y^4/12 + O(y^6)
```

$$-\frac{y^2}{2} - \frac{y^4}{12} + O(y^6) = -\frac{y^2}{2} - \frac{y^4}{12} + O(y^6)$$

```
- y^2/2 - y^4/12 + O(y^6)
```

$$-\frac{y^2}{2} - \frac{y^4}{12} + O(y^6)$$

If the left argument is not of type `Series::Puiseux`, it is implicitly expanded around the limit point of the right argument before the composition:

```
f := series(sin(-x), x = 0); sqrt(y) @ f = Series::Puiseux(sqrt(y), y) @ f;- x +
x^3/6 - x^5/120 + O(x^7)
```

$$-x + \frac{x^3}{6} - \frac{x^5}{120} + O(x^7)$$

```
sqrt(-x) - (-x)^(5/2)/12 + (-x)^(9/2)/1440 + O(x^(13/2)) = sqrt(-x) -
(-x)^(5/2)/12 + (-x)^(9/2)/1440 + O(x^(13/2))
```

$$\sqrt{-x} - \frac{(-x)^{5/2}}{12} + \frac{(-x)^{9/2}}{1440} + O\left(x^{13/2}\right) = \sqrt{-x} - \frac{(-x)^{5/2}}{12} + \frac{(-x)^{9/2}}{1440} + O\left(x^{13/2}\right)$$

If the right argument is not of type `Series::Puiseux`, it is implicitly expanded around the origin via the constructor before the composition:
f @ sqrt(y) = f @ Series::Puiseux(sqrt(y), y)- sqrt(y) + y^(3/2)/6 - y^(5/2)/120 + O(y^(7/2)) = - sqrt(y) + y^(3/2)/6 - y^(5/2)/120 + O(y^(7/2))

$$-\sqrt{y}+\frac{y^{3/2}}{6}-\frac{y^{5/2}}{120}+O\left(y^{7/2}\right)=-\sqrt{y}+\frac{y^{3/2}}{6}-\frac{y^{5/2}}{120}+O\left(y^{7/2}\right)$$

This may not work if the argument to be converted contains special mathematical functions, but you can explicitly expand it into a series via series in this case:
f @ tan(y)FAIL

FAIL

f @ series(tan(y), y = 0)- y - y^3/6 + y^5/40 + O(y^7)

$$-y-\frac{y^3}{6}+\frac{y^5}{40}+O(y^7)$$

Mathematically, the composition of series expansions is not defined if the limit point of the right argument is not the expansion point of the left argument:
g := series(y^2 - 1, y = 0); f @ g- 1 + y^2 + O(y^6)

$$-1+y^2+O(y^6)$$

FAIL

f @ (y^2 - 1)FAIL

FAIL

f @ series(y^2 - 1, y = 1, 4)- 2*(y - 1) - (y - 1)^2 + (4*(y - 1)^3)/3 + 2*(y - 1)^4 + O((y - 1)^5)

$$-2(y-1)-(y-1)^2+\frac{4(y-1)^3}{3}+2(y-1)^4+O\left((y-1)^5\right)$$

The method `revert` computes the inverse of a truncated series expansion with respect to composition. The expansion point of the inverse is the limit point of the input and vice versa:
f := series(ln(x), x = 1, 4); revert(f) = series(exp(x), x = 0, 5)x - 1 - (x - 1)^2/2 + (x - 1)^3/3 - (x - 1)^4/4 + O((x - 1)^5)

$$x-1+\frac{(x-1)^2}{2}+\frac{(x-1)^3}{3}+\frac{(x-1)^4}{4}+O\left((x-1)^5\right)$$

1 + x + x^2/2 + x^3/6 + x^4/24 + O(x^5) = 1 + x + x^2/2 + x^3/6 + x^4/24 + O(x^5)

$$1+x+\frac{x^2}{2}+\frac{x^3}{6}+\frac{x^4}{24}+O\left(x^5\right),\ 1+x+\frac{x^2}{2}+\frac{x^3}{6}+\frac{x^4}{24}+O\left(x^5\right)$$

f := series(cot(x), x = 0); revert(f) = series(arccot(x), x = complexInfinity);1/x - x/3 - x^3/45 + O(x^5)

$$\frac{1}{x}-\frac{x}{3}-\frac{x^3}{45}+O\left(x^5\right)$$

1/x - 1/(3*x^3) + 1/(5*x^5) + O(1/x^7) = 1/x - 1/(3*x^3) + 1/(5*x^5) + O(1/x^7)

$$\frac{1}{x}\ f\circ revert(f),\ revert(f)\circ fx+O(1/x^5),\ x+O(x^7)$$

$$\frac{1}{x}-\frac{1}{3x^3}+\frac{1}{5x^5}+O\left(\frac{1}{x^7}\right),\ \frac{1}{x}-\frac{1}{3x^3}+\frac{1}{5x^5}+O\left(\frac{1}{x^7}\right)$$

$$x+O\left(\frac{1}{x}\right),\ x+O\left(x^7\right)$$

If the series variable occurs in the coefficients or the type flag is 1, an error occurs:

f := series(ln(sin(x)), x); g := series(arcsin(x + 1), x, 2);ln(x) - x^2/6 - x^4/180 + O(x^6)

PI/2 - sqrt(2)*sqrt(-x) - (sqrt(2)*(-x)^(3/2))/12 + O(x^(5/2))

revert(f) Error: Cannot compute the functional inverse. [Series::Puiseux::revert] revert(g) Error: Cannot compute the functional inverse. [Series::Puiseux::revert]

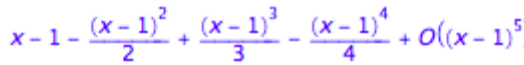
Example 9

The methods `diff` and `int` implement term-by-term differentiation and integration:
f := series(ln(x), x = 1, 4); g := diff(f, x); series(1/x, x = 1, 4); int(g, x);x - 1 - (x - 1)^2/2 + (x - 1)^3/3 - (x - 1)^4/4 + O((x - 1)^5)

1 - (x - 1) + (x - 1)^2 - (x - 1)^3 + O((x - 1)^4)

1 - (x - 1) + (x - 1)^2 - (x - 1)^3 + O((x - 1)^4)

x - 1 - (x - 1)^2/2 + (x - 1)^3/3 - (x - 1)^4/4 + O((x - 1)^5)



If you specify a range of integration, then the result is an arithmetical expression plus a symbolic definite integral of the *O*-term:
int(f, x = 1..2);int(O((x - 1)^5, x = 1), x = 1..2) + 11/30

$$\int_1^2 O\left((x-1)^5, x=1\right)\,dx + \frac{11}{30}$$

Example 10

Most special mathematical functions are overloaded for `Series::Puiseux`:
f := series(x/(1 - x), x, 4); exp(f) = series(exp(x/(1 - x)), x, 4); ln(f) = series(ln(x/(1 - x)), x, 4);x + x^2 + x^3 + x^4 + O(x^5)

$$x + x^2 + x^3 + x^4 + O(x^5)$$

1 + x + (3*x^2)/2 + (13*x^3)/6 + O(x^4) = 1 + x + (3*x^2)/2 + (13*x^3)/6 + O(x^4)

$$1 + x + \frac{3x^2}{2} + \frac{13x^3}{6} + O(x^4) \quad 1 + x + \frac{3x^2}{2} + \frac{13x^3}{6} + O(x^4)$$

ln(x) + x + x^2/2 + x^3/3 + O(x^4) = ln(x) + x + x^2/2 + x^3/3 + O(x^4)

$$\ln(x) + x + \frac{x^2}{2} + \frac{x^3}{3} + O(x^4) = \ln(x) + x + \frac{x^2}{2} + \frac{x^3}{3} + O(x^4)$$

If the system is unable to compute the composition, it returns a symbolic function call with evaluated arguments:
delete g: g(f)g(x + x^2 + x^3 + x^4 + O(x^5))

$$g(x + x^2 + x^3 + x^4 + O(x^5))$$

exp(series(x + 1/x, x = infinity, 5))exp(x + 1/x + O(1/x^4))

$$e^{x+\frac{1}{x}+O\left(\frac{1}{x^4}\right)}$$

In this case, you can try series to compute the composition:
series(exp(x + 1/x), x = infinity, 5)exp(x) + exp(x)/x + exp(x)/(2*x^2) + exp(x)/(6*x^3) + exp(x)/(24*x^4) + O(exp(x)/x^5)

$$e^x + \frac{e^x}{x} + \frac{e^x}{2x^2} + \frac{e^x}{6x^3} + \frac{e^x}{24x^4} + O\left(\frac{e^x}{x^5}\right)$$

Example 11

The system functions `Re`, `Im`, and `conjugate` work for all real series expansions:
f := series(exp(I*x), x, Real); Re(f) = series(cos(x), x, Real); Im(f) = series(sin(x), x, Real) + O(x^6); conjugate(f) = series(exp(-I*x), x, Real);1 + x*I - x^2/2 - (x^3*I)/6 + x^4/24 + (x^5*I)/120 + O(x^6)

$$1 + xi - \frac{x^2}{2} - \frac{x^3 i}{6} + \frac{x^4}{24} + \frac{x^5 i}{120} + O(x^6)$$

1 - x^2/2 + x^4/24 + O(x^6) = 1 - x^2/2 + x^4/24 + O(x^6)

$$1 - \frac{x^2}{2} + \frac{x^4}{24} + O(x^6)$$

x - x^3/6 + x^5/120 + O(x^6) = x - x^3/6 + x^5/120 + O(x^6)

$$x - \frac{x^3}{6} + \frac{x^5}{120} + O(x^6)$$

1 - x*I - x^2/2 + (x^3*I)/6 + x^4/24 - (x^5*I)/120 + O(x^6) = 1 - x*I - x^2/2 + (x^3*I)/6 + x^4/24 - (x^5*I)/120 + O(x^6)

$$1 - xi - \frac{x^2}{2} + \frac{x^3 i}{6} + \frac{x^4}{24} - \frac{x^5 i}{120} + O(x^6) = 1 - xi - \frac{x^2}{2} + \frac{x^3 i}{6} + \frac{x^4}{24} - \frac{x^5 i}{120} + O(x^6)$$

Except in trivial cases, a symbolic function call is returned for an undirected expansion:
Re(series(PI, x)); Re(series(exp(I*x), x));PI + O(x^6)

$$\pi + O(x^6)$$

Re(1 + x*I - x^2/2 - (x^3*I)/6 + x^4/24 + (x^5*I)/120 + O(x^6))

$$\Re\left(1 + x\,\mathrm{i} - \frac{x^2}{2} - \frac{x^3\,\mathrm{i}}{6} + \frac{x^4}{24} + \frac{x^5\,\mathrm{i}}{120} + O(x^6)\right)$$

Example 12

The method `contfrac` converts a series expansion into a continued fraction:
f := series(exp(x), x, 10); contfrac(f);1 + x + x^2/2 + x^3/6 + x^4/24 + x^5/120 + x^6/720 + x^7/5040 + x^8/40320 + x^9/362880 + O(x^10)

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{720} + \frac{x^7}{5040} + \frac{x^8}{40320} + \frac{x^9}{362880} + O(x^{10})$$

1 + x/(1 + x/(- 2 + x/(- 3 + x/(2 + x/(5 + x/(- 2 + x/(- 7 + x/(2 + x/(9 + O(x))))))))))

g := series(tan(x), x = PI, 10); contfrac(g);x - PI - (PI - x)^3/3 - (2*(PI - x)^5)/15 - (17*(PI - x)^7)/315 - (62*(PI - x)^9)/2835 + O(-(PI - x)^11)

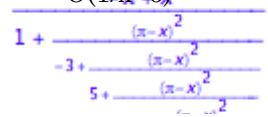
$$1 + \cfrac{x}{1 + \cfrac{x}{x}}$$

$$x - \pi - \frac{(\pi - x)^3}{3} - \frac{2\,(\pi - x)^5}{15} - \frac{17\,(\pi - x)^7}{315} - \frac{62\,(\pi - x)^9}{2835} + O\left(-(\pi - x)^{11}\right)$$

(- PI + x)/(1 + (PI - x)^2/(- 3 + (PI - x)^2/(5 + (PI - x)^2/(- 7 + (PI - x)^2/(9 + O((PI - x)^2))))))

$$\cfrac{x}{2 + \cfrac{x}{9 + O(x)}}$$

If the coefficients of a series expansion depend on the series variable, then so do the coefficients of the corresponding continued fraction:
h := series(ln(x + 1/x), x = infinity); contfrac(h)ln(x) + 1/x^2 - 1/(2*x^4) + O(1/x^6)

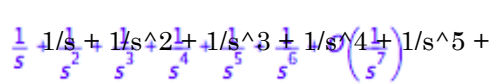


ln(x) + x^-2/(1 + x^-2/(2 + O(x^-2)))

Example 13

For series expansions around the origin, the method `laplace`, overloading `laplace`, computes the Laplace transform term by term, if the second argument is the series variable. The result is a series expansion around infinity:
delete s: f := series(exp(x), x); g := laplace(f, x, s); series(laplace(exp(x), x, s), s = infinity);1 + x + x^2/2 + x^3/6 + x^4/24 + x^5/120 + O(x^6)

1/s + 1/s^2 + 1/s^3 + 1/s^4 + 1/s^5 + 1/s^6 + O(1/s^7)



1/s + 1/s^2 + 1/s^3 + 1/s^4 + 1/s^5 + 1/s^6 + O(1/s^7)

$$\frac{1}{s} + \frac{1}{s^2} + \frac{1}{s^3} + \frac{1}{s^4} + \frac{1}{s^5} + \frac{1}{s^6} + O\left(\frac{1}{s^7}\right)$$

Similarly, the method `ilaplace` computes the inverse Laplace transform term by term for series expansions around infinity, if the second argument is the series variable. The result is a series expansion around 0:

```
ilaplace(g, s, x)1 + x + x^2/2 + x^3/6 + x^4/24 + x^5/120 + O(x^6)
```

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + O(x^6)$$

The Laplace transform and the inverse Laplace transform, respectively, of a series do not make sense for expansion points other than 0 or infinity, respectively, and in these cases a symbolic function call is returned:

```
laplace(series(ln(x), x = 1, 2), x, s);laplace(x - 1 - (x - 1)^2/2 + O((x -
1)^3), x, s)
```

$$\text{laplace}\left(x - 1 - \frac{(x-1)^2}{2} + O\left((x-1)^3\right), x, s\right)$$

If the second argument is not the series variable, then the coefficients are transformed:

```
h := series(sin(x*y), x = 1, 2); laplace(h, y, s);sin(y) + y*cos(y)*(x - 1) +
O((x - 1)^2)
```

$$\sin(y) + y\cos(y)\,(x-1) + O\left((x-1)^2\right)$$

```
1/(s^2 + 1) - (1/(s^2 + 1) - (2*s^2)/(s^2 + 1)^2)*(x - 1) + O((x - 1)^2)
```

$$\frac{1}{s^2+1} - \left(\frac{1}{s^2+1} - \frac{2s^2}{(s^2+1)^2}\right)(x-1) + O\left((x-1)^2\right)$$

Example 14

When called with one argument, the method `coeff` returns the sequence of all coefficients of a series expansion:
f := series(tan(x), x); coeff(f)x + x^3/3 + (2*x^5)/15 + O(x^7)

$$x + \frac{x^3}{3} + \frac{2\,x^5}{15} + O\left(x^7\right)$$

1, 0, 1/3, 0, 2/15

g := series(1/(x - 1)^2, x = infinity); coeff(g)1/x^2 + 2/x^3 + 3/x^4 + 4/x^5 + 5/x^6 + 6/x^7 + O(1/x^8)

$$\frac{1}{x^2} + \frac{2}{x^3} + \frac{3}{x^4} + \frac{4}{x^5} + \frac{5}{x^6} + \frac{6}{x^7} + O\left(\frac{1}{x^8}\right)$$

1, 2, 3, 4, 5, 6

When called with two arguments, `coeff` returns an individual coefficient:
coeff(f, -1), coeff(f, 1), coeff(f, 2), coeff(f, 13/2);0, 1, 0, 0

0, 1, 0, 0

If the second argument exceeds the order of the error term, `coeff` returns FAIL:
coeff(f, 10)FAIL

FAIL

When the expansion point is `complexInfinity`, `coeff(s, n)` returns the coefficient of x^(-n) , where `x` is the series variable of `s`:

$$\frac{1}{x^n}$$

coeff(g, 2), coeff(g, -3), coeff(g, -15/2)0, 2, 0

0, 2, 0

Specifying the series variable as second or third argument, respectively, is optional:
coeff(f) = coeff(f, x); coeff(f, 3) = coeff(f, x, 3)(1, 0, 1/3, 0, 2/15) = (1, 0, 1/3, 0, 2/15)

$\left(1, 0, \frac{1}{3}, 0, \frac{2}{15}\right) - \left(1, 0, \frac{1}{3}, 0, \frac{2}{15}\right)$

1/8 = 1/3

$\frac{1}{3} - \frac{1}{3}$

For series expansions of type 1, the “coefficients” in general involve the series variable:
h := series(sin(sqrt(-x)), x); coeff(h); coeff(h, 3/2);sqrt(-x) - (-x)^(3/2)/6 + (-x)^(5/2)/120 + O(x^(7/2))

$\sqrt{-x} - \frac{(-x)^{3/2}}{6} + \frac{(-x)^{5/2}}{120} + O\left(x^{7/2}\right)$

sqrt(-x)/sqrt(x), 0, -(-x)^(3/2)/(6*x^(3/2)), 0, (-x)^(5/2)/(120*x^(5/2))

$\frac{\sqrt{-x}}{\sqrt{x}}, 0, -\frac{(-x)^{3/2}}{6\,x^{3/2}}, 0, \frac{(-x)^{5/2}}{120\,x^{5/2}}$

-(-x)^(3/2)/(6*x^(3/2))

$-\frac{(-x)^{3/2}}{6\,x^{3/2}}$

Example 15

The method `ldegree` returns the order of the leading term of a series expansion. When the expansion point is `complexInfinity` and the leading term is x^(-n) , then this is *n*:
f := series(x*sin(sqrt(-x)), x); g := series(cot(x), x = PI); h := series(2*arccot(x), x = infinity);- (-x)^(3/2) + (-x)^(5/2)/6 - (-x)^(7/2)/120 + O(x^(9/2))

- 1/(PI - x) - (x - PI)/3 + (PI - x)^3/45 + O(-(PI - x)^5)

2/x - 2/(3*x^3) + 2/(5*x^5) + O(1/x^7)

ldegree(f), ldegree(g), ldegree(h)3/2, -1, 1

The method `lcoeff` returns the coefficient of the leading term. For an expansion of type 1, it generally involves the series variable:
lcoeff(f), lcoeff(g), lcoeff(h)-(-x)^(3/2)/x^(3/2), 1, 2

The method `lterm` returns the leading term itself:
lterm(f), lterm(g), lterm(h)x^(3/2), -1/(PI - x), 1/x

$$x^{3/2},\ -\frac{1}{\pi - x},\ \frac{1}{x}$$

Finally, the method `lmonomial` returns the whole summand:
lmonomial(f) = lcoeff(f)*lterm(f); lmonomial(g) = lcoeff(g)*lterm(g);
lmonomial(h) = lcoeff(h)*lterm(h);-(-x)^(3/2) = -(-x)^(3/2)

$$-(-x)^{3/2} = -(-x)^{3/2}$$

-1/(PI - x) = -1/(PI - x)

$$-\frac{1}{\pi - x} = \frac{1}{\pi - x}$$

2/x = 2/x

$$\frac{2}{x} = \frac{2}{x}$$

If the series expansion consists only of an *O*-term, all four methods return `FAIL`:
s := Series::Puiseux::zero(x, 6); ldegree(s), lcoeff(s), lterm(s),
lmonomial(s)O(x^6)

$$O(x^6)$$

FAIL, FAIL, FAIL, FAIL

FAIL, FAIL, FAIL, FAIL

Example 16

The methods `nthcoeff`, `nthmonomial`, and `nthterm` return the *n*th non-zero coefficient, monomial, or term, respectively, of a series expansion. In contrast to polynomials, they count from the term of lowest order on, i.e., the ordering is ascending by exponent for finite

expansion points and descending by exponent when the expansion point is `complexInfinity`:
f := series(x*sin(sqrt(-x)), x); g := series(cot(x), x = PI); h := series(2*arccot(x), x = infinity);- (-x)^(3/2) + (-x)^(5/2)/6 - (-x)^(7/2)/120 + O(x^(9/2))

$$-(-x)^{3/2} + \frac{(-x)^{5/2}}{6} - \frac{(-x)^{7/2}}{120} + O\left(x^{9/2}\right)$$

- 1/(PI - x) - (x - PI)/3 + (PI - x)^3/45 + O(-(PI - x)^5)

$$-\frac{1}{\pi - x} - \frac{x - \pi}{3} + \frac{(x - \pi)^3}{45} + O\left((x - \pi)^5\right)$$

- 2/x - 2/(3*x^3) + 2/(5*x^5) + O(1/x^7)

$$-\frac{2}{x} - \frac{2}{3x^3} + \frac{2}{5x^5} + O\left(\frac{1}{x^7}\right)$$

nthcoeff(f, 1) = lcoeff(f); nthmonomial(g, 1) = lmonomial(g); nthterm(h, 1) = lterm(h);-(-x)^(3/2)/x^(3/2) = -(-x)^(3/2)/x^(3/2)

$$-\frac{(-x)^{3/2}}{x^{3/2}} = -\frac{(-x)^{3/2}}{x^{3/2}}$$

-1/(PI - x) = -1/(PI - x)

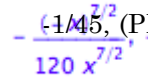
$$-\frac{1}{\pi - x} = -\frac{1}{\pi - x}$$

- 1/x = 1/x

$$-\frac{1}{x} = \frac{1}{x}$$

nthcoeff(f, 3), nthmonomial(f, 3), nthterm(f, 3); nthcoeff(g, 3), nthmonomial(g, 3), nthterm(g, 3); nthcoeff(h, 3), nthmonomial(h, 3), nthterm(h, 3);-(-x)^(7/2)/(120*x^(7/2)), -(-x)^(7/2)/120, x^(7/2)

-1/45, (PI - x)^3/45, -(PI - x)^3



-2/5, 2/(5*x^5), 1/x^5

If the second argument is not positive or exceeds the number of non-zero summands, all three methods return FAIL:
nthcoeff(f, -4), nthterm(g, 0), nthmonomial(h, 4)FAIL, FAIL, FAIL

FAIL, FAIL, FAIL

Example 17

We illustrate the difference between the ordering of terms in polynomials and series expansions. The ordering of the terms in a polynomial agrees with the ordering of the terms in a series expansion with expansion point `complexInfinity`:
f := poly(2*(x^2 + x)^3); g := series(f, x = complexInfinity); [lcoeff(f), lmonomial(f), lterm(f)]; [lcoeff(g), lmonomial(g), lterm(g)];poly(2*x^6 + 6*x^5 + 6*x^4 + 2*x^3, [x])

2*x^6 + 6*x^5 + 6*x^4 + 2*x^3 + O(1)

[2, poly(2*x^6, [x]), poly(x^6, [x])]

$$[2, \mathrm{poly}(2\,x^6, [x]), \mathrm{poly}(x^6, [x])]$$

[2, 2*x^6, x^6]

$$[2, 2\,x^6, x^6]$$

[nthcoeff(f, 2), nthmonomial(f, 3), nthterm(f, 4)]; [nthcoeff(g, 2), nthmonomial(g, 3), nthterm(g, 4)];[6, poly(6*x^4, [x]), poly(x^3, [x])]

$$[6, \mathrm{poly}(6\,x^4, [x]), \mathrm{poly}(x^3, [x])]$$

[6, 6*x^4, x^3]

$$[6, 6\,x^4, x^3]$$

For finite expansion points, however, the ordering of the terms in a series expansion is the reverse of the ordering of the terms in the corresponding polynomial:
h := series(f, x = 0); [lcoeff(h), lmonomial(h), lterm(h)]; [nthcoeff(h, 2), nthmonomial(h, 3), nthterm(h, 4)];2*x^3 + 6*x^4 + 6*x^5 + 2*x^6 + O(x^9)

$$2\,x^3 + 6\,x^4 + 6\,x^5 + 2\,x^6 + O(x^9)$$

[2, 2*x^3, x^3]

$$[2, 2\,x^3, x^3]$$

[6, 6*x^5, x^6]

$$[6, 6\,x^5, x^6]$$

Example 18

The method `iszero` checks whether a series expansion has no non-zero summands apart from the *O*-term:

```
f := series(exp(x), x); g := Series::Puiseux(0, x = 2, 4); iszero(f), iszero(g)1
+ x + x^2/2 + x^3/6 + x^4/24 + x^5/120 + O(x^6)
```

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + O(x^6)$$

```
O((x - 2)^4)
```

$$O((x-2)^4)$$

```
FALSE, TRUE
```

FALSE, TRUE

Example 19

The methods `convert` tries to convert an arbitrary object into an element of `Series::Puiseux`. If the input does not suggest an expansion point, `convert` uses the origin:

```
f := asympt(1/(x + 1), x = infinity); g := sin(x)/(1 - x); h := poly((x +
1)^10); u := O((x - 1)^3, x = 1);1/x - 1/x^2 + 1/x^3 - 1/x^4 + 1/x^5 - 1/x^6
+ O(1/x^7)
```

$$\frac{1}{x} - \frac{1}{x^2} + \frac{1}{x^3} - \frac{1}{x^4} + \frac{1}{x^5} - \frac{1}{x^6} + O\left(\frac{1}{x^7}\right)$$

```
-sin(x)/(x - 1)
```

$$-\frac{\sin(x)}{x-1}$$

```
poly(x^10 + 10*x^9 + 45*x^8 + 120*x^7 + 210*x^6 + 252*x^5 + 210*x^4
+ 120*x^3 + 45*x^2 + 10*x + 1, [x])
```

$$\mathrm{poly}(x^{10} + 10x^9 + 45x^8 + 120x^7 + 210x^6 + 252x^5 + 210x^4 + 120x^3 + 45x^2 + 10x + 1, [x])$$

```
O((x - 1)^3, x = 1)
```

$O((x-1)^3, x=1)$

domtype(f), domtype(g), domtype(h), domtype(u)'Series::gseries', DOM_EXPR, DOM_POLY, O

Series::gseries, DOM_EXPR, DOM_POLY, O

F := Series::Puiseux::convert(f); G := Series::Puiseux::convert(g); H := Series::Puiseux::convert(h); U := Series::Puiseux::convert(u);1/x - 1/x^2 + 1/x^3 - 1/x^4 + 1/x^5 - 1/x^6 + O(1/x^7)

$\frac{1}{x} - \frac{1}{x^2} + \frac{1}{x^3} - \frac{1}{x^4} + \frac{1}{x^5} - \frac{1}{x^6} + O\left(\frac{1}{x^7}\right)$

sin(x) + x*sin(x) + x^2*sin(x) + x^3*sin(x) + x^4*sin(x) + x^5*sin(x) + O(x^6)

$\sin(x) + x\sin(x) + x^2\sin(x) + x^3\sin(x) + x^4\sin(x) + x^5\sin(x) + O(x^6)$

1 + 10*x + 45*x^2 + 120*x^3 + 210*x^4 + 252*x^5 + 210*x^6 + 120*x^7 + 45*x^8 + 10*x^9 + x^10 + O(x^16)

$1 + 10x + 45x^2 + 120x^3 + 210x^4 + 252x^5 + 210x^6 + 120x^7 + 45x^8 + 10x^9 + x^{10} + O(x^{16})$

O((x - 1)^3)

$O((x-1)^3)$

`convert` returns `FAIL`, if it is unable to convert the input, e.g., because the input contains no or more than one indeterminate: Series::Puiseux::convert(sin(1)), Series::Puiseux::convert([1, y, 3])FAIL, FAIL

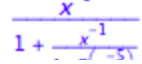
FAIL, FAIL

The method `convert_to` tries to convert an element of `Series::Puiseux` into a specified type:

Series::Puiseux::convert_to(F, Series::gseries);
Series::Puiseux::convert_to(F, contfrac); Series::Puiseux::convert_to(G, DOM_EXPR); Series::Puiseux::convert_to(H, DOM_POLY);
Series::Puiseux::convert_to(H, O); Series::Puiseux::convert_to(U, O);1/x - 1/x^2 + 1/x^3 - 1/x^4 + 1/x^5 - 1/x^6 + O(1/x^7)

x^(-1)/(1 + x^(-1))(1 + O(x^(-5)))

sin(x) + x^2*sin(x) + x^3*sin(x) + x^4*sin(x) + x^5*sin(x) + x*sin(x)



poly(x^10 + 10*x^9 + 45*x^8 + 120*x^7 + 210*x^6 + 252*x^5 + 210*x^4 + 120*x^3 + 45*x^2 + 10*x + 1, [x])

O(1)

O((x - 1)^3, x = 1)

`convert_to` returns `FAIL`, if it is unable to perform the requested conversion:
Series::Puiseux::convert_to(F, O), Series::Puiseux::convert_to(F, DOM_LIST)FAIL, FAIL

FAIL, FAIL

Example 20

The method `expr` converts an element of `Series::Puiseux` into an arithmetical expression, discarding the *O*-term. In general, the ordering of the summands is not preserved:

```
f := series(exp(x*y), x); g := series(ln(x), x = 1, 3);1 + x*y + (x^2*y^2)/2 +
(x^3*y^3)/6 + (x^4*y^4)/24 + (x^5*y^5)/120 + O(x^6)
```

$$1 + x\,y + \frac{x^2\,y^2}{2} + \frac{x^3\,y^3}{6} + \frac{x^4\,y^4}{24} + \frac{x^5\,y^5}{120} + O\left(x^6\right)$$

```
x - 1 - (x - 1)^2/2 + (x - 1)^3/3 + O((x - 1)^4)
```

$$x - 1 - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{3} + O\left((x-1)^4\right)$$

```
expr(f); expr(g);(x^5*y^5)/120 + (x^4*y^4)/24 + (x^3*y^3)/6 +
(x^2*y^2)/2 + x*y + 1
```

$$\frac{x^5\,y^5}{120} + \frac{x^4\,y^4}{24} + \frac{x^3\,y^3}{6} + \frac{x^2\,y^2}{2} + x\,y + 1$$

```
x - (x - 1)^2/2 + (x - 1)^3/3 - 1
```

$$x - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{3} - 1$$

The method `float` applies the system function float to all coefficients:

```
float(f); float(g);1.0 + x*y + 0.5*x^2*y^2 + 0.1666666667*x^3*y^3 +
0.04166666667*x^4*y^4 + 0.008333333333*x^5*y^5 + O(x^6)
```

```
1.0*(x - 1) - 0.5*(x - 1)^2 + 0.3333333333*(x - 1)^3 + O((x - 1)^4)
```

$$1.0 + x\,y + 0.5\,x^2\,y^2 + 0.1666666667\,x^3\,y^3 + 0.04166666667\,x^4\,y^4 + 0.008333333333\,x^5\,y^5 + O\left(x^6\right)$$

$$1.0\,(x-1)-0.5\,(x-1)^2+0.3333333333\,(x-1)^3+O\left((x-1)^4\right)$$

Example 21

The methods `combine`, `expand`, and `normal` apply the corresponding system functions to all coefficients:

```
delete a, y: f := series(y/(x + y^a), x, 4); g := combine(f); expand(g);y/y^a
```

```
- (x*y)/y^(2*a) + (x^2*y)/y^(3*a) - (x^3*y)/y^(4*a) + O(x^4)
```

$$\frac{y}{y^a}$$

```
y^(1 - a) - x*y^(1 - 2*a) + x^2*y^(1 - 3*a) - x^3*y^(1 - 4*a) + O(x^4)
```

$$y^{1-a}-x\,y^{1-2\,a}+x^2\,y^{1-3\,a}-x^3\,y^{1-4\,a}+O\left(x^4\right)$$

```
y/y^a - (x*y)/y^(2*a) + (x^2*y)/y^(3*a) - (x^3*y)/y^(4*a) + O(x^4)
```

$$\frac{y}{y^a}-\frac{x\,y}{y^{2\,a}}+\frac{x^2\,y}{y^{3\,a}}-\frac{x^3\,y}{y^{4\,a}}+O\left(x^4\right)$$

For efficiency reasons, the arithmetical methods of `Series::Puiseux` usually do not perform any symbolic simplifications. Use `expand` or `normal` to simplify the results:

```
h := series(exp(x), x, 4)^a; expand(h); normal(h);1 + a*x + x^2*(a/2
+ (a*(a - 1))/2) + x^3*(a/6 + ((a/2 + (a*(a - 1))/2)*(a - 2))/3 + (a*(2*a -
1))/6) + O(x^4)
```

$$1+a\,x+x^2\left(\frac{a}{2}+\frac{a\,(a-1)}{2}\right)+x^3\left(\frac{a}{6}+\frac{\left(\frac{a}{2}+\frac{a\,(a-1)}{2}\right)\,(a-2)}{3}+\frac{a\,(2\,a-1)}{6}\right)+O\left(x^4\right)$$

```
1 + a*x + (a^2*x^2)/2 + (a^3*x^3)/6 + O(x^4)
```

$$1+a\,x+\frac{a^2\,x^2}{2}+\frac{a^3\,x^3}{6}+O\left(x^4\right)$$

```
1 + a*x + (a^2*x^2)/2 + (a^3*x^3)/6 + O(x^4)
```

$$1 + a\,x + \frac{a^2 x^2}{2} + \frac{a^3 x^3}{6} + O(x^4)$$

u := series(arctanh(x + y), x, 4); normal(u);arctanh(y) - x/(y^2 - 1) + (x^2*y)/(y^2 - 1)^2 + (x^3*(3*y^2*I + I)*I)/(3*(y^2 - 1)^3) + O(x^4)

$$\operatorname{arctanh}(y) - \frac{x}{y^2 - 1} + \frac{x^2 y}{(y^2 - 1)^2} + \frac{x^3 (3 y^2 + 1) i^2}{3 (y^2 - 1)^3} + O(x^4)$$

arctanh(y) - x/(y^2 - 1) + (x^2*y)/(y^2 - 1)^2 - (x^3*(3*y^2 + 1))/(3*(y^2 - 1)^3) + O(x^4)

$$\operatorname{arctanh}(y) - \frac{x}{y^2 - 1} + \frac{x^2 y}{(y^2 - 1)^2} - \frac{x^3 (3 y^2 + 1)}{3 (y^2 - 1)^3} + O(x^4)$$

Besides normalizing the coefficients, the method normal also removes leading and trailing zeroes from the coefficient list:
v := Series::Puiseux::create(1, 3, 10, [0, 1/2, 0, 5, 0, 0], x, 2); coeff(v); normal(v); coeff(%);(x - 2)^4/2 + 5*(x - 2)^6 + O((x - 2)^10)

$$\frac{(x-2)^4}{2} + 5\,(x-2)^6 + O\left((x-2)^{10}\right)$$

0, 1/2, 0, 5, 0, 0

$$0,\ \frac{1}{2},\ 0,\ 5,\ 0,\ 0$$

(x - 2)^4/2 + 5*(x - 2)^6 + O((x - 2)^10)

$$\frac{(x-2)^4}{2} + 5\,(x-2)^6 + O\left((x-2)^{10}\right)$$

1/2, 0, 5

$$\frac{1}{2},\ 0,\ 5$$

The method `map` applies a given function to all coefficients. E.g., the system function factor is not overloaded for `Series::Puiseux`, but you can use `map` to express all coefficients in factored form:
map(u, factor);arctanh(y) - x/((y - 1)*(y + 1)) + (y*x^2)/((y - 1)^2*(y + 1)^2) - ((y^2 + 1/3)*x^3)/((y - 1)^3*(y + 1)^3) + O(x^4)

$$\operatorname{arctanh}(y) - \frac{x}{(y-1)(y+1)} + \frac{y\,x^2}{(y-1)^2(y+1)^2} - \frac{\left(y^2+\frac{1}{3}\right)x^3}{(y-1)^3(y+1)^3} + O(x^4)$$

In the next example, we use `map` to multiply all coefficients of a series expansion by a constant:
w := series(exp(x), x, 3); map(w, _mult, PI) = PI*w1 + x + x^2/2 + O(x^3)

$$1 + x + \frac{x^2}{2} + O(x^3)$$

PI+PI*x + (PI*x^2)/2 + O(x^3) = PI + PI*x + (PI*x^2)/2 + O(x^3)

$$\pi + \pi x + \frac{\pi x^2}{2} + O(x^3) = \pi + \pi x + \frac{\pi x^2}{2} + O(x^3)$$

For series expansions of type 1, `map` applies the function to all non-zero coefficients as returned by `coeff`:
z := series(sin(sqrt(-x)), x); coeff(z); map(z, cos);sqrt(-x) - (-x)^(3/2)/6 + (-x)^(5/2)/120 + O(x^(7/2))

$$\sqrt{-x} - \frac{(-x)^{3/2}}{6} + \frac{(-x)^{5/2}}{120} + O\left(x^{7/2}\right)$$

sqrt(-x)/sqrt(x), 0, -(-x)^(3/2)/(6*x^(3/2)), 0, (-x)^(5/2)/(120*x^(5/2))

$$\frac{\sqrt{-x}}{\sqrt{x}},\ 0,\ -\frac{(-x)^{3/2}}{6\,x^{3/2}},\ 0,\ \frac{(-x)^{5/2}}{120\,x^{5/2}}$$

sqrt(x)*cos(sqrt(-x)/sqrt(x)) + x^(3/2)*cos((-x)^(3/2)/(6*x^(3/2))) + x^(5/2)*cos((-x)^(5/2)/(120*x^(5/2))) + O(x^(7/2))

$$\sqrt{x}\cos\left(\frac{\sqrt{-x}}{\sqrt{x}}\right) + x^{3/2}\cos\left(\frac{(-x)^{3/2}}{6\,x^{3/2}}\right) + x^{5/2}\cos\left(\frac{(-x)^{5/2}}{120\,x^{5/2}}\right) + O\left(x^{7/2}\right)$$

Example 22

Three different methods can be used to substitute for the series variable: `_fconcat`, `func_call`, and `subs`. Suppose `f` is an element of `Series::Puiseux` and we want to substitute an expression `t` for the series variable `x`. Then `_fconcat` converts `t` into a series expansion around the origin via the constructor, computes the functional composition, and returns the result as an element of `Series::Puiseux`:
f := series(exp(x), x = 0, 5); Series::Puiseux::_fconcat(f, y) = f @ y; f @ (y^2 + y);1 + x + x^2/2 + x^3/6 + x^4/24 + O(x^5)

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + O\left(x^5\right)$$

1 + y + y^2/2 + y^3/6 + y^4/24 + O(y^5) = 1 + y + y^2/2 + y^3/6 + y^4/24 + O(y^5)

$$1 + y + \frac{y^2}{2} + \frac{y^3}{6} + \frac{y^4}{24} + O\left(y^5\right) = 1 + y + \frac{y^2}{2} + \frac{y^3}{6} + \frac{y^4}{24} + O\left(y^5\right)$$

1 + y + (3*y^2)/2 + (7*y^3)/6 + (25*y^4)/24 + O(y^5)

$$1 + y + \frac{3\,y^2}{2} + \frac{7\,y^3}{6} + \frac{25\,y^4}{24} + O\left(y^5\right)$$

The composition may fail if the limit point of `t` around the origin differs from the expansion point of `f` or if `t` contains special mathematical functions:
f @ (y + 1);FAIL

FAIL

f @ sin(y);FAIL

FAIL

Moreover, the composition does not work if the expression `t` is constant or contains more than one indeterminate:
f @ PI; Error: Cannot compute composition. [Series::Puiseux::_fconcat] f @ (x + y); Error: Cannot compute composition. [Series::Puiseux::_fconcat]

You can enforce the composition by explicitly converting `t` into a series:
f @ series(y + 1, y = -1); f @ series(sin(y), y = 0); f @ series(x + y, x = -y);1 + y + 1 + (y + 1)^2/2 + (y + 1)^3/6 + (y + 1)^4/24 + O((y + 1)^5)

$$1 + y + 1 + \frac{(y+1)^2}{2} + \frac{(y+1)^3}{6} + \frac{(y+1)^4}{24} + O((y+1)^5)$$

1 + y + y^2/2 - y^4/8 + O(y^5)

$$1 + y + \frac{y^2}{2} - \frac{y^4}{8} + O(y^5)$$

1 + x + y + (x + y)^2/2 + (x + y)^3/6 + (x + y)^4/24 + O((x + y)^5)

$$1 + x + y + \frac{(x+y)^2}{2} + \frac{(x+y)^3}{6} + \frac{(x+y)^4}{24} + O((x+y)^5)$$

Substitution with `func_call` always works. It discards the error term, `t` is substituted literally, and the result is an expression and not an object of type `Series::Puiseux`:
f(5) = Series::Puiseux::func_call(f, 5); f(y) = Series::Puiseux::func_call(f, y);523/8 = 523/8

$$\frac{523}{8} = \frac{523}{8}$$

y^4/24 + y^3/6 + y^2/2 + y + 1 = y^4/24 + y^3/6 + y^2/2 + y + 1

$\frac{y^4}{24} + \frac{y^3}{6} + \frac{y^2}{2} + y + 1$ f(y^2 + y); f(y + 1); f(sin(y)); f(PI); f(x + y);y + (y^2 + y)^2/2 + (y^2 + y)^3/6 + (y^2 + y)^4/24 + y^2 + 1

$y + \frac{(y^2+y)^2}{2} + \frac{(y^2+y)^3}{6} + \frac{(y^2+y)^4}{24} + y^2 + 1$ y + (y + 1)^2/2 + (y + 1)^3/6 + (y + 1)^4/24 + 2

$y + \frac{(y+1)^2}{2} + \frac{(y+1)^3}{6} + \frac{(y+1)^4}{24} + 2$ sin(y)^4/24 + sin(y)^3/6 + sin(y)^2/2 + sin(y) + 1

$\frac{\sin(y)^4}{24} + \frac{\sin(y)^3}{6} + \frac{\sin(y)^2}{2} + \sin(y) + 1$ PI + PI^2/2 + PI^3/6 + PI^4/24 + 1

$\pi + \frac{\pi^2}{2} + \frac{\pi^3}{6} + \frac{\pi^4}{24} + 1$ x + y + (x + y)^2/2 + (x + y)^3/6 + (x + y)^4/24 + 1

$x + y + \frac{(x+y)^2}{2} + \frac{(x+y)^3}{6} + \frac{(x+y)^4}{24} + 1$

Finally, if `subs` is used to substitute for the series variable, only very special substitutions are allowed (see the description of `subs` above for more details). Then a change of variable is performed, and the result is again of type `Series::Puiseux`:

subs(f, x = y^2 + y) Error: Invalid substitution. [Series::Puiseux::subs] subs(f, x = y + 1)1 + y + 1 + (y + 1)^2/2 + (y + 1)^3/6 + (y + 1)^4/24 + O((y + 1)^5)

$$1 + y + 1 + \frac{(y+1)^2}{2} + \frac{(y+1)^3}{3} + \frac{(y+1)^4}{24} + O\left((y+1)^5\right)$$

subs(f, x = sin(y)) Error: Invalid substitution. [Series::Puiseux::subs] subs(f, x = PI) Error: The substitution is invalid. Exactly one indeterminate is expected. [Series::Puiseux::subs] subs(f, x = x + y) Error: The substitution is invalid. Exactly one indeterminate is expected. [Series::Puiseux::subs]

All three methods can handle the case where the series variable occurs in the coefficients:
s := series(ln(x^2 + x), x); s @ (2*y); s(2*y); subs(s, x = 2*y);ln(x) + x - x^2/2 + x^3/3 - x^4/4 + x^5/5 + O(x^6)

$$\ln(x) + x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5} + O(x^6)$$

ln(2) + ln(y) + 2*y - 2*y^2 + (8*y^3)/3 - 4*y^4 + (32*y^5)/5 + O(y^6)

$$\ln(2) + \ln(y) + 2y - 2y^2 + \frac{8y^3}{3} - 4y^4 + \frac{32y^5}{5} + O(y^6)$$

2*y + ln(2*y) - 2*y^2 + (8*y^3)/3 - 4*y^4 + (32*y^5)/5

$$2y + \ln(2y) - 2y^2 + \frac{8y^3}{3} - 4y^4 + \frac{32y^5}{5}$$

ln(2*y) + 2*y - 2*y^2 + (8*y^3)/3 - 4*y^4 + (32*y^5)/5 + O(y^6)

$$\ln(2y) + 2y - 2y^2 + \frac{8y^3}{3} - 4y^4 + \frac{32y^5}{5} + O(y^6)$$

Of course, subs can also be used to substitute for other objects than the series variable in the coefficients and in the expansion point:
g := series(cos(x + y), x, 4); h := series(1/x, x = y, 4);cos(y) - x*sin(y) - (x^2*cos(y))/2 + (x^3*sin(y))/6 + O(x^4)

$\cos(y) - x\sin(y) - \frac{x^2\cos(y)}{2} + \frac{x^3\sin(y)}{6} + O(x^4)$

1/y - (x - y)/y^2 + (x - y)^2/y^3 - (x - y)^3/y^4 + O((x - y)^4)

$\frac{1}{y} - \frac{x-y}{y^2} + \frac{(x-y)^2}{y^3} - \frac{(x-y)^3}{y^4} + O((x-y)^4)$

subs(g, y = PI) = series(cos(x + PI), x, 4); subs(h, y = 2) = series(1/x, x = 2, 4);- 1 + x^2/2 + O(x^4) = - 1 + x^2/2 + O(x^4)

$-1 + \frac{x^2}{2} + O(x^4) = -1 + \frac{x^2}{2} + O(x^4)$

1/2 - (x - 2)/4 + (x - 2)^2/8 - (x - 2)^3/16 + O((x - 2)^4) = 1/2 - (x - 2)/4 + (x - 2)^2/8 - (x - 2)^3/16 + O((x - 2)^4)

$\frac{1}{2} - \frac{x-2}{4} + \frac{(x-2)^2}{8} - \frac{(x-2)^3}{16} + O((x-2)^4) = \frac{1}{2} - \frac{x-2}{4} + \frac{(x-2)^2}{8} - \frac{(x-2)^3}{16} + O((x-2)^4)$

Even simultaneous substitutions are possible in the coefficients: subs(g, [hold(sin) = cos, hold(cos) = sin, y = 2])sin(2) - x*cos(2) - (x^2*sin(2))/2 + (x^3*cos(2))/6 + O(x^4)

$\sin(2) - x\cos(2) - \frac{x^2\sin(2)}{2} + \frac{x^3\cos(2)}{6} + O(x^4)$

An error occurs, if the right hand side contains the series variable: subs(h, y = x) Error: The substitution is invalid. The right side must not contain the series variable. [Series::Puiseux::subs]

Example 23

The method `has` checks, whether an object occurs syntactically in the coefficients, the series variable, the expansion point, or the direction of an element of `Series::Puiseux`:
f := series(sin(x + 2*y), x = PI, 2); has(f, x), has(f, y), has(f, PI), has(f, 2), has(f, Undirected); has(f, hold(sin)), has(f, 3), has(f, sin(2*y)), has(f, x - PI);- sin(2*y) + cos(2*y)*(PI - x) + O((PI - x)^2)

$$-\sin(2\,y) + \cos(2\,y)\,(\pi - x) + O\left((\pi - x)^2\right)$$

TRUE, TRUE, TRUE, TRUE, TRUE

TRUE, TRUE, TRUE, TRUE, TRUE

TRUE, FALSE, TRUE, FALSE

TRUE, FALSE, TRUE, FALSE

The last call returns `FALSE` since the expression `x - PI` occurs only in the screen output, but not in the internal representation of `f`.

g := series(sign(x), x, Right); has(g, Right), has(g, Undirected);1 + O(x^6)

$$1 + O\left(x^6\right)$$

TRUE, FALSE

TRUE, FALSE

Example 24

The method `truncate` discards summands up to the given order:

f := series(x*sin(sqrt(x)), x); Series::Puiseux::truncate(f, 10); Series::Puiseux::truncate(f, 9/2); Series::Puiseux::truncate(f, 7/2); Series::Puiseux::truncate(f, 3); Series::Puiseux::truncate(f, 3/2); Series::Puiseux::truncate(f, 1);x^(3/2) - x^(5/2)/6 + x^(7/2)/120 + O(x^(9/2))

$$x^{3/2} - \frac{x^{5/2}}{6} + \frac{x^{7/2}}{120} + O\left(x^{9/2}\right)$$

x^(3/2) - x^(5/2)/6 + x^(7/2)/120 + O(x^(9/2))

$$x^{3/2} - \frac{x^{5/2}}{6} + \frac{x^{7/2}}{120} + O\left(x^{9/2}\right)$$

x^(3/2) - x^(5/2)/6 + x^(7/2)/120 + O(x^(9/2))

x^(3/2) - x^(5/2)/6 + O(x^(7/2))

x^(3/2) - x^(5/2)/6 + O(x^(7/2))

O(x^(3/2))

O(x^(3/2))

Parameters

f

An arithmetical expression representing a function in x

x

An identifier

x_0

The expansion point: an arithmetical expression. If not specified, the default expansion point 0 is used.

order

The number of terms to be computed: a nonnegative integer. The default order is given by the environment variable ORDER (default value 6).

dir

Either `Left`, `Right`, `Real`, or `Undirected`. This optional argument can be used to specify that the resulting expansion is possibly valid along the real line only. The default is `Undirected`, which means that the expansion is valid in a neighborhood of the expansion point in the complex plane.

Return Values

an object of domain type `Series::Puiseux`, or the value `FAIL`, if the `f` cannot be converted, e.g., if powers with non-rational exponents occur in `f`.

Function Calls

Calling an element of `Series::Puiseux` as a function discards the error term and substitutes the first argument for the series variable. See the description of the method `"func_call"` and “Example 22” on page 6-422.

Operations

`Series::Puiseux` implements the basic arithmetic of truncated series expansions. Use the ordinary arithmetical operators `+, -, *, /, ^`, and `@` for composition.

The arithmetical methods of `Series::Puiseux` usually do not perform any symbolic simplifications. Use `combine`, `expand`, or `normal` to request such simplifications explicitly.

See “Example 5” on page 6-393 and “Example 21” on page 6-419.

Special mathematical functions, such as exp or sin, are overloaded for elements of `Series::Puiseux`; cf. “Example 10” on page 6-403.

The system functions coeff, lcoeff, nthcoeff, ldegree, lmonomial, nthmonomial, lterm, and nthterm work on truncated series expansions. Note that in contrast to polynomials, coefficients, monomials, and terms are counted from the term of lowest order term on. Cf. “Example 17” on page 6-413.

Use the function expr to convert a series expansion to an arithmetical expression (as an element of a kernel domain).

Operands

A series of the domain type `Series::Puiseux` has the following seven operands:

1. a *type flagt* {0, 1},
2. the *branching orderb*, a positive integer,
3. an integer v such that v/b$_{\frac{v}{b}}$ is the order of the leading term,
4. an integer $e \geq v$ such that e/b$_{\frac{e}{b}}$ is the order of the error term,
5. a list of coefficients $l_1, \ldots, l_n$,
6. the *series variablex* and the *expansion pointx*$_0$ in form of an equation $x = x_0$; the expansion point x_0 may be complexInfinity as well,
7. a *direction*, `Undirected`, `Real`, `Left`, or `Right`.

The type flag distinguishes between two different internal representations.

If $t = 0$, then the operands above represent the truncated series expansion

sum(l[(i)](x-x[0])^(fenced(v+i-1)/b)+O(fenced(x-x[0])^(e/b)), 1<=i<=n)

$$\sum_{1 \leq i \leq n} \left(l_i (x - x_0)^{\frac{(v+i-1)}{b}} + O\left((x - x_0)^{e/b}\right) \right)$$

If the expansion point x_0 is complexInfinity, then the operands represent the truncated expansion

sum(l[(i)] * x^(-fenced(v+i-1)/b)+O(x^(-e/b)), 1<=i<=n)

$$\sum_{1 \leq i \leq n} \left(\frac{l_i}{x^{\frac{(i+v-1)}{b}}} + O\left(\frac{1}{x^{\frac{e}{b}}}\right) \right)$$

- A summand l[(i)](x-x[0])^(fenced(v+i-1)/b) $l_i(x - x_0)^{\frac{(v+i-1)}{b}}$ (or l[(i)] * x^(-fenced(v+i-1)/b) $\frac{l_i}{x^{\frac{(i+v-1)}{b}}}$, respectively) is called a *monomial* of the expansion,
- the power fenced(x-x[0])^(fenced(v+i-1)/b) $(x - x_0)^{\frac{(v+i-1)}{b}}$ (or x^(-fenced(v+i-1)/b) $\frac{1}{x^{\frac{(v+i-1)}{b}}}$, respectively) is called a *term*,
- l_i is the corresponding *coefficient*, and
- the exponent fenced(v+i-1)/b $\frac{(v+i-1)}{b}$ is the *order* of the corresponding term or monomial.

If $t = 1$, then the operands above represent the expansion

sum(l[(i)]+O(fenced(x-x[0])^(e/b)), 1<=i<=n) $\sum_{1 \le i \le n} \left(l_i + O\left((x - x_0)^{e/b}\right)\right)$

In this case, the powers of $x - x_0$ are explicitly stored in the list, and l_i contains only terms of growth order O(fenced(x-x[0])^(fenced(v+i-1)/b)) $O\left((x - x_0)^{\frac{(v+i-1)}{b}}\right)$. The corresponding expansion for `x0 = complexInfinity` is

sum(l[(i)]+O(x^(-e/b)), 1<=i<=n) $\sum_{1 \le i \le n} \left(l_i + O\left(\frac{1}{x^{\frac{e}{b}}}\right)\right)$

and l_i contains only terms of growth order O(x^(-fenced(v+i-1)/b)) $O\left(\frac{1}{x^{\frac{(v+i-1)}{b}}}\right)$.

The notions term and order are the same as for $t = 0$, a summand l_i is called a monomial, and the corresponding coefficient is

l[i]/(x-x[0])^((v+i-1)/b)

(or $\frac{l_i}{(x - x_0)^{\frac{v+i-1}{b}}}$

l[i]/x^((v+i-1)/b)

respectively).

The latter type of representation serves for correct expansions around branch points. For example, if we want to expand f(x)=sqrt(x) $f(x) = \sqrt{x}$ around $x = 0$, then the truncated Puiseux series sqrt(-1)*x^(1/2)+O(x^(13/2)) $\sqrt{-1}\sqrt{x} + O\left(x^{13/2}\right)$ does not approximate $f(x)$ in the lower half of the complex plane. With $t = 1$, the expansion fenced(-x)^(1/2)+O(x^(13/2)) $\sqrt{(-x)} + O\left(x^{13/2}\right)$, which approximates $f(x)$ also in the lower part of the complex plane near the origin, can be represented as an object of domain type `Series::Puiseux`.

The direction d has the same meaning as the parameter `dir` of the constructor. If d = *Undirected*, the operands above represent an expansion valid in some neighborhood of the expansion point in the complex plane. Usually, this is an open disc centered at `x0`. If $d \neq$ *Undirected* and x_0 represents a real number, this means that the expansion is valid for real values of x only. If d = *Left* or d = *Right*, then the expansion is valid for $x < x_0$ or $x > x_0$, respectively.

In the case `x_0 = complexInfinity`, and if d = *Undirected*, we have an expansion valid in the neighborhood of the north pole of the Riemann sphere, i.e., for all x in C_$x \in \mathbb{C}$ of sufficiently large absolute value. If d =

Left, we have an expansion around the positive real infinity valid for sufficiently large real values of *x*. Similarly, if *d* = *Right*, we have an expansion around the negative real infinity valid for sufficiently large negative real values of *x*. Finally, if *d* = *Real*, the expansion is valid both around *infinity* and around - ∞.

Cf. "Example 2" on page 6-386.

Element Creation

Typically, objects of type `Series::Puiseux` are generated by calls to series or taylor.

Methods

Mathematical Methods

conjugateComplex conjugation

```
conjugate(s)
```

This method overloads the system function conjugate. Cf. "Example 11" on page 6-404.

contfracConversion into a continued fraction

```
contfrac(s)
```

This method overloads the system function contfrac. Cf. "Example 12" on page 6-405.

diffDifferentiation

```
diff(s, t)
```

This method overloads the system function diff. Cf. "Example 9" on page 6-402.

_divideDivision

```
_divide(s, t)
```

_fconcatFunctional composition

```
_fconcat(s, t)
```

If both `s` and `t` are of type `Series::Puiseux`, then the functional composition can only be defined if the limit point of *t* for values close to its expansion point is equal to the expansion point of *s*. Otherwise, an error occurs.

At least one of the arguments must be of type `Series::Puiseux`. If one of the arguments is not of this type, then it is converted into an element of

`Series::Puiseux` via the constructor. If *s* is not of type `Series::Puiseux`, then it is converted into a series expansion around the limit point of *t*. If *t* is not of type `Series::Puiseux`, then it is converted into a series expansion around 0. The implicit conversion is performed only if the corresponding expression contains exactly one free variable.

This method overloads the system function _fconcat for series expansions, i.e., you may use it in the form `s@t`. See “Example 8” on page 6-398 and “Example 22” on page 6-422.

ImImaginary part

```
Im(s)
```

This method overloads the system function Im. Cf. “Example 11” on page 6-404.

intIntegration

```
int(s, t | t = a ..  b)
```

This method overloads the system function int. Cf. “Example 9” on page 6-402, and the help page of int for a description of further optional arguments.

_invertReciprocal of a series

```
_invert(s)
```

This method overloads the system function _invert, i.e., you may use it in the form `1/s`.

ilaplaceInverse Laplace transform

```
ilaplace(s, u, v)
```

If `u` is not the series variable of `s`, then the coefficients of `s` are transformed, but not the expansion point. Otherwise, the expansion point of `s` must be infinity, `v` must be an identifier, and `s` is transformed term by term. The result is then a series expansion around $v = 0$.

This method overloads the function ilaplace for series expansions. Cf. “Example 13” on page 6-406.

laplaceLaplace transform

```
laplace(s, u, v)
```

If u is not the series variable of s, then the coefficients of s are transformed, but not the expansion point. Otherwise, the expansion point of s must be 0, the order of the leading term of s must be nonnegative, v must be an identifier, and s is transformed term by term. The result is then a series expansion around $v = \infty$.

This method overloads the function laplace for series expansions. Cf. "Example 13" on page 6-406.
_multMultiplication

```
_mult(s, t, , )
```

Use the method `Series::Puiseux::scalmult` to multiply a series expansion s by a constant or a power of $x - x_0$.

This method overloads the system function _mult for series expansions, i.e., you may use it in the form `s*t*...`. Cf. "Example 5" on page 6-393.
_negateNegation

```
_negate(s)
```

This method overloads the system function _negate, i.e., you may use it in the form `-s`.
_plusAddition

```
_plus(s, t, , )
```

This method overloads the system function _plus for series expansions, i.e., you may use it in the form `s+t+...`. Cf. "Example 5" on page 6-393.
_powerExponentiation

```
_power(s, n)
```

If n is a rational number, the direction of s is `Undirected` or `Real`, and the leading coefficient of s is not positive, then the type flag of the result is 1 in general.

If n is not a rational number, then the leading summand of s must not contain the series variable. Otherwise, an error occurs.

This method overloads the system function _power for series expansions, i.e., you may use it in the form `s^n`. Cf. "Example 7" on page 6-397.
ReReal part

```
Re(s)
```

This method overloads the system function Re. Cf. “Example 11” on page 6-404.

revertFunctional inversion

```
revert(s)
```

The expansion point of the inverse is the limit point of `s`.

This method overloads the system function revert. Cf. “Example 8” on page 6-398.

scalmultMultiplication by a single monomial

```
Series::Puiseux::scalmult(s, a, k)
```

seriesSerie expansion

```
series(s, y | y = y0, <order>, <dir>)
```

This method overloads the system function series.

_subtractSubtraction

```
_subtract(s, t)
```

Access Methods

coeffExtract coefficients

```
coeff(s, <x>, n)
```

```
coeff(s, <x>)
```

The second call returns the sequence of all coefficients of `s`, starting with the coefficient of lowest order. (This is the coefficient of the term with the highest exponent if x_0=complexInfinity.)

Specifying the variable `x` is optional; if it is present, it must coincide with the series variable of `s`.

This method overloads the system function coeff. Cf. “Example 14” on page 6-408.

directionDirection of expansion

```
Series::Puiseux::direction(s)
```

indetSerie variable

`Series::Puiseux::indet(s)`
: iszeroZero test

`iszero(s)`

This method overloads the system function iszero. Cf. “Example 18” on page 6-414.

: lcoeffLeading coefficient (of lowest order)

`lcoeff(s)`

This method overloads the system function lcoeff. See “Example 15” on page 6-410 and “Example 17” on page 6-413.

: ldegreeLeading degree

`ldegree(s)`

This method overloads the system function ldegree. See “Example 2” on page 6-386 and “Example 15” on page 6-410.

: lmonomialLeading monomial (of lowest order)

`lmonomial(s)`

This method overloads the system function lmonomial. See “Example 15” on page 6-410 and “Example 17” on page 6-413.

: ltermLeading term (of lowest order)

`lterm(s)`

This method overloads the system function lterm. See “Example 15” on page 6-410 and “Example 17” on page 6-413.

: nthcoeffExtract coefficients

`nthcoeff(s, n)`

This method overloads the system function nthcoeff. See “Example 16” on page 6-411 and “Example 17” on page 6-413

: nthmonomialExtract monomials

`nthmonomial(s, n)`

This method overloads the system function nthmonomial. See “Example 16” on page 6-411 and “Example 17” on page 6-413.

: nthtermExtract terms

```
nthterm(s, n)
```

This method overloads the system function nthterm. See “Example 16” on page 6-411 and “Example 17” on page 6-413.

orderOrder of the error term

```
Series::Puiseux::order(s)
```

pointExpansion point

```
Series::Puiseux::point(s)
```

Conversion Methods

convertConvert any object into a series expansion

```
convert(f)
```

If no expansion point can be determined from `f`, the origin is used. Cf. “Example 19” on page 6-415.

convert_toConvert a series expansion into another domain

```
convert_to(s, T)
```

Use the function expr to convert `s` into an object of a kernel domain.

convert01Convert into a series expansion of type 1

```
Series::Puiseux::convert01(s)
```

convert10Try to convert into a series expansion of type 0

```
Series::Puiseux::convert10(s)
```

For undirected expansions, the conversion is not possible in general, and then `s` is returned. However, you can enforce a conversion (with a not necessarily equivalent result) by using properties. Cf. “Example 3” on page 6-390.

exprConvert a series expansion into an element of a kernel domain

```
expr(s)
```

This method overloads the system function expr. Cf. “Example 20” on page 6-418.

floatConvert numeric parts of the coefficients into floats

```
float(s)
```

This method overloads the system function float. Cf. “Example 20” on page 6-418.

Technical Methods

combineCombine coefficients

```
combine(s)
```

This method overloads the system function combine; see the corresponding help page for further optional arguments. Cf. “Example 21” on page 6-419.

constConvert a constant expression into a truncated series

```
Series::Puiseux::const(f, x | x = x0, n, <d>)
```

If the expansion point `x0` is omitted, `x0 = 0` is assumed. If the direction `d` is omitted, `d = Undirected` is assumed.

Use with care, since this function does not perform type checking. Cf. “Example 1” on page 6-383.

createSyntactical constructor

```
Series::Puiseux::create(b, v, e, l, x, <x0>, <d>)
```

If the expansion point `x0` is omitted, `x0 = 0` is assumed. If the direction `d` is omitted, `d = Undirected` is assumed.

Use with care, since this function does not perform type checking. Cf. “Example 1” on page 6-383.

expandExpand coefficients

```
expand(s)
```

This method overloads the system function expand; see the corresponding help page for further optional arguments. Cf. “Example 21” on page 6-419.

func_callEvaluation at a point

```
Series::Puiseux::func_call(s, t)
```

You may also use this method in the form `s(t)`. Cf. “Example 22” on page 6-422.

hasCheck whether an object occurs syntactically

```
has(s, t)
```

This method overloads the system function has. Cf. “Example 23” on page 6-426.

mapApply a function to all non-zero coefficients

```
map(s, f, <arg1, ,  >)
```

This method overloads the system function map. Cf. “Example 21” on page 6-419.

normalNormal form

```
normal(s)
```

This method overloads the system function normal. Cf. “Example 21” on page 6-419.

oneCreate a truncated series with constant term 1

```
Series::Puiseux::one(x, <x0>, n, <d>)
```

If the expansion point `x0` is omitted, `x0 = 0` is assumed. If the direction `d` is omitted, `d = Undirected` is assumed.

Use with care, since this function does not perform type checking. Cf. “Example 1” on page 6-383.

printPretty-print routine

```
print(s)
```

truncateTruncate a series expansion

```
Series::Puiseux::truncate(s, n)
```

Cf. “Example 24” on page 6-427.

subsReplace subexpressions

```
subs(s, old = new)
```

```
subs(s, [old1 = new1, old2 = new2,  ])
```

If the series variable `x` of `s` does not occur in the left hand sides `old, old1, old2, ...`, then the substitution takes place in the coefficients and in the expansion point of `s`. The series variable must not occur in the right hand sides `new, new1, new2, ...`.

Note In contrast to the usual behavior of `subs`, the result of the substitution is subjected to an additional evaluation.

In the second call, the series variable `x` of `s` must not occur anywhere in the substitution equations. In the first call, `x` is allowed to occur in `old` only if `old` equals `x`. In this case, a change of variable is performed, and `new` must be of the form

```
x0 + a*(b*y - c)^k
```

if `x0 <> complexInfinity` and

```
a*(b*y - c)^k
```

if `x0 = complexInfinity`, where

- `x0` is the expansion point of `s`
- `k` is a non-zero rational number
- `y` is an identifier, which may well be equal to `x`, and otherwise `y` must not occur in the coefficients of `s`.
- `a, b, c` are arithmetical expressions not involving `y`, with `a, b` being non-zero. If the direction of `s` is not `Undirected`, then `a` and `b` must represent real numbers.
- `c` is zero if either `x0 <> complexInfinity` and `k` is positive or `x0 = complexInfinity` and `k` is negative. In this case, the result of the substitution has expansion point complexInfinity.
- If `c` is non-zero, then the result of the substitution has expansion point `c/b`.

Use one of the methods `"_fconcat"` or `"func_call"` for more general substitutions for the series variable.

This method overloads the system function subs; Cf. “Example 22” on page 6-422.

zeroCreate a truncated series with an error term only

```
Series::Puiseux::zero(x, <x0>, n, <d>)
```

If the expansion point `x0` is omitted, `x0 = 0` is assumed. If the direction `d` is omitted, `d = Undirected` is assumed.

Note Although `Series::Puiseux::zero(x, n)` and `O(x^n)` are mathematically equivalent and are printed in the same way, they are different MuPAD objects. The former is an element of type `Series::Puiseux`, while the latter is an element of type O.

Use with care, since this function does not perform type checking. Cf. "Example 1" on page 6-383.

See Also

Series::gseriesasymptseries

Series::gseries

Purpose

Generalized series expansions

Syntax

```
Series::gseries(f, x, <order>, <Left | Right>)
Series::gseries(f, x = a, <order>, <Left | Right>)
```

Description

`Series::gseries` is the domain of series expansions generalizing Taylor, Laurent and Puiseux expansions.

The call `Series::gseries(f, x)` computes a series expansion at the right hand side of $x = 0$.

The system functions series and asympt are the main application of this domain. The latter function only returns elements of this domain, whereas `series` can return an element of `Series::gseries` in cases, where a Puiseux series expansion does not exist.

There may be no need to explicitly create elements of this domain, but to work with the results of the mentioned system functions.

See the help page of the system function asympt for a detailed description of the parameters and examples for working with elements of the domain `Series::gseries`.

Note Note that elements of `Series::gseries` only represents *directional* (real) series expansions.

Environment Interactions

The function is sensitive to the global variable ORDER, which determines the default number of terms of the expansion.

Parameters

f

An arithmetical expression

x

The series variable: an identifier

a

The expansion point: an arithmetical expression or ±infinity

order

The truncation order: a nonnegative integer

Options

Left

Compute a series expansion that is valid for real x smaller than a.

Right

Compute a series expansion that is valid for real x larger than a (the default case).

Return Values

Object of domain type `Series::gseries`, or the value `FAIL`.

Function Calls

Calling an element of `Series::gseries` as a function yields the object itself, regardless of the arguments. The arguments are *not* evaluated.

Operations

`Series::gseries` implements standard arithmetic of generalized series expansions. Use the ordinary arithmetical operators `+`, `-`, `*`, `/`, and `^`.

The system functions coeff, lcoeff, nthcoeff, lterm, nthterm, lmonomial, nthmonomial, and ldegree work on generalized series expansions. See the corresponding help pages of these functions for calling parameters. See the description of these methods below for further details.

The method `"indet"` returns the series variable of the series expansion, i.e., if `s` is an object of the domain `Series::gseries`, then `s::dom::indet(s)` returns the series variable.

The method `"point"` returns the expansion point of the series.

Use the function expr to convert a generalized series expansion into an arithmetical expression (as an element of a kernel domain).

Operands

A series of the domain type `Series::gseries` consists of four operands:

1. A list of pairs $[c_i, f_i]$. Each pair represents a $monomial c_i f_i$ of the series expansion, where the c_i are the *coefficients* and f_i the *terms* of `s`. The coefficients do not contain the series variable.

   This list can be empty, if the order of the expansion is zero.

2. An arithmetical expression `g` representing the *error term* of the form $O(g)$. It may be the integer 0, in which case the expansion is exact.

3. The *series variable* `x`.

4. The *expansion point* `a`.

Methods

Mathematical Methods

_divideDivide two series expansions

```
_divide(s, t)
```

If the arguments are not of domain type `Series::gseries`, then they are converted into such objects. FAIL is returned, if one of these conversions fails.

This method overloads the function _divide for elements of `Series::gseries`, i.e., you may use it in the form `s/t`.

_invertMultiplicative inverse of a series expansion

```
_invert(s)
```

This method overloads the function _invert for elements of `Series::gseries`, i.e., you may use it in the form `1/s`.

_multMultiply series expansions

```
_mult(s, t,  )
```

If both `s` and `t` are series expansions of the domain `Series::gseries`, then the result is a series expansion of the domain `Series::gseries`, too. Both series expansions must have the same series variable and expansion point, otherwise FAIL is returned.

If `s` or `t` is a series expansion of the domain Series::Puiseux, then it is converted into an object of `Series::gseries`. If this fails, then FAIL is

returned. Otherwise, the product is computed and returned as an object of the domain `Series::gseries`.

If `s` is a series expansion and `t` is an arithmetical expression, then `t` is converted into a series expansion via the constructor `Series::gseries` (and vice versa).

Each argument of this method that is not of the domain type `Series::gseries` is converted into such an element, i.e., a generalized series expansion is computed. If this fails, then `FAIL` is returned.

This method overloads the function _mult for elements of `Series::gseries`, i.e., you may use it in the form `s*t*...`.
_negateNegative of a series expansion

```
_negate(s)
```

This method overloads the function _negate for elements of `Series::gseries`, i.e., you may use it in the form `-s`.
_plusAdd series expansions

```
_plus(s, t,  )
```

If both `s` and `t` are series expansions of the domain `Series::gseries`, then the result is a series expansion of the domain `Series::gseries`, too. Both series expansions must have the same series variable and expansion point, otherwise FAIL is returned.

If `s` or `t` is a series expansion of the domain Series::Puiseux, then it is converted into an object of `Series::gseries`. If this fails, then FAIL is returned. Otherwise, the sum is computed and returned as an object of the domain `Series::gseries`.

If `s` is a series expansion and `t` is an arithmetical expression, then `t` is converted into a series expansion via the constructor `Series::gseries` (and vice versa).

Each argument of this method that is not of the domain type `Series::gseries` is converted into such an element, i.e., a generalized series expansion is computed. If this fails, then `FAIL` is returned.

This method overloads the function _plus for elements of `Series::gseries`, i.e., you may use it in the form `s+t+ ...`.
_powerExponentiation of a series expansion

```
_power(s, n)
```

The exponent *n* must not involve the series variable of *s*. Otherwise, an error occurs.

If *n* is a positive integer, then repeated squaring is used for computing the `n`th power of `s`. Otherwise, the binomial theorem is applied after factoring out the leading monomial.

This method overloads the function _power for elements of `Series::gseries`, i.e., you may use it in the form `s^n`.
_subtractSubtract two series expansions

```
_subtract(s, t)
```

If the arguments are not of domain type `Series::gseries`, then they are converted into such objects. FAIL is returned, if one of these conversions fails.

This method overloads the function _subtract for elements of `Series::gseries`, i.e., you may use it in the form `s-t`.
Access Methods

coeffExtract coefficients

```
coeff(s, <n>)
```

This method overloads the function coeff for elements of `Series::gseries`.

indetSerie variable

```
Series::gseries::indet(s)
```

Use the method `"point"` to get the expansion point of `s`.

iszeroZero test

```
iszero(s)
```

This method overloads the function iszero for elements of `Series::gseries`.

lcoeffLeading coefficient

```
lcoeff(s)
```

This method overloads the function lcoeff for elements of `Series::gseries`.

ldegreeLeading degree

```
ldegree(s)
```

This method overloads the function ldegree for elements of `Series::gseries`.

lmonomialLeading monomial

```
lmonomial(s)
```

This method overloads the function lmonomial for elements of `Series::gseries`.

ltermLeading term

```
lterm(s)
```

This method overloads the function lterm for elements of `Series::gseries`.

nthcoeffExtract a coefficient

```
nthcoeff(s, n)
```

This method overloads the function nthcoeff for elements of `Series::gseries`.

nthmonomialExtract a monomial

```
nthmonomial(s, n)
```

This method overloads the function nthmonomial for elements of `Series::gseries`.

nthtermExtract a term

```
nthterm(s, n)
```

This method overloads the function nthterm for elements of `Series::gseries`.

pointExpansion point

```
Series::gseries::point(s)
```

Use the method `"indet"` to get the series variable of `s`.

Conversion Methods

convertConvert an object into a generalized series expansion

```
Series::gseries::convert(x)
```

convert_toConvert a generalized series expansion into other domains

```
Series::gseries::convert_to(s, T)
```

`T` might be the domain DOM_POLY, where the sum of monomials is considered as a polynomial in the indeterminates of the third operand of `s`.

If `T` is the domain DOM_EXPR, then the conversion is the same as implemented by the method `"expr"` (see below).

If `T` is the domain Series::Puiseux, then the system tries to convert `s` into a Puiseux series. If the conversion is not possible, FAIL is returned.

Use the function expr to convert `s` into an object of a kernel domain.

createCreate simple and fast a generalized series expansion

```
Series::gseries::create(list, errorTerm, x = a)
```

Note This method should be used with caution, because no argument checking is performed. Use it to *create*, not to compute elements of `Series::gseries`.

---

exprConvert a generalized series expansion into an element of a kernel domain

```
expr(s)
```

This method overloads the function expr for elements of `Series::gseries`.

seriesApply the function `series` to a generalized series expansion

```
series(s, x | x = x0, <order>, <dir>)
```

This method overloads the function series for elements of `Series::gseries`. See the corresponding help page for a description of the possible arguments.

Technical Methods

combineApply the function `combine` to all terms

```
combine(s, <target>)
```

This method overloads the system function combine. See the corresponding help page for a description of the optional argument `target`.

hasCheck whether an object occurs syntactically

```
has(s, t)
```

This method overloads the system function has.

mapMap a function to the coefficients

```
map(s, func,  )
```

This method overloads the function map for elements of `Series::gseries`.

printPretty-print routine

```
print(s)
```

subsSubstitute into a generalized series expansion

```
subs(s, x = a,  )
```

This method overloads the function subs for elements of `Series::gseries`.

TeXLaTeX formatting

```
Series::gseries::TeX(s)
```

This method is called by the system function generate::TeX.

Series::Puiseux

export – Export Data

==REFNAME==

export::stl

Purpose

Export STL data

Syntax

```
export::stl(filename, [x, y, z], u = u_min .. u_max,
v = v_min .. v_max, options)
export::stl(n, [x, y, z], u = u_min .. u_max, v =
v_min .. v_max, options)
export::stl(filename, object_1, <object_2,  >, options)
export::stl(n, object_1, <object_2,  >, options)
```

Description

`export::stl` is used to create a triangulation of a parametrized surface and write the triangulation data in STL format to an external file.

STL files contain triangulation data of 3D surfaces. Each triangle is stored as a unit normal and three vertices. The normal and the vertices are specified by three coordinates each, so there is a total of 12 numbers stored for each triangle. Read the "Background" section of this help page for further details.

If the surface is closed, it is regarded as the boundary of a 3D solid. The normals of the triangles written into the STL file should point from the inside of the body to the outside.

Note Note that the direction of the normals that `export::stl` writes into the STL file depend on the parametrization $x(u, v)$, $y(u, v)$, $z(u, v)$!

If `p_1 = (x(u, v), y(u, v), z(u, v))`, `p_2 = (x(u + du, v), y(u + du, v), z(u + du, v))`, `p_3 = (x(u, v + dv), y(u, v + dv), z(u, v + dv))` are the corners of a triangle, the normal associated with this triangle is the cross product of the side `p_2 - p_1` times the side `p_3 - p_2`. The routine `export::stl` chooses neighboring values of the surface parameters with `du = (`u_{max}` - `u_{min}`)/(n_u - 1)` and `dv = (`v_{max}` - `v_{min}`)/(n_v - 1)`, respectively.

Note Thus, if your parametrization is such that the cross product of the vectors $p_2 - p_1$ and $p_3 - p_2$ does not point to the outside of your body, you just need to let one of the parameters (u, say) run from u_{max} to u_{min} instead of from u_{min} to u_{max}. Just replace your call

```
export::stl(filename, [x,y,z], u = `u_{min}` ..  `u_{max}`,
v = `v_{min}` ..  `v_{max}`)
```

by

```
export::stl(filename, [x,y,z], u = `u_{max}` ..  `u_{min}`,
v = `v_{min}` ..  `v_{max}`).
```

Up to the irrelevant ordering in the STL file, the triangles generated by these calls are the same apart from the direction of the normal associated with each triangle.

If the file is specified by a character string, the corresponding file is opened and closed, automatically.

As an alternative to specifying the file by a string, the user may open the file herself via fopen in `Write` mode and pass the file descriptor returned by fopen to `export::stl`. If binary data are to be written to the file, make sure that it is opened with the `Raw`, i.e., call `fopen(filename, Write, Raw)`.

Note Note that `export::stl` does not close the file automatically if it is specified by a file descriptor. It remains open after `export::stl` has finished its job. The file needs to be closed explicitly by the user using fclose.

If the file is specified by a character string, the name may correspond to an absolute or a relative path name. In particular, the environment

variable WRITEPATH is taken into account. The details on the help page of fopen hold for `export::stl`, too.

Note With the option `Append`, the file is first opened for reading and, after reading of the data in the file, opened for writing. If no absolute pathname is used to specify the file, make sure that the environment variables READPATH and WRITEPATH point to the same folder. Alternatively, it is a good idea to place the file in the same folder as the MuPAD notebook which you are currently using. If this notebook is saved on the disk of your computer, the absolute path is available as the environment variable NOTEBOOKPATH. Thus, specifying a file named "myfile.stl", say, by the absolute path name `NOTEBOOKPATH."myfile.stl"` ensures that the file is found in the same folder as your notebook.

Text files generated with the option `Text` or the equivalent `Ascii` can be opened and read with any text editor. However, binary files generated with the option `Bin` or the equivalent options `Binary` or `Raw` are faster to create and to process.

The file generated by `export::stl` can be read and visualized in MuPAD using the plot primitive plot::SurfaceSTL.

If the file name given ends in "`.gz`", `export::stl` writes a compressed file which can be read by any program supporting `gzip` compression.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. The current value of DIGITS determines the number of significant decimal digits with which the STL data are written to the specified file. (This holds for text files. In binary STL files all numerical values have a precision of about 7 decimal digits.) For the internal computation of the data by MuPAD, the value of DIGITS is temporarily increased by 10 to minimize round-off effects.

The STL data generated by `export::stl` are written to the specified file.

Examples

Example 1

We generate a sphere given by the following parametrization:
x:= cos(u)*sin(v): y:= sin(u)*sin(v): z:= cos(v):

We call `export::stl` to generate the STL data and write them into a file named “sphere.stl”. The file is to be generated in the same directory as the current MuPAD notebook that we are using. Hence, we specify an absolute path name for the file using the path of the current notebook. If this notebook was saved to the disk of your computer, this path is available in the environment variable NOTEBOOKPATH:
sysassign(NOTEBOOKPATH, null()):filename:= NOTEBOOKPATH."sphere.stl": export::stl(filename, [x, y, z], u = 0 .. 2*PI, v = 0 .. PI, Text)

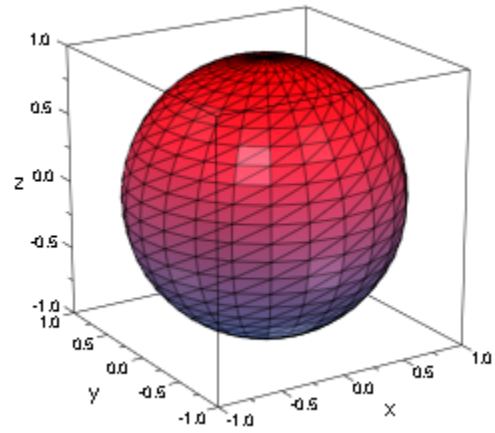
Since the file was created in `Text` format, it can be opened with any text editor. It should look like this:

```
solid MuPADtoSTL1
 facet normal -0.06540070486 -0.008610166138 -0.9978219344
  outer loop
   vertex 100.0 100.0 300.0
   vertex 112.607862 103.3782664 298.7167292
   vertex 113.0526192 100.0 298.7167292
  endloop
 endfacet
 facet normal -0.1950260058 -0.02567566076 -0.9804619409
  outer loop
   vertex 113.0526192 100.0 298.7167292
   vertex 112.607862 103.3782664 298.7167292
   vertex 125.0 106.6987298 294.8888739
  endloop
 endfacet

 ...
```

```
endsolid MuPADtoSTL1
```

We reimport the STL data and visualize the surface using plot::SurfaceSTL:
plot(plot::SurfaceSTL(filename, MeshVisible))



We reduce the number of significant output digits to a reasonable size. Further, we specify a mesh size and request a specific output box:
DIGITS:= 7: export::stl(filename, [x, y, z], u = 0 .. 2*PI, v = 0 .. PI, Mesh = [10, 10], OutputBox = [-100 .. 100, -100 .. 100, -100 .. 100], Text):

The file now should look like this:

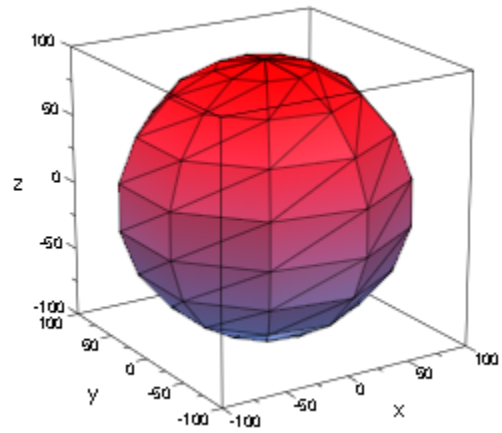
```
solid MuPADtoSTL2
 facet normal -0.1733024 -0.06307691 -0.9828467
  outer loop
   vertex -3.10912 0.000000002143114 100.0
   vertex 24.32249 22.66816 93.96926
   vertex 32.7003 0.000000002143114 93.96926
```

```
  endloop
 endfacet

 ...

endsolid MuPADtoSTL2
```

We visualize the new content of the file:
plot(plot::SurfaceSTL(filename, MeshVisible))

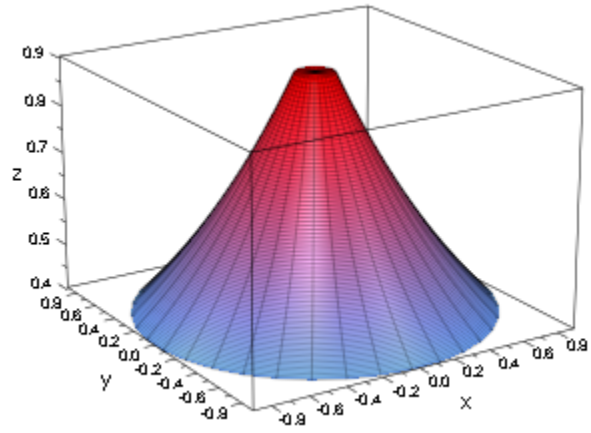


stdlib::gprof(NIL, filename):delete x, y, z, filename, DIGITS:

Example 2

We specify the parametrization of the surface by a mixture of expressions and procedures:
x:= piecewise([0.1 < u < 0.9, u*cos(v)], [Otherwise, 0]): y:= (u, v) -> piecewise([0.1 < u < 0.9, u*sin(v)], [Otherwise, 0]): z:= (u, v) -> if u <= 0.1 then exp(-0.1) elif u < 0.9 then exp(-u) else exp(-0.9) end_if:

This is the surface that we wish to export to STL:
plot(plot::Surface([x, y, z], u = 0 .. 1, v = 0 .. 2*PI, Mesh = [100, 36])):

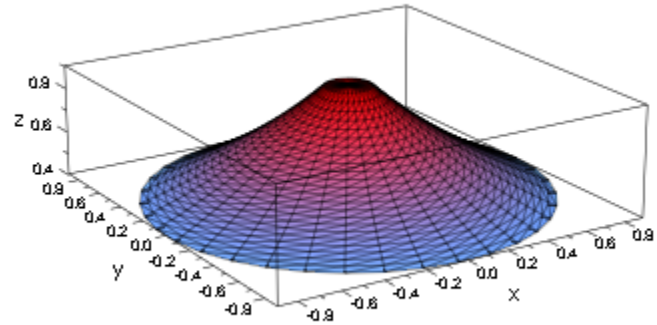


We assume that there is no external file “sample.stl”. We create it by opening it in `Write` mode in the same directory as the current MuPAD notebook that we are using. Hence, we specify an absolute path name for the file using the path of the current notebook. If this notebook was saved to the disk drive of your computer, this path is available in the environment variable NOTEBOOKPATH. The file descriptor `n` returned by fopen is passed to `export::stl`:

```
filename:= NOTEBOOKPATH."sample.stl":  DIGITS:= 7:
export::stl(filename, [x, y, z], u = 0 ..  1, v = 0 ..  2*PI, Mesh = [30,
36])filename:= "sample.stl": DIGITS:= 7: export::stl(filename, [x, y, z], u
= 0 ..  1, v = 0 ..  2*PI, Mesh = [30, 36])
```

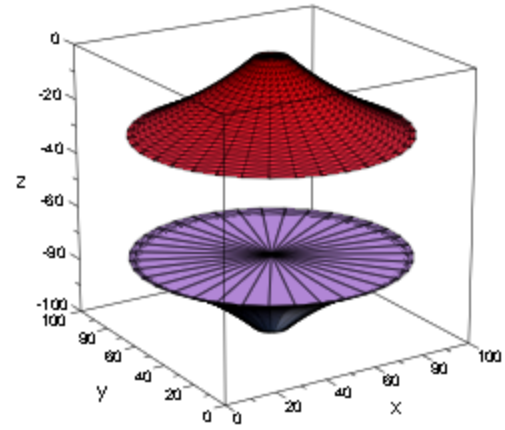
We reimport the STL data and visualize the surface using plot::SurfaceSTL:

```
plot(plot::SurfaceSTL(filename, MeshVisible))
```



We can append a further surface to the file using the option `Append`:
export::stl(filename, [x, y, -z], u = 0 .. 1, v = 0 .. 2*PI, Mesh = [30, 36], OutputBox = [0 .. 100, 0 .. 100, -100 .. 0], Append)

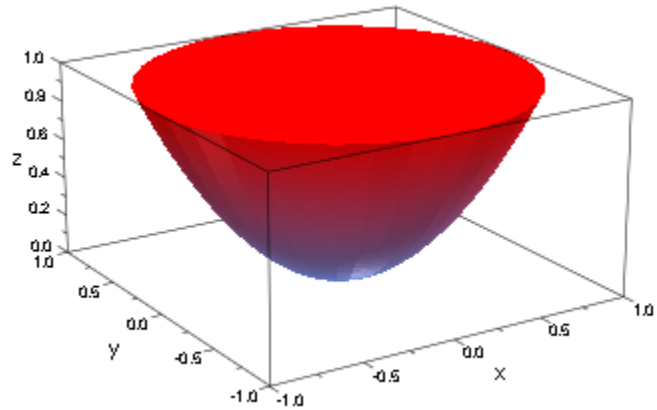
We visualize the new content of the file via plot::SurfaceSTL:
plot(plot::SurfaceSTL(filename, MeshVisible))



stdlib::gprof(NIL, filename):delete x, y, z, filename, DIGITS:

Example 3

We wish to create a closed surface consisting of a “bowl” with a “lid”. bowl:= [u*cos(v), u*sin(v), u^2], u = 0 .. 1, v = 0 .. 2*PI: lid:= [u*cos(v), u*sin(v), 1], u = 0 .. 1, v = 0 .. 2*PI:NOTEBOOKPATH:= "":filename:= NOTEBOOKPATH."sample.stl": DIGITS:= 7: export::stl(filename, bowl, Mesh = [30, 36]): export::stl(filename, lid, Mesh = [30, 36], Append): plot(plot::SurfaceSTL(filename), Scaling = Constrained):

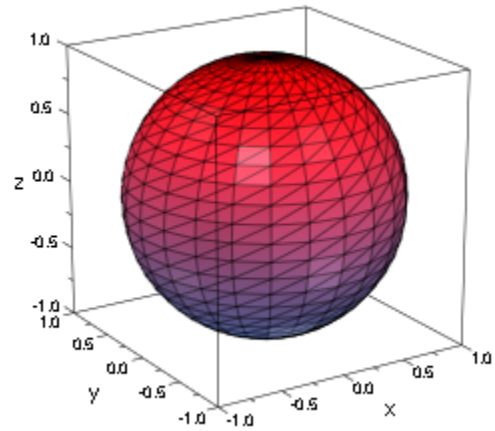


stdlib::gprof(NIL, filename):delete filename, DIGITS:

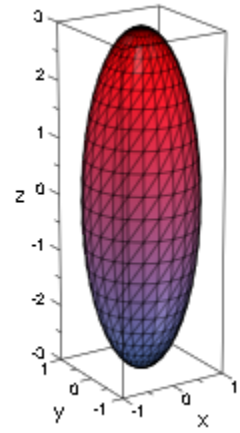
Example 4

We demonstrate the options `Scaling = Constrained` and `Scaling = Unconstrained`. With `Scaling = Constrained`, the coordinates given by the parametrization `x, y, z` are scaled by the same factor to fit the surface into the output box. Here, we create a sphere of radius 1. The output box is not a cube: the range for the `z` coordinate is notably larger than for `x` and `y`. Nevertheless, the sphere stays a sphere when using `Scaling = Constrained`. However, the output box is not completely filled by the sphere:
sysassign(NOTEBOOKPATH, null()):x:= cos(u)*sin(v): y:= sin(u)*sin(v): z:= cos(v): DIGITS:= 7: filename:= NOTEBOOKPATH."sphere.stl": export::stl(filename, [x, y, z], u = 0 .. 2*PI, v = 0 .. PI, OutputBox = [-1 ..

1, -1 .. 1, -3 .. 3], Scaling = Constrained): plot(plot::SurfaceSTL(filename, Scaling = Constrained, MeshVisible))



With `Scaling = Unconstrained`, the sphere is deformed to an ellipsoid filling the output box:
export::stl(filename, [x, y, z], u = 0 .. 2*PI, v = 0 .. PI, OutputBox = [-1 .. 1, -1 .. 1, -3 .. 3], Scaling = Unconstrained): plot(plot::SurfaceSTL(filename, Scaling = Constrained, MeshVisible))



stdlib::gprof(NIL, filename):delete x, y, z, filename, DIGITS:

Parameters

filename

A file name: a non-empty character string

n

A file descriptor provided by fopen: a positive integer

object$_1$, object$_2$, ...

3D graphical objects of the `plot` library

x

y

z

The coordinate functions: arithmetical expressions or piecewise objects depending on the surface parameters u and v. Alternatively, procedures that accept 2 input parameters u, v and return a numerical value when the input parameters are numerical.

u

The first surface parameter: an identifier or an indexed identifier.

u_{min} .. u_{max}

The range for the parameter u: u_{min}, u_{max} must be numerical real values.

v

The second surface parameter: an identifier or an indexed identifier.

v_{min} .. v_{max}

The range for the parameter v: v_{min}, v_{max} must be numerical real values.

Options

Mesh

Option, specified as `Mesh = [nu, nv]`

Sets the mesh size: the integer n_u determines, how many equidistant points in the `u` direction are used to sample the parametrization `x, y, z` numerically. Correspondingly, the integer n_v determines, how many equidistant points in the `v` direction are used. Thus, a regular mesh of $(n_u - 1)(n_v - 1)$ rectangles is used. Each rectangle is split into 2 triangles, resulting in a triangulation consisting of $2(n_u - 1)(n_v - 1)$ triangles. The default is `Mesh = [25, 25]`.

OutputBox

Option, specified as `OutputBox = [xmin .. xmax, ymin .. ymax, zmin .. zmax]`

By default, the coordinates of the mesh points defining the STL object are written into the file as provided by the parametrization of the surface. Thus, if several objects are written into the file via the option `Append`, the position of the objects in space is transparent and can be controlled by the user via a suitable parametrization. However, many devices such as Rapid Prototyping tools with which the STL file shall be processed,

impose severe restrictions on the data in the STL file. E.g., the original STL specification requires that the x, y, z coordinates of the mesh points are positive. Many devices require that the coordinates must lie in a prescribed range (between 0 and 100, say). The option `OutputBox` provides a simple mean to shift and scale the coordinates given by the parametrization to a prescribed range.

The option `OutputBox = [` x_{min}`..` x_{max}`,` y_{min}`..` y_{max}`,` z_{min}`..` z_{max}`]` sets the output box defined by numerical values x_{min}, , z_{max}. The mathematical coordinates `x(u, v), y(u, v), z(u, v)` with `u`, `v` ranging from u_{min} to u_{max} and from v_{min} to v_{max}, respectively, are shifted and scaled such that the output coordinates written to the STL file range between the values x_{min} and x_{max}, y_{min} and y_{max}, z_{min} and z_{max}.

Note If several objects are written to the file via the option `Append`, only the very last call of `export::stl` should bear the option `OutputBox`!

This last call shifts and scales all coordinates of all surfaces inside the file such that the entire scene of objects fits into the output box. The relative size and positions of the objects are preserved.

See “Example 3” on page 7-10.

This option is rather expensive since all data in the STL file need to be modified!

This option is not available if the file was opened outside `export::stl` and passed by a file descriptor `n`.

Scaling

Option, specified as `Scaling = Unconstrained` or `Scaling = Constrained`

With `Scaling = Unconstrained`, the surface is scaled by different factors in the x, y, and z direction, such that it fills the output box set by the option `OutputBox - [`x_{min}` .. `x_{max}`, `y_{min}` .. `y_{max}`, `z_{min}` .. `z_{max}`]` . Thus, the output coordinates of a sphere define an ellipsoid with diameters given by the side lengths of the output box. This is the default setting.

With `Scaling = Constrained`, the surface is scaled by the same factor in the x, y, and z direction such that it fits into the output box set by the option `OutputBox = [`x_{min}` .. `x_{max}`, `y_{min}` .. `y_{max}`, `z_{min}` .. `z_{max}`]` . A sphere will remain a sphere even if the sides of the output box have different lengths.

This option is ignored if not used in conjunction with the `OutputBox` option.

Ascii

Bin

Binary

Raw

Text

With the synonymous flags `Bin`, `Binary`, or `Raw`, respectively, the STL file is created as a binary file. If a binary file is specified by a file descriptor `n`, make sure that is was opened by the command `n:= fopen(filename, Write, Raw)`. With the synonymous flags `Text` and `Ascii`, repectively, the STL file is created as a text file. The default is `Bin`.

Append

With this flag, the STL data of the surface are appended to an existing STL file named “filename”. If no such file exists, it is created and processed as without `Append`. This option is not available if the file was opened outside `export::stl` and passed by a file descriptor `n`.

Return Values

`null()` object.

Algorithms

There are two storage formats available for STL files, which are ASCII and BINARY. ASCII files are human-readable while BINARY files are smaller and faster to process. Both ASCII as well as BINARY files can be generated by `export::stl`. A typical ASCII STL file looks like this:

```
solid sample
 facet normal -4.470293E-02 7.003503E-01 -7.123981E-01
  outer loop
   vertex -2.812284E+00 2.298693E+01 0.000000E+00
   vertex -2.812284E+00 2.296699E+01 -1.960784E-02
   vertex -3.124760E+00 2.296699E+01 0.000000E+00
  endloop
 endfacet
 ...
endsolid sample
```

STL BINARY files have the following format:

```
Bytes  Type   Description
80     ASCII  header, no data significance
4      uint   number of facets in file

4      float  normal  x - start of facet
4      float  normal  y
4      float  normal  z
4      float  vertex1 x
4      float  vertex1 y
```

```
4      float  vertex1 z
4      float  vertex2 x
4      float  vertex2 y
4      float  vertex2 z
4      float  vertex3 x
4      float  vertex3 y
4      float  vertex3 z
2      byte   not used  - end of facet
       ...
```

Facet orientation: The facets define the surface of a 3D object. As such, each facet is part of the boundary between the interior and the exterior of the object. The orientation of the facets (which way is "out" and which way is "in") is specified redundantly in two ways which should be consistent. First, the direction of the normal is outward. Second, which is most commonly used nowadays, the facet vertices are listed in counter-clockwise order when looking at the object from the outside (right-hand rule).

Vertex-to-vertex rule: Each triangle must share two vertices with each of its adjacent triangles. In other words, a vertex of one triangle cannot lie on the side of another.

Axes: The format specifies that all vertex coordinates must be strictly positive numbers. However, it seems that – with a few exceptions – most software used today (MuPAD included) allow negative coordinates as well.

Units: The STL file does not contain any scale information; the coordinates may be interpreted in arbitrary units.

Further details about the STL file format are available in the web, e.g., at:

- www.ennex.com/fabbers/StL.asp,
- www.math.iastate.edu/burkardt/data/stl/stl.html and

- rpdrc.ic.polyu.edu.hk/content/stl/stl_introduction.htm.

Collections of STL sample files can be found in the web, e.g., at:

fp – Functional Programming

==REFNAME==

fp::apply

Purpose

Apply function to arguments

Syntax

```
fp::apply(f, <e,  >)
```

Description

`fp::apply(f,a)` returns `f(a)`.

`fp::apply` applies the function `f` to the arguments given by `e`, ...

Environment Interactions

Same side effects as when calling `f(e,...)` directly.

Examples

Example 1

Apply the function `f` to `x` and `y`:
fp::apply(f, x, y)f(x, y)

$$f(x, y)$$

Example 2

Apply the functions of the first list to the arguments given by the second list:
zip([sin, cos], [x, y], fp::apply)[sin(x), cos(y)]

$$[\sin(x), \cos(y)]$$

Parameters

f

Function

e

Object used as argument

Return Values

Result of the function call `f(e,...)`.

fp::bottom

Purpose

Function that never returns

Syntax

```
fp::bottom()
```

Description

`fp::bottom()` never returns because it raises an error.

Environment Interactions

Raises an error in any case.

Examples

Example 1

Calling `fp::bottom` is equivalent to calling error with a fixed error string:
fp::bottom() Error: The bottom is reached. [fp::bottom]

`fp::bottom` is used to indicate the bottom of a recursion inside a traperror call. In most cases, programs not using `fp::bottom` will be more readable.

Return Values

This function never returns.

fp::curry

Purpose

Curry an n-ary function

Syntax

```
fp::curry(f, <n>)
```

Description

`fp::curry(f)` returns the higher-order function (x) -> fenced((y) -> f(x, y)) $x \to (y \to f(x, y))$.

`fp::curry` returns the curried version of the `n`-ary function `f`. If no arity `n` is given, then the function is assumend to be binary.

If `n` is smaller than 2 then `f` is returned. Otherwise, given a *n*-ary function *f*, `fp::curry` returns the function (x_1) -> fenced((x_2, '…', x_n) -> f(x_1, '…',x_n)) $x_1 \to ((x_2, \ldots, x_n) \to f(x_1, \ldots, x_n))$

Examples

Example 1

Create curried versions of binary and 3-nary functions:
cf := fp::curry(f): cf(x)(y)f(x, y)

$f(x, y)$

cg := fp::curry(g, 3): cg(x)(y)(z)g(x, y, z)

$g(x, y, z)$

Example 2

A curried version of `_plus` may be used to create a function which increments its argument by `1`:
inc := fp::curry(_plus)(1): inc(x)x + 1

$x + 1$

Parameters

f

n-ary function

n

Nonnegative integer

Return Values

Unary higher-order function.

fp::expr_unapply

Purpose

Create a functional expression from an expression

Syntax

```
fp::expr_unapply(e, <x,  >)
```

Description

`fp::expr_unapply(e,x)` tries to interpret the expression `e` as a function in `x` and to return a functional expression computing that function.

`fp::expr_unapply` views the expression `e` as a function in the indeterminates `x,...` and tries to return a functional expression computing that function. If `fp::expr_unapply` cannot find a functional expression `FAIL` is returned.

If no indeterminates are given, any indeterminates of `e` found by indets are used.

Examples

Example 1

Get the functional expression computing `sin(x)`:
fp::expr_unapply(sin(x), x)sin

sin

fp::expr_unapply(sin(x[1]), x[1])sin

sin

Example 2

Get the functional expression computing `sin(x)^2+cos(x)^2`:
fp::expr_unapply(sin(x)^2 + cos(x)^2)cos^2 + sin^2

$\cos^2 + \sin^2$

Parameters

e

Expression

x

Identifier or indexed identifier

Return Values Functional expression or `FAIL`.

See Also fp::unapply

fp::fixargs

Purpose

Create function by fixing all but one argument

Syntax

```
fp::fixargs(f, n, <e,  >)
```

Description

`fp::fixargs(f,1,y)` returns the function (x) -> f(x, y)$x \to f(x, y)$.

`fp::fixargs` returns an unary function, defined by fixing all but the `n`-th argument of the function `f` to the values given by `e...`.

Thus, given a m-ary function f and m - 1 values e_1, ..., e_{m-1}, `fp::fixargs` returns the function

(x) -> f(e[1], Symbol::hellip, e[(n-1)], x, e[n], Symbol::hellip, e[(m-1)])

$$x \to f(e_1, \ldots, e_{n-1}, x, e_n, \ldots, e_{m-1})$$

Examples

Example 1

Fix the first and third argument of `f` to `x1` and `x3`:
fp::fixargs(f, 2, x1, x3)(y)f(x1, y, x3)

$$f(x1, y, x3)$$

Example 2

Create a function which increments its argument by one:
inc := fp::fixargs(_plus, 1, 1): inc(x)x + 1

$$x + 1$$

Example 3

Create a function which tests the identifier `x` for a type:
type_of_x := fp::fixargs(testtype, 2, x): map([DOM_INT, DOM_IDENT], type_of_x)[FALSE, TRUE]

[FALSE, TRUE]

Parameters

f

Function

n

Positive integer defining free argument

e

Object used as fixed argument

Return Values

Unary function.

fp::fixedpt

Purpose

Returns fixed point of a function

Syntax

```
fp::fixedpt(f)
```

Description

`fp::fixedpt(f)` returns the fixed point of the unary function `f`.

`fp::fixedpt` is implemented as the *Y* combinator which is defined as follows:

funcDecl(Y, f,g(f)(g(f)))

$Y: f \to g(f)(g(f))$

where the function *g* is defined as

funcDecl(g, f, _outputSequence(h, Symbol::blank, Symbol::rightarrow, Symbol::blank, x, Symbol::blank, Symbol::rightarrow, Symbol::blank, f(h(h))(x)))

$g: f \to h \to x \to f(h(h))(x)$

Examples

Example 1

A function computing the Fibonacci numbers is created as a fixed point: fb2 := (f,n) -> if n <= 2 then 1 else f(n-1) + f(n-2) end: fib := fp::fixedpt(fp::curry(fb2)): fib(i) $ i=1..91, 1, 2, 3, 5, 8, 13, 21, 34

```
1, 1, 2, 3, 5, 8, 13, 21, 34
```

Parameters

f

Unary function

Return Values

Unary function.

fp::fold

Purpose

Create function which iterates over sequences

Syntax

```
fp::fold(f, <e,  >)
```

Description

`fp::fold` returns a function which repeatedly applies `f` to sequences of arguments, where the expressions `e...` are used as starting values.

Thus, given the function *f* and the starting values e_1, …, e_n, `fp::fold` returns the function which is defined by

(x_1, x_2, ‘…‘, x_m) -> f(x_m, _outputSequence(‘…‘, f(x_2, f(x_1, e_1, ‘…‘, e_n)), ‘…‘))

$$(x_1, x_2, \ldots, x_m) \to f(x_m, \ldots f(x_2, f(x_1, e_1, \ldots, e_n))\ldots)$$

for any positive integer m. If the argument sequence is void (i.e. $m = 0$) the function simply returns the sequence (e_1, …, e_n).

Examples

Example 1

A call to `fp::fold` returns a function, which accepts an arbitrary number of arguments:
fp::fold(f, x)(y1, y2, y3)f(y3, f(y2, f(y1, x)))

$$f(y3, f(y2, f(y1, x)))$$

Example 2

The function `pset` returns the power set of the set given by its arguments:
addelem := (x,y) -> y union map(y, _union, {x}): pset := fp::fold(addelem, {{}}): pset(a,b,c){{}, {c}, {a}, {b}, {b, c}, {a, b}, {a, c}, {a, b, c}}

$$\{\varnothing, \{c\}, \{a\}, \{b\}, \{b, c\}, \{a, b\}, \{a, c\}, \{a, b, c\}\}$$

Parameters

f

Function

e

Object used as starting value

Return Values

Function.

fp::nest

Purpose

Repeated composition of function

Syntax

```
fp::nest(f, n)
```

Description

`fp::nest(f,n)` returns the `n`-fold repeated composition of the function `f`.

Thus, given the function `f`, `fp::nest` returns the identity function id if `n` is 0 and otherwise the function

f(f(_outputSequence(‘…‘, f(x), ‘…‘)))

$f(f(\ldots f(x)\ldots))$

`n`-fold repeated.

Note that `fp::nest` is obsolete, one should use the `@@` operator or its functional form _fnest instead. It is only supported for compatibility with former versions of MuPAD.

Examples

Example 1

Apply the 3-fold repeated composition of `f` to `x`:
fp::nest(f, 3)(x)f(f(f(x)))

$f(f(f(x)))$

Example 2

Numerically finding a fixed point of the function cos by repeated application:
p :=fp::nest(cos, 100)(1.0): p, cos(p)0.7390851332, 0.7390851332

0.7390851332, 0.7390851332

Parameters

f

Function

n

Nonnegative integer

Return Values

Function.

See Also

_fconcat_fnestfp::nestvals

fp::nestvals

Purpose

Repeated composition returning intermediate values

Syntax

```
fp::nestvals(f, n)
```

Description

`fp::nestvals(f, n)` returns a function which applies the function `f` *n*-fold repeatedly to its argument and returns the intermediate *n* + 1 values as a list.

Thus `fp::nestvals` returns the function [x, f(x), ‘…‘, f(f(_outputSequence(‘…‘, f(x), ‘…‘)))] $[x, f(x), \ldots, f(f(\ldots f(x)\ldots))]$

The function returned is equivalent to `[_fnest(f,i) $i=0..n]`, but more efficient.

Examples

Example 1

Apply `f` 3 times nested to `x`:
fp::nestvals(f, 3)(x)[x, f(x), f(f(x)), f(f(f(x)))]

$[x, f(x), f(f(x)), f(f(f(x)))]$

Example 2

Apply cos 4 times nested to `1.0` and return the result and intermediate values:
fp::nestvals(cos, 4)(1.0)[1.0, 0.5403023059, 0.8575532158, 0.6542897905, 0.7934803587]

[1.0, 0.5403023059, 0.8575532158, 0.6542897905, 0.7934803587]

Parameters

f

Function

n

Nonnegative integer

Return Values Function.

See Also _fconcat_fnest

fp::unapply

Purpose

Create a procedure from an expression

Syntax

```
fp::unapply(e, <x,  >)
```

Description

`fp::unapply` views the expression `e` as a function in the indeterminates `x,...` and returns a procedure computing that function.

If no indeterminates are given, any indeterminates of `e` found by indets are used.

Examples

Example 1

Get the procedure computing `sin(x)^2+cos(y)^2`:
s := fp::unapply(sin(x)^2 + cos(y)^2, x, y)(x, y) -> cos(y)^2 + sin(x)^2

$$(x, y) \to \cos(y)^2 + \sin(x)^2$$

Parameters

e

Expression

x

Identifier or indexed identifier

Return Values

Procedure.

Overloaded By

`e`

See Also

fp::expr_unapply

9

generate – Generate Input to Other Programs

==REFNAME==

generate::C

Purpose

Generate C formatted string

Syntax

```
generate::C(e, <NoWarning>)
```

Description

`generate::C(e)` generates C code for the MuPAD expression `e`.

`generate::C` returns a C formatted string representing an expression, equation, list of equations or a matrix.

An equation represents an assignment in C code. The type of the assignment is `double`.

When generating C code for a matrix, the generator assigns only nonzero elements. See “Example 3” on page 9-3.

To print an output string to a file, use the fprint function. Use the printing option `Unquoted` to remove quotation marks and to expand special characters like line breaks and tabs.

Use the generate::optimize function to optimize the MuPAD code before converting it to C code. See “Example 5” on page 9-3.

The `NoWarning` option lets you suppress warnings. See “Example 6” on page 9-3.

Examples

Example 1

The code generator converts a list of equations to a sequence of assignments:

```
generate::C([x1 = y2^2*(y1 + sin(z)), x2 = tan(x1^4)]): print(Unquoted,
%) x1 = (y2*y2)*(y1+sin(z)); x2 = tan(x1*x1*x1*x1);
```

Example 2

MuPAD matrix and array indexing differs from C array indexing. By default, MuPAD array indices start with 1, and C array indices start with 0. To create the code compatible with the default indexing in C, the `generate::C` function decrements each index by one:

```
A:= matrix([[1,2],[3,4]]):  generate::C(A)."\n".
generate::C(hold(Determinante = A[1,1]*A[2,2] - A[1,2]*A[2,1])):
```

print(Unquoted, %) A[0][0] = 1.0; A[0][1] = 2.0; A[1][0] = 3.0; A[1][1] = 4.0; Determinante = A[0][0]*A[1][1]-A[0][1]*A[1][0];

Example 3

Generated C code does not include assignments for zero elements of a matrix:
A:= matrix([[1, 0, 0],[0, 0, 1]]): print(Unquoted, generate::C(A)) A[0][0] = 1.0; A[1][2] = 1.0;

Example 4

If the first index of an array is not 1, the `generate::C` function issues a warning:
A:= array(1..2, 2..3, [[1,2],[3,4]]): print(Unquoted, generate::C(A)) Warning: The array index 'A[1..2, 2..3]' is out of range 1..n. [DOM_ARRAY::CF] A[0][1] = 1.0; A[0][2] = 2.0; A[1][1] = 3.0; A[1][2] = 4.0;

Example 5

The `generate::C` function does not optimize your code:
print(Unquoted, generate::C([x = a + b, y = (a + b)^2])): x = a+b; y = pow(a+b,2.0);

You can use the generate::optimize function before converting your MuPAD expression to C code. For example, this function can reduce the number of operations by finding common subexpressions:
print(Unquoted, generate::C(generate::optimize([x = a + b, y = (a + b)^2]))): x = a+b; y = x*x;

Example 6

By default, the `generate::C` function can issue warnings:
print(Unquoted, generate::C(f(x))) Warning: Function "f" is not verified to be a valid C function. t0 = f(x);

If you started using `generate::C` recently, the warnings can help you identify the potential issues in the converted code. If you want to suppress warnings, use the `NoWarning` option:
print(Unquoted, generate::C(f(x), NoWarning)) t0 = f(x);

Parameters

e

An expression, equation, list of equations, or a matrix

Options

NoWarning

Suppress warnings.

Return Values

`generate::C` returns a string containing C code.

See Also

fprintprintgenerate::optimize

generate::fortran

Purpose

Generate FORTRAN formatted string

Syntax

```
generate::fortran(e, <NoWarning>)
```

Description

`generate::fortran(e)` generates FORTRAN code for the MuPAD expression `e`.

`generate::fortran` returns a FORTRAN formatted string representing an expression, equation, list of equations or a matrix.

An equation represents an assignment in FORTRAN code. The type of the assignment is `double`.

When generating FORTRAN code for a matrix, the generator assigns only nonzero elements. See “Example 2” on page 9-5.

To print an output string to a file, use the fprint function. Use the printing option `Unquoted` to remove quotation marks and to expand special characters like line breaks and tabs.

Use the generate::optimize function to optimize the MuPAD code before converting it to FORTRAN code. See “Example 4” on page 9-6.

The `NoWarning` option lets you suppress warnings. See “Example 5” on page 9-6.

Examples

Example 1

The code generator converts a list of equations to a sequence of assignments:

```
generate::fortran([x[1] = y[2 + i]^2*(y[1] + sin(z)), x[2] = tan(x[1]^4)]):
print(Unquoted,%) x(1) = (sin(z)+y(1))*y(i+2)**2 x(2) = tan(x(1)**4)
```

Example 2

Generated FORTRAN code does not include assignments for zero elements of a matrix:

```
A:= matrix([[1, 0, 0],[0, 0, 1]]): print(Unquoted, generate::fortran(A))
A(1,1) = 1.0D0 A(2,3) = 1.0D0
```

Example 3

If the first index of an array is not 1, the `generate::fortran` function issues a warning:
A:= array(1..2, 2..3, [[1,2],[3,4]]): print(Unquoted, generate::fortran(A)) Warning: The array index 'A[1..2, 2..3]' is out of range 1..n. [DOM_ARRAY::CF] A(1,2) = 1.0D0 A(1,3) = 2.0D0 A(2,2) = 3.0D0 A(2,3) = 4.0D0

Example 4

The `generate::fortran` function does not optimize your code:
print(Unquoted, generate::fortran([x = a + b, y = (a + b)^2])): x = a+b y = (a+b)**2

You can use the generate::optimize function before converting your MuPAD expression to FORTRAN code. For example, this function can reduce the number of operations by finding common subexpressions:
print(Unquoted, generate::fortran(generate::optimize([x = a + b, y = (a + b)^2]))): x = a+b y = x**2

Example 5

By default, the `generate::fortran` function can issue warnings:
print(Unquoted, generate::fortran(gamma(x))) Warning: Function "gamma" requires a FORTRAN_2008 compiler. t0 = gamma(x)

If you started using `generate::fortran` recently, the warnings can help you identify the potential issues in the converted code. If you want to suppress warnings, use the `NoWarning` option:
print(Unquoted, generate::fortran(gamma(x), NoWarning)) t0 = gamma(x)

Parameters

e

An expression, equation, list of equations, or a matrix

Options

NoWarning

Suppress warnings.

Return Values `generate::fortran` returns a string containing FORTRAN code.

See Also fprintprintgenerate::optimize

generate::MATLAB

Purpose

Generate MATLAB formatted string

Syntax

```
generate::MATLAB(e, <NoWarning>)
```

Description

`generate::MATLAB(e)` generates MATLAB code for the MuPAD expression `e`.

`generate::MATLAB` returns a MATLAB formatted string representing an expression, equation, list of equations or a matrix.

`generate::MATLAB` assumes that the type of converted data is `double`. See “Example 1” on page 9-9.

An equation represents an assignment in MATLAB code. See “Example 4” on page 9-10.

When generating MATLAB code for a matrix, the generator produces a matrix of zeros, and then it substitutes nonzero elements. See “Example 2” on page 9-9.

Use the generate::optimize function to optimize the MuPAD code before converting it to the MATLAB syntax. See “Example 5” on page 9-10.

To display generated MATLAB code on screen, use the print function. Use the printing option `Unquoted` to remove quotation marks and to expand special characters like line breaks and tabs. If a generated code line is longer than the TEXTWIDTH setting, the print function breaks that line into several shorter lines. The inserted line continuation character (\) is not valid in MATLAB. To avoid inserting line continuation characters, increase the TEXTWIDTH setting or use the fprint function to write generated code to a file.

`generate::MATLAB` does not create a MATLAB function. You can print an output string to a file using the fprint function with the `Unquoted` option. See “Example 6” on page 9-10.

Working from the MATLAB workspace you can create a MATLAB function containing your expression. To call the MuPAD expression

from the MATLAB workspace, use `evalin` or `feval` functions. See "Create MATLAB Functions from MuPAD Expressions".

If you work with the Simulink® products, you can copy the generated code and paste it into a Simulink block. Also, you can call the MuPAD expression from the MATLAB workspace using `evalin` or `feval` functions. Working from the MATLAB workspace you can automatically create a Simulink block containing your expression. See "Create MATLAB Function Blocks from MuPAD Expressions".

The `NoWarning` option lets you suppress warnings. See "Example 7" on page 9-10.

Examples

Example 1

By default, MATLAB stores all numeric values as double-precision floating-point. In accordance with the default MATLAB data type, `generate::MATLAB` converts the elements of expressions, equations, and matrices to the `double` format:

```
print(Unquoted, generate::MATLAB(x^2 + y/3 + 1/6)) t0 =
y*(1.0/3.0)+x^2+1.0/6.0;
```

Example 2

The generator produces a matrix of zeros, and then it replaces nonzero elements:

```
A:= matrix([[1, 0, 0],[0, 0, 1]]): print(Unquoted, generate::MATLAB(A))
A = zeros(2,3); A(1,1) = 1.0; A(2,3) = 1.0;
```

Example 3

If the first index of an array is not 1, the `generate::MATLAB` function issues a warning:

```
A:= array(1..2, 2..3, [[1,2],[3,4]]): print(Unquoted,
generate::MATLAB(A)) Warning: The array index 'A[1..2,
2..3]' is out of range 1..n. [DOM_ARRAY::CF] A = zeros(2,2); A(1,2) =
1.0; A(1,3) = 2.0; A(2,2) = 3.0; A(2,3) = 4.0;
```

Example 4

When generating MATLAB code from equations, you get assignments instead of equations. For example, generate MATLAB code for the following list of equations:
f := generate::MATLAB([x = exp(t*s), y = sin(t)*cos(s)]): print(Unquoted, f) x = exp(s*t); y = cos(s)*sin(t);

Example 5

The `generate::MATLAB` function does not optimize your code:
print(Unquoted, generate::MATLAB([x = a + b, y = (a + b)^2])): x = a+b; y = (a+b)^2;

You can use the generate::optimize function before converting your MuPAD code to MATLAB syntax. For example, this function can reduce the number of operations by finding common subexpressions:
f := generate::optimize([x = a + b, y = (a + b)^2]): print(Unquoted, generate::MATLAB(f)): x = a+b; y = x^2;

Example 6

To create a file with a MATLAB formatted string representing a symbolic expression, use the fprint function:
A:= matrix([[1, 0, 0],[0, 0, 1]]): fprint(Unquoted, Text, "matrixA.m", generate::MATLAB(A))

If the file matrixA.m already exists, fprint replaces the existing MATLAB code with the converted symbolic expression. You can open and edit the resulting file.

Example 7

By default, the `generate::MATLAB` function can issue warnings:
print(Unquoted, generate::MATLAB(g(x))) Warning: Function "g" is not verified to be a valid MATLAB function. t0 = g(x);

If you started using `generate::MATLAB` recently, the warnings can help you identify the potential issues in the converted code. If you want to suppress warnings, use the `NoWarning` option:
print(Unquoted, generate::MATLAB(g(x), NoWarning)) t0 = g(x);

Parameters

e

An expression, equation, list of equations, or a matrix

Options

NoWarning

Suppress warnings.

Return Values

`generate::MATLAB` returns a string containing MATLAB code.

See Also

`matlabFunction` | `matlabFunctionBlock` | `simscapeEquation`fprintprintgenerate::optimizegenerate::Simscape

generate::MathML

Purpose

Generate MathML from expressions

Syntax

```
generate::MathML(e, options)
```

Description

`generate::MathML(e)` returns a MathML object representing `e`. This object may be printed to a file using fprint.

Examples

Example 1

`generate::MathML` generates an object containing the MathML code:

```
generate::MathML(hold(int)(exp(x^2)/x, x))
```

<math xmlns='http://www.w3.org/1998/Math/MathML'> <semantics> <mrow xref='No8'> <mo>∫</mo> <mfrac xref='No7'> <msup xref='No5'> <mn>ⅇ</mn> <msup xref='No4'> <mi xref='No2'>x</mi> <mn xref='No3'>2</mn> </msup> </msup> <mi xref='No6'>x</mi> </mfrac> <mo>ⅆ</mo> <mi xref='No1'>x</mi> </mrow> <annotation-xml encoding='MathML-Content'> <apply id='No8'> <int/> <bvar> <ci id='No1'>x</ci> </bvar> <apply id='No7'> <divide/> <apply id='No5'> <exp/> <apply id='No4'> <power/> <ci id='No2'>x</ci> <cn id='No3' type='integer'>2</cn> </apply> </apply> <ci id='No6'>x</ci> </apply> </apply> </annotation-xml> <annotation encoding='MuPAD'> int(exp(x^2)/x, x) </annotation> </semantics> </math>

The output of annotations and MathML presentation can be suppressed with the options `Presentation` and `Annotation`:

```
generate::MathML(hold(int)(exp(x^2)/x, x),
Presentation = FALSE, Annotation = FALSE)
```

<math xmlns='http://www.w3.org/1998/Math/MathML'> <apply id='No8'> <int/> <bvar> <ci id='No1'>x</ci> </bvar> <apply id='No7'> <divide/> <apply id='No5'> <exp/> <apply id='No4'> <power/> <ci id='No2'>x</ci> <cn id='No3' type='integer'>2</cn> </apply> </apply> <ci id='No6'>x</ci> </apply> </apply> </math>

MathML output can be written into a file using fprint:

```
fprint(Text, "filename.mathml", generate::MathML(hold(int)(exp(x^2)/x, x))):
```

Parameters

e

An arithmetical expression

Options

Annotation

Option, specified as `Annotation = FALSE`

Disables the output of annotations.

Content

Option, specified as `Content = FALSE`

Disables the MathML Content output.

Presentation

Option, specified as `Presentation = FALSE`

Disables the MathML Presentation output.

Return Values

`generate::MathML` returns an object containing MathML code.

Overloaded By

`e`

See Also

fprintprint

generate::optimize

Purpose

Generate optimized code

Syntax

```
generate::optimize(r)
```

Description

`generate::optimize(r)` returns a sequence of equations representing an "optimized computation sequence" for the input expression `r`. Each equation in the sequence corresponds to an assignment of a subexpression of the input expression to a "temporary variable." Common subexpressions are computed only once, thus reducing the total operation count.

The number of operations, namely additions (or subtractions), multiplications (or divisions) and in particular functions calls of the output is usually lower than the number of such operations of the input. This facility is useful for code generation.

Examples

Example 1

In this first example, we show the effects of optimization for a simple expression:
generate::optimize(cos(x^2) + x^2*sin(x^2) + x^4)[t2 = x^2, t1 = cos(t2) + t2*sin(t2) + t2^2]

$$[t2 = x^2,\ t1 = \cos(t2) + t2\,\sin(t2) + t2^2]$$

The "blind" computation of the input expression requires 7 multiplications, 2 additions and 2 function calls. The optimized version introduces a "temporary variable" `t2` storing the subexpression `x^2` that is used to compute the final result `t1`. This reduces the total cost to 3 multiplications, 2 additions and 2 function calls, albeit using 1 extra assignment to the temporary variable `t2`.

Example 2

Here we repeat the exercise of the first example but with an array of expressions:

```
generate::optimize(array(1..2, 1..2, [[x^3, x^2],[x^2, x^4]]))[t2 = x^2, t1
= array(1..2, 1..2, [[t2*x, t2], [t2, t2^2]])]
```

$$\left[t2 = x^2,\ t1 = \begin{pmatrix} t2\,x & t2 \\ t2 & t2^2 \end{pmatrix}\right]$$

The original input requires 6 multiplications. The optimized version needs only 3 multiplications and 1 extra assignment.

Example 3

We optimize a list of equations representing a computation sequence for 3 variables `t`, `C[1]`, `C[2]`:

```
generate::optimize([t = u, C[1] = t*(u - w)^2, C[2] = 2*(u - w)^3])[t = u,
t1 = u - w, t2 = t1^2, C[1] = t*t2, C[2] = 2*t1*t2]
```

$$[t = u,\ t1 = u - w,\ t2 = t1^2,\ C_1 = t\,t2,\ C_2 = 2\,t1\,t2]$$

The original computation requires 5 multiplications and 2 subtractions. The optimized version needs 4 multiplications and 1 subtraction.

Note that since these examples involve small expressions, the computational savings are slight. In the case of very large expressions, optimization can yield a considerable dividend.

Parameters

r

An expression, array or list of equations

Return Values

List of equations.

Algorithms

A number of FORTRAN compilers provide optimizers. However, they use algorithms of complexity $O(n^2)$ and $O(n^3)$ where n is the size of the input expressions. For large amounts of code, these algorithms may "break." MuPAD provides a reasonably good scalar (as in non-vectorized and non-parallelized) optimizer which is limited

to common subexpression optimization and using binary powering for integer powers. It uses hashing of expressions so that given a sub-expression, it can determine in constant time if this subexpression has already occurred. This results in an overall efficiency which is of lower complexity namely, $O(n)$ i.e. linear in the size of the input expressions to be optimized, Hence overall efficiency is not compromised by very large expressions. This does mean that not all possible optimizations are made but nonetheless a number of reductions including the exploitation of some symmetries are possible.

It should be understood that "optimization" is meant in the sense of compiler optimization. The end-result rarely corresponds to the absolute irreducible minimum number of operations – or as in the case of FORTRAN code generation, the absolute minimum of floating-point operations (FLOPS). Achieving this limit can be extremely difficult if not impossible especially for large computational sequences. Nonetheless, in a number of real-life instances, the MuPAD optimizer can yield a very useful result. Additionally, MuPAD provides symbolic manipulation tools such as `factor` which can yield additional reduction in operation costs.

In many cases of optimization, it is most often a matter of how best to pose the problem so as to fully exploit every possible symmetry or useful natural property of the given problem.

generate::Simscape

Purpose

Generate Simscape equation

Syntax

```
generate::Simscape(e, <NoWarning>)
```

Description

`generate::Simscape(e)` generates Simscape™ code for the MuPAD expression `e`.

Simscape software extends the Simulink product line with tools for modeling and simulating multidomain physical systems, such as those with mechanical, hydraulic, pneumatic, thermal, and electrical components. Unlike other Simulink blocks, which represent mathematical operations or operate on signals, Simscape blocks represent physical components or relationships directly. With Simscape blocks, you build a model of a system just as you would assemble a physical system. For more information about Simscape software, see www.mathworks.com/products/simscape/.

You can extend the Simscape modeling environment by creating custom components. When you define a component, use the equation section of the component file to establish the mathematical relationships among a component's variables, parameters, inputs, outputs, time, and the time derivatives of each of these entities. MuPAD and Simscape software let you perform symbolic computations and use the results of these computations in the equation section. The `generate::Simscape` function translates the results of symbolic computations to Simscape language equations.

`generate::Simscape` returns a Simscape formatted string representing an expression, equation, list of expressions or equations, or a matrix.

`generate::Simscape` converts the identifier `t` to the variable `time` in the resulting Simscape code. However, the name `t` of a function call does not change during conversion. See "Example 1" on page 9-19 and "Example 2" on page 9-19.

`generate::Simscape` converts any derivative with respect to the variable `t` to the Simscape notation `x.der`, where `x` is the time-dependent variable. See "Example 3" on page 9-19.

`generate::Simscape` assumes that the type of converted data is `double`. See “Example 4” on page 9-19.

When generating Simscape code for a matrix, the generator produces a dense matrix. See “Example 5” on page 9-20.

Use the generate::optimize function to optimize the MuPAD code before converting it to the Simscape syntax. See “Example 6” on page 9-20.

`generate::Simscape` converts piecewise expressions to Simscape code by using the `if` statements. See “Example 7” on page 9-20.

The equation section of a Simscape component file supports a limited number of functions. See the list of Supported Functions for more information. If a symbolic equation contains the functions that are not available in the equation section of a Simscape component file, `generate::Simscape` cannot correctly convert these equations to Simscape equations. Such expressions do not trigger an error. The following types of expressions are prone to invalid conversion:

- Expressions with infinities
- Expressions that contain programming structures, such as loops, coditional statements (except for the `if` statement), and map function calls
- Expressions that contain intervals, sets, and lists

To display generated Simscape code on screen, use the print function. To remove quotation marks and to expand special characters like line breaks and tabs, use the printing option `Unquoted`. If a generated code line is longer than the TEXTWIDTH setting, the print function breaks that line into several shorter lines. The inserted line continuation character (\) is not valid in Simscape. To avoid inserting line continuation characters, increase the TEXTWIDTH setting or use the fprint function to write generated code to a file.

To write generated Simscape code to a file, use the fprint function with the `Unquoted` option. See “Example 8” on page 9-21.

The `NoWarning` option lets you suppress warnings. See "Example 2" on page 9-19.

Examples

Example 1

The `generate::Simscape` function replaces all instances of the MuPAD identifier `t` with the variable `time`. For example, convert the following equation to the Simscape equation:

```
e := A*sin(w*t) + B*cos(w*t) = 0: print(Unquoted, generate::Simscape(e))
B*cos(time*w)+A*sin(time*w) == 0.0;
```

Example 2

The `generate::Simscape` function does not change the function name `t` in function calls:

```
print(Unquoted, generate::Simscape([t(), t(0), t(x)])) Warning: Function
"t" is not verified to be a valid Simscape function. Warning: Function
"t" is not verified to be a valid Simscape function. Warning: Function
"t" is not verified to be a valid Simscape function. t(); t(0.0); t(x);
```

This example produces a few identical warnings. If you started using `generate::Simscape` recently, warnings can help you identify potential issues in the converted code. If you want to suppress warnings, use the `NoWarning` option:

```
print(Unquoted, generate::Simscape([t(), t(0), t(x)], NoWarning)) t();
t(0.0); t(x);
```

Example 3

When generating Simscape code, the `generate::Simscape` function converts the derivatives with respect to the variable `t` to the Simscape notation `x.der`. Here `x` is the time-dependent variable. For example, generate the Simscape code for the equation `e` that has two time-dependent variables:

```
e := x'(t) + diff(y(t), t) + 2*x + 5 = 0:  print(Unquoted,
generate::Simscape(e)) x*2.0+x.der+y.der+5.0 == 0.0;
```

Example 4

By default, Simscape stores all numeric values as double-precision floating-point values. In accordance with this default data type,

`generate::Simscape` converts the elements of expressions, equations, and matrices to the double format:
print(Unquoted, generate::Simscape(x^2 + y/3 + 1/6))
y*(1.0/3.0)+x^2+1.0/6.0;

Example 5

`generate::Simscape` can generate Simscape code for a MuPAD matrix. In contrast to generate::MATLAB (which produces sparse matrices), the Simscape code generator produces dense matrices:
A:= matrix([[1, 0, 0],[0, 0, 1]]): print(Unquoted, generate::Simscape(A))
A = [1.0 0.0 0.0 0.0 0.0 1.0];

Example 6

The `generate::Simscape` function does not optimize your code:
print(Unquoted, generate::Simscape([x = a + b, y = (a + b)^2])): x == a+b; y == (a+b)^2;

You can use the generate::optimize function before converting your MuPAD code to Simscape syntax. For example, this function can reduce the number of operations by finding common subexpressions:
print(Unquoted, generate::Simscape(generate::optimize([x = a + b, y = (a + b)^2]))): x == a+b; y == x^2;

Example 7

The `generate::Simscape` function also accepts piecewise expressions. The function uses `if` statements when generating Simscape code for piecewise expressions. For example, the Fourier transform of the following expression is a piecewise function:
FT := fourier(exp(-abs(x)*abs(t))*sin(t)/t, t, s)piecewise([x <> 0, arctan((s + 1)/abs(x)) - arctan((s - 1)/abs(x))])

$$\begin{cases} \arctan\left(\frac{s+1}{|x|}\right) - \arctan\left(\frac{s-1}{|x|}\right) & \text{if } x \neq 0 \end{cases}$$

`generate::Simscape` converts this result to a valid Simscape expression:
print(Unquoted, generate::Simscape(FT)) if (x ~= 0.0),
-atan((s-1.0)/abs(x))+atan((s+1.0)/abs(x)); else NaN; end;

Example 8

To create a text file with a Simscape formatted string representing a symbolic expression, use the fprint command:
e := x'(t) + 2*x + 5 = 0: fprint(Unquoted, Text, "eqn.txt", generate::Simscape(e))

If the file `eqn.txt` already exists, fprint replaces the existing Simscape code with the converted symbolic expression. You can open and edit the resulting text file.

Parameters

e

An expression, equation, list of equations, or a matrix

Options

NoWarning

Suppress warnings.

Return Values

`generate::Simscape` returns a string containing Simscape code. In case of invalid conversion, the returned value is an arbitrary string.

See Also

`matlabFunction` | `matlabFunctionBlock` | `simscapeEquation`fprintprintgenerate::optimizegenerate::MATLAB

generate::TeX

Purpose

Generate formatted string from expressions

Syntax

```
generate::TeX(e)
```

Description

`generate::TeX(e)` returns a TeX formatted string representing `e`. This string may be printed to a file using fprint. Use the printing option `Unquoted` to remove quotes and to expand special characters like newlines and tabs.

The output string may be used in the math-mode of TeX. Note that `generate::TeX` doesn't break large formulas into smaller ones.

Examples

Example 1

`generate::TeX` generates a string containing the TeX code:
generate::TeX(hold(int)(exp(x^2)/x, x))"\\int \\frac{\\mathrm{e}^{x^2}}{x} \\,\\mathrm{d} x"

```
"\int \frac{\mathrm{e}^{x^2}}{x} \,\mathrm{d} x"
```

Use print with option `Unquoted` to get a more readable output:
print(Unquoted, generate::TeX(hold(int)(exp(x^2)/x, x))) \int \frac{\mathrm{e}^{x^2}}{x} \,\mathrm{d} x

Example 2

This example shows how to write a `"TeX"`-method for a domain. The domain elements represent open intervals. The `"TeX"`-method makes recursive use of `generate::TeX` in order to TeX-format its operands and concatenates the resulting strings to a new string containing the TeX output of the interval.
Interval := newDomain("Interval"): Interval::TeX := e -> "\\left]".generate::TeX(extop(e, 1)). ", ".generate::TeX(extop(e, 2))."\\right[": print(Unquoted, generate::TeX(new(Interval, 1, x^(a+2)))): \left]1, x^{a + 2}\right[

Parameters

e

An arithmetical expression

Return Values

`generate::TeX` returns a string containing TeX code.

Overloaded By

e

Algorithms

The TeX packages amsmath and amssymb are needed.

A domain overloading `generate::TeX` has to provide a function as its `"TeX"`-slot which translates its elements into a TeX formatted string. This function may use `generate::TeX` recursively. See “Example 2” on page 9-22.

Graph – Graph Theory

Graph

Graph::addEdges

Purpose

Adds one or several edges to a graph

Syntax

```
Graph::addEdges(G, Edge)
Graph::addEdges(G, Edge, <EdgeWeights = ew>, <EdgeCosts
= ec>, <EdgeDescriptions = ed>)
```

Description

`Graph::addEdges` adds one or several edges to an already existing Graph. An edge is represented by a list containing two vertices of the graph. A warning is raised if one of the specified edges does already exist in the graph.

`Graph::addEdges(G,Edge)` adds the edge(s) `Edge` to the graph `G`. The two vertices of each edge must be vertices in the given graph. Otherwise an error is raised. If an edge is specified that already exists, a warning will be printed that this edge is not used.

With `Graph::addEdges(G, Edge,EdgeWeights=ew,EdgeCosts=ec, EdgeDescriptions=ed)` the weight, cost and description of each edge can be set to every edge additionally. If these specifications are missing, the default value `0(=None)` is assumed. If a specification is used it has to hold exactly the same number of values as there are edges. Otherwise an error will be raised.

Note The value `None` can be used in the specification lists for every edge that is not to be specified explicitly.

Examples

Example 1

First, an undirected graph with two vertices and no edges is created. Then two edges are added:
G := Graph([a, b, c, d], []): Graph::printEdgeInformation(G): G := Graph::addEdges(G, [[a, b], [c, d]]): Graph::printEdgeInformation(G)
No edges. Edges existing in the graph: ---------- [a, b], [c, d], [b, a], [d, c]

As you can see, `[b,a]` and `[d,c]` were inserted automatically.
G2 := Graph::addEdges(G, [[a,d]]):Graph::getEdges(G2)[[a, d], [d, a], [a, b], [c, d], [b, a], [d, c]]

[[a, d], [d, a], [a, b], [c, d], [b, a], [d, c]]

Now, what happens if an edge is inserted that already exists in the graph?
G := Graph::addEdges(G, [[d, c]]) Warning: The following edges were not used for operation: [[d, c]]. [Graph::selectEdge] 'Graph(...)'

Graph(...)

Suppose, we try to insert an edge with a vertex not existing in the graph:
G := Graph::addEdges(G, [[a, 5]]) Error: One or more edges contain vertices that are not in list '[5]'. [Graph::addEdges]

Now let's see what happens when a directed graph is created:
G := Graph([a, b, c, d], [], Directed): G := Graph::addEdges(G, [[a, b], [b, c], [c, d]], EdgeWeights = [2/8, -5, PI], EdgeCosts = [30, -40, None]): Graph::printGraphInformation(G) Vertices: [a, b, c, d] Edges: [[a, b], [b, c], [c, d]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: [a, b] = 1/4, [b, c] = -5, [c, d] = PI (other existing edges have no weight) Edge costs: [a, b] = 30, [b, c] = -40 (other existing edges have costs zero) Adjacency list (out): a = [b], b = [c], c = [d], d = [] Adjacency list (in): a = [], b = [a], c = [b], d = [c] Graph is directed.

Have a close look at the Edge costs line. The edge `[c,d]` is not mentioned explicitly due to the value `None`:
G2 := Graph::addEdges(G, [[a, b], [a, d]], EdgeWeights=[10, 20], EdgeCosts = [80, 90], EdgeDescriptions = ["First way", "Second way"]): Graph::printGraphInformation(G2) Warning: The following edges were not used for operation: [[a, b]]. [Graph::selectEdge] Vertices: [a, b, c, d] Edges: [[a, d], [a, b], [b, c], [c, d]] Vertex weights: no vertex weights. Edge descriptions: [a, d] = "Second way" Edge weights: [a, b] = 1/4, [b, c] = -5, [c, d] = PI, [a, d] = 20 (other existing edges have no weight) Edge costs: [a, b] = 30, [b, c] = -40, [a, d] = 90 (other existing edges have costs

zero) Adjacency list (out): a = [b, d], b = [c], c = [d], d = [] Adjacency list (in): a = [], b = [a], c = [b], d = [a, c] Graph is directed.

If an edge has specifications, but exist already in the graph, the specifications will not change. (see Information for edge `[a, b]` above)

Parameters

G

Graph

Edge

List of one or more edges

ew

ec

Lists of numbers

ed

List of texts

b

Boolean value

Options

EdgeWeights

The weight(s) of the new edge(s). Default is 0.

EdgeCosts

The cost(s) of the new edge(s). Default is 0.

EdgeDescriptions

The description(s) for the new edge(s). Default is no text.

Return Values

Graph with the correct edges inserted.

Graph::addVertices

Purpose

Adds one or several vertices to a graph

Syntax

```
Graph::addVertices(G, Vertex, <VertexWeights = vw>)
```

Description

`Graph::addVertices` adds one or several vertices to an already existing graph. A vertex is represented by an arbitrary expression. A warning is raised if one of the specified vertices does already exist in the graph.

`Graph::addVertices(G, Vertex)` adds the vertices in `Vertex` to the graph `G`. If a vertex is specified that already exists, a warning will be printed that this vertex (and it's vertex weight) is not used.

With `Graph::addVertices(G, Vertex,VertexWeights=vw)` the weight can be set to every vertex additionally. If these specifications are missing, the default value `0(=None)` is assumed. If a specification is used it has to hold exactly the same number of values as there are vertices. Otherwise an error will be raised.

Note The value `None` can be used in the specification lists for every edge that is not to be specified explicitly.

Examples

Example 1

First, an undirected graph with two vertices and no edges is created. Then two vertices are added:
G := Graph([a, b, c, d], []): Graph::printVertexInformation(G): G := Graph::addVertices(G, [e, f]): Graph::printVertexInformation(G)
Vertices existing in the graph: ---------- Vertex a has weight None Vertex b has weight None Vertex c has weight None Vertex d has weight None Vertices existing in the graph: ---------- Vertex a has weight None Vertex b has weight None Vertex c has weight None Vertex d has weight None Vertex e has weight None Vertex f has weight None

No weights were specified, so every vertex has weight `None`. In the algorithms default-values will be used accordingly.

Now, what happens if a vertex is inserted that already exists in the graph?
G2 := Graph::addVertices(G, [a, g], VertexWeights=[10, 100]): Graph::printVertexInformation(G2) Warning: The following vertices already exist: [a]. [Graph::selectVertex] Vertices existing in the graph: ---------- Vertex a has weight None Vertex b has weight None Vertex c has weight None Vertex d has weight None Vertex e has weight None Vertex f has weight None Vertex g has weight 100

If a vertex weight is specified for a vertex already existing, it will not be changed (see Vertex `a` above)

Parameters

G

Graph

Vertex

List of one or more vertices

vw

Lists of numbers

Options

VertexWeights

The weight(s) of the new vertex/vertices. Default is 0.

Return Values

Graph with the correct vertices inserted.

Graph::admissibleFlow

Purpose

Checks a flow for admissibility in a Graph

Syntax

```
Graph::admissibleFlow(G, f)
```

Description

`Graph::admissibleFlow(G, f)` checks if the flow `f` is admissible in the Graph `G` according to its vertices and their capacities.

`Graph::admissibleFlow` checks whether a given flow is an admissible flow in the specified graph. A flow in a graph is a table `t`, where `t[[i,j]]` gives the number of units flowing from vertex `i` to vertex `j`. `Graph::admissibleFlow` returns TRUE if the flow is admissible. Otherwise FALSE is returned.

`Graph::admissibleFlow` does not check whether the flow is admissible, if a flow from vertex `i` to vertex `j` is allowed to pass through other vertices. See “Example 2” on page 10-7.

Examples

Example 1

In a cyclic graph with default capacities (1), the flow with one unit flowing from each vertex to its successor is certainly admissible:
G1 := Graph::createCircleGraph([v1, v2, v3, v4]):
Graph::admissibleFlow(G1, table([v1, v2] = 1, [v2, v3] = 1, [v3, v4] = 1, [v4, v1] = 1))TRUE

```
TRUE
```

Example 2

The flow must be specified in whole. `Graph::admissibleFlow` does not include “hops”, like skipping vertices in the path:
Graph::admissibleFlow(Graph::createCircleGraph([v1, v2, v3]), table([v1, v3] = 1))FALSE

```
FALSE
```

Parameters

G

Graph

f

The flow, specified in a table

Return Values

Either TRUE or FALSE

Graph::bipartite

Purpose

Finds out if a graph is bipartite.

Syntax

```
Graph::bipartite(G, <Bool | Lists>)
```

Description

`Graph::bipartite(G)` finds out wether G is bipartite or not.

`Graph::bipartite(G, Sets)`: If G is bipartite, then a list containing two lists will be returned. Each of the lists contains the vertices belonging to the set. If G is not bipartite, then `FAIL` will be returned instead of any list.

`Graph::bipartite(G, Bool)` offers the same result as `Graph::bipartite(G)`. If G is bipartite, then `TRUE` will be returned, otherwise `FALSE`.

Examples

Example 1

A small graph containing 3 vertices with 2 edges connecting them is created:
G := Graph([a, b, c], [[a, b], [b, c]]): Graph::bipartite(G, Lists);
Graph::bipartite(G, Bool)[[b], [a, c]]

[[*b*], [*a*, *c*]]
TRUE

TRUE

Two lists with vertices are shown. Another word for bipartite is two-colorable. This means that the graph above can be colored with only two colors so that no two vertices have the same color if connected with an edge. The bottom output could also be accomplished without using the parameter `Bool`:
Graph::bipartite(G)TRUE

TRUE

The following example shows what happens when a graph is not bipartite (an edge is added to connect the vertices a and c):
G2 := Graph::addEdges(G, [[a, c]]): Graph::bipartite(G2, Lists);
Graph::bipartite(G2, Bool)FAIL

```
FAIL
```
FALSE

```
FALSE
```

Parameters

G

Graph

Options

Lists

If Lists is stated the return value will be a list of two lists containing the (sorted) vertices belonging to each set, or `FAIL`.

Bool

If Bool is stated the return value will be either `TRUE` or `FALSE`. This is the default.

Return Values

Depending on the options either a boolean value or list-sets will be returned.

Graph::breadthFirstSearch

Purpose

Makes a breadth first Search in a graph.

Syntax

```
Graph::breadthFirstSearch(G, <StartVertex = v>)
```

Description

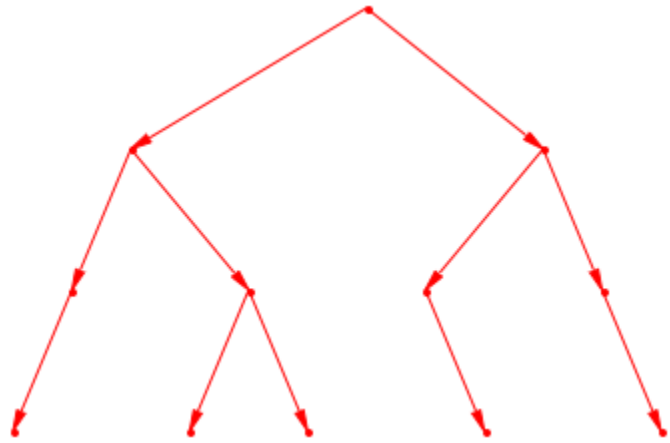
`Graph::breadthFirstSearch` traverses through a graph via breadth first search. The output shows the first time of identification and the predecessor of each vertex. If a vertex is a single vertex with no predecessor its predecessor is *infinity*.

`Graph::breadthFirstSearch(G, StartVertex = v)` traverses through a graph via breadth first search starting from vertex `v`. The output shows the first time of identification and the predecessor of each vertex. If a vertex is a single vertex with no predecessor its predecessor is *infinity*.

Examples

Example 1

A typical tree is created and drawn for a better understanding of the algorithm:
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l], [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g], [d, h], [e, i], [e, j], [f, k], [g, l]], Directed): plot(Graph::plotGridGraph(G, VerticesPerLine = [12, 12, 12, 12], VertexOrder = [None, None, None, None, None, None, a, None, None, None, None, None, None, None, None, b, None, None, None, None, None, None, None, c, None, None, None, d, None, None, e, None, None, f, None, None, g, None, h, None, None, i, None, j, None, None, k, None, None, l]))



Now we call breadthFirstSearch to find out the starting times and predecessors
Graph::breadthFirstSearch(G)[table(l = 12, k = 11, j = 10, i = 9, h = 8, g = 7, f = 6, e = 5, d = 4, c = 3, b = 2, a = 1), table(l = 3, k = 3, j = 3, i = 3, h = 3, g = 2, f = 2, e = 2, d = 2, c = 1, b = 1, a = 0), table(l = g, k = f, j = e, i = e, h = d, g = c, f = c, e = b, d = b, c = a, b = a, a = a)]

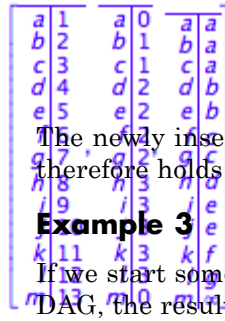
a	1	a	0	a	a
b	2	b	1	b	a
c	3	c	1	c	a
d	4	d	2	d	b
e	5	e	2	e	b
f	6	f	2	f	c
g	7	g	2	g	c
h	8	h	3	f	d
i	9	i	3	i	e
j	10	j	3	j	e
k	11	k	3	k	f
l	12	l	3	l	g

Vertex a is dicovered first, then vertex b and so on. The right table shows the predecessor of every vertex. The backtracking from a single vertex is therefore really simple. a as the first vertex discovered in its component can not be backtracked any further. The distance of each

vertex in its component can be read in the middle table. Root-vertices always have the value `0` (they `are` the roots).

Example 2

What happens now, if there exist a vertex that has no connection to any other vertex. The upper example is taken and a single vertex is added without changing anything else. Then a breadth first search is invoked on the graph:
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l], [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g], [d, h], [e, i], [e, j], [f, k], [g, l]], Directed):G2 := Graph::addVertices(G, [m]): Graph::breadthFirstSearch(G2, StartVertex = [a])[table(m = 13, l = 12, k = 11, j = 10, i = 9, h = 8, g = 7, f = 6, e = 5, d = 4, c = 3, b = 2, a = 1), table(m = 0, l = 3, k = 3, j = 3, i = 3, h = 3, g = 2, f = 2, e = 2, d = 2, c = 1, b = 1, a = 0), table(m = infinity, l = g, k = f, j = e, i = e, h = d, g = c, f = c, e = b, d = b, c = a, b = a, a = a)]

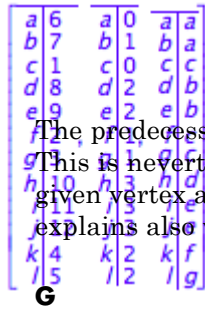


The newly inserted vertex `m` has no predecessor. The predecessor therefore holds the value *infinity*.

Example 3

If we start somewhere in the graph without knowing the root of the DAG, the results are of course different:
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l], [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g], [d, h], [e, i], [e, j], [f, k], [g, l]], Directed):Graph::breadthFirstSearch(G, StartVertex = [c])[table(l = 5, k = 4, j = 12, i = 11, h = 10, g = 3, f = 2, e = 9, d = 8, c = 1, b = 7, a = 6), table(l = 2, k = 2, j = 3, i = 3, h = 3, g = 1,

f = 1, e = 2, d = 2, c = 0, b = 1, a = 0), table(l = g, k = f, j = e, i = e, h = d, g = c, f = c, e = b, d = b, c = c, b = a, a = a)]



The predecessor of `c` is `c`, but if we look at the graph it should be `a`. This is nevertheless not quite correct. Breadth first search takes the given vertex and uses this as the root of the graph (no in-vertices!). This explains also why the next call shows a *infinity* as predecessor to l.

Parameters

G

Graph

v

List containing one vertex.

Options

StartVertex

Defines a vertex from which to start the breadth first traversal.

Return Values

List containing three tables. The first table holds the timestamp of the discovery. The second the distance to the root-vertex. The last table holds the predecessor vertices.

Graph::checkForVertices

Purpose

Checks if all vertices in edges really exist.

Syntax

```
Graph::checkForVertices(Edge, Vertex)
```

Description

`Graph::checkForVertices(Edge, Vertex)` checks if all vertices out of Edge are in Vertex.

Examples

Example 1

What vertices are within the stated edges, but not in the vertex list?
Graph::checkForVertices([[a, b], [1, 2]], [a, 2])[b, 1]

[*b*, 1]

Neither `b` nor `1` were in the second list. `a` was in the first edge and `2` in the second.

Example 2

A more complex example. The second list contains a vertex that does not exist in the graph at all. For the checking it does not matter though. Every vertex `NOT` in the second list is to be returned. In the end it does not matter if the vertex-list contains vertices that are not existent, because only existing vertices are returned.
G := Graph::createCompleteGraph(10):
Graph::checkForVertices(Graph::getEdges(G), [1, 2, 3, 11])[4, 5, 6, 7, 8, 9, 10]

[4, 5, 6, 7, 8, 9, 10]

Parameters

Edge

List of one or more Edges

Vertex

List of one or more vertices

Return Values

List with the vertices out of the Edges that were not stated in Vertex.

Graph::chromaticNumber

Purpose

Chromatic number of a graph

Syntax

```
Graph::chromaticNumber(G)
```

Description

`Graph::chromaticNumber(G)` returns the chromatic number of the graph `G`. The chromatic number of a graph is defined to be the number of colors necessary to color it such that no two adjacent vertices have the same color.

Examples

Example 1

We compute the chromatic number of the complete graph with 5 vertices; it must be 5 since any two vertices are adjacent:

```
Graph::chromaticNumber(Graph::createCompleteGraph(5))
```

```
5
```

Parameters

`G`

An undirected graph

Return Values

Positive integer

Algorithms

Internally, the chromatic polynomial is used to compute the chromatic number.

See Also

Graph::chromaticPolynomial

Graph::chromaticPolynomial

Purpose

Calculates a chromatic polynomial

Syntax

```
Graph::chromaticPolynomial(G, x)
```

Description

`Graph::chromaticPolynomial(G, x)` returns the chromatic polynomial of the graph `G`. Evaluating the result at $x = n$, for any integer n, gives the number of possible ways to color the graph `G` using n colors such that no two adjacent vertices have the same color.

`G` must be an undirected graph: if an edge goes from a to$b$, another edge must go from b to a, for any two vertices$a$, b.

Examples

Example 1

We compute the chromatic polynomial of the complete graph with 5 vertices:
f:= Graph::chromaticPolynomial(Graph::createCompleteGraph(5), x)poly(x^5 - 10*x^4 + 35*x^3 - 50*x^2 + 24*x, [x])

$$\text{poly}\left(x^5 - 10\,x^4 + 35\,x^3 - 50\,x^2 + 24\,x, [x]\right)$$

There are 240 ways to color a complete graph with 5 vertices, since this is the number of bijective mappings between the set of colors and the set of vertices:
f(5)120

120

delete f:

Example 2

Now let us delete one edge from a complete graph:
G:= Graph::createCompleteGraph(5): G:= Graph::removeEdge(G, [[2, 3]]): G:= Graph::removeEdge(G, [[3, 2]])‘Graph(...)‘

Graph(...)

Now there are some additional possible colourings: vertices 2 and 3 may now have the same color, in five different ways; in each case, there must be one of the four remaining colors that does not occur at all. In each of the 20 cases, we are left with 3 vertices that form a complete graph and 3 colors, such that there are 6 colourings. Altogether this gives us 120 additional colourings:
Graph::chromaticPolynomial(G, x)(5)240

240

Parameters

G

An undirected graph

x

An identifier

Return Values

polynomial

Algorithms

Computing the chromatic polynomial of a graph with n vertices reduces to computing two chromatic polynomials of graphs with n - 1 vertices. The running time is hence roughly 2^n.

See Birkhoff and Lewis, *Chromatic Polynomials*, Trans. AMS, Vol. 60, p.355–451, 1946.

Graph::contract

Purpose

Contracts vertices

Syntax

```
Graph::contract(G, VertexTable)
```

Description

`Graph::contract(G, VertexTable)` contracts the vertices for each entry in the table.

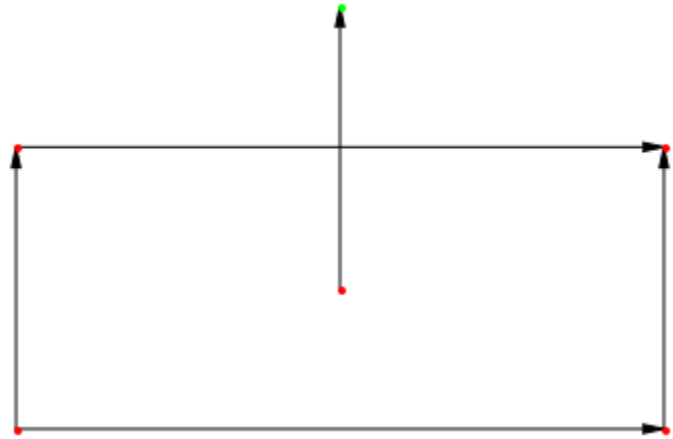
Note The graph to be contracted must not have edge weights, costs or descriptions. If it has, an error will be raised.

Note If `VertexTable` contains vertices not in `G`, these will be skipped.

Examples

Example 1

A simple example to see how a contraction is done.
ConG := Graph([a, b, c, d, e, f], [[a, c], [d, a], [f, c], [d, f], [e, b]], Directed): Graph::printGraphInformation(ConG) Vertices: [a, b, c, d, e, f] Edges: [[a, c], [d, a], [d, f], [e, b], [f, c]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): a = [c], b = [], c = [], d = [a, f], e = [b], f = [c] Adjacency list (in): a = [d], b = [e], c = [a, f], d = [], e = [], f = [d] Graph is directed. plot(Graph::plotGridGraph(ConG, VerticesPerLine = 3, VertexOrder = [None, b, None, a, None, c, None, e, None, d, None, f], EdgeColor = RGB::Black))

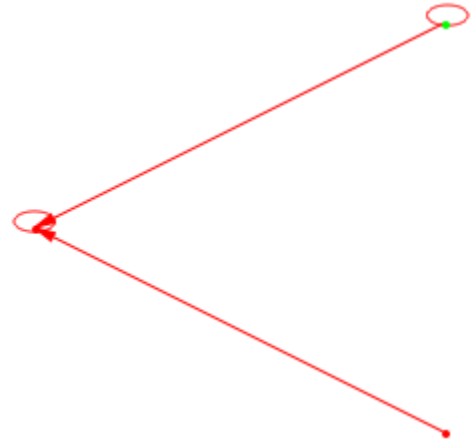


t := table(A = [a, b, c], B = [d, f])table(B = [d, f], A = [a, b, c])

A	[a, b, c]
B	[d, f]

newG := Graph::contract(ConG, t):
Graph::printGraphInformation(newG) Vertices: [A, B, e] Edges: [[A, A], [B, A], [B, B], [e, A]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): e = [A], A = [A], B = [A, B] Adjacency list (in): e = [], A = [A, B, e], B = [B] Graph is directed.

Since vertices *a*, *b*, *c* were contracted to vertex *A*, edge [a,c] was removed and edge [A, A] was created. Vertices *d*, *f* took care of the deletion of edges [*d*, *a*], [*d*, *f*], [*f*, *c*]. Instead edges [*B*, *A*] and[*B*, *B*] were created. In the end edge [*e*, *b*] was changed to [*e*, *A*] since vertex *b* does not exist any longer because it was replaced by *A*.
plot(Graph::plotGridGraph(newG, VerticesPerLine = 2, VertexOrder = [None, B, A, None, None, e]))



Example 2

`Graph::contract` ignores vertices not in the graph:
Con2 := Graph([], []): t := table(A = [a, b, c], B = [d, f]): Graph::printGraphInformation(Graph::contract(Con2, t)) Vertices: no vertices. Edges: [] Adjacency list (out): no edges. Adjacency list (in): no edges. Graph is undirected.

Parameters

G

Graph

VertexTable

A table with the name of the new vertex on the left side and a list of vertices to contract on the right side.

Return Values

Graph consisting of the new vertices and edges.

Graph::convertSSQ

Purpose

Converts a Graph into a single source single sink Graph

Syntax

```
Graph::convertSSQ(G, q, s)
```

Description

`Graph::convertSSQ(G, q, s)` converts the graph `G` into a directed single source single sink graph. The specified vertices `q` and `s` are added to the graph. It is an error if they are already predefined. Otherwise they are connected to the other vertices of the graph in the following way:

A new edge `[q,i]` is added for every vertex `i` with a positive weight. A new edge `[i,s]` is added for every vertex `i` with a negative weight. The capacities of these edges are in each case the weight of node `i`. The edge weights are zero.

Examples

Example 1

A testexample to show the transformation.
V := [1, 2, 3, 4]: Vw := [4, 0, 0, -4]: Ed := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4]]: Ec := [2, 2, 1, 3, 1]: Ew := [4, 2, 2, 3, 5]: G1 := Graph(V, Ed, VertexWeights = Vw, EdgeWeights = Ew,EdgeCosts = Ec): G2 := Graph::convertSSQ(G1, [q], [s]): Graph::printGraphInformation(G2) Vertices: [1, 2, 3, 4, q, s] Edges: [[1, 2], [1, 3], [2, 1], [2, 3], [2, 4], [3, 1], [3, 2], [3, 4], [4, 2], [4, 3], [4, s], [q, 1]] Vertex weights: 1 = 0, 2 = 0, 3 = 0, 4 = 0, q = 4, s = -4 (other existing vertices have no weight) Edge descriptions: no edge descriptions. Edge weights: [1, 2] = 4, [1, 3] = 2, [2, 3] = 2, [2, 4] = 3, [3, 4] = 5, [2, 1] = 4, [3, 1] = 2, [3, 2] = 2, [4, 2] = \ 3, [4, 3] = 5, [q, 1] = 4, [4, s] = 4 (other existing edges have no weight) Edge costs: [1, 2] = 2, [1, 3] = 2, [2, 3] = 1, [2, 4] = 3, [3, 4] = 1, [2, 1] = 2, [3, 1] = 2, [3, 2] = 1, [4, 2] = 3,\ [4, 3] = 1, [q, 1] = 0, [4, s] = 0 (other existing edges have costs zero) Adjacency list (out): 1 = [2, 3], 2 = [1, 3, 4], 3 = [1, 2, 4], 4 = [2, 3, s], q = [1], s = [] Adjacency list (in): 1 = [2, 3, q], 2 = [1, 3, 4], 3 = [1, 2, 4], 4 = [2, 3], q = [], s = [4] Graph is directed.

The former undirected graph was transformed into a directed one!

Parameters

`q`

s

Vertices not predefined in the Graph

G

A Graph

Return Values

Directed augmented Graph

Algorithms

Both, Bellman and Dijkstra expect a Graph without negative circles. Only Dijkstra may return erroneous results when negative edges (either weights or costs) are specified.

The Bellman algorithm originated from: Ahuja, Magnanti, Orlin: Dom::Graph Flows, Prentice-Hall, 1993 Section 5.4

Graph::createCircleGraph

Purpose

Generates a circle Graph

Syntax

```
Graph::createCircleGraph(L, <Directed | Undirected>)
Graph::createCircleGraph(N, <Directed | Undirected>)
```

Description

`Graph::createCircleGraph(L)` generates a circle Graph

`Graph::createCircleGraph([v1,...,vn])` generates a new graph which is the cycle `[v1,v2]`, `[v2,v3]`, ..., `[vn,v1]`. The values for the edge weights, edge costs and vertex weights can be set manually via Graph::setEdgeWeights, Graph::setEdgeCosts and Graph::setVertexWeights

`Graph::createCircleGraph(3)` generates a new graph which is the cycle `[1,2]`, `[2,3]`, `[3,1]`. The values for the edge weights, edge capacities and vertex weights can be set manually via Graph::setEdgeWeights, Graph::setEdgeCosts and Graph::setVertexWeights

`Graph::createCircleGraph(3, Undirected)` generates a new graph which includes the vertices `[1,2]`, `[2,3]`, `[3,1][2,1]`, `[3,2]`, `[1,3]`.

Examples

Example 1

A (directed) circle graph with four vertices:
G1 := Graph::createCircleGraph(4): Graph::printGraphInformation(G1) Vertices: [1, 2, 3, 4] Edges: [[1, 2], [2, 3], [3, 4], [4, 1]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [1] Adjacency list (in): 1 = [4], 2 = [1], 3 = [2], 4 = [3] Graph is directed.

Example 2

The same graph but this time with parameter `Undirected`:
G2 := Graph::createCircleGraph(4, Undirected):
Graph::printGraphInformation(G2) Vertices: [1, 2, 3, 4] Edges: [[1, 2], [1, 4], [2, 1], [2, 3], [3, 2], [3, 4], [4, 1], [4, 3]] Vertex weights: no vertex

weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [2, 4], 2 = [1, 3], 3 = [2, 4], 4 = [1, 3] Adjacency list (in): 1 = [2, 4], 2 = [1, 3], 3 = [2, 4], 4 = [1, 3] Graph is undirected.

Example 3

The circle graph with predefined vertices:
G3 := Graph::createCircleGraph([a, b, c, d, 4, 5, 6]):
Graph::printGraphInformation(G3) Vertices: [4, 5, 6, a, b, c, d] Edges: [[4, 5], [5, 6], [6, a], [a, b], [b, c], [c, d], [d, 4]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): a = [b], b = [c], c = [d], d = [4], 4 = [5], 5 = [6], 6 = [a] Adjacency list (in): a = [6], b = [a], c = [b], d = [c], 4 = [d], 5 = [4], 6 = [5] Graph is directed.

Parameters

L

List of vertices

N

A positive Integer

Options

Directed

The Graph is created as a directed graph. `Default`.

Undirected

The Graph is created as an undirected graph.

Return Values

Graph

Graph::createCompleteGraph

Purpose

Generates a complete graph

Syntax

```
Graph::createCompleteGraph(n)
```

Description

`Graph::createCompleteGraph(n)` generates the complete Graph with `n` vertices. A complete graph has a connection between each pair of vertices (except to itself).

The vertices of the generated graph are labeled with the numbers `1` to `n`.

Examples

Example 1

The complete Graph with three vertices has 32 = 6 edges:
G := Graph::createCompleteGraph(3):
Graph::printGraphInformation(G) Vertices: [1, 2, 3] Edges: [[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2] Adjacency list (in): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2] Graph is undirected.

Parameters

`n`

A positive integer

Return Values

Graph

Graph::createGraphFromMatrix

Purpose

Transfers a squared matrix into a directed graph

Syntax

```
Graph::createGraphFromMatrix(M)
```

Description

`Graph::createGraphFromMatrix(M)` generates a directed Graph where each $m_{i,j}$ in the matrix defines an edge from$i$ to j. The value of the cell defines the weight of the resulting edge.

The vertices of the generated graph are labeled with the numbers `1` to `n`, where n defines the column/row-dimension of the matrix. Since the matrix has to be squared, n stays the same.

Examples

Example 1

A matrix is defined and the resulting squared matrix is transfered into a Graph.

```
a := matrix([[3, 2, 4], [2, 3, 6], [4, 8, 3]]);
G := Graph::createGraphFromMatrix(a):
Graph::printGraphInformation(G)matrix([[3, 2, 4], [2, 3, 6], [4, 8, 3]])
```

$$\begin{pmatrix} 3 & 2 & 4 \\ 2 & 3 & 6 \\ 4 & 8 & 3 \end{pmatrix}$$

Vertices: [1, 2, 3] Edges: [[1, 1], [1, 2], [1, 3], [2, 1], [2, 2], [2, 3], [3, 1], [3, 2], [3, 3]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: [1, 1] = 3, [1, 2] = 2, [1, 3] = 4, [2, 1] = 2, [2, 2] = 3, [2, 3] = 6, [3, 1] = 4, [3, 2] = 8, [3, 3] = \ 3 (other existing edges have no weight) Edge costs: no edge costs. Adjacency list (out): 1 = [1, 2, 3], 2 = [1, 2, 3], 3 = [1, 2, 3] Adjacency list (in): 1 = [1, 2, 3], 2 = [1, 2, 3], 3 = [1, 2, 3] Graph is directed.

Parameters

M

A matrix

Return Values

Graph

Graph::createRandomEdgeWeights

Purpose

Sets random weights to edges

Syntax

```
Graph::createRandomEdgeWeights(G, r, <Dom::Integer
| Dom::Real>)
```

Description

`Graph::createRandomEdgeWeights(G, x..y)` creates random integer edge weights within the range `x..y`.

`Graph::createRandomEdgeWeights(G, x..y, Dom::Integer)` does exactly the same.

`Graph::createRandomEdgeWeights(G, x..y, Dom::Real)` creates random real edge weights within the range `x..y`.

Note Already existing edge weights will be changed, too!

Examples

Example 1

Creating edge weights for a small cyclic graph. First, it has no specified weights:
G1 := Graph::createCircleGraph(5): Graph::printGraphInformation(G1) Vertices: [1, 2, 3, 4, 5] Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1] Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4] Graph is directed.

Now the weights are set within the range `-100..50` (your output may differ due random assignment):
G2 := Graph::createRandomEdgeWeights(G1, -100..50): Graph::printGraphInformation(G2) Vertices: [1, 2, 3, 4, 5] Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: [1, 2] = 47, [2, 3] = -12, [3, 4] = 28, [4, 5] = 1, [5, 1] = -36 (other existing edges have no weight) Edge costs: no edge costs. Adjacency list (out): 1 = [2], 2 = [3], 3

= [4], 4 = [5], 5 = [1] Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4] Graph is directed.

If the weights should be of type Real it can be set optionally: G2 := Graph::createRandomEdgeWeights(G1, -100..50, Dom::Real): Graph::printGraphInformation(G2) Vertices: [1, 2, 3, 4, 5] Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: [1, 2] = -67.72964183, [2, 3] = -10.16896282, [3, 4] = -72.84684348, [4, 5] = -61.00518722, [5, 1] = 18.2\ 662729 (other existing edges have no weight) Edge costs: no edge costs. Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1] Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4] Graph is directed.

Parameters

G

A graph

r

A range

Return Values

Graph

Graph::createRandomEdgeCosts

Purpose

Sets random costs to edges

Syntax

```
Graph::createRandomEdgeCosts(G, r, <Dom::Integer
| Dom::Real>)
```

Description

`Graph::createRandomEdgeCosts(G, x..y)` creates random edge weights of type Integer within the range `x..y`.

`Graph::createRandomEdgeCosts(G, x..y, Dom::Integer)` does exactly the same.

`Graph::createRandomEdgeCosts(G, x..y, Dom::Real)` creates random edge weights of type Real within the range x..y.

Note Already existing edge costs will be changed, too!

Examples

Example 1

Creating edge weights for a small cyclic graph. First, it has no specified weights:
G1 := Graph::createCircleGraph(5): Graph::printGraphInformation(G1) Vertices: [1, 2, 3, 4, 5] Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1] Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4] Graph is directed.

Now the costss are set within the range `-100..50` (your output may differ due random assignment):
G2 := Graph::createRandomEdgeCosts(G1, -100..50): Graph::printGraphInformation(G2) Vertices: [1, 2, 3, 4, 5] Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: [1, 2] = 47, [2, 3] = -12, [3, 4] = 28, [4, 5] = 1, [5, 1] = -36 (other existing edges have costs zero) Adjacency list (out): 1

= [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1] Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4] Graph is directed.

If the costs should be of type Real it can be set optionally: G2 := Graph::createRandomEdgeCosts(G1, -100..50, Dom::Real): Graph::printGraphInformation(G2) Vertices: [1, 2, 3, 4, 5] Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: [1, 2] = -67.72964183, [2, 3] = -10.16896282, [3, 4] = -72.84684348, [4, 5] = -61.00518722, [5, 1] = 18.266\ 2729 (other existing edges have costs zero) Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1] Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4] Graph is directed.

Parameters

G

A graph

r

A range

Return Values

Graph

Graph::createRandomGraph

Purpose

Generates a random graph.

Syntax

```
Graph::createRandomGraph(VertexNr, EdgeNr,
<Directed | Undirected>)
```

Description

`Graph::createRandomGraph` generates a random graph.

`Graph::createRandomGraph(VertexNr, EdgeNr)` generates a random graph with VertexNr vertices and EdgeNr edges.

Note If the number EdgeNr is too great (i.e. EdgeNr>=VertexNr*(VertexNr-1)/2$EdgeNr \geq \frac{VertexNr\ (VertexNr-1)}{2}$), a complete graph will be created.

`Graph::createRandomGraph(VertexNr, EdgeNr, Undirected)` generates a random graph with VertexNr vertices and 2*EdgeNr* edges is created. This is due to the fact that no odd number of undirected edges could be created otherwise.

Examples

Example 1

The following graph was created `randomly`, meaning that your results will most probably differ:
G := Graph::createRandomGraph(5,6):
Graph::printGraphInformation(G) Vertices: [1, 2, 3, 4, 5] Edges: [[1, 4], [2, 1], [2, 4], [2, 5], [3, 1], [3, 4]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [4], 2 = [1, 4, 5], 3 = [1, 4], 4 = [], 5 = [] Adjacency list (in): 1 = [2, 3], 2 = [], 3 = [], 4 = [1, 2, 3], 5 = [2] Graph is directed.

Example 2

The same number of vertices, but this time the edges are undirected (and therefore the number of Edges is (2*EdgeNr*)). As you can clearly see, the edges differ from the edges created above:
G := Graph::createRandomGraph(5, 6, Undirected): Graph::printGraphInformation(G) Vertices: [1, 2, 3, 4, 5] Edges: [[1, 4], [1, 5], [2, 3], [2, 4], [2, 5], [3, 2], [4, 1], [4, 2], [4, 5], [5, 1], [5, 2], [5, 4]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [4, 5], 2 = [3, 4, 5], 3 = [2], 4 = [1, 2, 5], 5 = [1, 2, 4] Adjacency list (in): 1 = [4, 5], 2 = [3, 4, 5], 3 = [2], 4 = [1, 2, 5], 5 = [1, 2, 4] Graph is undirected.

Example 3

If the number of edges to be created extends the possible limit (vertices*(vertices-1)/2$\frac{\text{vertices}\cdot(\text{vertices}-1)}{2}$), a complete graph will be returned:
G := Graph::createRandomGraph(3, 6, Undirected): Graph::printGraphInformation(G) Warning: Cannot produce the required number of edges. Creating a complete graph instead. [Graph::createRandomGraph] Vertices: [1, 2, 3] Edges: [[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2] Adjacency list (in): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2] Graph is undirected.

Parameters

VertexNr

Positive integer

EdgeNr

Positive integer

Options

Directed

If `Directed` is stated, a directed Graph is created `Default`

Undirected

If `Undirected` is stated, an undirected Graph is created.

Return Values

`Graph`

Graph::createRandomVertexWeights

Purpose

Sets random weights to vertices

Syntax

```
Graph::createRandomVertexWeights(G, r, <Int | Real>)
```

Description

`Graph::createRandomVertexWeights(G, x..y)` creates random vertex weights of type Integer within the range x..y.

`Graph::createRandomVertexWeights(G, x..y, Real)` creates random vertex weights of type Real within the range x..y.

Note Already existing vertex weights will be changed, too!

Examples

Example 1

Creating vertex weights for a small cyclic graph. First, it has no specified weights:
G1 := Graph::createCircleGraph(5): Graph::printGraphInformation(G1) Vertices: [1, 2, 3, 4, 5] Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1] Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4] Graph is directed.

Now the weights are set within the range `-100..50` (your output may differ due random assignment):
G2 := Graph::createRandomVertexWeights(G1, -100..50): Graph::printGraphInformation(G2) Vertices: [1, 2, 3, 4, 5] Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]] Vertex weights: 1 = 47, 2 = -12, 3 = 28, 4 = 1, 5 = -36 (other existing vertices have no weight) Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1] Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4] Graph is directed.

If the weights should be of type Real it can be set optionally:

G2 := Graph::createRandomVertexWeights(G1, -100..50, Real): Graph::printGraphInformation(G2) Vertices: [1, 2, 3, 4, 5] Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]] Vertex weights: 1 = -67.72964183, 2 = -10.16896282, 3 = -72.84684348, 4 = -61.00518722, 5 = 18.2662729 (other existing \ vertices have no weight) Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1] Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4] Graph is directed.

Parameters

G

A graph

r

A range

Options

Int

If stated, the weights are only of type integer. (Default)

Real

If stated, the weights are only of type real.

Return Values

Graph

Graph::depthFirstSearch

Purpose

Makes a depth first Search in a graph.

Syntax

```
Graph::depthFirstSearch(G, <StartVertex = v>)
```

Description

`Graph::depthFirstSearch` traverses through a graph via depth first search. The output shows the first time of identifikation, the finishing time and the predecessor of each vertex. If a vertex is a single vertex with no predecessor its predecessor is *infinity*.

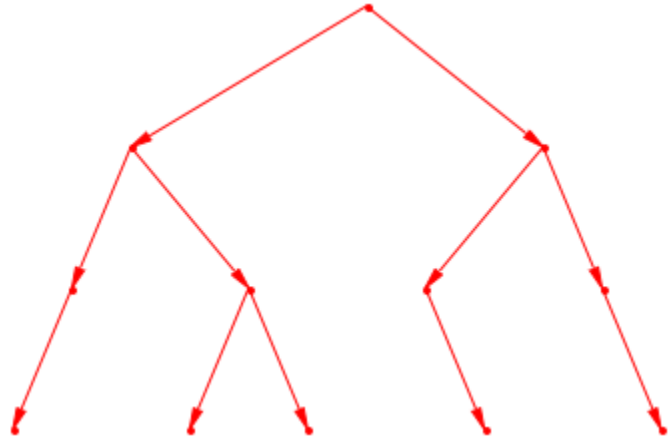
`Graph::depthFirstSearch(G, StartVertex=v)` traverses through a graph via depth first search starting from vertex `v`. The output shows the first time of identification, the finishing time and the predecessor of each vertex. If a vertex is a single vertex with no predecessor its predecessor is *infinity*.

Examples

Example 1

A typical tree is created and drawn for a better understanding of the algorithm.

```
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l], [[a, b], [a, c], [b, d], [b,
e], [c, f], [c, g], [d, h], [e, i], [e, j], [f, k], [g, l]], Directed): plot(
Graph::plotGridGraph(G, VerticesPerLine = [12, 12, 12, 12],
VertexOrder = [ None, None, None, None, None, None, a, None, None,
None, None, None, None, None, None, b, None, None, None, None, None,
None, c, None, None, None, d, None, None, e, None, None, f, None, None,
g, None, h, None, None, i, None, j, None, None, k, None, None, l ] ) )
```



Now we call `Graph::depthFirstSearch` to find out the starting times, the finishing times and the predecessors of each vertex: Graph::depthFirstSearch(G)[table(l = 20, k = 16, j = 10, i = 8, h = 4, g = 19, f = 15, e = 7, d = 3, c = 14, b = 2, a = 1), table(l = 21, k = 17, j = 11, i = 9, h = 5, g = 22, f = 18, e = 12, d = 6, c = 23, b = 13, a = 24), table(l = g, k = f, j = e, i = e, h = d, g = c, f = c, e = b, d = b, c = a, b = a, a = a)]

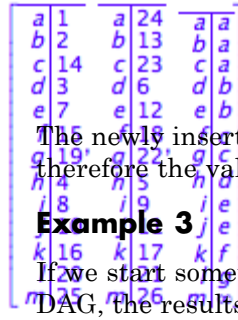
a	1	a	24	a	a
b	2	b	13	b	a
c	14	c	23	c	a
d	3	d	6	d	b
e	7	e	12	e	b
f	15	f	18	f	c
g	19	g	22	g	c
h	4	h	5	h	d
i	8	i	9	i	e
j	10	j	11	j	e
k	16	k	17	k	f
l	20	l	21	l	g

Vertex a is dicovered first, then vertex b and so on. The table in the middle shows the finishing times. `h` for example has the finishing time of 5, meaning that vertices `a, b, c, d` and `h` itself were visited before it was recognized that `h` is a leaf (finishing time = starting time + 1). The right table shows the predecessor of every vertex. The backtacking

from a single vertex is therefore really simple. `a` as the first vertex discovered in its component can not be backtracked any further.

Example 2

What happens now, if there exist a vertex that has no connection to any other vertex. The upper example is taken and a single vertex is added without changing anything else. Then a depth first search is invoked on the graph:
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l], [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g], [d, h], [e, i], [e, j], [f, k], [g, l]], Directed):G2 := Graph::addVertices(G, [m]): Graph::depthFirstSearch(G2, StartVertex = [a])[table(m = 25, l = 20, k = 16, j = 10, i = 8, h = 4, g = 19, f = 15, e = 7, d = 3, c = 14, b = 2, a = 1), table(m = 26, l = 21, k = 17, j = 11, i = 9, h = 5, g = 22, f = 18, e = 12, d = 6, c = 23, b = 13, a = 24), table(m = infinity, l = g, k = f, j = e, i = e, h = d, g = c, f = c, e = b, d = b, c = a, b = a, a = a)]

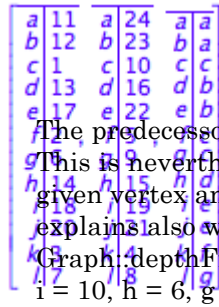


The newly inserted vertex `m` has no predecessor. The predecessor holds therefore the value *infinity*.

Example 3

If we start somewhere in the graph without knowing the root of the DAG, the results are of course different:
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l], [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g], [d, h], [e, i], [e, j], [f, k], [g, l]], Directed):Graph::depthFirstSearch(G, StartVertex = [c])[table(l = 7, k = 3, j = 20, i = 18, h = 14, g = 6, f = 2, e = 17, d = 13, c = 1, b = 12, a = 11), table(l = 8, k = 4, j = 21, i = 19, h = 15, g

= 9, f = 5, e = 22, d = 16, c = 10, b = 23, a = 24), table(l = g, k = f, j = e, i = e, h = d, g = c, f = c, e = b, d = b, c = c, b = a, a = a)]



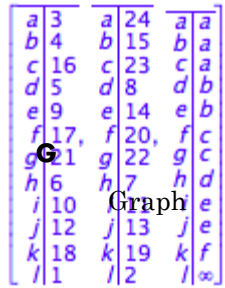
The predecessor of `c` is `c`, but if we look at the graph it should be `a`. This is nevertheless not quite correct. Breadth first search takes the given vertex and uses this as the root of the graph (no in-vertices!). This explains also why the next call shows a *infinity* as predecessor to l:

Graph::depthFirstSearch(G, StartVertex = [l])[table(l = 1, k = 18, j = 12, i = 10, h = 6, g = 21, f = 17, e = 9, d = 5, c = 16, b = 4, a = 3), table(l = 2, k = 19, j = 13, i = 11, h = 7, g = 22, f = 20, e = 14, d = 8, c = 23, b = 15, a = 24), table(l = infinity, k = f, j = e, i = e, h = d, g = c, f = c, e = b, d = b, c = a, b = a, a = a)]

Parameters

G

Graph



v

List containing one vertex.

Options

StartVertex

Defines a vertex from which to start the depth first traversal.

Return Values

List containing three tables. The first table holds the first identification timestamp of each vertex, the second the finishing timestamp and the third the predecessor vertex.

Graph::getAdjacentEdgesEntering

Purpose

Returns the incident edges.

Syntax

```
Graph::getAdjacentEdgesEntering(G, Vertex)
```

Description

`Graph::getAdjacentEdgesEntering(G, Vertex)` returns a list with vertices `v1..vn`, where `[v1, Vertex] .. [vn, Vertex]` are incident (incoming) Edges to `Vertex`.

Examples

Example 1

First, a complete graph is defined:
G1 := Graph::createCompleteGraph(5):
Graph::printGraphInformation(G1) Vertices: [1, 2, 3, 4, 5] Edges: [[1, 2], [1, 3], [1, 4], [1, 5], [2, 1], [2, 3], [2, 4], [2, 5], [3, 1], [3, 2], [3, 4], [3, 5], [4, 1], [4, 2],\ [4, 3], [4, 5], [5, 1], [5, 2], [5, 3], [5, 4]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2, 4, 5], 4 = [1, 2, 3, 5], 5 = [1, 2, 3, 4] Adjacency list (in): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2, 4, 5], 4 = [1, 2, 3, 5], 5 = [1, 2, 3, 4] Graph is undirected.

Now we get the vertices that form all incident edges `[2, 1] .. [5, 1]`:
Graph::getAdjacentEdgesEntering(G1, [1])[2, 3, 4, 5]

```
[2, 3, 4, 5]
```

Now we get the vertices that form all incident edges `[1, 5] .. [4, 5]`:
Graph::getAdjacentEdgesEntering(G1, [5])[1, 2, 3, 4]

```
[1, 2, 3, 4]
```

Parameters

G

A graph

Vertex

One vertex of `G`.

Return Values

List

Graph::getAdjacentEdgesLeaving

Purpose

Returns the adjacent edges.

Syntax

```
Graph::getAdjacentEdgesLeaving(G, Vertex)
```

Description

`Graph::getAdjacentEdgesLeaving(G, Vertex)` returns a list with vertices `v1..vn`, where `[Vertex, v1] .. [Vertex, vn]` are adjacent (outgoing) Edges to `Vertex`.

Examples

Example 1

First, a complete graph is defined:
G1 := Graph::createCompleteGraph(5):
Graph::printGraphInformation(G1) Vertices: [1, 2, 3, 4, 5] Edges: [[1, 2], [1, 3], [1, 4], [1, 5], [2, 1], [2, 3], [2, 4], [2, 5], [3, 1], [3, 2], [3, 4], [3, 5], [4, 1], [4, 2],\ [4, 3], [4, 5], [5, 1], [5, 2], [5, 3], [5, 4]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2, 4, 5], 4 = [1, 2, 3, 5], 5 = [1, 2, 3, 4] Adjacency list (in): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2, 4, 5], 4 = [1, 2, 3, 5], 5 = [1, 2, 3, 4] Graph is undirected.

Now we get the vertices that form all adjacent edges `[1, 2] .. [1, 5]`:
Graph::getAdjacentEdgesLeaving(G1, [1])[2, 3, 4, 5]

```
[2, 3, 4, 5]
```

Now we get the vertices that form all adjacent edges `[2, 1] .. [2, 5]`:
Graph::getAdjacentEdgesLeaving(G1, [2])[1, 3, 4, 5]

```
[1, 3, 4, 5]
```

Parameters

G

A graph

Vertex

One vertex of `G`.

Return Values

List

Graph::getBestAdjacentEdge

Purpose

Returns the "best" incident edges.

Syntax

```
Graph::getBestAdjacentEdge(G, Vertex, Vertices, <Min
| Max>, <Weights | Costs>)
```

Description

`Graph::getBestAdjacentEdge(G, Vertex)` returns the best incident edge according to specified attributes.

`Graph::getBestAdjacentEdge(G, Vertex, Vertices)` returns a vertex `v` out of `Vertices`. The best edge is (Vertex, v) according to the specifications.

Examples

Example 1

Let us create a graph and find out the edge with the least weight: G1 := Graph([1, a, 3, 4], [[1, a], [1, 3], [1, 4]], EdgeWeights = [10, 20, 30], EdgeCosts = [30, 20, 10]): Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1)), Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1), Min, Weights)a, a

a, a

The result shows that edge [1, a] has the least weight. It also shows that `Min` and `Weights` are the defaults if omitted. Next, we want to know the edge with maximum weight: Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1), Max)4

4

The vertex with maximum weight is edge [1,4]. Now we have a look at the costs. The minimum cost edge can be found with: Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1), Costs)4

4

So the vertex with maximum weight is also the edge with minimum costs. Finally let us search for the edge with maximum costs: Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1), Costs, Max)a

Parameters

G

A graph

Vertex

One vertex of G.

Vertices

Vertices in G.

Options

Min

If stated, the edge with the minimum attribute will be found. (Default)

Max

If stated, the edge with the maximum attribute will be found.

Weights

If stated, edge weights will be used for comparison. (Default)

Costs

If stated, edge costs will be used for comparison.

Return Values

Vertex

Graph::getEdgeCosts

Purpose

Returns a table with the edge costs.

Syntax

```
Graph::getEdgeCosts(G)
```

Description

`Graph::getEdgeCosts(G)` returns a table with the edge costs of the graph `G`. Thus `Graph::getEdgeCosts(G)` returns the costs of all edges in `G`.

Note Costs will most probably only be defined, if transportation problems occur.

Note If FAIL is returned, no costs werde defined (this way both, network and graph algorithms handle this situation correct.)

Examples

Example 1

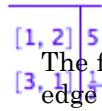
First lets define a graph without edge costs:
G1 := Graph::createCircleGraph(3): Graph::getEdgeCosts(G1)FAIL

```
FAIL
```

`FAIL` was returned, because no edge costs were defined.
Graph::getEdges(G1); G1 := Graph::setEdgeCosts(G1, [[1, 2], [3, 1]], [5, 1/2]): Graph::getEdgeCosts(G1)[[1, 2], [2, 3], [3, 1]]

```
[[1, 2], [2, 3], [3, 1]]
```

table([3, 1] = 1/2, [1, 2] = 5)



The first output shows all the edges and the second one the assigned edge costs.

Parameters

G

A graph

Return Values

Table

Graph::getEdgeDescriptions

Purpose

Returns a table with the edge descriptions.

Syntax

```
Graph::getEdgeDescriptions(G)
```

Description

`Graph::getEdgeDescriptions(G)` returns a table with the edge descriptions of the graph `G`. Thus `Graph::getEdgeDescriptions(G)` returns the weight of all edges in `G`.

Note Descriptions will most probably only be defined, if transportation problems occur.

Note If FAIL is returned, no descriptions were defined (this way both, network and graph algorithms handle this situation correct.)

Examples

Example 1

First lets define a graph without edge descriptions:
G1 := Graph::createCircleGraph(3):
Graph::getEdgeDescriptions(G1)FAIL

FAIL

`FAIL` was returned, because no edge descriptions were defined. Graph::getEdges(G1); G1 := Graph::setEdgeDescriptions(G1, [[1, 2], [3, 1]], ["Shortcut", "Highway 66"]): Graph::getEdgeDescriptions(G1)[[1, 2], [2, 3], [3, 1]]

[[1, 2], [2, 3], [3, 1]]
table([3, 1] = "Highway 66", [1, 2] = "Shortcut")

```
[1, 2] "Shortcut"
[3, 1] "Highway 66"
```

The first output shows all the edges and the second one the assigned edge descriptions.

Parameters

G

A graph

Return Values

Table

Graph::getEdges

Purpose

Returns a list with all edges

Syntax

```
Graph::getEdges(G)
```

Description

`Graph::getEdges(G)` returns a list containing all edges of the graph `G`. Each edge is represented by a list containing the two connected vertices.

Examples

Example 1

`Graph::getEdges` only returns the edges, without their capacities:

```
G1 := Graph::createCircleGraph([v1, v2, v3, v4]):
Graph::getEdges(G1)
```

```
[[v1, v2], [v2, v3], [v3, v4], [v4, v1]]
```

```
G2 := Graph::createCompleteGraph(3): Graph::getEdges(G2)
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

Parameters

G

A Graph

Return Values

List of all edges, a list of lists

Graph::getEdgesEntering

Purpose

Returns the incoming edges

Syntax

```
Graph::getEdgesEntering(G)
```

Description

`Graph::getEdgesEntering(G)` returns a table with the adjacency lists for incident (incoming) edges. Thus `Graph::getEdgesEntering(G)` returns a table containing all those vertices `w` for which there is an edge `[w, v]` in `G`.

Examples

Example 1

A small directed graph is created to show the incoming (incident) edges: V := [1, 2, 3, 4, 5]: Ed := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4], [3, 5], [4, 5]]: G1 := Graph(V, Ed, Directed): Graph::getEdgesEntering(G1)table(5 = [3, 4], 4 = [2, 3], 3 = [1, 2], 2 = [1], 1 = [])

```
1 []
2 [1]
3 [1, 2]
4 [2, 3]
5 [3, 4]
```

In an undirected graph the output could look like this:
G1 := Graph::createCompleteGraph(5):
Graph::getEdgesEntering(G1)table(5 = [1, 2, 3, 4], 4 = [1, 2, 3, 5], 3 = [1, 2, 4, 5], 2 = [1, 3, 4, 5], 1 = [2, 3, 4, 5])

1	[2, 3, 4, 5]
2	[1, 3, 4, 5]
3	[1, 2, 4, 5]
4	[1, 2, 3, 5]
5	[1, 2, 3, 4]

Parameters

G

A graph

Return Values

Table

Graph::getEdgesLeaving

Purpose

Returns the outgoing edges

Syntax

```
Graph::getEdgesLeaving(G)
```

Description

`Graph::getEdgesLeaving(G)` returns a table with the adjacency lists for adjacent (outgoing) edges. Thus `Graph::getEdgesLeaving(G)` returns a table containing all those vertices `w` for which there is an edge `[v,w]` in `G`.

Examples

Example 1

A small directed graph is created to show the outgoing (adjacent) edges: V := [1, 2, 3, 4, 5]: Ed := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4], [3, 5], [4, 5]]: G1 := Graph(V, Ed, Directed): Graph::getEdgesLeaving(G1)table(5 = [], 4 = [5], 3 = [4, 5], 2 = [3, 4], 1 = [2, 3])

```
1 [2, 3]
2 [3, 4]
3 [4, 5]
4 [5]
5 []
```

In an undirected graph the output could look like this:
G1 := Graph::createCompleteGraph(5):
Graph::getEdgesLeaving(G1)table(5 = [1, 2, 3, 4], 4 = [1, 2, 3, 5], 3 = [1, 2, 4, 5], 2 = [1, 3, 4, 5], 1 = [2, 3, 4, 5])

1	[2, 3, 4, 5]
2	[1, 3, 4, 5]
3	[1, 2, 4, 5]
4	[1, 2, 3, 5]
5	[1, 2, 3, 4]

Parameters

G

A graph

Return Values

Table

Graph::getEdgeNumber

Purpose

Returns the number of edges.

Syntax

```
Graph::getEdgeNumber(G)
```

Description

`Graph::getEdgeNumber(G)` returns a number representing the number of edges in `G`.

Examples

Example 1

Let us create a graph and find out the number of edges:
G1 := Graph([1, a, 3, 4], [[1, a], [1, 3], [1, 4]]):
Graph::getEdgeNumber(G1)6

```
6
```

We know that a complete graph consists of $|Vertices|^2$ - $|Vertices|$ edges:
G2 := Graph::createCompleteGraph(4): Graph::getEdgeNumber(G2)12

```
12
```

Parameters

G

A graph

Return Values

Number

Graph::getEdgeWeights

Purpose

Returns a table with the edge weights.

Syntax

```
Graph::getEdgeWeights(G)
```

Description

`Graph::getEdgeWeights(G)` returns a table with the edge weights of the graph `G`. Thus `Graph::getEdgeWeights(G)` returns the weight of all edges in `G`.

Note Weights will most probably only be defined, if transportation problems occur.

Note If FAIL is returned, no weights were defined (this way both, network and graph algorithms handle this situation correct.)

Examples

Example 1

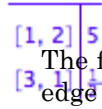
First lets define a graph without edge weights:
G1 := Graph::createCircleGraph(3): Graph::getEdgeWeights(G1)FAIL

```
FAIL
```

`FAIL` was returned, because no edge weights were defined.
Graph::getEdges(G1); G1 := Graph::setEdgeWeights(G1, [[1, 2], [3, 1]], [5, 1/2]): Graph::getEdgeWeights(G1)[[1, 2], [2, 3], [3, 1]]

```
[[1, 2], [2, 3], [3, 1]]
```

table([3, 1] = 1/2, [1, 2] = 5)



The first output shows all the edges and the second one the assigned edge weights.

Parameters

G

A graph

Return Values

Table

Graph::getSubGraph

Purpose

Returns a subgraph.

Syntax

```
Graph::getSubGraph(G, Vertex)
```

Description

`Graph::getSubGraph(G, Vertex)` returns a subgraph according to the specified vertices.

`Graph::getSubGraph(G)` returns a graph that only holds the specified vertices and the belonging edges.

Examples

Example 1

First, a complete graph is defined with some additional settings:
G1 := Graph::createCompleteGraph(5): G1 := Graph::setEdgeWeights(G1, [[1,2]], [20]): G1 := Graph::setEdgeCosts(G1, [[1, 2]], [20]): G1 := Graph::setEdgeDescriptions(G1, [[1, 2]], ["Shortcut"]): Graph::printGraphInformation(G1) Vertices: [1, 2, 3, 4, 5] Edges: [[1, 2], [1, 3], [1, 4], [1, 5], [2, 1], [2, 3], [2, 4], [2, 5], [3, 1], [3, 2], [3, 4], [3, 5], [4, 1], [4, 2],\ [4, 3], [4, 5], [5, 1], [5, 2], [5, 3], [5, 4]] Vertex weights: no vertex weights. Edge descriptions: [1, 2] = "Shortcut", [2, 1] = "Shortcut" Edge weights: [1, 2] = 20, [2, 1] = 20 (other existing edges have no weight) Edge costs: [1, 2] = 20, [2, 1] = 20 (other existing edges have costs zero) Adjacency list (out): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2, 4, 5], 4 = [1, 2, 3, 5], 5 = [1, 2, 3, 4] Adjacency list (in): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2, 4, 5], 4 = [1, 2, 3, 5], 5 = [1, 2, 3, 4] Graph is undirected.

Now we get the subgraph for the vertices `1,2,4`:
G2 := Graph::getSubGraph(G1, [1, 2, 4]): Graph::printGraphInformation(G2) Vertices: [1, 2, 4] Edges: [[1, 2], [1, 4], [2, 1], [2, 4], [4, 1], [4, 2]] Vertex weights: no vertex weights. Edge descriptions: [1, 2] = "Shortcut", [2, 1] = "Shortcut" Edge weights: [1, 2] = 20, [2, 1] = 20 (other existing edges have no weight) Edge costs: [1, 2] = 20, [2, 1] = 20 (other existing edges have costs zero) Adjacency list (out): 1 = [2, 4], 2 = [1, 4], 4 = [1, 2] Adjacency list (in): 1 = [2, 4], 2 = [1, 4], 4 = [1, 2] Graph is undirected.

The subgraph for the vertices `1,3,4` looks like:
G2 := Graph::getSubGraph(G1, [1, 3, 4]):
Graph::printGraphInformation(G2) Vertices: [1, 3, 4] Edges: [[1, 3], [1, 4], [3, 1], [3, 4], [4, 1], [4, 3]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [3, 4], 3 = [1, 4], 4 = [1, 3] Adjacency list (in): 1 = [3, 4], 3 = [1, 4], 4 = [1, 3] Graph is undirected.

Parameters

`G`

A graph

Vertex

A list containing one or more vertices of `G`.

Return Values

Graph

Graph::getVertexNumber

Purpose

Returns the number of vertices.

Syntax

```
Graph::getVertexNumber(G)
```

Description

`Graph::getVertexNumber(G)` returns a number representing the number of vertices in `G`.

Examples

Example 1

An example with 100 vertices:
G1 := Graph::createCompleteGraph(100):
Graph::getVertexNumber(G1)100

```
100
```

Parameters

G

A graph

Return Values

Number

Graph::getVertexWeights

Purpose

Returns a table with the vertex weights.

Syntax

```
Graph::getVertexWeights(G)
```

Description

`Graph::getVertexWeights(G)` returns a table with the vertex weights of the graph `G`. Thus `Graph::getVertexWeights(G)` returns the weight of all vertices in `G`.

Note If FAIL is returned, no weights were defined (this way both, network and graph algorithms handle this situation correct.)

Examples

Example 1

First lets define a graph without vertex weights:
G1 := Graph::createCircleGraph(3): Graph::getVertexWeights(G1)FAIL

FAIL

`FAIL` was returned, because no vertex weights were defined.
Graph::getVertices(G1); G1 := Graph::setVertexWeights(G1, [1, 3], [5, 1/2]): Graph::getVertexWeights(G1)[1, 2, 3]

[1, 2, 3]

table(3 = 1/2, 1 = 5)

1	5
3	1/2

The first output shows all the vertices and the second one the assigned vertex weights.

Parameters

G

A graph

Return Values

Table

Graph::getVertices

Purpose

Returns a list with all vertices

Syntax

```
Graph::getVertices(G)
```

Description

`Graph::getVertices(G)` returns the list of all vertices of the Graph `G`.

Examples

Example 1

A small creation of two different graphs and the output `getVertices` generates:

```
G1 := Graph::createCompleteGraph(10): Graph::getVertices(G1)[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```

```
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```

```
G2 := Graph::createCircleGraph([x.i $ i = 1..12]):
Graph::getVertices(G2)[x1, x2, x3, x4, x5, x6, x7, x8, x9, x10, x11, x12]
```

```
[x1, x2, x3, x4, x5, x6, x7, x8, x9, x10, x11, x12]
```

Parameters

G

A graph

Return Values

List

Graph::inDegree

Purpose

Returns the indegree of one or more vertices.

Syntax

```
Graph::inDegree(G, <Vertex>)
```

Description

`Graph::inDegree(G, Vertex)` returns the indegree of the vertex `Vertex` in the Graph `G`, i.e., the number of edges `[u,Vertex]`.

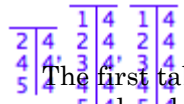
`Graph::inDegree(G, [v1, v2, ..., vn])` returns a table in which the keys are `v1, v2, ..., vn` and the corresponding values are the indegrees.

`Graph::inDegree(G)` returns a table in which each node of `G` is mapped to its indegree. `Graph::inDegree(G)` is equivalent to `Graph::inDegree(G, Graph::getVertices(G)))`.

Examples

Example 1

In a complete graph of n vertices, each vertex has indegree n - 1:
G := Graph::createCompleteGraph(5): Graph::inDegree(G, [2, 4, 5]), Graph::inDegree(G), Graph::inDegree(G, Graph::getVertices(G))table(5 = 4, 4 = 4, 2 = 4), table(5 = 4, 4 = 4, 3 = 4, 2 = 4, 1 = 4), table(5 = 4, 4 = 4, 3 = 4, 2 = 4, 1 = 4)



The first table shows what happens, if some vertices are specified. The second and third table return all indegrees, but with two different calls (the second is redundant).

Example 2

Remember that also only one vertex needs to be specified as a list!
G := Graph::createCompleteGraph(5): Graph::inDegree(G, [2])table(2 = 4)

Parameters

G

A Graph

Vertex

A list containing one or more vertices.

Return Values

Table containing all the indegrees of the specified vertices.

Graph::isConnected

Purpose

Finds out if the graph is connected

Syntax

```
Graph::isConnected(G)
```

Description

`Graph::isConnected(G)` returns `TRUE` if `G` is connected, `FALSE` otherwise.

Examples

Example 1

A circle graph is made to create a connected Graph:
G1 := Graph::createCircleGraph(3): Graph::isConnected(G1)TRUE

```
TRUE
```

After adding a single vertex to the graph, it is not connected any more:
G2 := Graph::addVertices(G1, [4]): Graph::isConnected(G2)FALSE

```
FALSE
```

Parameters

G

A graph

Return Values

TRUE or FALSE

Graph::isDirected

Purpose

Finds out if the graph is directed

Syntax

```
Graph::isDirected(G)
```

Description

`Graph::isDirected(G)` returns `TRUE` if `G` is directed, `FALSE` otherwise.

Examples

Example 1

A circle graph is made to create a directed Graph:
G1 := Graph::createCircleGraph(3): Graph::isDirected(G1)TRUE

```
TRUE
```

Example 2

Now a complete graph is created in order to get an undirected graph:
G1 := Graph::createCompleteGraph(3): Graph::isDirected(G1)FALSE

```
FALSE
```

Parameters

G

A graph

Return Values

TRUE or FALSE

Graph::isEdge

Purpose

Finds out if the edges exists

Syntax

```
Graph::isEdge(G, Edge)
```

Description

`Graph::isEdge(G)` returns `TRUE` if `ALL` specified edges exist in `G`, `FALSE` otherwise.

Examples

Example 1

A circle graph is made to create a directed Graph:
G1 := Graph::createCircleGraph(3): Graph::printGraphInformation(G1)
Vertices: [1, 2, 3] Edges: [[1, 2], [2, 3], [3, 1]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [2], 2 = [3], 3 = [1] Adjacency list (in): 1 = [3], 2 = [1], 3 = [2] Graph is directed.

First let us check for an existing single edge:
Graph::isEdge(G1, [[1, 2]])TRUE

```
TRUE
```

Now we check if several edges exist:
Graph::isEdge(G1, [[1, 2], [2, 3]])TRUE

```
TRUE
```

What about a non existing edge?
Graph::isEdge(G1, [[3, 2]])FALSE

```
FALSE
```

Finally a list of some existing and non existing edges is checked:
Graph::isEdge(G1, [[1, 2], [2, 3], [3, 2]])FALSE

```
FALSE
```

Parameters

G

A graph

Edge

A list containing one or more edges

Return Values

TRUE or FALSE

Graph::isVertex

Purpose

Finds out if special vertices exist in the Graph

Syntax

```
Graph::isVertex(G, Vertex)
```

Description

`Graph::isVertex(G)` returns `TRUE` if `ALL` specified vertices exist in `G`, `FALSE` otherwise.

Examples

Example 1

A circle graph is made to create a directed Graph:
G1 := Graph::createCircleGraph(3): Graph::printGraphInformation(G1)
Vertices: [1, 2, 3] Edges: [[1, 2], [2, 3], [3, 1]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [2], 2 = [3], 3 = [1] Adjacency list (in): 1 = [3], 2 = [1], 3 = [2] Graph is directed.

First, let us check for an existing vertex:
Graph::isVertex(G1, [1])TRUE

```
TRUE
```

Now we check if several vertices exist:
Graph::isVertex(G1, [1, 2])TRUE

```
TRUE
```

What about a non existing vertex?
Graph::isVertex(G1, [4])FALSE

```
FALSE
```

Finally a list of some existing and non existing vertices is checked:
Graph::isVertex(G1, [1, 2, 4])FALSE

```
FALSE
```

Parameters

G

A graph

Vertex

A list containing one or more vertices

Return Values

TRUE or FALSE

Graph::longestPath

Purpose

Longest paths from one single node

Syntax

```
Graph::longestPath(G, v, <w>, <Length>, <Path>)
```

Description

`Graph::longestPath(G, v)` returns a table with the length of longest paths from `v` to all other nodes in the Graph with respect to the edge weight.

`Graph::longestPath(G, v, w)` returns the length of a longest path from `v` to `w`.

If the optional argument `Path` is given, a table with longest paths is returned. If both `Length` and `Path` are given, then both the length of the longest paths and the paths are returned. Paths are given as lists of nodes in reverse order.

If `Path` is not given, the option `Length` has no effect.

Note The Graph `G` must be directed and should not contain cycles.

Examples

Example 1

We construct a Graph and try a few calls to `Graph::longestPath`:
V := [1, 2, 3, 4, 5]: Ed := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4], [3, 5], [4, 5]]: Ew := [7, 6, 5, 4, 2, 2, 1]: G := Graph(V, Ed, EdgeWeights = Ew, Directed):
Graph::longestPath(G, 1)table(5 = 15, 4 = 14, 3 = 12, 2 = 7, 1 = 0)

1	0
2	7
3	12
4	14
5	15

Graph::longestPath(G, 1, Path)table(5 = [5, 4, 3, 2, 1], 4 = [4, 3, 2, 1], 3 = [3, 2, 1], 2 = [2, 1])

2	[2, 1]
3	[3, 2, 1]
4	[4, 3, 2, 1]
5	[5, 4, 3, 2, 1]

Parameters

G

A Graph

v

w

Vertices in `G`

Options

Length

Return a table with the lengths of shortest paths

Path

Return a table with the paths themselves

Return Values

Table, an integer or a list of nodes

Algorithms

The implemented algorithm is a variation of the algorithm of Bellman.

Graph::maxFlow

Purpose

Computes a maximal flow through a graph

Syntax

```
Graph::maxFlow(G, s, t)
```

Description

`Graph::maxFlow(G,s,t)` computes a maximal flow from `s` to `t` in `G` with respect to the edge capacities. `s` and `t` must be nodes in `G`.

`Graph::maxFlow(G,s,t)` returns a sequence containing the flow value, that is the inflow of `s`, which equals the outflow of `s`, and the flow itself in form of table `tbl` with the flow from vertex `v` to vertex `w` is `tbl[[v,w]]`.

Examples

Example 1

In the complete Graph with four vertices and default capacities of 1, the maximum flow from one vertex to another one consists of sending one unit through each of the remaining vertices and one directly, which makes three units altogether:
G1 := Graph::createCompleteGraph(4): Graph::maxFlow(G1, [1], [4])3, table([4, 3] = 0, [3, 4] = 1, [4, 2] = 0, [2, 4] = 1, [4, 1] = 0, [3, 2] = 0, [2, 3] = 0, [1, 4] = 1, [3, 1] = 0, [1, 3] = 1, [2, 1] = 0, [1, 2] = 1)

[1, 2]	1
[2, 1]	0
[1, 3]	1
[3, 1]	0
[2, 3]	0
[3, 2]	0
[4, 1]	0
[2, 4]	1
[4, 2]	0
[3, 4]	1
[4, 3]	0

Example 2

As a more complex example, the following graph shows that this function also finds flows through multiple edges, unlike Graph::admissibleFlow, which only works on completely described flows:

```
V := [1, 2, 3, s, t]: Edge := [[s, 1], [t, 2], [1, 2], [1, 3], [2, 3], [3, t]]: up
:= [5, 5, 2, 6, 6, 1]: G2 := Graph(V, Edge, EdgeCosts = up, Directed):
Graph::maxFlow(G2, [s], [t])1, table([3, t] = 1, [t, 2] = 0, [s, 1] = 1, [2, 3]
= 0, [1, 3] = 1, [1, 2] = 0)
```

[1, 2]	0
[1, 3]	1
[2, 3]	0
[s, 1]	1
[t, 2]	0
[3, t]	1

Parameters

G

Graph

s

t

Expressions (vertices in `G`)

Return Values

List, containing a number and a table

Algorithms

The implemented algorithm is the preflow-push algorithm of Goldberg &Tarjan with the FIFO selection strategy and an exact distance labeling (“A new approach to the maximum-flow problem”, Journal of the ACM 35(4), 1988).

The running time is $O(n^3)$, where n is the number of vertices in the Graph.

Graph::minCost

Purpose

Computes a minimal cost flow

Syntax

```
Graph::minCost(G)
```

Description

`Graph::minCost(G)` computes a minimal cost flow in `G` with respect to the edge capacities, the edge weights and the vertex weights of `G`.

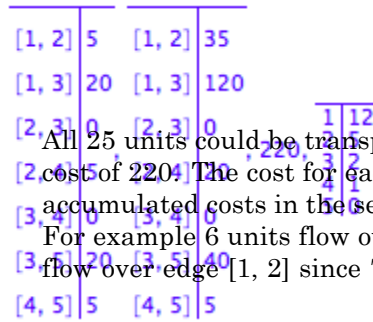
The vertex weights are interpreted as supply and demand. The edge weights give restrictions for the flow on every edge. The edge costs are the cost for one unit flow over an edge.

The algorithm computes a flow, if there is any, which is possible and satisfactory, i.e., it is within the supply and demand range, which respects the capacities and which has minimal cost.

Examples

Example 1

We construct a Graph with five vertices and seven edges. One of the vertices is a pure source (1), another one is a pure sink (5). No other vertices supply or demand any goods, they only serve as transportation junctions:
V := [1, 2, 3, 4, 5]: Vw := [25, 0, 0, 0, -25]: edges := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4], [3, 5], [4, 5]]: Ec := [7, 6, 5, 4, 2, 2, 1]: Ew := [30, 20, 25, 10, 20, 25, 20]: G1 := Graph(V, edges, EdgeCosts = Ec, EdgeWeights = Ew, VertexWeights = Vw, Directed): Graph::minCost(G1)table([4, 5] = 5, [3, 5] = 20, [3, 4] = 0, [2, 4] = 5, [2, 3] = 0, [1, 3] = 20, [1, 2] = 5), table([4, 5] = 5, [3, 5] = 40, [3, 4] = 0, [2, 4] = 20, [2, 3] = 0, [1, 3] = 120, [1, 2] = 35), 220, table(5 = 0, 4 = 1, 3 = 2, 2 = 5, 1 = 12)



All 25 units could be transported from vertex 1 to vertex 5, for a total cost of 220. The cost for each edge can be found in the first table, the accumulated costs in the second and the last table holds the dual prices. For example 6 units flow over edge [1, 3] since 620 = 120 and 7 units flow over edge [1, 2] since 75 = 35.

Parameters

G

Graph

Return Values

Sequence, consisting of three tables and a number. The first table holds the amount flowing over the edge, the second the accumulated costs for each used edge and the number is the sum of all edge-costs for the flow. The last table holds the dual prices for each vertex.

Algorithms

The implemented algorithm is the relaxation algorithm due to Bertsekas (taken from Bertsekas, “Linear Network Optimization”, MIT Press, Cambridge(Mass.)-London, 1991) which is known to be one of the fastest algorithms in practice.

Graph::minCut

Purpose

Computes a minimal cut

Syntax

```
Graph::minCut(G, q, s)
```

Description

`Graph::minCut(G,q,s)` computes a minimal cut in `G` that separates `q` from `s`, i.e., a subset `T` of the set `S` of edges of `G` such that every path from `q` to`s` contains at least one edge in `T`. The cut is minimal with respect to the capacities of the edges.

`Graph::minCut(G,q,s)` returns a sequence consisting of the cut value (the sum of the edge weights of the cut edges) and a list with the edges of the cut.

Note that `q` is separated from `s`, not vice versa.

Examples

Example 1

In a complete graph, a vertex can be separated from another one only by cutting all edges starting at the first vertex:
G1 := Graph::createCompleteGraph(4): Graph::minCut(G1, [1], [4])3, [[1, 2], [1, 3], [1, 4]]

3, [[1, 2], [1, 3], [1, 4]]

Example 2

In the following example, the edge from vertex `q` to vertex `1` could have been used as well, but its edge capacity is higher than that of the edge used, so the minimality condition precludes this choice:
V := [1, 2, 3, q, s]: Edge := [[q, 1], [1, 2], [1, 3], [2, 3], [3, s]]: up := [5, 2, 6, 6, 1]: G2 := Graph(V, Edge, EdgeWeights = up, Directed): Graph::minCut(G2, [q], [s])1, [[3, s]]

1, [[3, *s*]]

There is no path from vertex `s` to vertex `q` (or any other vertex of the Graph), so no cut is necessary to separate `s` from `q`:

Graph::minCut(G2, [s], [q])0, []

0, []

Parameters

q

s

Vertices that have to be defined within G

G

Graph

Return Values

Sequence, consisting of the “cut value” and a list of edges cut

Graph::minimumSpanningTree

Purpose

Creates a MST

Syntax

```
Graph::minimumSpanningTree(G, <SearchFor = Weights
| Costs>, <ReturnAsTable>)
```

Description

`Graph::minimumSpanningTree(G)` creates a minimum spanning tree according to the weights of the edges and returns a Graph consisting only of them. The same result would be achieved using `Graph::minimumSpanningTree(G, SearchFor = Weights)`

`Graph::minimumSpanningTree(G, SearchFor = Costs)` creates a minimum spanning tree according to the costs of the edges and returns a Graph consisting only of them.

`Graph::minimumSpanningTree(G, ReturnAsTable)` creates a minimum spanning tree according to the weights of the edges and returns a list with two objects. The first is a table consisting of the used edges and their weights. The second object is a number containing the sum of all the edge weights.(The same result can be achieved using: `Graph::minimumSpanningTree(G, SearchFor=Weights, ReturnAsTable)`.)

`Graph::minimumSpanningTree(G, SearchFor=Costs, ReturnAsTable)` creates a minimum spanning tree according to the costs of the edges and returns a list with two objects. The first is a table consisting of the used edges and their costs. The second object is a number containing the sum of all the edge costs.

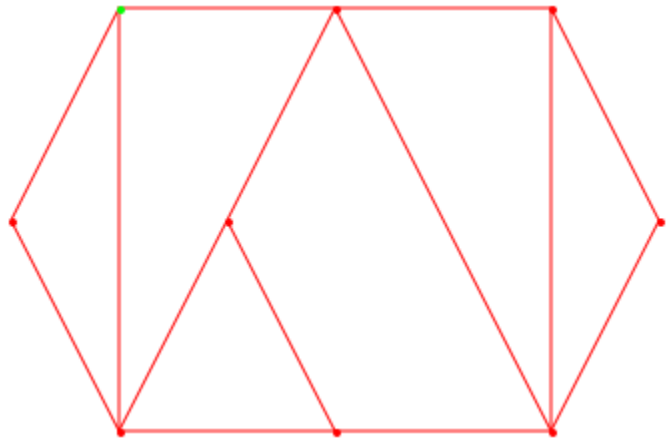
Examples

Example 1

The following graph will be used throughout all the following examples. MuPAD does not allow placement of any text at a specified coordinate. Thus the output of this description was not created with MuPAD. (Have a look at the edge [*c*, *f*]. This edge is responsible for the different outputs whether `Costs` or `Weights` was chosen.)
G := Graph([a, b, c, d, e, f, g, h, i], [[a, b], [a, h], [b, h], [b, c], [c, d], [d, f], [d, e], [f, e], [h, g], [g, f], [c, i], [h, i], [g, i], [c, f]], EdgeWeights = [4,

8, 11, 8, 7, 14, 9, 10, 1, 2, 2, 7, 6, 4], EdgeCosts = [4, 8, 11, 8, 7, 14, 9, 10, 1, 2, 2, 7, 6, 12]):

We will plot this graph and all graphs derived from it using Graph::plotGridGraph with the following options: plotOptions := VerticesPerLine=7, VertexOrder = [None, b, None, c, None, d, None, a, None, i, None, None, None, e, None, h, None, g, None, f, None]:plot(Graph::plotGridGraph(G, plotOptions))



Now we use this Graph to create a minimum spanning tree according to the weights of the edges and have a look which edges were used: Graph::minimumSpanningTree(G, SearchFor = Weights, ReturnAsTable), Graph::minimumSpanningTree(G, ReturnAsTable)[table([h, g] = 1, [g, h] = 1, [g, f] = 2, [f, g] = 2, [i, c] = 2, [c, i] = 2, [f, c] = 4, [e, d] = 9, [d, e] = 9, [c, f] = 4, [d, c] = 7, [c, d] = 7, [c, b] = 8, [b, c] = 8, [b, a] = 4, [a, b] = 4), 37], [table([h, g] = 1, [g, h] = 1, [g, f] = 2, [f, g] = 2, [i, c] = 2, [c, i] = 2, [f, c] = 4, [e, d] = 9, [d, e] = 9, [c, f] = 4, [d, c] = 7, [c, d] = 7, [c, b] = 8, [b, c] = 8, [b, a] = 4, [a, b] = 4), 37]

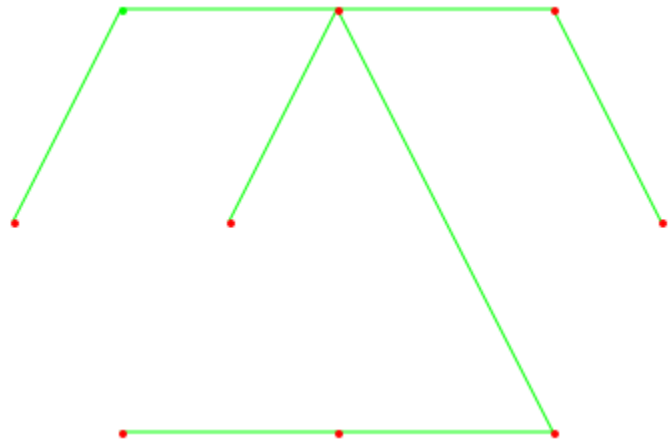
[a, b]	4
[b, a]	4
[b, c]	8
[c, b]	8
[c, d]	7
[d, c]	7
[d, e]	9, 37
[e, d]	9
[f, c]	4
[i, c]	2
[f, g]	2
[g, f]	2
[g, h]	1
[h, g]	1

[a, b]	4
[b, a]	4
[b, c]	8
[c, b]	8
[c, d]	7
[d, c]	7
[d, e]	9, 37
[e, d]	9
[f, c]	4
[i, c]	2
[f, g]	2
[g, f]	2
[g, h]	1
[h, g]	1

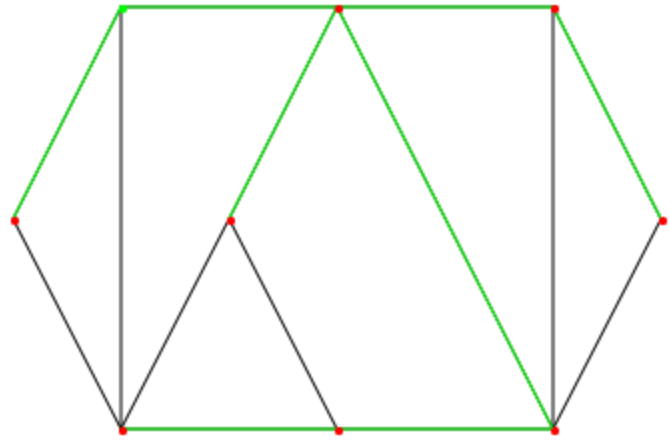
Both calls return exactly the same tables. That was expected and just to show that it is of no importance if the additional `SearchFor=Weights` is omitted.

Now we want to get the minimum spanning tree returned as a Graph so we can have a look how it looks like

```
weightMST := Graph::minimumSpanningTree(G):
plot(Graph::plotGridGraph(weightMST, plotOptions, EdgeColor =
RGB::Green))
```

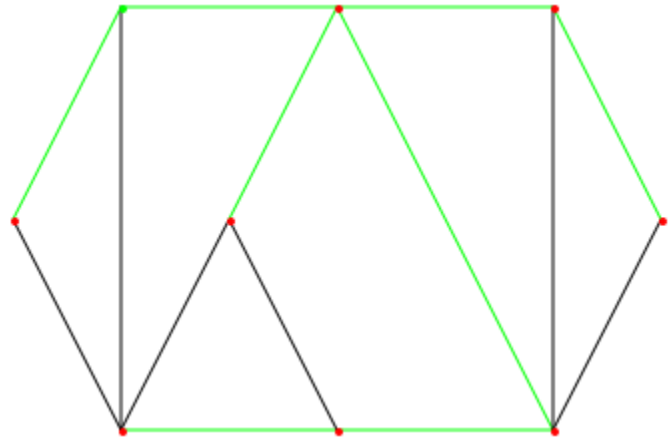


There are two ways of displaying both graphs at the same time:
plot(Graph::plotGridGraph(G, plotOptions, EdgeColor = RGB::Black), Graph::plotGridGraph(weightMST, plotOptions, EdgeColor = RGB::Green))



edgesWeightMST := Graph::getEdges(weightMST):
plot(Graph::plotGridGraph(G, plotOptions, EdgeColor =

RGB::Black, SpecialEdges = edgesWeightMST, SpecialEdgeColor = RGB::Green))



Example 2

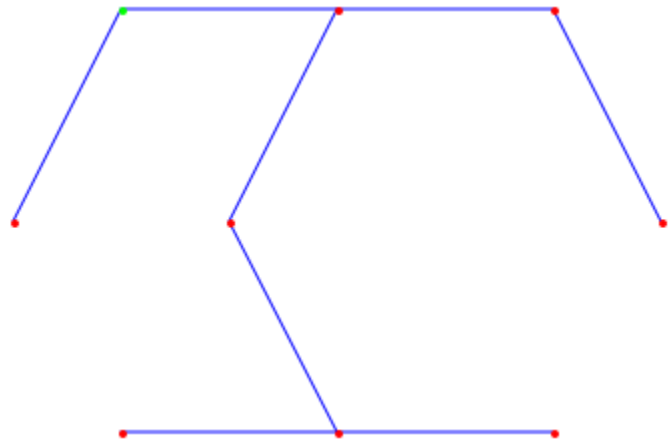
Maybe instead of the weights there is an interest in getting the MST for the costs of the edges.

G := Graph([a, b, c, d, e, f, g, h, i], [[a, b], [a, h], [b, h], [b, c], [c, d], [d, f], [d, e], [f, e], [h, g], [g, f], [c, i], [h, i], [g, i], [c, f]], EdgeWeights = [4, 8, 11, 8, 7, 14, 9, 10, 1, 2, 2, 7, 6, 4], EdgeCosts = [4, 8, 11, 8, 7, 14, 9, 10, 1, 2, 2, 7, 6, 12]):Graph::minimumSpanningTree(G, SearchFor = Costs, ReturnAsTable)[table([i, g] = 6, [g, i] = 6, [h, g] = 1, [g, h] = 1, [g, f] = 2, [f, g] = 2, [i, c] = 2, [c, i] = 2, [e, d] = 9, [d, e] = 9, [d, c] = 7, [c, d] = 7, [c, b] = 8, [b, c] = 8, [b, a] = 4, [a, b] = 4), 39]

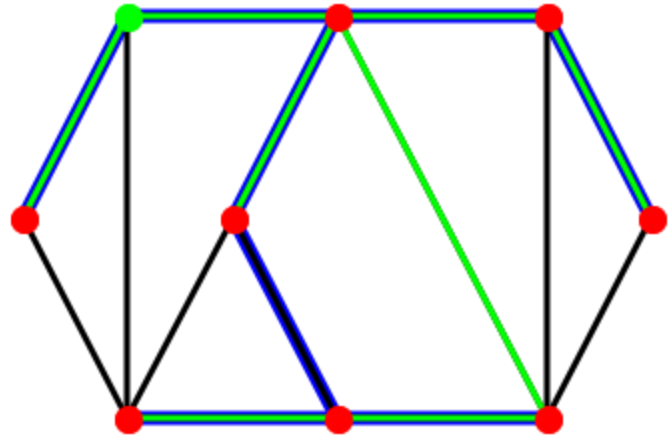
[a, b]	4
[b, a]	4
[b, c]	8
[c, b]	8
[c, d]	7
[d, c]	7
[d, e]	9
[e, d]	9
[c, i]	2
[i, c]	2
[f, g]	2
[g, f]	2
[g, h]	1
[h, g]	1
[g, i]	6
[i, g]	6

Plotting this spanning tree is just as easy as above:

```
costMST := Graph::minimumSpanningTree(G, SearchFor = Costs):
plot(Graph::plotGridGraph(costMST, plotOptions, EdgeColor =
RGB::Blue))
```



To combine both spanning trees, we use different line widths, to avoid one graph being completely covered by the other:
plot(plot::Group2d(Graph::plotGridGraph(costMST, plotOptions, EdgeColor = RGB::Blue), LineWidth = 2.5), plot::Group2d(Graph::plotGridGraph(G, plotOptions, EdgeColor = RGB::Black), Graph::plotGridGraph(weightMST, plotOptions, EdgeColor = RGB::Green), PointSize = 5, LineWidth = 1))



Parameters

G

Graph

Options

SearchFor

Can either be `Costs` or `Weights`. Default is `Weights`

ReturnAsTable

If omitted, a Graph is returned, otherwise a list containing a table and the sum of the edge weights/costs.

Return Values

Graph consisting of the MST. Only if `ReturnAsTable` was specified, a list containing a table and a number are returned. The table holds the edges with either the weights or costs of each edge and the number is the sum of all edges.

Purpose

Creates a new Graph

Syntax

```
Graph(V, E, <VertexWeights = vw>, <EdgeDescriptions
= ed>, <EdgeWeights = ew>, <EdgeCosts = ec>,
<Directed | Undirected>)
```

Description

`Graph(V, E)` creates a Graph

`Graph([v1,...,vn],[e1,...,em])` generates a new undirected graph with n vertices and m edges.

`Graph([1,a,3], [[1,a],[1,3]], Directed)` generates a new directed graph with the vertices `1`, `a`, `3` and the edges `[1,a]`, `[1,3]`.

`Graph([a,b,3], [[a,b],[b,3]], VertexWeights = [1,2,3], EdgeWeights = [4,5])` generates a new directed graph where the vertices have the values `a=1`, `b=2`, `3=3` and the edges `[a,b]=4`, `[b,3]=5`.

`Graph([a,b,3], [[a,b],[b,3]], VertexWeights = [1,None,3], EdgeWeights = [4, None])` generates a new directed graph where the vertices have the values `a=1`, `3=3` and the edges `[a,b]=4`. The difference to the example directly above is that the keyword `None` can be used to not assign a value to a vertex or edge.

Examples

Example 1

An (undirected) graph with four vertices:
G1 := Graph([1,a,3], [[1,a],[1,3]]): Graph::printGraphInformation(G1) Vertices: [1, 3, a] Edges: [[1, 3], [1, a], [3, 1], [a, 1]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [3, a], a = [1], 3 = [1] Adjacency list (in): 1 = [3, a], a = [1], 3 = [1] Graph is undirected.

Example 2

The same graph but this time with parameter `Directed`:
G1 := Graph([1,a,3], [[1,a],[1,3]], Directed):
Graph::printGraphInformation(G1) Vertices: [1, 3, a] Edges: [[1, 3], [1, a]] Vertex weights: no vertex weights. Edge descriptions: no edge

descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [3, a], a = [], 3 = [] Adjacency list (in): 1 = [], a = [1], 3 = [1] Graph is directed.

Example 3

The circle graph with predefined vertices:
G3 := Graph([a,b,3], [[a,b],[b,3]], VertexWeights = [1,2,3], EdgeWeights = [4,5]): Graph::printGraphInformation(G3) Vertices: [3, a, b] Edges: [[3, b], [a, b], [b, 3], [b, a]] Vertex weights: a = 1, b = 2, 3 = 3 (other existing vertices have no weight) Edge descriptions: no edge descriptions. Edge weights: [a, b] = 4, [b, 3] = 5, [b, a] = 4, [3, b] = 5 (other existing edges have no weight) Edge costs: no edge costs. Adjacency list (out): a = [b], b = [3, a], 3 = [b] Adjacency list (in): a = [b], b = [3, a], 3 = [b] Graph is undirected.

Example 4

The circle graph with predefined vertices:
G3 := Graph([a,b,3,7], [[a,b],[b,3],[3,7]], VertexWeights = [1,2,3,4], EdgeWeights = [-1,-2,-5], EdgeDescriptions = ["Small", None, "Smallest"]): Graph::printGraphInformation(G3) Vertices: [3, 7, a, b] Edges: [[3, 7], [3, b], [7, 3], [a, b], [b, 3], [b, a]] Vertex weights: a = 1, b = 2, 3 = 3, 7 = 4 (other existing vertices have no weight) Edge descriptions: [a, b] = "Small", [3, 7] = "Smallest", [b, a] = "Small", [7, 3] = "Smallest" Edge weights: [a, b] = -1, [b, 3] = -2, [3, 7] = -5, [b, a] = -1, [3, b] = -2, [7, 3] = -5 (other existing edges have n\ o weight) Edge costs: no edge costs. Adjacency list (out): a = [b], b = [3, a], 3 = [7, b], 7 = [3] Adjacency list (in): a = [b], b = [3, a], 3 = [7, b], 7 = [3] Graph is undirected.

If you look at the edge descriptions, the keyword `None` can be used for every edge which is not supposed to have a description.

Parameters

V

List of vertices

E

List of edges

vw

ew

ec

List of numbers

ed

List of strings

Options

Directed

The Graph is created as a directed graph.

Undirected

The Graph is created as an undirected graph. `Default`.

Graph::outDegree

Purpose

Returns the outdegree of one or more vertices.

Syntax

```
Graph::outDegree(G, <Vertex>)
```

Description

`Graph::outDegree(G)` returns the number of edges leaving each vertex `Vertex` of the Graph `G`.

`Graph::outDegree(G, Vertex)` returns the outdegree of the vertex `Vertex` in the Graph `G`, i.e., the number of edges `[Vertex, u]`.

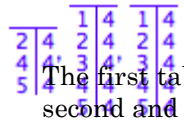
`Graph::outDegree(G, [v1, v2, ..., vn])` returns a table in which the keys are `v1, v2, ..., vn` and the corresponding values are the outdegrees.

`Graph::outDegree(G)` returns a table in which each node of `G` is mapped to its outdegree. `Graph::outDegree(G)` is equivalent to `Graph::outDegree(G, Graph::getVertices(G)))`.

Examples

Example 1

In a complete graph of n vertices, each vertex has outdegree n - 1:
G := Graph::createCompleteGraph(5): Graph::outDegree(G, [2, 4, 5]), Graph::outDegree(G), Graph::outDegree(G, Graph::getVertices(G))table(5 = 4, 4 = 4, 2 = 4), table(5 = 4, 4 = 4, 3 = 4, 2 = 4, 1 = 4), table(5 = 4, 4 = 4, 3 = 4, 2 = 4, 1 = 4)



The first table shows what happens, if some vertices are specified. The second and third table return all indegrees, but with two different calls (the second is redundant).

Example 2

Remember that also only one vertex needs to be specified as a list !

```
G := Graph::createCompleteGraph(5):Graph::outDegree(G, [2])table(2
= 4)
```

```
2|4
```

Parameters

G

A Graph

Options

Vertex

A list containing one or more vertices.

Return Values

Table containing all the outdegrees of the specified vertices.

Graph::plotBipartiteGraph

Purpose

Plots a Graph in a bipartite layout

Syntax

```
Graph::plotBipartiteGraph(G, <PointSize = n>,
<SpecialVertices = [v1,  ,vn]>, <SpecialEdges =
[e1,  ,en]>, <EdgeColor = RGB>, <SpecialEdgeColor =
RGB>, <SpecialVertexColor = RGB>, <Vertex1Color =
RGB>, <Vertex2Color = RGB>)
```

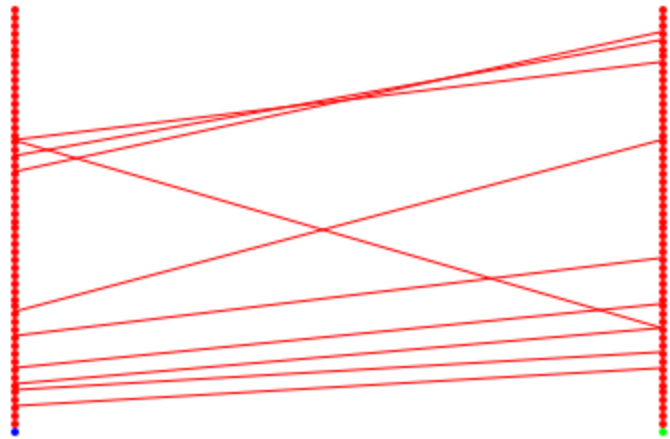
Description

`Graph::plotBipartiteGraph(G)` returns a plot::Group2d object in which the vertices are ordered in two rows (from bottom to top). The first vertex in the left row is drawn in blue and the second (the first vertex in the right row) in green. All other vertices are drawn in red. The width of the points is predefined with 40.

Examples

Example 1

A random graph is created and plotted (your output may differ due to random creation):
G1 := Graph::createRandomGraph(110, 10, Undirected):
plot(Graph::plotBipartiteGraph(G1)):

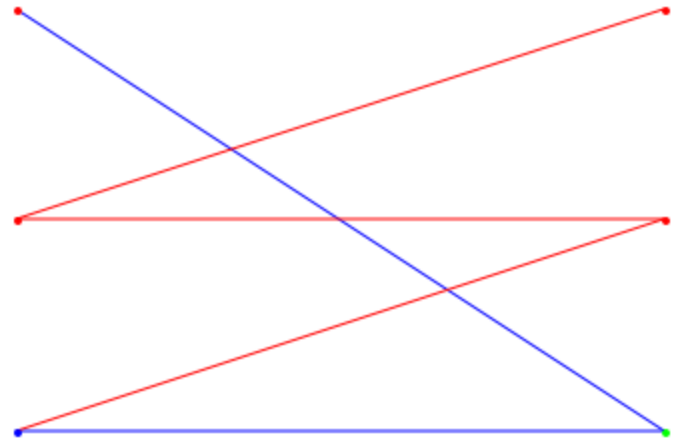


Example 2

If some edges are to be emphasized they can be drawn in a special color:
G2 := Graph([1, 2, 3, 4, 5, 6], [[1, 2], [2, 3], [3, 4], [4, 5], [1, 6]]):
Graph::bipartite(G2, Lists)[[2, 4, 6], [1, 3, 5]]

```
[[2, 4, 6], [1, 3, 5]]
```

edges := [[6, 1], [1, 2]]: plot(Graph::plotBipartiteGraph(G2, SpecialEdges = edges, SpecialEdgeColor = RGB::Blue))



Parameters

G

Graph

n

a positive integer.

$[v_1, \ldots, v_n]$

a list of vertices.

$[e_1, \ldots, e_n]$

a list of edges.

Options

PointSize

Defines the thickness in which the points are drawn. Default is 40.

SpecialVertices

Defines a set of vertices. This option makes only sense if used with the option `SpecialVertexColor`.

SpecialEdges

Defines a set of edges. This option makes only sense if used with the option `SpecialEdgeColor`.

EdgeColor

Defines a color with which to draw the edges. Default is `RGB ::Red`.

SpecialEdgeColor

Defines a color to be used to draw the set of edges specified. This option makes only sense if used with the option `SpecialEdges`.

VertexColor

Defines a color with which to draw the vertices. If this option is specified, the first two vertices are set to this color, too. They can be given different colors via `Vertex1Color` and `Vertex2Color`. Default is `RGB::Red`.

SpecialVertexColor

Defines a color to be used to draw the set of vertices specified. This option makes only sense if used with the option `SpecialVertices`.

Vertex1Color

Defines a color with which to draw the first vertex with (the starting vertex at the bottom of the first set). Default is `RGB::Blue`.

Vertex2Color

Defines a color with which to draw the second vertex with (the starting vertex at the bottom of the second set). Default is `RGB::Green`.

Return Values

plot::Group2d

Graph::plotCircleGraph

Purpose

Plots a Graph in a circle layout

Syntax

```
Graph::plotCircleGraph(G, <PointSize = n>, <SpecialVertices
= [v1,  ,vn]>, <SpecialEdges = [e1,  ,en]>, <EdgeColor =
RGB>, <SpecialEdgeColor = RGB>, <SpecialVertexColor = RGB>,
<Vertex1Color = RGB>, <Vertex2Color = RGB>)
```

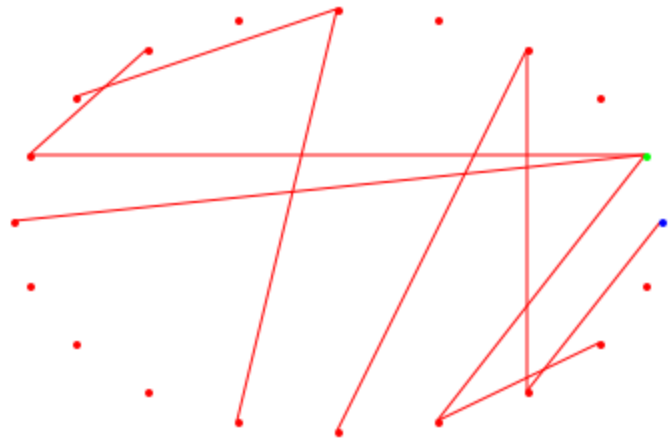
Description

`Graph::plotCircleGraph(G)` returns a plot::Group2d object in which the vertices are ordered in a circle (rightmost position upwards). The first vertex is drawn in blue and the second in green. All other vertices are drawn in red. The edges are drawn in red. The width of the points is predefined with 40. If a vertex points to itself it will be drawn outside

Examples

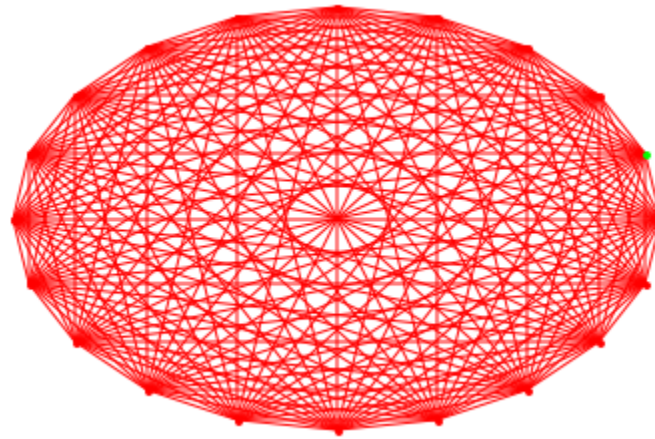
Example 1

A random graph is created and plotted (your output may differ due random creation):
G1 := Graph::createRandomGraph(20, 10, Undirected):
plot(Graph::plotCircleGraph(G1))



Next, a complete graph will be plotted.

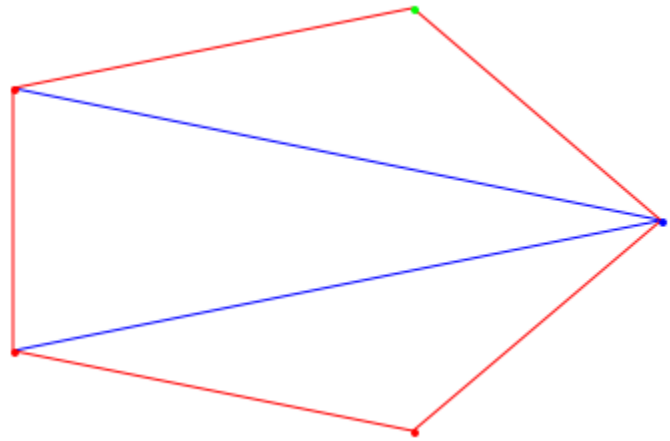
```
G1 := Graph::createCompleteGraph(20):
plot(Graph::plotCircleGraph(G1))
```



Example 2

If some edges are to be emphasized they can be drawn in a special color:

```
G2 := Graph([1, 2, 3, 4, 5], [[1, 2], [2, 3], [3, 4], [4, 5], [1, 3], [1, 4], [1, 5]]):
edges := [[1, 3], [1, 4]]: plot(Graph::plotCircleGraph(G2, SpecialEdges =
edges, SpecialEdgeColor = RGB::Blue))
```



Parameters

G

Graph

n

a positive integer.

[v_1, ...,v_n]

a list of vertices.

[e_1, ...,e_n]

a list of edges.

Options

PointSize

Defines the thickness in which the points are drawn. Default is 40.

SpecialVertices

Defines a set of vertices. This option makes only sense if used with the option `SpecialVertexColor`.

SpecialEdges

Defines a set of edges. This option makes only sense if used with the option `SpecialEdgeColor`.

EdgeColor

Defines a color with which to draw the edges. Default is RGB::Red

SpecialEdgeColor

Defines a color to be used to draw the set of edges specified. This option makes only sense if used with the option `SpecialEdges`

VertexColor

Defines a color with which to draw the vertices. If this option is specified, the first two vertices are set to this color, too. They must be specified via `Vertex1Color` and `Vertex2Color` to distinct them again. Default is RGB::Red

SpecialVertexColor

Defines a color to be used to draw the set of vertices specified. This option makes only sense if used with the option `SpecialVertices`

Vertex1Color

Defines a color with which to draw the uppermost left (first) vertex with (the starting vertex). Default is RGB::Blue

Vertex2Color

Defines a color with which to draw the second vertex with. Default is RGB::Green

Return Values

plot::Group2d

Graph::plotGridGraph

Purpose

Plots a Graph in a grid layout

Syntax

```
Graph::plotGridGraph(G, <PointSize = n>, <VerticesPerLine
= n>, <VertexOrder = [n1,  ,nm]>, <SpecialVertices = [v1,
 ,vn]>, <SpecialEdges = [e1,  ,en]>, <EdgeColor = RGB>,
<SpecialEdgeColor = RGB>, <SpecialVertexColor = RGB>,
<Vertex1Color = RGB>, <Vertex2Color = RGB>)
```

Description

`Graph::plotGridGraph(G)` returns a plot::Scene object in which the vertices are square ordered (topmost left to downmost right). The number of vertices per line is the floor of the squareroot of the number of the vertices. The first vertex is drawn in RGB::Blue and the second in RGB::Green. All other vertices are drawn in RGB::Red. The edges are drawn in RBG::Red. The width of the points is predefined with 40. If the last line contains only one vertex, it will be drawn centered in the middle of the line.

`Graph::plotGridGraph(G, VerticesPerLine=n)` returns a plot::Scene object like described above with one exception. In every line there are exactly `n` vertices. They appear in sorted order depending on their name. If the last row consists of only one vertex, this one will be centered.

`Graph::plotGridGraph(G, VerticesPerLine=[v1..vn])` returns a plot::Scene object like described above with one exception. In line 1 there are exactly `v1` vertices placed. In line 2 there are `v2` vertices and so on. The last line contains `vn` vertices. They appear in sorted order depending on their name. The sum of the numbers specified in VerticesPerLine must equal the number of vertices in the graph.

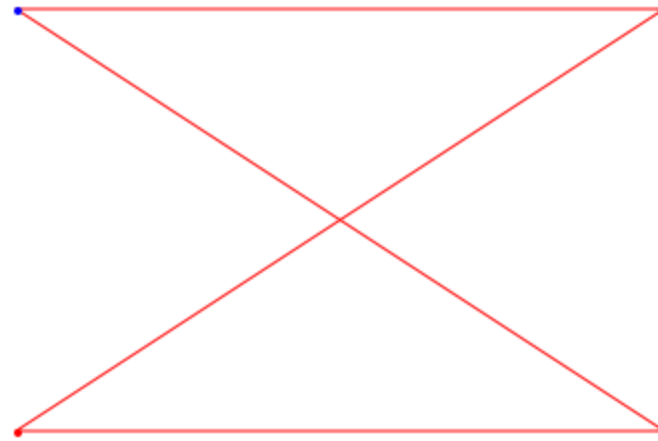
`Graph::plotGridGraph(G, VerticesPerLine=n, VertexOrder=[v1..vn])` returns a plot::Scene object like described above with one exception. In every line there are exactly `n` vertices. They appear in sorted order depending on the order that was specified in VertexOrder. `vi` can consist of any vertex defined as well as the substitute `None`. Nevertheless the number of vertices in `G` must not exceed the number of VerticesPerLine. If the last line holds only one vertex, it will be centered.

Examples

Example 1

First, a small graph is created and plotted with the default values:

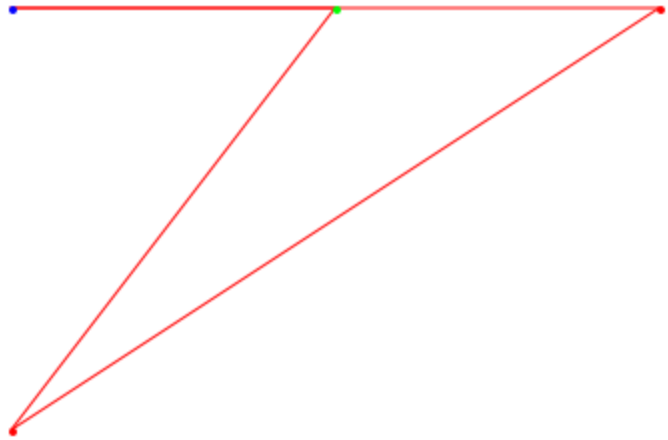
```
G := Graph([a, b, c, d], [[a, b], [b, c], [c, d], [d, a]]):
plot(Graph::plotGridGraph(G))
```



Now, we exchange the two vertices `c` and `d`. The order given above was `[a, b, c, d]`:

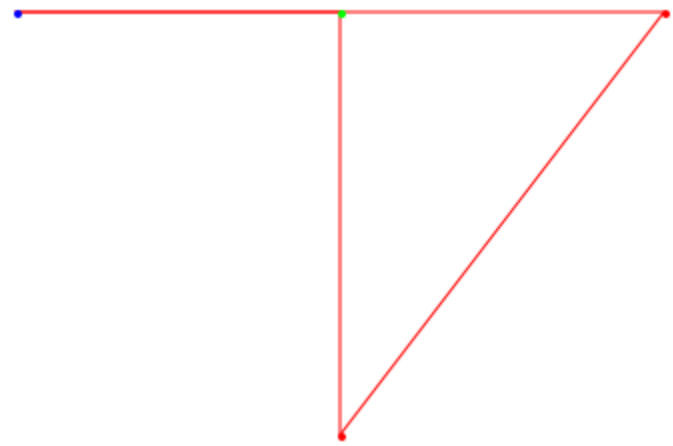
```
plot(Graph::plotGridGraph(G, VertexOrder = [a, b, d, c]))
```

If only one vertex is placed in the last line, it will be centered:
plot(Graph::plotGridGraph(G, VertexOrder = [a, b, d, c], VerticesPerLine = 3))

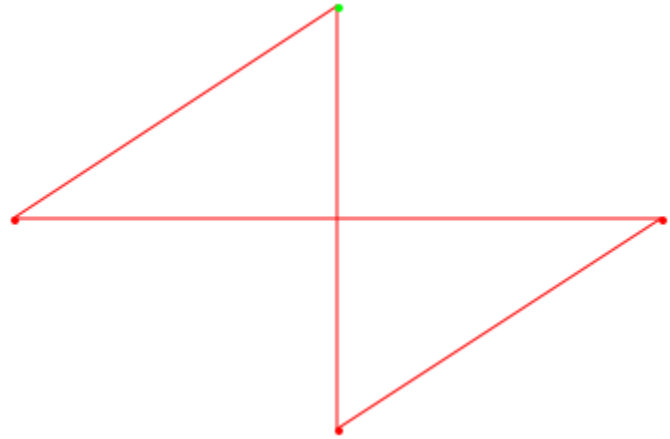


The same result can be gained by defining the Vertices per line specifically (in this case the number of vertices must be no less than the number of vertices in the graph):

plot(Graph::plotGridGraph(G, VertexOrder = [a, b, d, c], VerticesPerLine = [3, 1]))



Now we get to the point, why the plot routine got the name Grid. The substitute `None` can be used whenever a place should be skipped. Think of some drawing paper with caskets. The layout is exactly the same. In this case it would consist of 3 caskets in each row. None leaves it blank, while a vertex from the Graph is drawn. Because the first casket is empty, the first color is omitted, too. The vertex `a` which is placed in the second casket is drawn as predefined in `Vertex2Color` (`RGB::Green`):
plot(Graph::plotGridGraph(G, VertexOrder = [None, a, None, b, None, c, None, d, None], VerticesPerLine = 3))

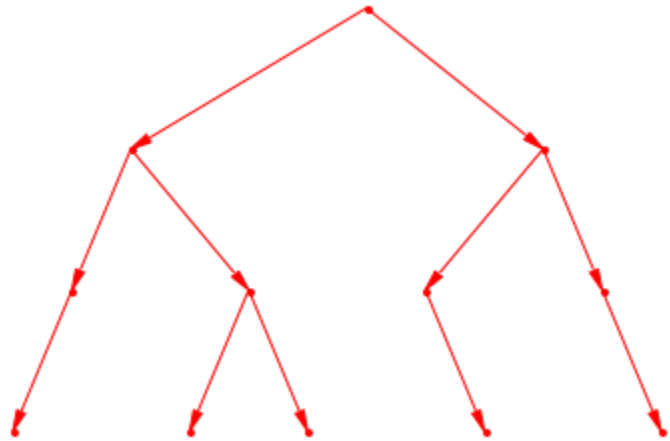


Example 2

With the knowledge obtained so far, it is possible to get deeper into the art of creating objects. One of the most usefull outputs is that of a tree. Thus a Graph is created to be used for the tree output:
TreeGraph := Graph([a, b, c, d, e, f, g, h, i, j, k, l], [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g], [d, h], [e, i], [e, j], [f, k], [g, l]], Directed):

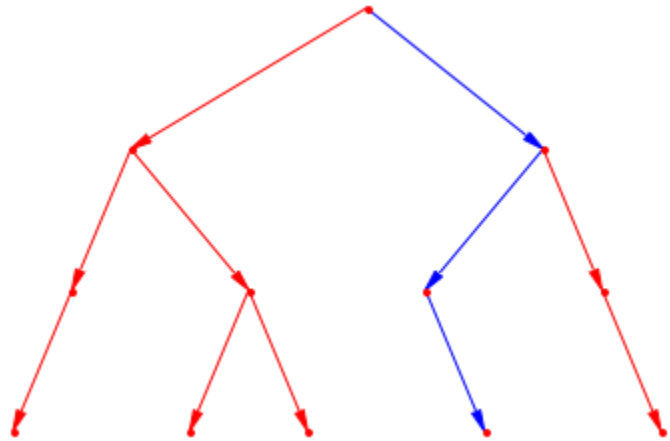
Next we define a special vertex order, because the vertices are not drawn the way they were defined:
vOrder := [None, None, None, None, None, None, a, None, None, None, None, None, None, None, b, None, None, None, None, None, None, c, None, None, None, d, None, None, e, None, None, f, None, None, g, None, h, None, None, i, None, j, None, None, k, None, None, l]:

Now it is time to have a look at how the tree looks:
plot(Graph::plotGridGraph(TreeGraph, VerticesPerLine = 12, VertexOrder = vOrder))



Now we want to see the path from vertex `a` to Vertexb. For this example it will be given explicitly. For bigger graphs one of the `shortestPath` procedures is recommended:
specialPath := [[a, c], [c, f], [f, k]]:

Finally we draw the path inside the Graph and have a good overview about the path it takes:
plot(Graph::plotGridGraph(TreeGraph, VerticesPerLine = 12, VertexOrder = vOrder, SpecialEdges = specialPath, SpecialEdgeColor = RGB::Blue))

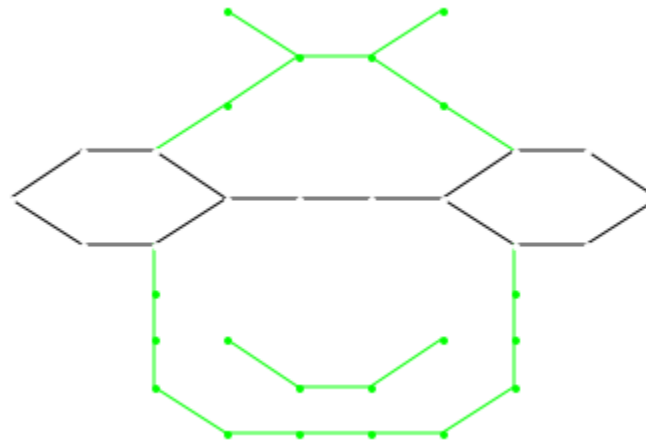


Example 3

To show what can be done with more detailed and complex examples a small outer face is being drawn (have a close look ath the Vertices which are not drawn, because the color is set to RBG::White and thus equals the background-color). Additionaly, the “eyes” have been colored differently, so the usage of `SpecialVertexColor` could be presented:

```
Smile := Graph([1,2,4,5,7,8,9,10,11,12,13,14,15,16,17,18,19,20,
21,22,23,24,25,26,27,28,29,30,31,32,33,34,35,36],
[[1,4],[2,5],[4,5],[7,4],[5,8],[7,10],[9,10],[10,14],[9,13],
[13,19],[19,20],[20,14],[14,15],[15,16],[16,17],[17,11],
[ 8,11],[11,12],[12,18],[18,22],[22,21],[21,17],[21,24],
[24,28],[28,32],[32,36],[36,35],[35,34],[34,33],[33,29],
[29,25],[25,23],[23,20],[26,30],[30,31],[31,27]]):  plot(
Graph::plotGridGraph(Smile, VerticesPerLine = 10, VertexOrder
= [ None,None,None, 1,None,None, 2,None,None,None,
None,None,None,None, 4, 5,None,None,None,None, None,None,None,
7,None,None, 8,None,None,None, None, 9, 10,None,None,None,None,
11, 12,None, 13,None,None, 14, 15, 16, 17,None,None, 18,
None, 19, 20,None,None,None,None, 21, 22,None, None,None,
23,None,None,None,None, 24,None,None, None,None, 25,
26,None,None, 27, 28,None,None, None,None, 29,None, 30, 31,None,
```

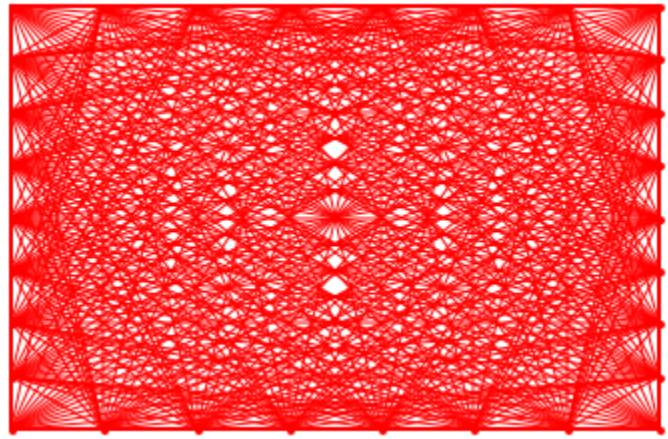
32,None,None, None,None,None, 33, 34, 35, 36,None,None,None],
SpecialEdges = [[13,9],[9,10],[10,14],[14,20],[20,19],[19,13],
[14,15],[15,16],[16,17],[17,21],[21,22],[22,18],[18,12],[12,11],
[11,17]], SpecialVertices = [1,2,4,5,7,8,23,24,25,26,27,28,29,30,31,
32,33,34,35,36], VertexColor = RGB::White, SpecialVertexColor =
RGB::Green, EdgeColor = RGB::Green, SpecialEdgeColor = RGB::Black)
)



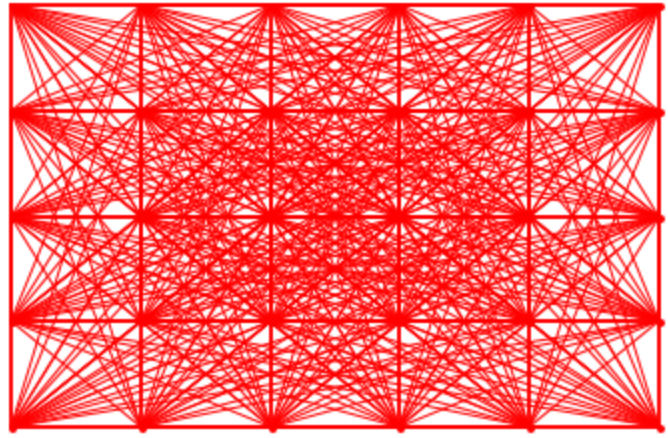
Example 4

The next example is a complete graph drawn with the vertices ordered in a square so that all vertices can be connected inside the square:

```
CG := Graph::createCompleteGraph(30):
plot(Graph::plotGridGraph(CG, VerticesPerLine = [8, 2, 2, 2, 2, 2, 2, 2,
8], Vertex1Color = RGB::Red, Vertex2Color = RGB::Red))
```



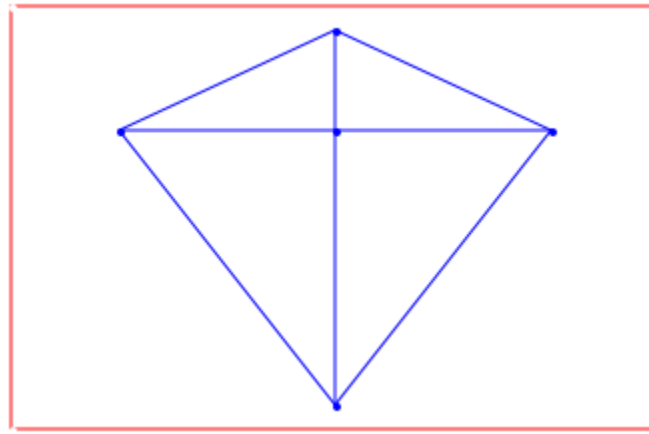
Using the default values in every line vertices are drawn and the graph looks not as “dense” as the above one:
plot(Graph::plotGridGraph(CG, Vertex1Color = RGB::Red, Vertex2Color = RGB::Red))



Example 5

The last example shows a small kite inside a frame:

```
Shield := Graph([1, 2, 3, 4, 5, 6, 7, 8, 9], [[1, 2], [1, 8], [2,
9], [8, 9], [3, 5], [4, 5], [5, 6], [5, 7], [3, 6], [6, 7], [3, 4],
[4, 7]]): plot(Graph::plotGridGraph(Shield, Vertex1Color
= RGB::White, Vertex2Color = RGB::White, VertexColor
= RGB::White, VerticesPerLine = 7, VertexOrder = [
1,None,None,None,None,None, 2, None,None,None,
3,None,None,None, None,None,None,None,None,None,None,
None,None,None,None,None,None,None,
None,None,None,None,None,None,None, None, 4,None,
5,None, 6,None, None,None,None,None,None,None,None,
None,None,None,None,None,None,None,
None,None,None,None,None,None,None,
None,None,None,None,None,None,None,
None,None,None,None,None,None,None,
None,None,None,None,None,None,None,
None,None,None,None,None,None,None,
None,None,None,None,None,None,None,
None,None,None,None,None,None,None,
None,None,None,None,None,None,None, None,None,None,
7,None,None,None, 8,None,None,None,None,None, 9], SpecialVertices
= [3, 4, 5, 6, 7], SpecialVertexColor = RGB::Blue, SpecialEdges = [[3,
5], [4, 5], [5, 6], [5, 7], [3, 6], [6, 7], [3, 4], [4, 7]], SpecialEdgeColor
= RGB::Blue))
```



Parameters

G

Graph

n

a positive integer.

[n_1, ...,n_m]

a list of positive integers.

[v_1, ...,v_n]

a list of vertices.

[e_1, ...,e_n]

a list of edges.

Options

PointSize

Defines the thickness in which the points are drawn. Default is 40.

VerticesPerLine

If specified as single number, this many vertices are placed in every row. If specified as list, the number of vertices per line are read out of the list. If the vertices are specified as list, the number of vertices must match either the number of vertices defined in the graph, or, if specified, the number defined in `VertexOrder`.

VertexOrder

Defines an order in which the vertices are to be placed. It starts in the upper left and ends in the lower right. The number of specified vertices must match the number of vertices defined in the graph or the sum of the vertices specified in VerticesPerLine.

SpecialVertices

Defines a set of vertices. This option makes only sense if used with the option `SpecialVertexColor`.

SpecialEdges

Defines a set of edges. This option makes only sense if used with the option `SpecialEdgeColor`.

EdgeColor

Defines a color with which to draw the edges. Default is RGB::Red

SpecialEdgeColor

Defines a color to be used to draw the set of edges specified. This option makes only sense if used with the option `SpecialEdges`

VertexColor

Defines a color with which to draw the vertices. If this option is specified, the first two vertices are set to this color, too. They must be specified via `Vertex1Color` and `Vertex2Color` to distinct them again. Default is RGB::Red

SpecialVertexColor

Defines a color to be used to draw the set of vertices specified. This option makes only sense if used with the option `SpecialVertices`

Vertex1Color

Defines a color with which to draw the uppermost left (first) vertex with (the starting vertex). If `VertexOrder` holds a `None` for this vertex, it will be skipped. Default is RGB::Blue

Vertex2Color

Defines a color with which to draw the second vertex with. If `VertexOrder` holds a `None` for this vertex, it will be skipped. Default is RGB::Green

Return Values

Plot::Scene.

Graph::printEdgeCostInformation

Purpose

Prints the edge costs of a graph

Syntax

```
Graph::printEdgeCostInformation(G)
```

Description

`Graph::printEdgeCostInformation` prints the edge costs of a graph.

`Graph::printEdgeCostInformation(G)` prints the edge costs of the graph *G*

Examples

Example 1

A circle graph is created and the edge costs of it printed to screen: G := Graph::createCircleGraph(3): Graph::printEdgeCostInformation(G) No edge costs defined. G := Graph::setEdgeCosts(G, [[1, 2], [2, 3], [3, 1]], [10, 20, 30]): Graph::printEdgeCostInformation(G) Edge costs existing in the graph: ---------- Edge [1, 2] has cost 10 Edge [2, 3] has cost 20 Edge [3, 1] has cost 30

Parameters

G

Graph

Return Values

Text containing information about the edge costs of a graph.

Graph::printEdgeDescInformation

Purpose

Prints the edge descriptions of a graph

Syntax

```
Graph::printEdgeDescInformation(G)
```

Description

`Graph::printEdgeDescInformation` prints the edge descriptions of a graph.

`Graph::printEdgeDescInformation(G)` prints the edge descriptions of the graph *G*

Examples

Example 1

A circle graph is created and the edge descriptions of it printed to screen:
G := Graph::createCircleGraph(3):
Graph::printEdgeDescInformation(G) No edge descriptions defined. G := Graph::setEdgeDescriptions(G, [[1, 2], [2, 3], [3, 1]], ["Shortcut","Highway","Speedup"]):
Graph::printEdgeDescInformation(G) Edge descriptions existing in the graph: ---------- Edge [1, 2] = "Shortcut" Edge [2, 3] = "Highway" Edge [3, 1] = "Speedup"

Parameters

G

Graph

Return Values

Text containing information about the edge descriptions of a graph.

Graph::printEdgeInformation

Purpose

Prints the edges of a graph

Syntax

```
Graph::printEdgeInformation(G)
```

Description

`Graph::printEdgeInformation` prints the edges of a graph.

`Graph::printEdgeInformation(G)` prints the edges used in the graph *G*.

Examples

Example 1

A circle graph is created and the edges of it printed to screen:
G := Graph::createCircleGraph(3): Graph::printEdgeInformation(G)
Edges existing in the graph: ---------- [1, 2], [2, 3], [3, 1]

Example 2

A complete graph is created and the edges of it printed to screen:
G := Graph::createCompleteGraph(3): Graph::printEdgeInformation(G)
Edges existing in the graph: ---------- [1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]

Parameters

G

Graph

Return Values

Text containing information about the edges of a graph.

Graph::printEdgeWeightInformation

Purpose

Prints the edge weights of a graph

Syntax

```
Graph::printEdgeWeightInformation(G)
```

Description

`Graph::printEdgeWeightInformation` prints the edge weights of a graph.

`Graph::printEdgeWeightInformation(G)` prints the edge weights of the graph *G*

Examples

Example 1

A circle graph is created and the edge weights of it printed to screen:
G := Graph::createCircleGraph(3):
Graph::printEdgeWeightInformation(G) No edge weights defined.
G := Graph::setEdgeWeights(G, [[1, 2], [2, 3], [3, 1]], [10, 20, 30]):
Graph::printEdgeWeightInformation(G) Edge weights existing in the graph: ---------- Edge [1, 2] has weight 10 Edge [2, 3] has weight 20 Edge [3, 1] has weight 30

Parameters

G

Graph

Return Values

Text containing information about the edge weights of a graph.

Graph::printGraphInformation

Purpose

Prints the edges of a graph

Syntax

```
Graph::printGraphInformation(G)
```

Description

`Graph::printGraphInformation` prints a summary of various information about a graph.

`Graph::printGraphInformation(G)` prints a summary of the graph *G*

Examples

Example 1

A circle graph is created and a summary of it printed to screen:
G := Graph::createCircleGraph(3): Graph::printGraphInformation(G) Vertices: [1, 2, 3] Edges: [[1, 2], [2, 3], [3, 1]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [2], 2 = [3], 3 = [1] Adjacency list (in): 1 = [3], 2 = [1], 3 = [2] Graph is directed.

Example 2

A complete graph is created and a summary of it printed to screen:
G := Graph::createCompleteGraph(3):
Graph::printGraphInformation(G) Vertices: [1, 2, 3] Edges: [[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2] Adjacency list (in): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2] Graph is undirected.

Parameters

G

Graph

Return Values

Text containing information about the graph.

Graph::printVertexInformation

Purpose

Prints vertex information of a graph

Syntax

```
Graph::printVertexInformation(G)
```

Description

`Graph::printVertexInformation` prints the edges of a graph.

`Graph::printVertexInformation(G)` prints the edges of the graph *G*

Examples

Example 1

A circle graph is created and information of the vertices printed to screen:
G := Graph::createCircleGraph(3): Graph::printVertexInformation(G)
Vertices existing in the graph: ---------- Vertex 1 has weight None Vertex 2 has weight None Vertex 3 has weight None

Example 2

A complete graph is created and information of the vertices printed to screen:
G := Graph::createCompleteGraph(3):
Graph::printVertexInformation(G) Vertices existing in the graph:
---------- Vertex 1 has weight None Vertex 2 has weight None Vertex 3 has weight None

Parameters

G

Graph

Return Values

Text containing information about the vertices of a graph.

Graph::removeEdge

Purpose

Removes one or several edges from a graph

Syntax

```
Graph::removeEdge(G, e)
Graph::removeEdge(G, l)
```

Description

`Graph::removeEdge(G, [e1, ..., en])` removes edges `e1...en` from graph `G`.

`Graph::removeEdge` deletes one or several edges from a graph. An edge is represented by a list containing two vertices of the graph. A warning is printed if the specified edge is not contained in the graph.

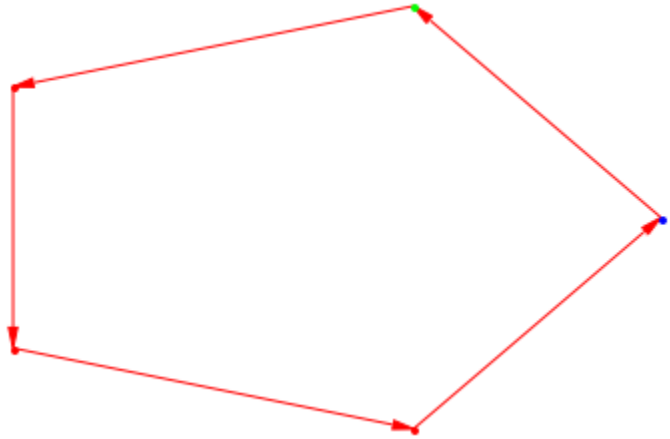
`Graph::removeEdge(G, e)` removes the edge `e` from the graph `G`.

`Graph::removeEdge(G, l)` removes all edges in list `l` from graph `G`.

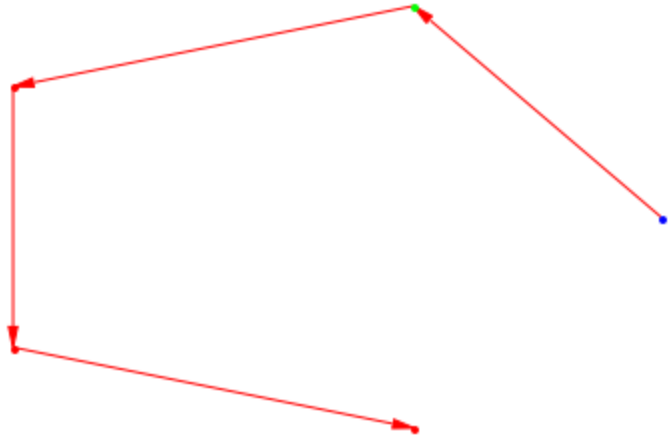
Examples

Example 1

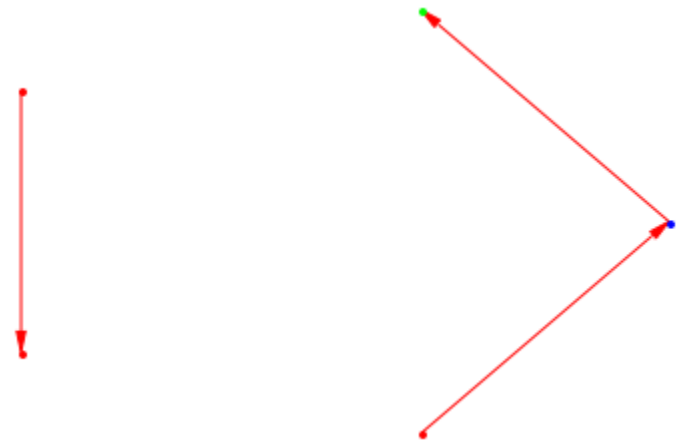
Removing an edge from a cyclic graph results in a (degenerated) tree: G1 := Graph::createCircleGraph(5): Graph::printGraphInformation(G1) Vertices: [1, 2, 3, 4, 5] Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1] Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4] Graph is directed. plot(Graph::plotCircleGraph(G1))



G2 := Graph::removeEdge(G1, [[5, 1]]):
Graph::printGraphInformation(G2) Vertices: [1, 2, 3, 4, 5] Edges: [[1, 2], [2, 3], [3, 4], [4, 5]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [] Adjacency list (in): 1 = [], 2 = [1], 3 = [2], 4 = [3], 5 = [4] Graph is directed. plot(Graph::plotCircleGraph(G2))



If more than one edge is to be removed they must also be specified in a list:
edges := [[2, 3], [4, 5]]: G3 := Graph::removeEdge(G1, edges): Graph::printGraphInformation(G3) Vertices: [1, 2, 3, 4, 5] Edges: [[1, 2], [3, 4], [5, 1]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [2], 2 = [], 3 = [4], 4 = [], 5 = [1] Adjacency list (in): 1 = [5], 2 = [1], 3 = [], 4 = [3], 5 = [] Graph is directed.
plot(Graph::plotCircleGraph(G3))



Parameters

l

A list of edges

e

An edge

G

A graph

Return Values

Graph

Graph::removeVertex

Purpose

Removes one or several vertices from a graph

Syntax

```
Graph::removeVertex(G, v)
Graph::removeVertex(G, l)
```

Description

`Graph::removeVertex(G, v)` removes vertex `v` from graph `G`.

`Graph::removeVertex(G, [v1, ..., vn])` removes vertices `v1...vn` from graph `G`.

`Graph::removeVertex` deletes one or several vertices from a graph. A warning is printed if the specified vertex is not contained in the graph.

Note If a vertex is connected to other vertices with edges, they will be removed from the graph, too!

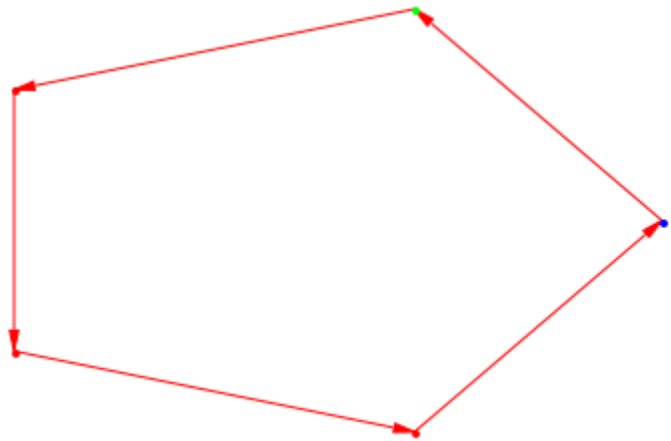
`Graph::removeVertex(G, v)` removes the vertex `v` from the graph `G`.

`Graph::removeVertex(G, l)` removes all vertices in list `l` from graph `G`.

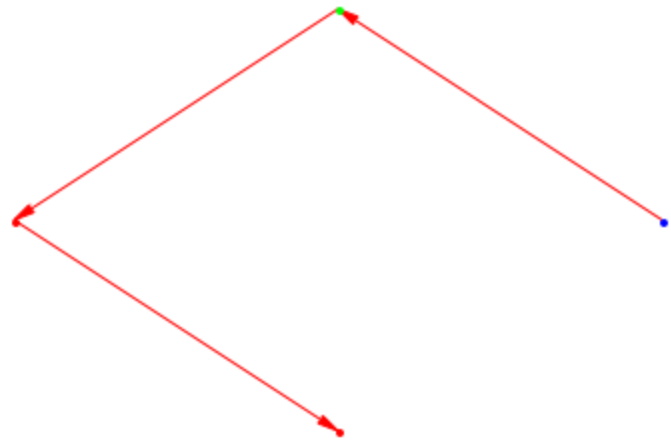
Examples

Example 1

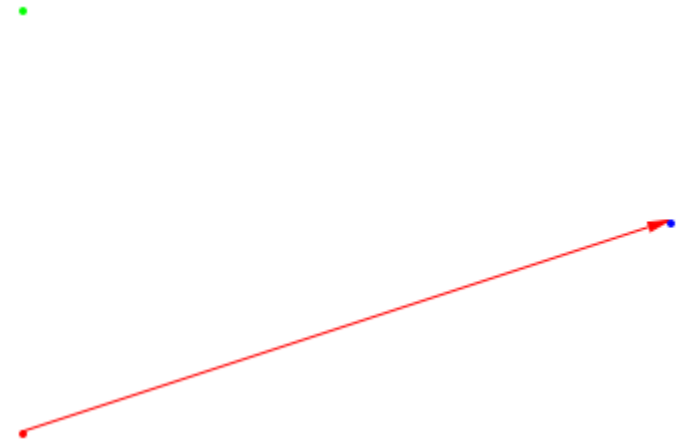
Removing a vertex from a cyclic graph removes also two edges:
G1 := Graph::createCircleGraph(5): Graph::printGraphInformation(G1)
Vertices: [1, 2, 3, 4, 5] Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1] Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4] Graph is directed.
plot(Graph::plotCircleGraph(G1))



G2 := Graph::removeVertex(G1, [1]):
Graph::printGraphInformation(G2) Vertices: [2, 3, 4, 5] Edges: [[2, 3], [3, 4], [4, 5]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 2 = [3], 3 = [4], 4 = [5], 5 = [] Adjacency list (in): 2 = [], 3 = [2], 4 = [3], 5 = [4] Graph is directed.
plot(Graph::plotCircleGraph(G2))



If more than one vertex is to be removed they must also be specified in a list:
vertices := [2, 4]: G3 := Graph::removeVertex(G1, vertices): Graph::printGraphInformation(G3) Vertices: [1, 3, 5] Edges: [[5, 1]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: no edge weights. Edge costs: no edge costs. Adjacency list (out): 1 = [], 2 = [], 3 = [], 5 = [1] Adjacency list (in): 1 = [5], 2 = [], 3 = [], 5 = [] Graph is directed. plot(Graph::plotCircleGraph(G3))



Parameters

l

A list of vertices

v

A vertex

G

A graph

Return Values

Graph

Graph::residualGraph

Purpose

Computes the residual graph

Syntax

```
Graph::residualGraph(G, f, <Extended>)
```

Description

`Graph::residualGraph(G, flow)` computes the residual of the graph `G` with respect to the flow `flow`, meaning the graph that remains when the flow `flow` is "subtracted" from `G`.

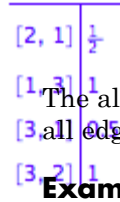
`Graph::residualGraph` computes the residual graph with respect to a given flow. A flow in a Graph is a table `tbl`, where `tbl[[i,j]]` gives the number of units flowing from vertex `i` to vertex `j`.

If the optional argument `Extended` is given, then also those edges with a zero residual capacity are considered, otherwise these edges are omitted.

Examples

Example 1

In the following call, `G2` is the graph consisting of the remaining transport capacities after a given flow:
G1 := Graph::createCompleteGraph(3): G2 := Graph::residualGraph(G1, table([1, 2] = 1, [2, 1] = 1/2, [1, 3] = 0, [3, 1] = 0.5, [2, 3] = 1, [3, 2] = 0)): Graph::getEdgeWeights(G2)table([3, 2] = 1, [3, 1] = 0.5, [1, 3] = 1, [2, 1] = 1/2)



The algorithm detects the lack of edge weights and edge costs and sets all edge weights and costs to default values of 1.

Example 2

The resulting graph depends on whether the option `Extended` is used:

V := [1, 2, 3, q, s]: Edge := [[q, 1], [1, 2], [1, 3], [2, 3], [3, s]]: up := [5, 4, 4, 2, 5]: G := Graph(V,Edge,EdgeWeights = up, Directed): flow := table([q, 1] = 5, [3, s] = 5, [1, 2] = 1, [1, 3] = 4, [2, 3] = 1): G1 := Graph::residualGraph(G, flow): Graph::printGraphInformation(G1); Vertices: [1, 2, 3, q, s] Edges: [[2, 1], [3, 1], [3, 2], [s, 3], [1, q], [1, 2], [2, 3]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: [1, 2] = 3, [2, 3] = 1, [2, 1] = 1, [3, 1] = 4, [3, 2] = 1, [s, 3] = 5, [1, q] = 5 (other existing edges \ have no weight) Edge costs: [1, 2] = 1, [2, 3] = 1, [2, 1] = -3, [3, 1] = 0, [3, 2] = -1, [s, 3] = 0, [1, q] = 0 (other existing edges \ have costs zero) Adjacency list (out): 1 = [2, q], 2 = [1, 3], 3 = [1, 2], q = [], s = [3] Adjacency list (in): 1 = [2, 3], 2 = [1, 3], 3 = [2, s], q = [1], s = [] Graph is directed.

Edge Weights contain the residual graph with all the flows. Edge Costs show the flow that was substracted or added. For example edge [1, 2] had weight 4. After a flow of 3 was sent over it, the residual edge [2, 1] contains the flow of -3 and the residual edge [1, 2] contains the flow of 1. Since the negative flow of the reverted edge plus the flow of the edge in the residual graph have to sum up to the flow it shows that the flow is calculated correctly. (- (- 3) + 1 = 4)
G1 := Graph::residualGraph(G, flow, Extended): Graph::printGraphInformation(G1); Vertices: [1, 2, 3, q, s] Edges: [[2, 1], [3, 1], [3, 2], [s, 3], [1, q], [1, 2], [1, 3], [2, 3], [3, s], [q, 1]] Vertex weights: no vertex weights. Edge descriptions: no edge descriptions. Edge weights: [q, 1] = 5, [1, 2] = 4, [1, 3] = 4, [2, 3] = 2, [3, s] = 5, [2, 1] = -4, [3, 1] = -4, [3, 2] = -2, [s, 3]\ = -5, [1, q] = -5 (other existing edges have no weight) Edge costs: [1, 2] = 3, [1, 3] = 0, [2, 3] = 1, [3, s] = 0, [q, 1] = 0, [2, 1] = 1, [3, 1] = 4, [3, 2] = 1, [s, 3] = 5,\ [1, q] = 5 (other existing edges have costs zero) Adjacency list (out): 1 = [2, 3, q], 2 = [1, 3], 3 = [1, 2, s], q = [1], s = [3] Adjacency list (in): 1 = [2, 3, q], 2 = [1, 3], 3 = [1, 2, s], q = [1], s = [3] Graph is directed.

Parameters

G

Graph

flow

The predefined flow

Options

Extended

Include edges with zero capacities

Return Values

`Graph`

Graph::revert

Purpose

Reverts the edges of a graph.

Syntax

```
Graph::revert(G)
```

Description

`Graph::revert(G)` returns a graph in which all edges [*u*, *v*] and their properties belong to edges [*v*, *u*].

`Graph::revert` overloads the system function revert.

Examples

Example 1

First, a circle graph is defined with some additional settings:
G1 := Graph::createCircleGraph(3): G1 := Graph::setEdgeWeights(G1, [[1, 2]], [20]): G1 := Graph::setEdgeCosts(G1, [[1, 2]], [20]):
G1 := Graph::setEdgeDescriptions(G1, [[1, 2]], ["Shortcut"]):
Graph::printGraphInformation(G1) Vertices: [1, 2, 3] Edges: [[1, 2], [2, 3], [3, 1]] Vertex weights: no vertex weights. Edge descriptions: [1, 2] = "Shortcut" Edge weights: [1, 2] = 20 (other existing edges have no weight) Edge costs: [1, 2] = 20 (other existing edges have costs zero) Adjacency list (out): 1 = [2], 2 = [3], 3 = [1] Adjacency list (in): 1 = [3], 2 = [1], 3 = [2] Graph is directed.

Now we revert the graph:
G2 := revert(G1): Graph::printGraphInformation(G2) Vertices: [1, 2, 3] Edges: [[1, 3], [2, 1], [3, 2]] Vertex weights: no vertex weights. Edge descriptions: [2, 1] = "Shortcut" Edge weights: [2, 1] = 20 (other existing edges have no weight) Edge costs: [2, 1] = 20 (other existing edges have costs zero) Adjacency list (out): 1 = [3], 2 = [1], 3 = [2] Adjacency list (in): 1 = [2], 2 = [3], 3 = [1] Graph is directed.

Parameters

G

A graph

Return Values

Graph

Graph::setEdgeCosts

Purpose

Assigns edge costs to edges.

Syntax

```
Graph::setEdgeCosts(G, Edge, EdgeCosts,
<OnlySpecifiedEdges>)
```

Description

`Graph::setEdgeCosts(G, Edges, EdgeCosts)` returns a graph where `Edges` have the edge costs `EdgeCosts`.

Note If *OnlySpecifiedEdges* is stated and an undirected graph is to be changed, only the edges specified are used and not the inverted ones. For example if a call `Graph::setEdgeCosts(G, [[u,v]], [1])` is invoked, only the edge [*u*, *v*] gets 1. The edge [*v*, *u*] will not be changed.

Note The substitute `None` can be used when a specified edge should not get the assigned costs.

Examples

Example 1

First lets define a graph without edge costs:
G1 := Graph::createCircleGraph(3): Graph::getEdgeCosts(G1)FAIL

```
FAIL
```

`FAIL` was returned, because no edge costs werde defined.
Graph::getEdges(G1); G1 := Graph::setEdgeCosts(G1, [[1, 2], [3, 1]], [5, 1/2]): Graph::getEdgeCosts(G1)[[1, 2], [2, 3], [3, 1]]

```
[[1, 2], [2, 3], [3, 1]]
```

table([3, 1] = 1/2, [1, 2] = 5)

[1, 2]	5
[3, 1]	1/2

The first output shows all the edges and the second one the assigned edge costs.

```
G1 := Graph::setEdgeCosts(G1, [[2, 3]], [infinity]):
Graph::getEdgeCosts(G1)table([2, 3] = infinity, [3, 1] = 1/2,
[1, 2] = 5)
```

[1, 2]	5
[3, 1]	1/2
[2, 3]	infinity

It is easy to see that only the edge cost of `[2,3]` was changed.

Example 2

First lets define a graph without edge costs:

```
G1 := Graph::createCompleteGraph(3): Graph::getEdgeCosts(G1)FAIL
```

```
FAIL
```

`FAIL` was returned, because no edge costs werde defined.

```
Graph::getEdges(G1); G2 := Graph::setEdgeCosts(G1, [[1, 2], [3, 1]], [5,
1/2]): Graph::getEdgeCosts(G2)[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

table([3, 1] = 1/2, [1, 3] = 1/2, [2, 1] = 5, [1, 2] = 5)

[1, 2]	5
[2, 1]	5
[1, 3]	2
[3, 1]	1

The first output shows all the edges (the graph is undirected !) and the second one the assigned edge costs. Not only the specified edges were set, but also the reverted edges.
Graph::getEdges(G1); G2 := Graph::setEdgeCosts(G1, [[1, 2], [3, 1]], [5, 1/2], OnlySpecifiedEdges): Graph::getEdgeCosts(G2)[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]

[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
table([3, 1] = 1/2, [1, 2] = 5)

[1, 2]	5
[3, 1]	1

It is easy to see that only the specified edge costs were changed and not the reverted edges, too.

Example 3

There exist also the possibility to set the costs via a table instead of a list.
tbl := table([1, 2] = 15, [1, 3] = 20): G2 := Graph::createCompleteGraph(3):G2 := Graph::setEdgeCosts(G2, [[1, 2], [3, 1]], tbl): Graph::getEdgeCosts(G2)table([3, 1] = 20, [1, 3] = 20, [2, 1] = 15, [1, 2] = 15)

[1, 2]	15
[2, 1]	15
[1, 3]	20
[3, 1]	20

And again, but this time only the specified edges: tbl := table([1, 2] = 15, [1, 3] = 20): G2 := Graph::createCompleteGraph(3):G2 := Graph::setEdgeCosts(G2, [[1, 2], [3, 1]], tbl, OnlySpecifiedEdges): Graph::getEdgeCosts(G2)table([3, 1] = 20, [1, 2] = 15)

[1, 2]	15
[3, 1]	20

Parameters

G

A graph

Edge

A list of one or more edges

EdgeCosts

A list of one or more numbers, or a table consisting of the edges with their costs.

Options

OnlySpecifiedEdges

Only the edges specified in `Edge` will be set.

Return Values

New graph with the corrected edge costs.

Graph::setEdgeDescriptions

Purpose

Assigns edge Descriptions to edges.

Syntax

```
Graph::setEdgeDescriptions(G, Edge, EdgeDescriptions,
<OnlySpecifiedEdges>)
```

Description

`Graph::setEdgeDescriptions(G, Edges, EdgeDescriptions)` returns a graph where `Edges` have the edge descriptions `EdgeDescriptions`.

Note If *OnlySpecifiedEdges* is stated and an undirected graph is to be changed, only the edges specified are used and not the inverted ones. For example if a call `Graph::setEdgeDescriptions(G, [[u,v]], [1])` is invoked, only the edge [*u*, *v*] gets 1. The edge [*v*, *u*] will not be changed.

Note The substitute `None` can be used when a specified edge should not get the assigned description.

Examples

Example 1

First lets define a graph without edge descriptions:
G1 := Graph::createCircleGraph(3):
Graph::getEdgeDescriptions(G1)FAIL

FAIL

`FAIL` was returned, because no edge descriptions werde defined.
Graph::getEdges(G1); G1 := Graph::setEdgeDescriptions(G1, [[1, 2],[3, 1]], ["Route 66", "Speedway"]): Graph::getEdgeDescriptions(G1)[[1, 2], [2, 3], [3, 1]]

```
[[1, 2], [2, 3], [3, 1]]
```

table([3, 1] = "Speedway", [1, 2] = "Route 66")

[1, 2]	"Route 66"
[3, 1]	"Speedway"

The first output shows all the edges and the second one the assigned edge descriptions.

```
G1 := Graph::setEdgeDescriptions(G1, [[2, 3]], ["Shortcut"]):
Graph::getEdgeDescriptions(G1)table([2, 3] = "Shortcut", [3, 1] =
"Speedway", [1, 2] = "Route 66")
```

[1, 2]	"Route 66"
[3, 1]	"Speedway"
[2, 3]	"Shortcut"

It is easy to see that only the edge description of `[2,3]` was changed.

Example 2

First lets define a graph without edge Descriptions:

```
G1 := Graph::createCompleteGraph(3):
Graph::getEdgeDescriptions(G1)FAIL
```

```
FAIL
```

`FAIL` was returned, because no edge descriptions werde defined.

```
Graph::getEdges(G1); G2 := Graph::setEdgeDescriptions(G1, [[1, 2], [3,
1]], ["Route 66", "Speedway"]): Graph::getEdgeDescriptions(G2)[[1, 2],
[1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

table([3, 1] = "Speedway", [1, 3] = "Speedway", [2, 1] = "Route 66", [1, 2] = "Route 66")

[1, 2]	"Route 66"
[2, 1]	"Route 66"
[1, 3]	"Speedway"
[3, 1]	"Speedway"

The first output shows all the edges (the graph is undirected !) and the second one the assigned edge Descriptions. Not only the specified edges were set, but also the reverted edges.

```
Graph::getEdges(G1); G2 := Graph::setEdgeDescriptions(G1,
[[1, 2], [3, 1]], ["Route 66", "Speedway"], OnlySpecifiedEdges):
Graph::getEdgeDescriptions(G2)[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

```
table([3, 1] = "Speedway", [1, 2] = "Route 66")
```

[1, 2]	"Route 66"
[3, 1]	"Speedway"

It is easy to see that only the specified edge Descriptions were changed and not the reverted edges, too.

Example 3

There exist also the possibility to set the Descriptions via a table instead of a list.

```
tbl := table([1, 2] = "Highway", [1, 3] = "Road to nowhere"): G2 :=
Graph::createCompleteGraph(3): Graph::getEdgeDescriptions(G2):G2
:= Graph::setEdgeDescriptions(G2, [[1, 2], [3, 1]], tbl):
Graph::getEdgeDescriptions(G2)table([3, 1] = "Road to nowhere", [1, 3]
= "Road to nowhere", [2, 1] = "Highway", [1, 2] = "Highway")
```

[1, 2]	"Highway"
[2, 1]	"Highway"
[1, 3]	"Road to nowhere"
[3, 1]	"Road to nowhere"

And again, but this time only the specified edges: tbl := table([1, 2] = "Highway", [1, 3] = "Road to nowhere"): G2 := Graph::createCompleteGraph(3): Graph::getEdgeDescriptions(G2): G2 := Graph::setEdgeDescriptions(G2, [[1, 2], [3, 1]], tbl, OnlySpecifiedEdges): Graph::getEdgeDescriptions(G2)table([3, 1] = "Road to nowhere", [1, 2] = "Highway")

[1, 2]	"Highway"
[3, 1]	"Road to nowhere"

Parameters

G

A graph

Edge

A list of one or more edges

EdgeDescriptions

A list of one or more numbers, or a table consisting of the edges with their descriptions.

Options

OnlySpecifiedEdges

Only the edges specified in `Edge` will be set.

Return Values

New graph with the corrected edge Descriptions.

Graph::setEdgeWeights

Purpose

Assigns edge weights to edges.

Syntax

```
Graph::setEdgeWeights(G, Edge, EdgeWeights,
<OnlySpecifiedEdges>)
```

Description

`Graph::setEdgeWeights(G, Edges, EdgeWeights)` returns a graph where `Edges` have the edge weights `EdgeWeights`.

Note If *OnlySpecifiedEdges* is stated and an undirected graph is to be changed, only the edges specified are used and not the inverted ones. For example if a call `Graph::setEdgeWeights(G, [[u,v]], [1])` is invoked, only the edge [*u*, *v*] gets 1. The edge [*v*, *u*] will not be changed.

Note The substitute `None` can be used when a specified edge should not get the assigned weights.

Examples

Example 1

How to set edge weights with a list:
G1 := Graph::createCircleGraph(3): Graph::getEdgeWeights(G1)FAIL

```
FAIL
```

`FAIL` was returned, because no edge weights were defined.
Graph::getEdges(G1); G1 := Graph::setEdgeWeights(G1, [[1, 2], [3, 1]], [5, 1/2]): Graph::getEdgeWeights(G1)[[1, 2], [2, 3], [3, 1]]

```
[[1, 2], [2, 3], [3, 1]]
```

table([3, 1] = 1/2, [1, 2] = 5)

[1, 2]	5
[3, 1]	$\frac{1}{2}$

The first output shows all the edges and the second one the assigned edge weights.

```
G1 := Graph::setEdgeWeights(G1, [[2, 3]], [infinity]):
Graph::getEdgeWeights(G1)table([2, 3] = infinity, [3, 1] = 1/2, [1, 2] = 5)
```

[1, 2]	5
[3, 1]	$\frac{1}{2}$
[2, 3]	∞

It is easy to see that only the edge weight of `[2, 3]` was changed.

Example 2

How to set edge weights with a table:

```
G1 := Graph::createCompleteGraph(3):
Graph::getEdgeWeights(G1)FAIL
```

```
FAIL
```

`FAIL` was returned, because no edge weights were defined.

```
Graph::getEdges(G1); G2 := Graph::setEdgeWeights(G1, [[1, 2], [3, 1]],
[5, 1/2]): Graph::getEdgeWeights(G2)[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1],
[3, 2]]
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

table([3, 1] = 1/2, [1, 3] = 1/2, [2, 1] = 5, [1, 2] = 5)

[1, 2]	5
[2, 1]	5
[1, 3]	2
[3, 1]	1

The first output shows all the edges (the graph is undirected !) and the second one the assigned edge weights. Not only the specified edges were set, but also the reverted edges.
Graph::getEdges(G1); G2 := Graph::setEdgeWeights(G1, [[1, 2], [3, 1]], [5, 1/2], OnlySpecifiedEdges): Graph::getEdgeWeights(G2)[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]

[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
table([3, 1] = 1/2, [1, 2] = 5)

[1, 2]	5
[3, 1]	1

It is easy to see that only the specified edge Weights were changed and not the reverted edges, too.

Example 3

There exist also the possibility to set the weights via a table instead of a list.
tbl := table([1, 2] = 15, [1, 3] = 20): G2 := Graph::createCompleteGraph(3):G2 := Graph::setEdgeWeights(G2, [[1, 2], [3, 1]], tbl): Graph::getEdgeWeights(G2)table([3, 1] = 20, [1, 3] = 20, [2, 1] = 15, [1, 2] = 15)

[1, 2]	15
[2, 1]	15
[1, 3]	20
[3, 1]	20

And again, but this time only the specified edges:
tbl := table([1, 2] = 15, [1, 3] = 20): G2 := Graph::createCompleteGraph(3):G2 := Graph::setEdgeWeights(G2, [[1, 2], [3, 1]], tbl, OnlySpecifiedEdges): Graph::getEdgeWeights(G2)table([3, 1] = 20, [1, 2] = 15)

[1, 2]	15
[3, 1]	20

Parameters

G

A graph

Edge

A list of one or more edges

EdgeWeights

A list of one or more numbers, or a table consisting of the edges with their weights.

Options

OnlySpecifiedEdges

Only the edges specified in `Edge` will be set.

Return Values

New graph with the corrected edge weights.

Graph::setVertexWeights

Purpose

Assigns vertex weights to vertices.

Syntax

```
Graph::setVertexWeights(G, Vertex, VertexWeights)
```

Description

`Graph::setVertexWeights(G, Vertex, VertexWeights)` returns a graph where the vertices in `Vertex` have the vertex weights `VertexWeights`.

Note The substitute `None` can be used when a specified edge should not get the assigned weights.

Examples

Example 1

How to set vertex weights with a list:
G1 := Graph::createCircleGraph(3): Graph::getVertexWeights(G1)FAIL

FAIL

`FAIL` was returned, because no vertex weights were defined.
Graph::getVertices(G1); G1 := Graph::setVertexWeights(G1, [1, 3], [5, 1/2]): Graph::getVertexWeights(G1)[1, 2, 3]

[1, 2, 3]

table(3 = 1/2, 1 = 5)

1	5
3	1/2

The first output shows all vertices and the second the assigned vertex weights.

Example 2

How to set vertex weights with a table:
G1 := Graph::createCompleteGraph(3):
Graph::getVertexWeights(G1)FAIL

FAIL

FAIL was returned, because no vertex weights were defined.
G2 := Graph::createCompleteGraph(3): tbl := table(1 = 15, 3 = 20): G2 := Graph::setVertexWeights(G2, [1, 3], tbl):
Graph::getVertexWeights(G2)table(3 = 20, 1 = 15)

1	15
3	20

Parameters

G

A graph

Vertex

A list of one or more vertices

VertexWeights

A list of one or more numbers, or a table consisting of the vertices with their weights.

Return Values

New graph with the corrected vertex weights.

Graph::shortestPathAllPairs

Purpose

Shortest paths from and to all vertices

Syntax

```
Graph::shortestPathAllPairs(G, <SearchFor =
Weights | Costs>)
```

Description

`Graph::shortestPathAllPairs(G)` returns a table with all paths between all vertices.

`Graph::shortestPathAllPairs(G, SearchFor=Costs)` returns a `table` with all paths according to the edge costs.

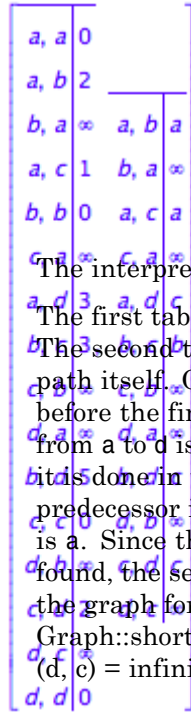
`Graph::shortestPathAllPairs(G, SearchFor=Weights)` returns a `table` with all paths according to the edge weights. (Default)

Examples

Example 1

A small graph to be used for the algorithms:
G := Graph([a, b, c, d], [[a, b], [a, c], [b, c], [c, d]], EdgeWeights = [2, 1, 3, 2], EdgeCosts = [1, 3,1, 2], Directed):

Now the shortest path between all vertices is found according to the edge weights, because no specification was given and defaults are used.
Graph::shortestPathAllPairs(G)[table((d, d) = 0, (d, c) = infinity, (c, d) = 2, (d, b) = infinity, (c, c) = 0, (b, d) = 5, (d, a) = infinity, (c, b) = infinity, (b, c) = 3, (a, d) = 3, (c, a) = infinity, (b, b) = 0, (a, c) = 1, (b, a) = infinity, (a, b) = 2, (a, a) = 0), table((d, c) = infinity, (c, d) = c, (d, b) = infinity, (b, d) = c, (d, a) = infinity, (c, b) = infinity, (b, c) = b, (a, d) = c, (c, a) = infinity, (a, c) = a, (b, a) = infinity, (a, b) = a)]

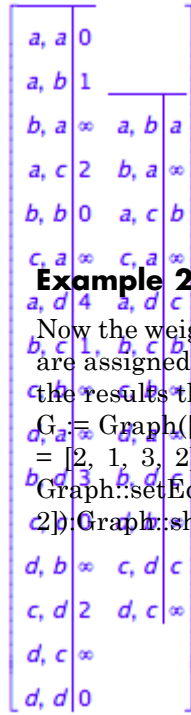


The interpretation of the table is as follows:

The first table holds each path: (FromVertex, ToVertex) = weight/cost. The second table is a bit more tricky. The left hand side again is the path itself. On the right hand side though, the vertex that was found before the final vertex was reached is stated. If for example the path from `a` to `d` is to be found with all vertices that are used within this path it is done in the following way: First take the path itself `(a, d)`. The predecessor is `c`. Now have a look for the path `(a, c)`. It's predecessor is `a`. Since the predecessor equals the first vertex in the path to be found, the search is over and the path `a -> c -> d` is found. To search the graph for costs the option `SearchFor=Costs` has to be added.

Graph::shortestPathAllPairs(G, SearchFor = Costs)[table((d, d) = 0, (d, c) = infinity, (c, d) = 2, (d, b) = infinity, (c, c) = 0, (b, d) = 3, (d, a) =

infinity, (c, b) = infinity, (b, c) = 1, (a, d) = 4, (c, a) = infinity, (b, b) = 0, (a, c) = 2, (b, a) = infinity, (a, b) = 1, (a, a) = 0), table((d, c) = infinity, (c, d) = c, (d, b) = infinity, (b, d) = c, (d, a) = infinity, (c, b) = infinity, (b, c) = b, (a, d) = c, (c, a) = infinity, (a, c) = b, (b, a) = infinity, (a, b) = a)]



Example 2

Now the weights of the graph are changed, so that negative edge weights are assigned. You will see that this does not influence the correctness of the results the algorithm returns (like for example Dijkstra).

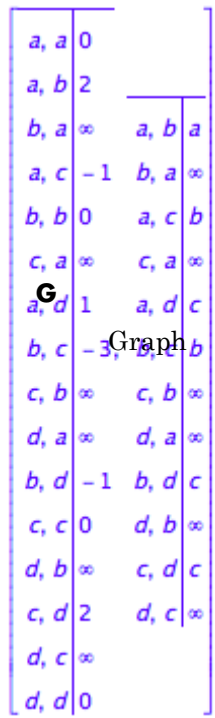
```
G := Graph([a, b, c, d], [[a, b], [a, c], [b, c], [c, d]], EdgeWeights
 = [2, 1, 3, 2], EdgeCosts = [1, 3,1, 2], Directed):G :=
 Graph::setEdgeWeights(G, Graph::getEdges(G), [2, 1, -3,
 2]):Graph::shortestPathAllPairs(G)[table((d, d) = 0, (d, c) = infinity, (c,
```

d) = 2, (d, b) = infinity, (c, c) = 0, (b, d) = -1, (d, a) = infinity, (c, b) = infinity, (b, c) = -3, (a, d) = 1, (c, a) = infinity, (b, b) = 0, (a, c) = -1, (b, a) = infinity, (a, b) = 2, (a, a) = 0), table((d, c) = infinity, (c, d) = c, (d, b) = infinity, (b, d) = c, (d, a) = infinity, (c, b) = infinity, (b, c) = b, (a, d) = c, (c, a) = infinity, (a, c) = b, (b, a) = infinity, (a, b) = a)]

Parameters

G

Graph



Options

SearchFor

Defines whether the weights of the graph are considered or the costs. Default is `Weights`.

Return Values

List consisting of two tables. The first table holds the sum of the path weights or costs and the second the predecessors for every path (to find the complete path).

Algorithms

The algorithm is also known as Floyd-Warshall or Roy-Warshall algorithm. The idea behind it is to solve the problem by continuous matrix multiplication. he only difference is that Floyd uses the assignment $a_{i,j} := min(a_{i,j}, a_{i,k} + a_{k,j})$.

Graph::shortestPathSingleSource

Purpose

Shortest paths from one single vertex

Syntax

```
Graph::shortestPathSingleSource(G, StartVertex, <EndVertex
= v>, <SearchWith = Dijkstra | Bellman>, <SearchFor =
Weights | Costs>, <ReturnAsGraph>)
```

Description

`Graph::shortestPathSingleSource(G, StartVertex=vertex)` gives the length of a shortest path from `StartVertex` to every other vertex in `G`.

`Graph::shortestPathSingleSource(G, StartVertex=sv)` returns a table with all paths from *sv* to any other.

`Graph::shortestPathSingleSource(G, StartVertex=sv, ReturnAsGraph)` returns a `table` with all paths from *sv* to any other because EndVertex has to be set in order to get a Graph as return value.

With `Graph::shortestPathSingleSource(G, StartVertex=sv, EndVertex=ev, SearchWith=Dijkstra, SearchFor=Costs)` returns a `table` from vertex *sv* to vertex *ev* according to Dijkstra which used the edge-costs for its algorithm.

Note Using Dijkstra for shortest path can be erroneus if the graph contains negative edges.

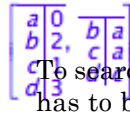
Note If `ReturnAsGraph` is stated and `EndVertex` omitted, a table is returned nevertheless.

Examples

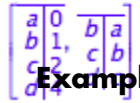
Example 1

A small graph to be used for the algorithms:
G := Graph([a, b, c, d], [[a, b], [a, c], [b, c], [c, d]], EdgeWeights = [2, 1, 3, 2], EdgeCosts = [1, 3, 1, 2], Directed):

Now the shortest path is found according to Bellman using edge weights, because no specification was given and defaults are used:
Graph::shortestPathSingleSource(G, StartVertex = [a])[table(d = 3, c = 1, b = 2, a = 0), table(d = c, c = a, b = a)]

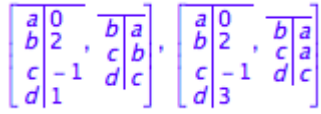


To search the graph with Bellman for costs the option `SearchFor=Costs` has to be added:
Graph::shortestPathSingleSource(G, StartVertex = [a], SearchFor=Costs)[table(d = 4, c = 2, b = 1, a = 0), table(d = c, c = b, b = a)]



Example 2

Now the weights of the graph are changed, so that negative edge weights are assigned. After this the procedure is called again with Bellman and afterwards with Dijkstra to compare the results:
G := Graph([a, b, c, d], [[a, b], [a, c], [b, c], [c, d]], EdgeWeights = [2, 1, 3, 2], EdgeCosts = [1, 3, 1, 2], Directed):G := Graph::setEdgeWeights(G, Graph::getEdges(G), [2, 1, -3, 2]):Graph::shortestPathSingleSource(G, StartVertex = [a], SearchWith = Bellman), Graph::shortestPathSingleSource(G, StartVertex = [a], SearchWith = Dijkstra)[table(d = 1, c = -1, b = 2, a = 0), table(d = c, c = b, b = a)], [table(d = 3, c = -1, b = 2, a = 0), table(d = c, c = a, b = a)]

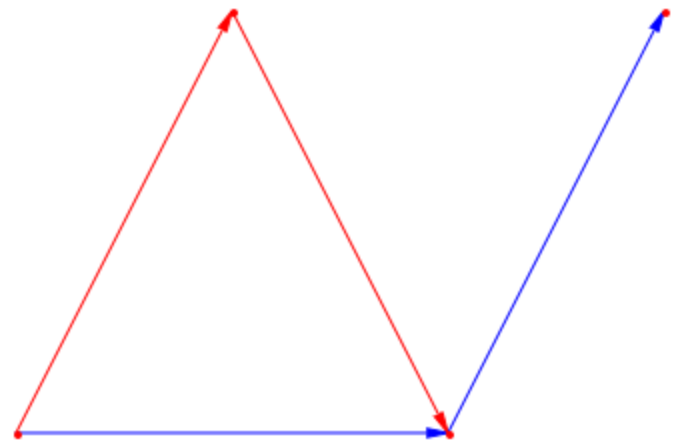


This is a typical example where Dijkstra can make a mistake because he does not correct earlier solutions (a so called greedy strategy). Although vertex `c` gets the correct value `-1`, at the time `d` got the value `3`, vertex `c` still held the value `1`. This happens because Dijkstra first searches the best solutions (a->c = 1) then traverses further (c->d = 1 + 2 = 3). In spite of changing the value of vertex `c` the value for d is never to be changed again (because no other path ever reaches it again):

It might be interesting to see a shortest path inside the graph. Here are two steps that accomplish this task:

Fist step (creation of a shortest path graph [in this case with Dijkstra]):
dijk := Graph::shortestPathSingleSource(G, StartVertex = [a], EndVertex = [d], SearchWith = Dijkstra, ReturnAsGraph):

Second step (combination of the graphs using `plotGridGraph`):
plot(Graph::plotGridGraph(G, VerticesPerLine = 4, VertexOrder = [None, b, None, d, a, None, c, None], VertexColor = RGB::Red, SpecialEdges = Graph::getEdges(dijk), SpecialEdgeColor = RGB::Blue))

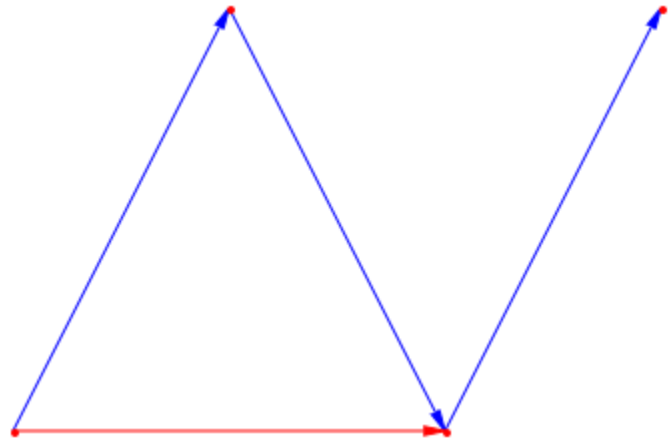


The same with Bellman to show the differences:

Fist step (creation of a shortest path graph [in this case with Dijkstra]):

bellm := Graph::shortestPathSingleSource(G, StartVertex = [a], EndVertex = [d], SearchWith = Bellman, ReturnAsGraph):

Second step (combination of the graphs using `plotGridGraph`): plot(Graph::plotGridGraph(G, VerticesPerLine = 4, VertexOrder = [None, b, None, d, a, None, c, None], VertexColor = RGB::Red, SpecialEdges = Graph::getEdges(bellm), SpecialEdgeColor = RGB::Blue))



Parameters

G

Graph

vertex

A vertex in G

Options

EndVertex

Specifies a single vertex to which the shortest path is to be found.

SearchWith

Defines the algorithm to use. Dijkstra can be erroneus if the graph consists of negative edges. Default is `Bellman`

SearchFor

Defines wether the weights of the graph are considered or the costs. Default is `Weights`.

ReturnAsGraph

If stated and EndVertex is set, the path is returned as a Graph. If stated and EndVertex is not set, this option is omitted.

Return Values

Either a list consisting of two tables or a Graph. The first table holds the weights or cost for each vertex and the second the predecessors for every vertex (to find the path)

Algorithms

Both, Bellman and Dijkstra expect a Graph without negative circles. Only Dijkstra may return erroneous results when negative edges (either weights or costs) are specified.

The Bellman algorithm originated from: Ahuja, Magnanti, Orlin: Graph Flows, Prentice-Hall, 1993 Section 5.4

Graph::stronglyConnectedComponents

Purpose

Finds the strongly connected components

Syntax

```
Graph::stronglyConnectedComponents(G)
```

Description

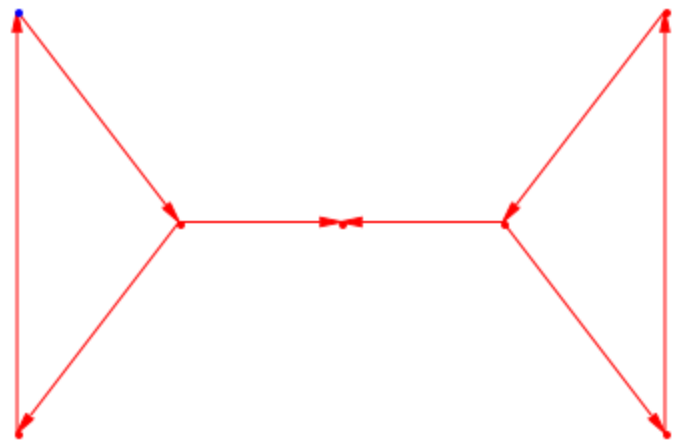
`Graph::stronglyConnectedComponents(G)` finds the strongly connected components of `G`

`Graph::stronglyConnectedComponents` returns all the strongly connected components of a graph. Single vertices form a component of themselves.

Examples

Example 1

Two obvious components pointing to a single vertex:
G1 := Graph([a, b, c, d, e, f, g], [[a, b], [b, g], [g, a], [b, c], [d, c], [e, d], [d, f], [f, e]], Directed):plot(Graph::plotGridGraph(G1, VertexOrder = [a, None, None, None, e, None, b, c, d, None, g, None, None, None, f], VerticesPerLine=5))



The graphical output reveals the two "big" components `[a, b, g]` and `[d, e, f]`. The single vertex `[c]` forms a component of itself:

G2 := Graph::stronglyConnectedComponents(G1)[‘Graph(...)‘, ‘Graph(...)‘, ‘Graph(...)‘]

[Graph(...), Graph(...), Graph(...)]

A list containing three Graphs is returned. Now we find out which vertices belong to each component:
Graph::getVertices(op(G2, 1))[d, e, f]

[*d*, *e*, *f*]

Graph::getVertices(op(G2, 2))[a, b, g]

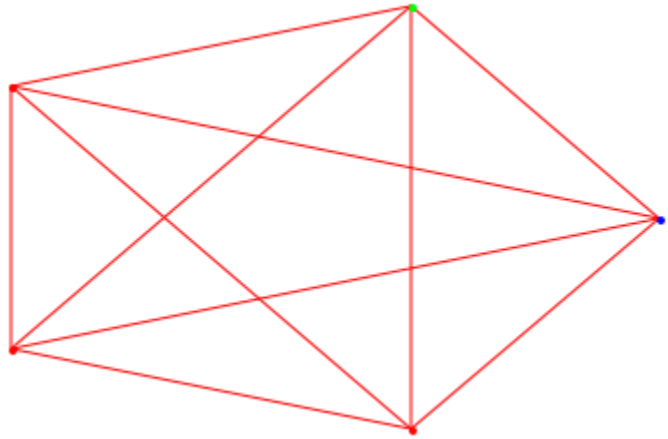
[*a*, *b*, *g*]

Graph::getVertices(op(G2, 3))[c]

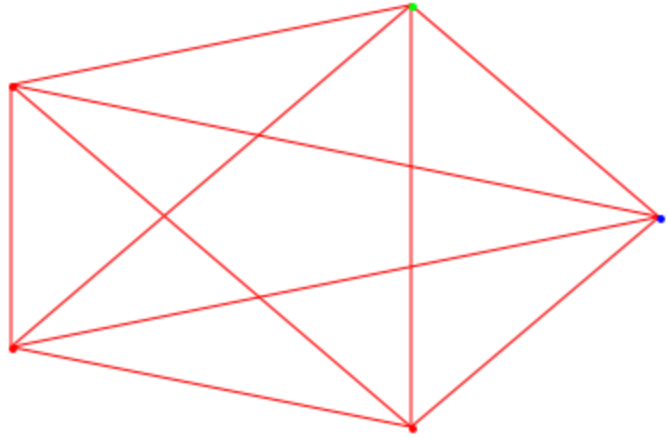
[*c*]

Example 2

A complete graph is returned as a single component:
G3 := Graph::createCompleteGraph(5):
plot(Graph::plotCircleGraph(G3))



```
G4 := Graph::stronglyConnectedComponents(G3):
plot(Graph::plotCircleGraph(op(G4)))
```



It was necessary to use op(G4), because G4 is a list containing a graph!

Parameters

G

A graph

Return Values

List of graphs containing the strongly connected components.

Graph::topSort

Purpose

Topological sorting of the vertices

Syntax

```
Graph::topSort(G)
```

Description

`Graph::topSort(G)` computes a topological sorting of the graph `G`, i.e., a numbering T of the vertices, such that $T_i < T_j$ whenever there is an edge $[i, j]$ in the graph. Single vertices are positioned at the beginning.

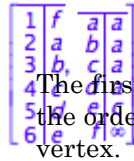
`Graph::topSort` returns a list containing two tables. The first table holds the ordering of the vertices. The second table shows the predecessors of each vertex. If several vertex u_i precede a vertex v, the first vertex in the ordering of u_i is the predecessor of v. If no predecessor exist, the value will be *infinity*.

Note If `G` contains any cycle then a topological sorting does not exist and the call of `Graph::topSort` results in an error.

Examples

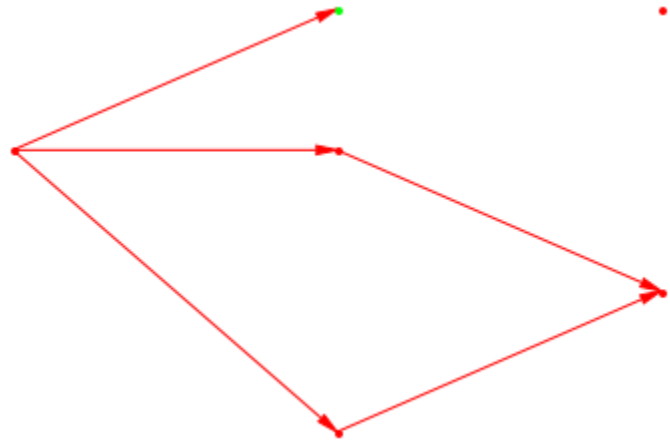
Example 1

A "butterfly" graph that is decomposed in three strongly connected components:
G1 := Graph([a, b, c, d, e, f], [[a, b], [a, c], [a, d], [c, e], [d, e]], Directed):
Graph::topSort(G1)[table(6 = e, 5 = d, 4 = c, 3 = b, 2 = a, 1 = f), table(f = infinity, e = c, d = a, c = a, b = a, a = a)]



The first table shows the ordering of the vertices. The left side holds the order for each vertex, whereas the right side holds the name of the vertex. The second table shows the predecessors of each vertex. If no predecessor exist, the right side holds *infinity*. Otherwise the right side

holds the vertex that is the direct predecessor of the vertex on the left side. To see how the graph looks a graphical plotting helps: plot(Graph::plotGridGraph(G1, VertexOrder = [None, b, f, a, c, None, None, None, e, None, d, None], VerticesPerLine=3))



Parameters

G

A graph

Return Values

List containing two tables.

11

groebner – Gröbner bases

==REFNAME==

groebner::dimension

Purpose

Dimension of the affine variety generated by polynomials

Syntax

```
groebner::dimension(polys, <order>)
```

Description

`groebner::dimension(polys)` computes the dimension of the affine variety generated by the polynomials in the set or list `polys`.

The rules laid down in the introduction to the groebner package concerning the polynomial types and the ordering apply.

The polynomials in the list `polys` must all be of the same type. In particular, do not mix polynomials created via poly and polynomial expressions!

Examples

Example 1

An example from the book of Cox, Little and O'Shea (see below):
groebner::dimension([y^2*z^3, x^5*z^4, x^2*y*z^2])2

2

Parameters

polys

A list or set of polynomials or polynomial expressions of the same type. The coefficients in these polynomials and polynomial expressions can be arbitrary arithmetical expressions.

order

One of the identifiers `DegInvLexOrder`, `DegreeOrder`, and `LexOrder`, or a user-defined term ordering of type Dom::MonomOrdering. The default ordering is `DegInvLexOrder`.

Return Values

Nonnegative integer

Algorithms

First, the Gröbner basis of the given polynomials with respect to the given monomial ordering is computed using groebner::gbasis. This Gröbner basis is then used to compute the dimension of the affine variety generated by the polynomials.

References

The implemented algorithm is described in Cox, Little, O'Shea: "Ideals, Varieties and Algorithms", Springer, 1992, Chapter 9.

See Also

groebner::gbasispoly

groebner::eliminate

Purpose

Eliminate variables

Syntax

```
groebner::eliminate(sys, vars)
```

Description

`groebner::eliminate(sys, vars)` returns a list of polynomial expressions obtained by eliminating the elements of `vars` from `sys`. In other words, the return value does not contain the variables in `vars`, every zero of the original system `sys` must be a zero of the return value, and every tuple of numbers that makes the return value zero can be extended to a solution of `sys`.

Examples

Example 1

Suppose that $x^2 + y = 0$ and $x + y = 0$, what does this imply for y?
groebner::eliminate({x^2 +y, y+x}, {x})[y^2 + y]

$$[y^2 + y]$$

We infer that for every pair (x, y) solving the system, y must satisfy $y^2 + y = 0$, that is, $y = 0$ or $y = -1$. Indeed:
solve({x^2 +y, y+x}, {x, y}){[x = 0, y = 0], [x = 1, y = -1]}

$$\{[x = 0, y = 0], [x = 1, y = -1]\}$$

Parameters

sys

A set or list of polynomial expressions. The coefficients in these polynomial expressions can be arbitrary arithmetical expressions.

vars

A set or list of identifiers

Return Values

List of polynomial expressions

Algorithms

`groebner::eliminate` proceeds by computing a lexical-order Gröbner basis. Hence the computation complexity grows fast when increasing the number of variables.

See Also

groebner::gbasis

groebner::gbasis

Purpose

Computation of a reduced Gröbner basis

Syntax

```
groebner::gbasis(polys, <order>, options)
```

Description

`groebner::gbasis(polys)` computes a reduced Gröbner basis of the ideal generated by the polynomials in the list `polys`.

The rules laid down in the introduction to the groebner package concerning the polynomial types and the ordering apply.

The polynomials in the list `polys` must all be of the same type. In particular, do not mix polynomials created via poly and polynomial expressions!

The ordering strategy indicated by `Reorder` is used automatically when polynomial expressions are used.

Examples

Example 1

We demonstrate the effect of various input formats. First, we use polynomial expressions to define the polynomial ideal. The Gröbner basis is returned as a list of polynomial expressions:
groebner::gbasis([x^2 - y^2, x^2 + y], LexOrder)[x^2 + y, x^4 - x^2]

$$[x^2 + y,\ x^4 - x^2]$$

Next, the same polynomials are defined via poly. Note that poly fixes the ordering of the variables.
groebner::gbasis([poly(x^2 - y^2, [x, y]), poly(x^2 + y, [x, y])], LexOrder)[poly(x^2 + y, [x, y]), poly(y^2 + y, [x, y])]

$$[\mathrm{poly}(x^2 + y, [x, y]),\ \mathrm{poly}(y^2 + y, [x, y])]$$

Changing the ordering of the variables in poly changes the lexicographical ordering. This results in a different basis:
groebner::gbasis([poly(x^2 - y^2, [y, x]), poly(x^2 + y, [y, x])], LexOrder)[poly(y + x^2, [y, x]), poly(x^4 - x^2, [y, x])]

$$[\text{poly}(y + x^2, [y, x]), \text{poly}(x^4 - x^2, [y, x])]$$

With `Reorder` the ordering of the variables may be changed internally: groebner::gbasis([poly(x^2 - y^2, [x, y]), poly(x^2 + y, [x, y])], LexOrder, Reorder)[poly(y + x^2, [y, x]), poly(x^4 - x^2, [y, x])]

$$[\text{poly}(y + x^2, [y, x]), \text{poly}(x^4 - x^2, [y, x])]$$

Example 2

Polynomials over arbitrary fields are allowed. In particular, you can use the field of rational functions in some given variable(s): F := Dom::Fraction(Dom::DistributedPolynomial([y])): F::Name := "Q(y)": groebner::gbasis([poly(y*z^2 + 1, [x, z], F), poly((y^2 + 1)*x^2 - y - z^3, [x, z], F)])[poly(x^2 + z/(y + y^3) - y/(y^2 + 1), [x, z], 'Q(y)'), poly(z^2 + 1/y, [x, z], 'Q(y)')]

$$\left[\text{poly}\left(x^2 + \frac{z}{y + y^3} - \frac{y}{y^2 + 1}, [x, z], \text{Q(y)}\right), \text{poly}\left(z^2 + \frac{1}{y}, [x, z], \text{Q(y)}\right)\right]$$

delete F:

Parameters

polys

A list or set of polynomials or polynomial expressions of the same type. The coefficients in these polynomials and polynomial expressions can be arbitrary arithmetical expressions. If `polys` are polynomials over an arbitrary domain, then their coefficients must be domain elements and the domain must be a field.

order

One of the identifiers `DegInvLexOrder`, `DegreeOrder`, and `LexOrder`, or a user-defined term ordering of type Dom::MonomOrdering. The default ordering is `DegInvLexOrder`.

Options

Factor

With this option, `groebner::gbasis` returns a set of lists, such that each list is the Gröbner basis of an ideal. The union of these ideals is a superset of the ideal given as input, and a subset of the radical of that ideal. In other words, it has the same variety (only the multiplicity of points can change).

IgnoreSpecialCases

With this option, `groebner::gbasis` handles all coefficients in all intermediate results as nonzero unless these coefficients are equal to zero for all parameter values. In other words, if the coefficients are rational functions of the free parameters, then results are correct on all of the parameter space except on an algebraic variety of lower dimension.

Reorder

With this option `groebner::gbasis` internally may change the lexicographical ordering of variables to decrease running time.

With this option the variables are sorted internally such that they have a "heuristic optimal" ordering. Consequently, the ordering of the variables in the output polynomials may differ from their ordering in the input polynomials. For details on the ordering strategy, see W. Boege, R. Gebauer und H. Kredel: "Some Examples for Solving Systems of Algebraic Equations by Calculating Groebner Bases" im J. Symbolic Comp. (1986) Vol. 1, 83-98.

Re-ordering is always applied when polynomial expressions are used for input.

Monic

Option, specified as `Monic = N`

This option sets the normalizing routine to `N`. For every polynomial `f` in the polynomial ring, `N(f, o)` must return some associate of `f`, where `o` is the chosen order.

The method `N` should be chosen such that it produces simple output.

By default, polylib::primpart is used for polynomials with integer coefficients; other polynomials are divided by their leading coefficient.

Order

Option, specified as `Order = order`

This option is equivalent to passing `order` as an argument.

Return Values

List of polynomials. The output polynomials have the same type as the polynomials of the input list.

Algorithms

In most cases, `groebner::gbasis` computes the basis via the Buchberger algorithm with the "sugar" selection strategy being used.

References

For general information, see T. Becker and V. Weispfenning: "Gröbner Bases", Springer (1993). For details on the sugar selection strategy, see A. Giovini, T. Mora, G. Niesi, L. Robbiano, C. Traverso: "One sugar cube, please — or Selection strategies in the Buchberger algorithm", Proc. ISSAC '91, Bonn, 49-54 (1991).

See Also

poly

groebner::normalf

Purpose

Complete reduction modulo a polynomial ideal

Syntax

```
groebner::normalf(p, polys, <order>)
```

Description

`groebner::normalf(p, polys)` computes a normal form of the polynomial `p` by complete reduction modulo all polynomials in the list `polys`.

The rules laid down in the introduction to the groebner package concerning the polynomial types and the ordering apply.

The polynomials in the list `polys` must all be of the same type as `p`. In particular, do not mix polynomials created via poly and polynomial expressions.

Examples

Example 1

We consider the ideal generated by the following polynomials:
p1 := poly(x^2 - x + 2*y^2, [x,y]): p2 := poly(x + 2*y - 1, [x,y]):

We compute the normal form of the following polynomial `p` modulo the ideal generated by `p1`, `p2` with respect to lexicographical ordering:
p := poly(x^2*y - 2*x*y + 1, [x,y]): groebner::normalf(p, [p1, p2], LexOrder);poly(- 2*y^3 + 2*y^2 - y + 1, [x, y])

$$\mathrm{poly}\left(-2\,y^3+2\,y^2-y+1,\,[x,\,y]\right)$$

Note that `p1`, `p2` do not form a Gröbner basis. The corresponding Gröbner basis leads to a different normal form of `p`:
groebner::normalf(p, groebner::gbasis([p1, p2]), LexOrder)poly(- (5*y)/9 + 1, [x, y])

$$\mathrm{poly}\left(-\frac{5\,y}{9}+1,\,[x,\,y]\right)$$

delete p1, p2, p:

Parameters

p

A polynomial or a polynomial expression. The coefficients in this polynomial and polynomial expression can be arbitrary arithmetical expressions.

polys

A list of polynomials of the same type as `p`. In particular, if `p` is a polynomial expression, `polys` must be a list of polynomial expressions.

order

One of the identifiers `DegInvLexOrder`, `DegreeOrder`, and `LexOrder`, or a user-defined term ordering of type Dom::MonomOrdering. The default ordering is `DegInvLexOrder`.

Return Values

Polynomial of the same type as the input polynomials. If polynomial expressions are used as input, then a polynomial expression is returned.

Algorithms

A polynomial g is a reduced form of a polynomial p modulo a list of polynomials $p_1, \ldots, p_n$, if _outputSequence(g, Symbol::equiv, p)$g=p$ and none of the leading terms of the p_i divides the leading term of p, or if — for some i — g is a reduced form of $p - qp_i$, where q is the quotient of the leading monomial of p and the leading monomial of p_i. A reduced form always exists, but need not be unique. It is unique, if the p_i form a Gröbner basis.

In the implementation of `groebner::normalf`, reduction modulo some p_i of largest possible total degree is preferred, if reduction modulo several p_i is possible.

See Also

groebner::gbasispoly

groebner::spoly

Purpose

The S-polynomial of two polynomials

Syntax

`groebner::spoly(`p_1`, `p_2`, <order>)`

Description

`groebner::spoly(p1, p2)` computes the S-polynomial of the polynomials `p1` and `p2`.

The rules laid down in the introduction to groebner concerning the polynomial types and the ordering apply.

The polynomials must be of the same type. In particular, do not mix polynomials created via poly and polynomial expressions!

Examples

Example 1

The polynomials
p1 := poly(x^2 - x + 2*y^2, [x, y]): p2 := poly(x + 2*y - 1, [x, y]):

generate the following S-polynomial with respect to lexicographical ordering:
groebner::spoly(p1, p2, LexOrder)poly(- 2*x*y + 2*y^2, [x, y])

$$\mathrm{poly}\left(-2\,x\,y+2\,y^2,\,[x,\,y]\right)$$

delete p1, p2:

Parameters

p_1

p_2

A list or set of polynomials or polynomial expressions of the same type. The coefficients in these polynomials and polynomial expressions can be arbitrary arithmetical expressions.

order

One of the identifiers `DegInvLexOrder`, `DegreeOrder`, and `LexOrder`, or a user-defined term ordering of type Dom::MonomOrdering. The default ordering is `DegInvLexOrder`.

Return Values

Polynomial of the same type as the input polynomials. If polynomial expressions are used as input, then a polynomial expression is returned.

Algorithms

The S-polynomial of two polynomials p_1, p_2 is defined to be

lcm(lterm(p[1]), lterm(p[2]))/lmonomial(p[1])*p[1] - lcm(lterm(p[1]), lterm(p[2]))/lmonomial(p[2])*p[2]

$$\frac{\mathrm{lcm}(\mathrm{lterm}(p_1), \mathrm{lterm}(p_2))}{\mathrm{lmonomial}(p_1)}\, p_1 - \frac{\mathrm{lcm}(\mathrm{lterm}(p_1), \mathrm{lterm}(p_2))}{\mathrm{lmonomial}(p_2)}\, p_2$$

where lterm and lmonomial are used in the same sense as the MuPAD functions of the same name. This formula is constructed such that the leading terms of the two summands cancel.

groebner::stronglyIndependentSets

Purpose

Strongly independent set of variables

Syntax

```
groebner::stronglyIndependentSets(G)
```

Description

`groebner::stronglyIndependentSets(G)` computes a strongly independent set of variables modulo the ideal generated by `G`.

A set of variables S is strongly independent modulo an ideal I if no leading term of an element of the Gröbner basis of I consists entirely of elements of S. A set is maximally strongly independent if no proper superset of it is strongly independent. Two maximally strongly independent set may be of different size.

`groebner::stronglyIndependentSets` accepts Gröbner bases in the format returned by groebner::gbasis.

Examples

Example 1

The following example has been given by Moeller and Mora in 1983. G:=map([X0^8*X2, X0*X3, X1^8*X3, X1^7*X3^2, X1^6*X3^3, X1^5*X3^4, X1^4*X3^5, X1^3*X3^6, X1^2*X3^7, X1*X3^8], poly, [X3, X2, X1, X0]): groebner::stronglyIndependentSets(G)[2, {X0, X1}, {{X2, X3}, {X0, X1}, {X1, X2}}]

```
[2, {X0, X1}, {{X2, X3}, {X0, X1}, {X1, X2}}]
```

delete G:

Parameters

G

The Gröbner basis of an ideal: a list.

Return Values

List of the form `[d, S, M]`, where `d` is an integer equal to the dimension of the ideal generated by `G`, `S` is the greatest strongly independent set of variables, and `M` is a set consisting of all maximal strongly independent sets of variables or a piecewise consisting of such lists.

import – Import Data

==REFNAME==

import::csv

Purpose

Read CSV data from an ASCII file

Syntax

```
import::csv(filename, <separator>, <NonNested>,
<Trim>, <DecimalComma>)
import::csv(n, <separator>, <NonNested>,
<Trim>, <DecimalComma>)
```

Description

`import::csv` is used to read CSV ("Comma Separated Values" or "Character Separated Values") data files produced by external programs, like Microsoft Excel®. CSV is an ASCII based tabular data file format, formally defined in RfC 4180, that has fields separated by the comma character.

Note Some localized versions of Microsoft Excel use semicolons instead of commas! Set the parameter `separator` to change the default separator.

`import::csv(filename)` reads the data in the file `filename`. File data separated by a comma are regarded as different data elements. The result is a list of lists, each sublist representing one line of the file.

`import::csv(filename, separator)` reads the data in the file `filename`. File data separated by the character `separator` are regarded as different data elements. The result is a list of lists, each sublist representing one line of the file.

`import::csv(filename, separator, NonNested)` reads the data in the file `filename` as a single data record. File data separated by the character `separator` are regarded as different data elements. The result is a plain non-nested list containing the data of all lines of the file.

In contrast to finput, the data must not be ended by a colon or semicolon. Data separated by `separator` are interpreted as single data items. The default separator is a comma.

Empty lines are ignored.

All data elements in the file that cannot be converted to valid MuPAD numbers are imported as MuPAD strings.

`import::csv` tries to convert a number contained in the CSV file to a valid MuPAD number. For example: 1,234.56 or 1 234.56 are converted to the MuPAD number 1234.56. Many countries use a comma to separate the integral and fractional part instead of the dot used in England and the US. For example: 1234,56 or 1.234,56 are converted to 1234.56. `import::csv` expects this number format if the option `DecimalComma` is given.

Note A comma as CSV separator doesn't make sense if the comma is used to separate thousands in a number or the decimal comma is used. In most cases, the CSV file uses a semicolon to separate data. So, a semicolon should be used as separator.

Note All numbers contained in the CSV file must use the same radix separator, mixed formats cannot be converted.

With `NonNested`, the result will be a list containing all data. Otherwise, the result is a list of list, each "inner" list representing a line of the CSV file.

With `Trim`, leading and trailing blanks in strings are removed.

If the file is specified by a string, the corresponding file is opened and closed, automatically. If the user has opened a text file in `Read` mode and passes the file descriptor to import::readdata, the file remains open and needs to be closed by the user.

Files compressed with `gzip` or in a compatible format, whose names end in "`.gz`", are automatically decompressed while being read by `import::csv`.

`import::csv(filename)` searches for the file in various directories:

- First, the name is interpreted as a relative file name: `filename` is concatenated to each directory given by the environment variable READPATH.
- Then the file name is interpreted as an absolute path name.
- Then the file name is interpreted relative to the "working directory".
- Last, the file name is concatenated to each directory given by the environment variable LIBPATH.

If a file can be opened with one of this names, then the file is read.

Note that the meaning of "working directory" depends on the operating system. On Microsoft Windows systems and on Apple Mac OS X systems, the "working directory" is the folder where MuPAD is installed. On UNIX systems, it is the current working directory in which MuPAD was started; when started from a menu or desktop item, this is typically the user's home directory.

A path separator ("/") is inserted as neccessary when concatenating a given path and `filename`.

If a file is specified by a file name, there is no need to open or close the file via fopen and fclose, respectively. This is done automatically by import::readdata.

Instead of a file name, also a file descriptor of a file opened via fopen can be used. Note that the file must have been opened in `Read` mode by fopen. If a file descriptor is used, the corresponding file is not closed automatically but must be closed by the user via fclose.

Examples

Example 1

We wish to read CSV data into a MuPAD session. Assume that the file "`datafile.csv`" contains the following two columns of ASCII data:

```
a ,12.5
```

```
a-b    ,1234.56
```

`import::csv` returns the following list representing the data in the file: n1 := fopen(Text, "datafile.csv", Write): fprint(Unquoted, n1, "a ,12.5"): fprint(Unquoted, n1, " a-b ,1234.56"): fclose(n1):data := import::csv("datafile.csv")[["a ", 12.5], [" a-b ", 1234.56]]

```
[["a ", 12.5], ["  a-b   ", 1234.56]]
```

data := import::csv("datafile.csv", Trim)[["a", 12.5], ["a-b", 1234.56]]

```
[["a", 12.5], ["a-b", 1234.56]]
```

data := import::csv("datafile.csv", NonNested)["a ", 12.5, " a-b ", 1234.56]

```
["a ", 12.5, "  a-b   ", 1234.56]
```

stdlib::gprof(NIL, "datafile.csv"):

Example 2

Let us assume that the file "`datafile.csv`" contains the following ASCII data:

```
a ;12.5
a-b;1,234.56
a b; -12345.6789E-02
```

We specify the data separator "`;`" for reading the data: n1 := fopen(Text, "datafile.csv", Write): fprint(Unquoted, n1, "a ;12.5"): fprint(Unquoted, n1, "a-b;1,234.56"): fprint(Unquoted, n1, "a b; -12345.6789E-02"): fclose(n1):import::csv("datafile.csv", ";")[["a ", 12.5], ["a-b", 1234.56], ["a b", -123.456789]]

```
[["a ", 12.5], ["a-b", 1234.56], ["a b", -123.456789]]
```

```
stdlib::gprof(NIL, "datafile.csv"):
```

Example 3

Let us assume that the file "`datafile.csv`" contains the following ASCII data:

```
abc;12,5
a-b;1.234,56
a b; -12345.6789E-02
```

We specify the data separator `";"` and the option `DecimalComma` for reading the data:

```
n1 := fopen(Text, "datafile.csv", Write): fprint(Unquoted, n1, "a
;12,5"): fprint(Unquoted, n1, "a-b;1.234,56"): fprint(Unquoted, n1,
"a b; -12345.6789E-02"): fclose(n1):import::csv("datafile.csv", ";",
DecimalComma)[["a ", 12.5], ["a-b", 1234.56], ["a b", -123.456789]]
```

```
[["a ", 12.5], ["a-b", 1234.56], ["a b", -123.456789]]
```

```
stdlib::gprof(NIL, "datafile.csv"):
```

Parameters

filename

The file name: a non-empty character string

n

A file descriptor provided by fopen: a positive integer

separator

The separator between data elements: a character string of length 1 (a single character). The default separator is a comma (the single character string `","`).

Options

NonNested

Return all file data as a single data record in a non-nested list. The data of all lines are ordered sequentially in this list.

Trim

Leading and trailing blanks in strings are removed.

DecimalComma

A decimal comma instead of a decimal point is used as the radix separator in the CSV file.

Return Values

Nested list of lists. The sublists contain the data of the individual lines. With the option `NonNested`, a plain list containing all data elements from every line in the file.

See Also

FILEPATHfopenimport::readdataLIBPATHreadbytesREADPATH

import::readbitmap

Purpose

Read bitmap data

Syntax

```
import::readbitmap(filename, <ReturnType = DOM_HFARRAY
| DOM_ARRAY | DOM_LIST>)
```

Description

`import::readbitmap` is used for reading ASCII or binary data files storing bitmap images of pictures. The following standard graphical formats can be read: BMP, DCX, DDS, WAD, GIF, ICO, JPG, LIF, MDL, PCD, PCX, PIC, PIX, PNG, PNM, PSD, PSP, PXR, RAW, SGI, TGA, TIF, WAL, XPM. The format of the pixel data is determined automatically from the contents of the file. The return value `[w, h, colordata]` provides the pixel height `h`, the pixel width `w`, and the color data of the bitmap image.

Either the complete return value or just the third element, `colordata`, can be passed to the function plot::Raster to generate a plot object that can be used in a MuPAD graphics. E.g., the command

```
plot(plot::Raster(import::readbitmap("mypicture.jpeg")))
```

creates a MuPAD graphics of the bitmap stored in the JPG file "`mypicture.jpeg`".

Note Most of the standard graphical formats store the pixel data row by row in the usual reading order starting with the upper left corner of the image. The pixel data in the returned array `colordata` (if requesting `ReturnType = DOM_ARRAY`), however, are to be interpreted as follows:

`colordata[1, 1]` is the RGB color of the lower left corner.

`colordata[h, 1]` is the RGB color of the upper left corner.

`colordata[1, w]` is the RGB color of the lower right corner.

`colordata[h, w]` is the RGB color of the upper right corner.

The interpretation of the other return types is analogous, see below for details on the return types.

This is consistent with the interpretation of a color array by plot::Raster.

`import::readbitmap(filename)` searches for the file in various directories:

- First, the name is interpreted as a relative file name: `filename` is concatenated to each directory given by the environment variable READPATH.
- Then the file name is interpreted as an absolute path name.
- Then the file name is interpreted relative to the "working directory."
- Last, the file name is concatenated to each directory given by the environment variable LIBPATH.

If a file can be opened with one of this names, then the file is read.

Note that the meaning of "working directory" depends on the operating system. On Microsoft Windows systems and on Apple Mac OS X

systems, the “working directory” is the folder where MuPAD is installed. On UNIX systems, it is the current working directory in which MuPAD was started; when started from a menu or desktop item, this is typically the user’s home directory.

A path separator (“/”) is inserted as neccessary when concatenating a given path and `filename`.

`import::readbitmap` does not accept file handles returned by fopen. Nor can it handle files which have been compressed by `gzip`, but since most bitmap formats employ high quality compression in any case, there is little reason to try compressing them again in any case.

Examples

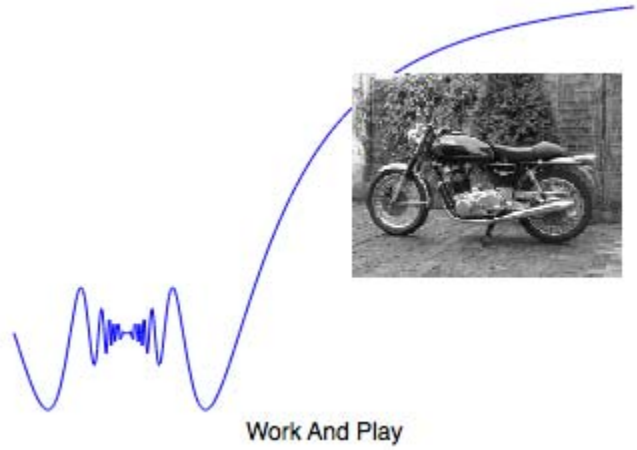
Example 1

We import a PGM (portable graymap) picture:

```
[w, h, Norton] := import::readbitmap("Norton.pgm"):
```

The bitmap image is to be embedded in a MuPAD graphics. We use the width `w` and the height `h` to place the bitmap in a rectangle whose sides have the same ratio as the original bitmap. With `Scaling = Constrained` we make sure that this aspect ratio is also used in the final graphics:

```
xmin := 2: xmax := xmin + w/100: ymin := 0.5: ymax := ymin + h/100:
plot(plot::Function2d(x*sin(PI/x), x = -1..4.5, AdaptiveMesh = 2),
plot::Raster(Norton, x = xmin ..xmax, y = ymin .. ymax), Scaling =
Constrained, Footer = "Work And Play"):
```



Parameters

filename

The file name: a non-empty character string

Options

ReturnType

Option, specified as `ReturnType = DOM_HFARRAY | DOM_ARRAY | DOM_LIST`

Set the type of the actual color data returned as `colordata`.

If set to DOM_LIST, `colordata` is a nested list, the outermost list containing `h` lists, each of which represents one row of image data and contains `w` lists of three floating-point numbers, each of which represents an "RGB Colors" color.

If set to DOM_ARRAY, `colordata` is an array containing lists with color information, as in `array(2, 1..h, 1..w, [color`$_1$`, color`$_2$`, ] )`. The interpretation is analogous to the nested lists described above.

If set to DOM_HFARRAY, which is the default setting, `colordata` is a DOM_HFARRAY of dimensions `hfarray(3, 1..h, 1..w,`

`1..3, [actual data]`). The interpretation of these floating-point values is as described above for the DOM_LIST case.

Return Values

list`[w, h, colordata]`. The integer `w` is the pixel width of the bitmap. The integer `h` is the pixel height of the bitmap. `colordata` provides the RGB colors of the bitmap. Its type depends on the setting of the option `ReturnType`.

See Also

import::readdataLIBPATHreadbytesREADPATHplot::Raster

import::readdata

Purpose

Read data from an ASCII file

Syntax

```
import::readdata(filename | n, <separator>, <NonNested>)
```

Description

`import::readdata(filename)` reads the data in the file `filename`. File data separated by whitespace are regarded as different data elements. The result is a list of lists, each sublist representing one line of the file.

`import::readdata(filename, separator)` reads the data in the file `filename`. File data separated by the character `separator` are regarded as different data elements. The result is a list of lists, each sublist representing one line of the file.

`import::readdata(filename, separator, NonNested)` reads the data in the file `filename` as a single data record. File data separated by the character `separator` are regarded as different data elements. The result is a plain non-nested list containing the data of all lines of the file.

`import::readdata(filename)` searches for the file in various directories:

- First, the name is interpreted as a relative file name: `filename` is concatenated to each directory given by the environment variable READPATH.
- Then the file name is interpreted as an absolute path name.
- Then the file name is interpreted relative to the "working directory."
- Last, the file name is concatenated to each directory given by the environment variable LIBPATH.

If a file can be opened with one of this names, then the file is read.

Note that the meaning of "working directory" depends on the operating system. On Microsoft Windows systems and on Apple Mac OS X systems, the "working directory" is the folder where MuPAD is installed. On UNIX systems, it is the current working directory in which MuPAD

was started; when started from a menu or desktop item, this is typically the user's home directory.

A path separator ("/") is inserted as neccessary when concatenating a given path and `filename`.

If a file is specified by a file name, there is no need to open or close the file via fopen and fclose, respectively. This is done automatically by `import::readdata`.

Instead of a file name, also a file descriptor of a file opened via fopen can be used. Note that the file must have been opened in `Read` mode by fopen. If a file descriptor is used, the corresponding file is not closed automatically but must be closed by the user via fclose.

Files compressed by `gzip` or a compatible program (having a name ending in "`.gz`") are decompressed automatically upon reading.

All data elements in the file are interpreted as MuPAD objects. If a data element cannot be interpreted as a MuPAD object, it is imported as a MuPAD string. Otherwise, the corresponding MuPAD object is inserted into the list returned by `import::readdata`.

Note Note that the MuPAD objects corresponding to the data elements are evaluated after reading. E.g., the data element "sin(0)" in the file is evaluated and imported as the MuPAD integer 0. Beware: the characters "`;`" and "`:`" have a specific meaning if not specified as separators in `import::readdata`: they separate MuPAD commands. Hence, if a read data element contains one of this characters, MuPAD interprets this data element as a sequence of statements and, upon evaluation, returns the value of the *last* statement as the MuPAD object corresponding to the data element. Cf. "Example 3" on page 12-17.

In contrast to finput, the data elements in the file do not have to be ended by a colon or a semicolon.

Empty lines in the file are ignored.

Examples

Example 1

We wish to read statistical data into a MuPAD session to test the correlation of two data samples. Assume that the file "`datafile`" contains the following two columns of ASCII data (each column representing a data sample):

```
 0.12     0.2534
 2.324    5.72
 1.02     2.2232
 4.02     7.321
 7.4     14.9
-7.4    -15.1
```

`import::readdata` returns the following list representing the data in the file:
n1 := fopen(Text, "datafile", Write): fprint(Unquoted, n1," ",0.12," ",0.2534): fprint(Unquoted, n1," ",2.324," ",5.72): fprint(Unquoted, n1," ",1.02," ",2.2232): fprint(Unquoted, n1," ",4.02," ",7.321): fprint(Unquoted, n1," ",7.4," ",14.9): fprint(Unquoted, n1," ",-7.4," ",-15.1): fclose(n1):data := import::readdata("datafile")[[0.12, 0.2534], [2.324, 5.72], [1.02, 2.2232], [4.02, 7.321], [7.4, 14.9], [-7.4, -15.1]]

```
[[0.12, 0.2534], [2.324, 5.72], [1.02, 2.2232], [4.02, 7.321], [7.4, 14.9], [-7.4, -15.1]]
```

The data structure stats::sample converts this nested list into two data columns:
s := stats::sample(data) 0.12 0.2534 2.324 5.72 1.02 2.2232 4.02 7.321 7.4 14.9 -7.4 -15.1

The following computation shows that there is a very strong correlation between the data in the first column and the data in the second column:
stats::correlation(s, 1, 2)0.9982703003

```
0.9982703003
```

If the data in the file are supposed to represent a single sample (data record), we may ignore the fact that the numbers are arranged on several lines. With `NonNested`, the data are read as a single sample: data := import::readdata("datafile", NonNested)[0.12, 0.2534, 2.324, 5.72, 1.02, 2.2232, 4.02, 7.321, 7.4, 14.9, -7.4, -15.1]

```
[0.12, 0.2534, 2.324, 5.72, 1.02, 2.2232, 4.02, 7.321, 7.4, 14.9, -7.4, -15.1]
```

Mean and standard deviation of the data are: stats::mean(data), stats::stdev(data)1.900133333, 7.568789783

```
1.900133333, 7.568789783
```

delete data, s:stdlib::gprof(NIL, "datafile"):

Example 2

Let us assume that the file "`datafile`" contains the following ASCII data:

```
1 | 2   | 3

4| 5 | 6.65786
7| 8 |9| 5 | "ahfjd" | ab100|-23
```

We specify the data separator "`|`" for reading the data: import::readdata("datafile", "|") [[1, 2, 3], [4, 5, 6.65786], [7, 8, 9, 5, "ahfjd", ab100, -23]]

```
[[1, 2, 3], [4, 5, 6.65786], [7, 8, 9, 5, "ahfjd", ab100, -23]]
```

Note that whitespace inside the data elements as well as the empty line in the file are ignored.

Example 3

We first create the ASCII data files that will be used in this example.

We recall that *x* degrees Celsius are 9/5*x + 32$\frac{9}{5}x + 32$ degrees Fahrenheit. First, two data files are created containing the matching temperatures from - 5 degrees Celsius to 30 degrees Celsius in steps of 5 degrees Celsius:

```
n1 := fopen(Text, "data1", Write): n2 := fopen(Text, "data2", Write):
for celsius from -5 to 20 step 5 do fahrenheit := 9/5*celsius + 32:
fprint(Unquoted, n1, celsius, " ", fahrenheit): fprint(n2, celsius,
fahrenheit): end_for: fclose(n1): fclose(n2):
```

The file "`data1`" now contains the following data:

```
-5 23
0 32
5 41
10 50
15 59
20 68
```

The file "`data2`" contains the following data:

```
-5:23:
0:32:
5:41:
10:50:
15:59:
20:68:
```

Now, we import the data:

```
import::readdata("data1")[[-5, 23], [0, 32], [5, 41], [10, 50], [15, 59], [20,
68]]
```

```
[[-5, 23], [0, 32], [5, 41], [10, 50], [15, 59], [20, 68]]
```

Reading data from the file "`data2`" yields an unexpected result:
import::readdata("data2")[[23], [32], [41], [50], [59], [68]]

```
[[23], [32], [41], [50], [59], [68]]
```

What went wrong? Remember that the default data separator is whitespace. Consequently, MuPAD reads the expression `-5:23:` as the only data element in the first line. When MuPAD evaluates this data element, it interprets it as a sequence of two MuPAD statements. The result of the statement sequence is the result of the last of the two statements, i.e., the number 23. This is the first datum in the resulting list. For getting the data as desired, an appropriate separator must be specified. The file "`data2`" should be read as follows:
import::readdata("data2", ":")[[-5, 23], [0, 32], [5, 41], [10, 50], [15, 59], [20, 68]]

```
[[-5, 23], [0, 32], [5, 41], [10, 50], [15, 59], [20, 68]]
```

We use the option `NonNested` to get a plain list containing all data elements without putting each record (line) in a sublist of its own:
import::readdata("data2", ":", NonNested)[-5, 23, 0, 32, 5, 41, 10, 50, 15, 59, 20, 68]

```
[-5, 23, 0, 32, 5, 41, 10, 50, 15, 59, 20, 68]
```

delete n1, n2:stdlib::gprof(NIL, "data1"): stdlib::gprof(NIL, "data2"):

Example 4

Here we can see that the data are evaluated after reading. First, we create the data file:
n1 := fopen(Text, "data3", Write) : fprint(Unquoted, n1, a, " 12 ", b): fclose(n1):

Now, the data are read:
import::readdata("data3")[[a, 12, b]]

[[a, 12, b]]

If a and b have values, we get:
a := 3: b := 34: import::readdata("data3")[[3, 12, 34]]

[[3, 12, 34]]

delete n1, a, b:stdlib::gprof(NIL, "data3"):

Example 5

First, we create a data file with random floating-point data that a separated by blank characters:
n := fopen(Text, "data4", Write): for i from 1 to 3 do fprint(Unquoted, n, (frandom(), " ") $ j = 1..4); end_for; fclose(n):

This file is reopened for reading with fopen:
n := fopen(Text, "data4", Read)64

64

The file descriptor n returned by fopen can be passed to `import::readdata`:
import::readdata(n) [[0.2703567032, 0.8142678572, 0.1145977439, 0.247668289], [0.436855213, 0.7507294917, 0.5143284818, 0.47002619], [0.06956333824, 0.5063265159, 0.4145331467, 0.365909575]]

[[0.2703567032, 0.8142678572, 0.1145977439, 0.247668289], [0.436855213, 0.7507294917, 0

[0.06956333824, 0.5063265159, 0.4145331467, 0.365909575]]

Note, however, that the file was opened explicitly by the user with fopen and is not closed automatically by `import::readdata`. Consequently, the user is supposed to close the file explicitly via fclose:
fclose(n): delete i, n:

Parameters

filename

The file name: a non-empty character string

n

A file descriptor provided by fopen: a positive integer

separator

The separator between data elements: a character string of length 1 (a single character). The default separator is whitespace.

Options

NonNested

Return all file data as a single data record in a non-nested list. The data of all lines are ordered sequentially in this list.

Return Values

Nested list of lists. The sublists contain the data of the indiviual lines. With the option `NonNested`, a plain list containing all data elements from every line in the file.

See Also

finputfopenfreadftextinputimport::csvimport::readbitmappathnameread

import::readlisp

Purpose

Parse Lisp-formatted string

Syntax

```
import::readlisp(s)
```

Description

`import::readlisp(s)` parses the Lisp-formatted string `s` and returns the corresponding MuPAD expression.

`import::readlisp` returns the constructed MuPAD expression as an unevaluated call. So the result of `import::readlisp` is in every case of type DOM_EXPR.

If the parsed string `s` contains only white spaces, then the unevaluated `null()` expression is returned.

Examples

Example 1

A first example:
import::readlisp("(INTEGRATE (EXPT X -1) X)")int(1/X, X)

$$\int \frac{1}{X}\, dX$$

import::readlisp("(EXP 2.0)")exp(2.0)

$$e^{2.0}$$

Example 2

In “Example 1” on page 12-21 above we can see that the corresponding MuPAD expression is not evaluated. Let us have a closer look at this behavior:
domtype(import::readlisp("(INTEGRATE (EXPT X -1) X)")), eval(import::readlisp("(INTEGRATE (EXPT X -1) X)")), domtype(import::readlisp("(EXP 2.0)")), eval(import::readlisp("(EXP 2.0)"))DOM_EXPR, ln(X), DOM_EXPR, 7.389056099

DOM_EXPR, ln(X), DOM_EXPR, 7.389056099

Example 3

Another example demonstrating that `import::readlisp` returns an unevaluated call:
x := 2: import::readlisp("(* x (/ 2 y))")x*(2/y)

$$x\,\frac{2}{y}$$

eval(import::readlisp("(* x (/ 2 y))"))4/y

$$\frac{4}{y}$$

Example 4

An empty string is converted into an unevaluated call of `null()`:
type(import::readlisp(""))"null"

"null"

We try to convert an illegal Lisp string:
import::readlisp("(* 2(EXP 3)") Error: The closing parenthesis is missing. [import::parseLambda]

Parameters

s

A string

Return Values

MuPAD expression of type DOM_EXPR

13

intlib – Integration Utilities

==REFNAME==

intlib::byparts

Purpose

Integration by parts

Syntax

```
intlib::byparts(integral, du)
```

Description

`intlib::byparts(integral, du)` performs on `integral` the integration by parts, where `du` is the part to be integrated and returns an expression containing the unevaluated partial integral.

Mathematically, the rule of integration by parts is formally defined for indefinite integrals as

int(u'(x)*v(x),x) = u(x)*v(x) - int(u(x)*v'(x),x)

$$\int u'(x)\, v(x)\, \mathrm{d}\, x = u(x)\, v(x) - \int u(x)\, v'(x)\, \mathrm{d}\, x$$

and for definite integrals as

int(u'(x) * v(x), x = a..b) = u(b)*v(b) - u(a)*v(a) - int(u(x)*v'(x), x=a..b)

$$\int_a^b u'(x)\, v(x)\, \mathrm{d}\, x = u(b)\, v(b) - u(a)\, v(a) - \int_a^b u(x)\, v'(x)\, \mathrm{d}\, x$$

`intlib::byparts` works for indefinite as well as for definite integrals.

If MuPAD cannot solve the integral for `du` in case of definite integration, the function call is returned unevaluated.

The first argument should contain a symbolic integral of type `"int"`. Such an expression can be obtained with hold or freeze (cf. “Example 1” on page 13-3).

The second argument `du` should typically be a partial expression of the integrand in `integral`.

Examples

Example 1

As a first example we apply the rule of integration by parts to the integral int(x * exp(x), x=a..b) $\int_a^b x\,e^x\,dx$. By using the funcion hold we ensure that the first argument is of type "int":
intlib::byparts(hold(int)(x*exp(x), x = a..b), exp(x))b*exp(b) - a*exp(a) - int(exp(x), x = a..b)

$$b\,e^b - a\,e^a - \int_a^b e^x\,dx$$

In this case the ansatz is choosen as u'(x)=exp(x) $u'(x) = e^x$ and thus $v(x) = x$.

Example 2

In the following we give a more advanced example using the method of integration by parts for solving the integral int(exp(a*x)*sin(b*x), x) $\int e^{a\,x}\sin(b\,x)\,dx$. For this we have to prevent that the integrator already evaluates the integrals. Thus we first inactivate the requested integral with the function freeze
F := freeze(int)(exp(a*x)*sin(b*x), x)int(exp(a*x)*sin(b*x), x)

$$\int e^{a\,x}\sin(b\,x)\,dx$$

and apply afterwards partial integration with u'(x)=exp(a*x) $u'(x) = e^{a\,x}$:
F1 := intlib::byparts(F, exp(a*x))(exp(a*x)*sin(b*x))/a - int((b*exp(a*x)*cos(b*x))/a, x)

$$\frac{e^{a\,x}\sin(b\,x)}{a} - \int \frac{b\,e^{a\,x}\cos(b\,x)}{a}\,dx$$

This result contains another symbolic integral, which MuPAD can solve directly:
eval(F1)(exp(a*x)*sin(b*x))/a - (b*exp(a*x)*(a*cos(b*x) + b*sin(b*x)))/(a*(a^2 + b^2))

$$\frac{e^{a\,x}\sin(b\,x)}{a} - \frac{b\,e^{a\,x}(a\cos(b\,x)+b\sin(b\,x))}{a\,(a^2+b^2)}$$

Example 3

Here we demonstrate the difference between indefinite and definite integration by parts. If in the indefinite case the partial part cannot be solved, simply the unevaluated integral is plugged into the integration rule:
intlib::byparts(hold(int)(x*f(x), x),f(x))x*int(f(x), x) - int(int(f(x), x), x)

$$x\int f(x)\,\mathrm{d}\,x - \int\int f(x)\,\mathrm{d}\,x\,\mathrm{d}\,x$$

This is no longer true for the definite case:
intlib::printWarnings(TRUE): intlib::byparts(hold(int)(x*f(x), x=a..b),f(x)) Warning: No closed form for 'int(f(x), x)' is found. [intlib::byparts] intlib::byparts(int(x*f(x), x = a..b), f(x))

$$\mathrm{intlib::byparts}\left(\int_a^b x\,f(x)\,\mathrm{d}\,x,\ f(x)\right)$$

Parameters

integral

Integral: an arithmetical expression containing a symbolic `"int"` call of the form `int(du*v, x)` or `int(du*v, x = a..b)`

du

The part to be integrated: an arithmetical expression

Return Values

Arithmetical expression.

See Also

subsintlib::changevar

intlib::changevar

Purpose

Change of variable

Syntax

```
intlib::changevar(integral, eq, <var>)
```

Description

`intlib::changevar(integral, eq)` performs a change of variable for indefinite and definite integrals.

Mathematically, the substitution rule is formally defined for indefinite integrals as

int(f(g(x))*g'(x), x) = (fenced(int(f(t), t)) | t=g(x))

$$\int f(g(x))\, g'(x)\, \mathrm{d}\, x = \left(\left(\int f(t)\, \mathrm{d}\, t \right) \Big|_{t = g(x)} \right)$$

and for definite integrals as

int(f(g(x))*g'(x), x=a..b) = int(f(t), t=g(a)..g(b))

$$\int_a^b f(g(x))\, g'(x)\, \mathrm{d}\, x = \int_{g(a)}^{g(b)} f(t)\, \mathrm{d}\, t$$

`intlib::changevar(integral, eq)` performs in `integral` the change of variable defined by `eq` and returns an unevaluated new integral. You can use the eval command to find the closed form of this new integral providing that the closed form exists.

`intlib::changevar` works for indefinite as well as for definite integrals.

The first argument should contain a symbolic integral of type `"int"`. Such an expression can be obtained with hold or freeze. See “Example 1” on page 13-6.

If more than two variables occur in `eq`, the new variable must be given as third argument.

If MuPAD cannot solve the given equation `eq` an error will occur.

Examples

Example 1

As a first example we perform a change of variable for the integral int(f(x+c), x=a..b) $\int_a^b f(x+c)\,dx$. By using the hold function we ensure that the first argument is of type `"int"`:
intlib::changevar(hold(int)(f(x + c), x = a..b), t = x + c, t)int(f(t), t = a + c..b + c)

$$\int_{a+c}^{b+c} f(t)\,dt$$

Note that in this case the substitution equation has two further variables besides *x*. Thus it is necessary to specify the new integration variable as third argument.

Example 2

In the following example we use the change of variable method for solving the integral int(cos(ln(x)), x) $\int \cos(\ln(x))\,dx$. First we perform the transformation $t = ln(x)$:
f1 := intlib::changevar(hold(int)(cos(ln(x)), x), t = ln(x), t)int(exp(t)*cos(t), t)

$$\int e^t \cos(t)\,dt$$

Now we can evaluate the integral with the MuPAD integrator:
f2:=eval(f1)(exp(t)*(cos(t) + sin(t)))/2

$$\frac{e^t(\cos(t)+\sin(t))}{2}$$

Finally we change the variable *t* back to *x* and get the result:
F := simplify(f2 | t = ln(x))(x*(cos(ln(x)) + sin(ln(x))))/2

$$\frac{x(\cos(\ln(x))+\sin(\ln(x)))}{2}$$

We can also verify the solution of the integral:
simplify(diff(F,x) - cos(ln(x)))0

0

Parameters

integral

The integral: an arithmetical expression containing a symbolic `"int"` call

eq

Equation defining the new integration variable in terms of the old one: an equation

var

The new integration variable: an identifier

Return Values

Arithmetical expression.

See Also

subsintlib::byparts

intlib::intOverSet

Purpose

Integration over a set

Syntax

```
intlib::intOverSet(f, x, S)
```

Description

`intlib::intOverSet(f, x, S)` computes the integral int(f(x)*i_S(x), x=-infinity..infinity) $\int_{-\infty}^{\infty} f(x)\, i_S(x)\, \mathrm{d}\, x$ where $i_S(x)$ is the indicator function of the set S.

If S is an interval Dom::Interval(a, b)(a, b) with $a \le b$, the call is equivalent to `int(f, x=a..b)`. However, by definition, interchanging the borders to `int(f, x=b..a)` just reverses the sign of the latter while Dom::Interval(b, a)(b, a) is empty and any integral over the empty set is zero.

The function may return unevaluated if the integral could not be computed.

Examples

Example 1

For intervals, calling `intlib::intOverSet` is just equivalent to calling definite integration:
int(1/x, x=1..2), intlib::intOverSet(1/x, x, Dom::Interval(1, 2))ln(2), ln(2)

ln(2), ln(2)

If the lower border is greater than the upper, this does not hold anymore:
int(1/x, x=2..1), intlib::intOverSet(1/x, x, Dom::Interval(2, 1))-ln(2), 0

-ln(2), 0

Example 2

In more complex cases, the function returns unevaluated:
intlib::intOverSet(1/x^2, x, solve(t > sin(t), t))intlib::intOverSet(1/x^2, x, solve(sin(t) < t, t))

$$\int_{x \in \mathrm{solve}(\sin(t) < t,\, t)} \frac{1}{x^2}\, \mathrm{d}\, x$$

Parameters

f

Arithmetical expression

x

Identifier

s

Set-theoretic expression

Return Values

Arithmetical expression.

See Also

int

intlib::printWarnings

Purpose

Enable or disable warnings

Syntax

```
intlib::printWarnings(TRUE)
intlib::printWarnings(FALSE)
intlib::printWarnings()
```

Description

`intlib::printWarnings` lets you enable or disable warnings.

By default, MuPAD does not display warnings during integration. To enable warnings, use the `intlib::printWarnings(TRUE)` function call. If later you want to disable warnings, use the `intlib::printWarnings(FALSE)` function call. See "Example 1" on page 13-10.

The `intlib::printWarnings()` function call shows whether warnings are enabled or disabled. See "Example 1" on page 13-10.

The output of `intlib::printWarnings` displays the previous setting. You can save this previous setting and switch to a new setting in a single function call. See "Example 2" on page 13-11.

Examples

Example 1

Enable the warnings by setting the value of `intlib::printWarnings` to TRUE:
intlib::printWarnings(TRUE):

Compute the integral of $|x|$ under the assumption that `x` is an integer. MuPAD cannot integrate the expression over a discrete subset of the real numbers. The system issues a warning and integrates over the set R_$\mathbb{R}$ of real numbers:
int(abs(x), x) assuming x in Z_ Warning: Cannot integrate when 'x' has property 'Z_'. The assumption that 'x' has the property 'R_' is used for integration. [intlib::int] (x^2*sign(x))/2

$$\frac{x^2\,\mathrm{sign}(x)}{2}$$

If you evaluate the same integral again, MuPAD does not recalculate the integral. The system remembers the previous result and returns it, skipping the warning:
int(abs(x), x) assuming x in Z_(x^2*sign(x))/2

$$\frac{x^2\,\mathrm{sign}(x)}{2}$$

To check whether the warnings are enabled or disabled, use the `intlib::printWarnings()` function call:
intlib::printWarnings()TRUE

TRUE

Disable the warnings for further computations:
intlib::printWarnings(FALSE):

Example 2

Enable the warnings and save the previous setting in a single function call:
old := intlib::printWarnings(TRUE):

Assume that `x` is positive. Then, integrate `x` over the interval [- 2, 1]. In this case, the system issues a warning, temporarily disregards the assumption `x > 0`, and integrates over the interval [- 2, 1]:
assume(x > 0): int(x, x = -2..1) Warning: The assumption that 'x' has property '[-2, 1]' instead of given property '(0, infinity)' is used for integration. [int] -3/2

$$-\frac{3}{2}$$

Restore the setting of `intlib::printWarnings`:
intlib::printWarnings(old):

The warnings are disabled now:
intlib::printWarnings()FALSE

```
FALSE
```

For further computations, clear the assumption on the variable `x`: unassume(x):

Return Values

Previously set value `TRUE` or `FALSE`

linalg – Linear Algebra

==REFNAME==

linalg::addCol

Purpose

Linear combination of matrix columns

Syntax

```
linalg::addCol(A, c1, c2, s1)
linalg::addCol(A, c1, c2, s1, s2)
```

Description

`linalg::addCol(A, c1, c2, s1)` adds `s1` times column `c1` to column `c2`, in the matrix `A`.

`linalg::addCol(A, c1, c2, s)` returns a copy of the matrix A in which column c_2 of A is replaced by $scol(A, c_1) + col(A, c_2)$.

`linalg::addCol(A, c1, c2, s1, s2)` returns a copy of the matrix A in which column c_2 of A is replaced by $s_1 col(A, c_1) + s_2 col(A, c_2)$.

Examples

Example 1

The following defines a 3 3 matrix over the integers:
A := Dom::Matrix(Dom::Integer)([[1, 2, 3], [4, 5, 6], [7, 8, 9]]
)Dom::Matrix(Dom::Integer)([[1, 2, 3], [4, 5, 6], [7, 8, 9]])

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

We replace the 2nd column by - $col(A, 1) + col(A, 2)$, i.e., we subtract the first column from the second:
linalg::addCol(A, 1, 2, -1)Dom::Matrix(Dom::Integer)([[1, 1, 3], [4, 1, 6], [7, 1, 9]])

$$\begin{pmatrix} 1 & 1 & 3 \\ 4 & 1 & 6 \\ 7 & 1 & 9 \end{pmatrix}$$

Example 2

The following defines a 2 3 matrix over the reals:
B := Dom::Matrix(Dom::Real)([[sin(2), 0, 1], [1, PI, 0]]
)Dom::Matrix(Dom::Real)([[sin(2), 0, 1], [1, PI, 0]])

$$\begin{pmatrix} \sin(2) & 0 & 1 \\ 1 & \pi & 0 \end{pmatrix}$$

If s is an expression that does not represent a real number then an error message is reported. The following tries to replace the 1st column by *xcol*(*B*, 3) + *col*(*B*, 1), where *x* is an identifier which cannot be converted to the component ring Dom::Real of *B*:
delete x: linalg::addCol(B, 3, 1, x) Error: Cannot convert 'x'. [linalg::addCol]

Example 3

If symbolic expressions are involved, then one may define matrices over a component ring created by Dom::ExpressionField. The following example defines a matrix over this default component ring:
delete a11, a12, a21, a22, x: C := matrix([[a11, a12], [a21, a22]])matrix([[a11, a12], [a21, a22]])

$$\begin{pmatrix} a11 & a12 \\ a21 & a22 \end{pmatrix}$$

We retry the input from the previous example:
linalg::addCol(C, 2, 1, x)matrix([[a11 + a12*x, a12], [a21 + a22*x, a22]])

$$\begin{pmatrix} a11 + a12\,x & a12 \\ a21 + a22\,x & a22 \end{pmatrix}$$

Parameters

A

An *m* *n* matrix of a domain of category Cat::Matrix

c_1

c_2

The column indices: positive integers less or equal to *n*

s_1

s_2

Expressions that can be converted to the component ring of A

Return Values

Matrix of the same domain type as A.

See Also

Dom::Matrixlinalg::addRowlinalg::collinalg::multCollinalg::multRow

linalg::addRow

Purpose

Linear combination of matrix rows

Syntax

```
linalg::addRow(A, r1, r2, s)
linalg::addRow(A, r1, r2, s1, s2)
```

Description

`linalg::addRow(A, r1, r2, s1)` adds s_1 times row r_1 to row r_2, in the matrix `A`.

`linalg::addRow(A, r1, r2, s)` returns a copy of the matrix A in which row r_2 of A is replaced by $srow(A, r_1) + row(A, r_2)$.

`linalg::addRow(A, r1, r2, s1, s2)` returns a copy of the matrix A in which row r_2 of A is replaced by $s_1 row(A, r_1) + s_2 row(A, r_2)$.

Examples

Example 1

The following defines a 3 3 matrix over the integers:
A := Dom::Matrix(Dom::Integer)([[1, 2, 3], [4, 5, 6], [7, 8, 9]]
)Dom::Matrix(Dom::Integer)([[1, 2, 3], [4, 5, 6], [7, 8, 9]])

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

We replace the 2nd row by - $row(A, 1) + row(A, 2)$, i.e., we subtract the first row from the second:
linalg::addRow(A, 1, 2, -1)Dom::Matrix(Dom::Integer)([[1, 2, 3], [3, 3, 3], [7, 8, 9]])

$$\begin{pmatrix} 1 & 2 & 3 \\ 3 & 3 & 3 \\ 7 & 8 & 9 \end{pmatrix}$$

Example 2

The following defines a 2 3 matrix over the reals:
B := Dom::Matrix(Dom::Real)([[sin(2), 0, 1], [1, PI, 0]]
)Dom::Matrix(Dom::Real)([[sin(2), 0, 1], [1, PI, 0]])

$$\begin{pmatrix} \sin(2) & 0 & 1 \\ 1 & \pi & 0 \end{pmatrix}$$

If `s` is an expression that does not represent a real number then an error message is reported. The following tries to replace the 1st row by *xrow*(*B*, 2) + *row*(*B*, 1), where *x* is an identifier which cannot be converted to the component ring Dom::Real of *B*:
delete x: linalg::addRow(B, 2, 1, x) Error: Cannot convert 'x'. [linalg::addRow]

Example 3

If symbolic expressions are involved, then one may define matrices over the component ring created by Dom::ExpressionField. The following example defines a matrix over this default component ring:
delete a11, a12, a21, a22, x: C := matrix([[a11, a12], [a21, a22]])matrix([[a11, a12], [a21, a22]])

$$\begin{pmatrix} a11 & a12 \\ a21 & a22 \end{pmatrix}$$

We retry the input from the previous example:
linalg::addRow(C, 2, 1, x)matrix([[a11 + a21*x, a12 + a22*x], [a21, a22]])

$$\begin{pmatrix} a11 + a21\,x & a12 + a22\,x \\ a21 & a22 \end{pmatrix}$$

Parameters

A

An *m* *n* matrix of a domain of category Cat::Matrix

r_1

r_2

The row indices: positive integers less or equal to *m*

s

s_1

s_2

Expressions that can be converted to the component ring of A

Return Values Matrix of the same domain type as A.

See Also linalg::addCollinalg::rowlinalg::multCollinalg::multRow

linalg::adjoint

Purpose

Adjoint of a matrix

Syntax

```
linalg::adjoint(A)
```

Description

`linalg::adjoint(A)` computes the adjoint $Adj(A)$ of the n n matrix A. The adjoint matrix satisfies the equation A*Adj(A)=det(A)*‘&I;‘[n]$A\ \mathrm{Adj}(A) = \det A\ I_n$, where I_n is the n n identity matrix.

The component ring of `A` must be of category Cat::CommutativeRing.

Examples

Example 1

We define a matrix over the rationals:
MatQ := Dom::Matrix(Dom::Rational): A := MatQ([[0, 2, 1], [2, 1, 0], [1, 0, 2]])Dom::Matrix(Dom::Rational)([[0, 2, 1], [2, 1, 0], [1, 0, 2]])

$$\begin{pmatrix} 0 & 2 & 1 \\ 2 & 1 & 0 \\ 1 & 0 & 2 \end{pmatrix}$$

Then the adjoint matrix of `A` is given by:
Ad := linalg::adjoint(A)Dom::Matrix(Dom::Rational)([[2, -4, -1], [-4, -1, 2], [-1, 2, -4]])

$$\begin{pmatrix} 2 & -4 & -1 \\ -4 & -1 & 2 \\ -1 & 2 & -4 \end{pmatrix}$$

We check the property of the adjoint matrix `Ad` mentioned above:
A * Ad = linalg::det(A)*MatQ::identity(3)Dom::Matrix(Dom::Rational)([[-9, 0, 0], [0, -9, 0], [0, 0, -9]]) = Dom::Matrix(Dom::Rational)([[-9, 0, 0], [0, -9, 0], [0, 0, -9]])

$$\begin{pmatrix} -9 & 0 & 0 \\ 0 & -9 & 0 \\ 0 & 0 & -9 \end{pmatrix} = \begin{pmatrix} -9 & 0 & 0 \\ 0 & -9 & 0 \\ 0 & 0 & -9 \end{pmatrix}$$

Parameters

A

A square matrix of a domain of category Cat::Matrix

Return Values

Matrix of the same domain type as A.

Algorithms

The adjoint of a square matrix A is the matrix whose (i, j)-th entry is the (j, i)-th cofactor of A.

The (j, i)-th *cofactor* of A is defined by a'[(ji)]=fenced(-1)^(i+j) * linalg::det(A[ij])$a'_{ji} = (-1)^{i+j} \det(A_{ij})$, where A_{ij} is the submatrix of A obtained from A by deleting the i-th row and j-th column.

linalg::det

linalg::angle

Purpose

Angle between two vectors

Syntax

```
linalg::angle(u, v)
```

Description

`linalg::angle(u,v)` computes the angle φ between the two vectors `u` and `v`, defined by

Symbol::phiv= acos(linalg::scalarProduct(‘u→‘,‘v→‘)/(norm(‘u→‘, 2) * norm(‘v→‘, 2)))

$$\varphi = \operatorname{acos}\left(\frac{\langle \vec{u}, \vec{v}\rangle}{\|\vec{u}\|_2 \, \|\vec{v}\|_2}\right)$$

where linalg::scalarProduct(‘u→‘, ‘v→‘)$\langle \vec{u}, \vec{v}\rangle$ denotes the scalar product of two vectors given by linalg::scalarProduct, and norm(Symbol::centerdot, 2)$\|\cdot\|_2$ the 2-norm of a vector, i.e., norm(‘u→‘, 2)=sqrt(linalg::scalarProduct(‘u→‘, ‘u→‘))$\|\vec{u}\|_2 = \sqrt{\langle \vec{u}, \vec{u}\rangle}$.

`linalg::angle` does not check if the computation is defined in the corresponding component ring. This can lead to an error message, as shown in “Example 2” on page 14-11.

The following relationship between the angle between ‘u→‘$\vec{u}$ and ‘v→‘$\vec{v}$ and the angle between ‘u→‘$\vec{u}$ and -‘v→‘$-\vec{v}$ holds: Symbol::phiv(‘u→‘, ‘v→‘)=PI-Symbol::phiv(‘u→‘, ‘v→‘)$\varphi(\vec{u}, \vec{v}) = \pi - \varphi(\vec{u}, \vec{v})$.

An error message is returned if the vectors are not defined over the same component ring.

Examples

Example 1

We compute the angle between the two vectors matrix([[2], [5]])$\begin{pmatrix} 2 \\ 5 \end{pmatrix}$ and matrix([[-3], [3]])$\begin{pmatrix} -3 \\ 3 \end{pmatrix}$:

phi := linalg::angle(matrix([2, 5]), matrix([-3, 3]))arccos((sqrt(18)*sqrt(29))/58)

$$\arccos\left(\frac{\sqrt{18}\,\sqrt{29}}{58}\right)$$

We use the function float to get a floating-point approximation of this number:
float(phi)1.165904541

1.165904541

We give two further examples:
linalg::angle(matrix([1, -1]), matrix([1, 1]))PI/2

$\frac{\pi}{2}$ linalg::angle(matrix([1, 1]), matrix([-1, -1]))PI

π

Example 2

`linalg::angle` does not check whether the term linalg::scalarProduct(‘u→‘,‘v→‘)/(norm(‘u→‘, 2) *

norm(‘v→‘, 2)) $\frac{(\vec{u},\vec{v})}{\|\vec{u}\|_2\,\|\vec{v}\|_2}$ is defined in the corresponding component ring.

As an example, we try to compute the angle between two vectors with components in $_7$:
MatZ7 :=
Dom::Matrix(Dom::IntegerMod(7))Dom::Matrix(Dom::IntegerMod(7))

Dom::Matrix(Dom::IntegerMod(7))

The following call leads to an error because the 2-norm cannot be computed:

linalg::angle(MatZ7([1, 1]), MatZ7([-1, -1])) Error: An integer exponent is expected. [(Dom::IntegerMod(7))::_power]

Note that the domain Dom::IntegerMod(7) does not implement the square root of an element, therefore in MuPAD you cannot compute the angle of any two vectors over $_7$.

Parameters

u

v

Vectors of the same dimension; a vector is a n 1 or 1 n matrix of a domain of category Cat::Matrix

Return Values

Arithmetical expression.

See Also

arccoslinalg::scalarProductlinalg::vecdim

linalg::basis

Purpose

Basis for a vector space

Syntax

```
linalg::basis(S)
```

Description

`linalg::basis(S)` returns a basis for the vector space spanned by the vectors in the set or list *S*.

`linalg::basis(S)` removes those vectors in `S` that are linearly dependent on other vectors in `S`. The result is a basis for the vector space spanned by the vectors in `S`.

For an ordered basis of vectors, `S` should be a list of vectors.

The vectors in `S` must be defined over the same component ring.

The component ring of the vectors in `S` must be a field, i.e., it must be of category Cat::Field.

Examples

Example 1

We define the domain of matrices over :
MatQ := Dom::Matrix(Dom::Rational):

and compute a basis for the vector space spanned by the vectors

matrix([[3], [-2]]) $\begin{pmatrix} 3 \\ -2 \end{pmatrix}$, matrix([[1], [0]]) $\begin{pmatrix} 1 \\ 0 \end{pmatrix}$ and matrix([[5], [-3]]) $\begin{pmatrix} 5 \\ -3 \end{pmatrix}$:

```
v1 := MatQ([3, -2]): v2 := MatQ([1, 0]): v3 := MatQ([5, -3]):
linalg::basis([v1, v2, v3])[Dom::Matrix(Dom::Rational)([[3], [-2]]),
Dom::Matrix(Dom::Rational)([[1], [0]])]
```

$$\left[\begin{pmatrix} 3 \\ -2 \end{pmatrix}, \begin{pmatrix} 1 \\ 0 \end{pmatrix}\right]$$

If not a list but a set of vectors is given, then the basis returned may not consist of the same vectors as above. The order of the vectors in the set depends on the internal order (see sysorder and DOM_SET), i.e., the order of the vectors appears to be random:

```
b := linalg::basis({v1, v2, v3}): op(b, 1)Dom::Matrix(Dom::Rational)([[3],
[-2]])
```

$$\begin{pmatrix} 3 \\ -2 \end{pmatrix}$$

Parameters

s

A set or list of n-dimensional vectors; a vector is a n 1 or 1 n matrix of a domain of category Cat::Matrix

Return Values

Set or a list of vectors, respectively.

See Also

linalg::intBasislinalg::sumBasislllint

linalg::charmat

Purpose

Characteristic matrix

Syntax

```
linalg::charmat(A, x)
```

Description

`linalg::charmat(A, x)` returns the characteristic matrix xI_n - A of the n n matrix A, where I_n denotes the n n identity matrix.

The component ring of `A` must be a commutative ring, i.e., a domain of category Cat::CommutativeRing.

The characteristic matrix $M = xI_n - A$ of A can be evaluated at a point $x = u$ via `evalp(M, x = u)`. See "Example 2" on page 14-16.

Examples

Example 1

We define a matrix over the rational numbers:

```
A := Dom::Matrix(Dom::Rational)([[1, 2], [3, 4]])Dom::Matrix(Dom::Rational)([[1, 2], [3, 4]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$$

and compute the characteristic matrix of A in the variable x:

```
MA := linalg::charmat(A, x)Dom::Matrix(Dom::DistributedPolynomial([x], Dom::Rational, LexOrder))([[Dom::DistributedPolynomial([x], Dom::Rational, LexOrder)(x - 1), Dom::DistributedPolynomial([x], Dom::Rational, LexOrder)(-2)], [Dom::DistributedPolynomial([x], Dom::Rational, LexOrder)(-3), Dom::DistributedPolynomial([x], Dom::Rational, LexOrder)(x - 4)]])
```

$$\begin{pmatrix} x-1 & -2 \\ -3 & x-4 \end{pmatrix}$$

The determinant of the matrix `MA` is a polynomial in x, the characteristic polynomial of the matrix A:

```
pA := linalg::det(MA)x^2 - 5*x - 2
```

$$x^2 - 5\,x - 2$$

domtype(pA)Dom::DistributedPolynomial([x], Dom::Rational, LexOrder)

Dom::DistributedPolynomial([x], Dom::Rational, LexOrder)

Of course, we can compute the characteristic polynomial of A directly via linalg::charpoly:
linalg::charpoly(A, x)x^2 - 5*x - 2

$$x^2 - 5\,x - 2$$

The result is of the same domain type as the polynomial `pA`.

Example 2

We define a matrix over the complex numbers:
B := Dom::Matrix(Dom::Complex)([[1 + I, 1], [1, 1 - I]])Dom::Matrix(Dom::Complex)([[1 + I, 1], [1, 1 - I]])

$$\begin{pmatrix} 1+i & 1 \\ 1 & 1-i \end{pmatrix}$$

The characteristic matrix of `B` in the variable z is:
MB := linalg::charmat(B, z)Dom::Matrix(Dom::DistributedPolynomial([z], Dom::Complex, LexOrder))([[Dom::DistributedPolynomial([z], Dom::Complex, LexOrder)(z - (1 + I)), Dom::DistributedPolynomial([z], Dom::Complex, LexOrder)(-1)], [Dom::DistributedPolynomial([z], Dom::Complex, LexOrder)(-1), Dom::DistributedPolynomial([z], Dom::Complex, LexOrder)(z - (1 - I))]])

$$\begin{pmatrix} z-1-i & -1 \\ -1 & z-1+i \end{pmatrix}$$

We evaluate `MB` at $z = i$ and get the matrix:
evalp(MB, z = I)Dom::Matrix(Dom::Complex)([[-1, -1], [-1, - 1 + 2*I]])

$$\begin{pmatrix} -1 & -1 \\ -1 & -1+2\,i \end{pmatrix}$$

Note that this is a matrix of the domain type `Dom::Matrix(Dom::Complex)`:
domtype(%)Dom::Matrix(Dom::Complex)

Dom::Matrix(Dom::Complex)

Parameters

A

A square matrix of a domain of category Cat::Matrix

x

An identifier

Return Values

Matrix of the domain `Dom::Matrix(Dom::DistributedPolynomial([x], R))` or of `Dom::DenseMatrix(Dom::DistributedPolynomial([x], R))`, where `R` is the component ring of `A`.

See Also

linalg::charpoly

linalg::charpoly

Purpose

Characteristic polynomial of a matrix

Syntax

```
linalg::charpoly(A, x)
```

Description

`linalg::charpoly(A, x)` computes the characteristic polynomial of the matrix *A*. The characteristic polynomial of a *n* *n* matrix is defined by p[A](x):=det(x * '&I;'[n]-A)$p_A(x) := \det(x\, I_n - A)$, where I_n denotes the *n* *n* identity matrix.

The component ring of `A` must be a commutative ring, i.e., a domain of category Cat::CommutativeRing.

Examples

Example 1

We define a matrix over the rational numbers:
A := Dom::Matrix(Dom::Rational)([[1, 2], [3, 4]])Dom::Matrix(Dom::Rational)([[1, 2], [3, 4]])

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$$

Then the characteristic polynomial $p_A(x)$ is given by:
linalg::charpoly(A, x)x^2 - 5*x - 2

$$x^2 - 5\,x - 2$$

It is of the domain type:
domtype(%)Dom::DistributedPolynomial([x], Dom::Rational, LexOrder)

Dom::DistributedPolynomial([x], Dom::Rational, LexOrder)

Example 2

We define a matrix over $_7$:
B := Dom::Matrix(Dom::IntegerMod(7))([[1, 2], [3, 0]])Dom::Matrix(Dom::IntegerMod(7))([[1, 2], [3, 0]])

$$\begin{pmatrix} 1 \bmod 7 & 2 \bmod 7 \\ 3 \bmod 7 & 0 \bmod 7 \end{pmatrix}$$

The characteristic polynomial $p_B(x)$ of `B` is given by:
p := linalg::charpoly(B, x)(1 mod 7)*x^2 + (6 mod 7)*x + (1 mod 7)

$$(1 \bmod 7)\, x^2 + (6 \bmod 7)\, x + (1 \bmod 7)$$

We compute the zeros of $p_B(x)$, i.e., the eigenvalues of the matrix `B`:
solve(p){[x = 3 mod 7], [x = 5 mod 7]}

$$\{[x = 3 \bmod 7], [x = 5 \bmod 7]\}$$

Parameters

A

A square matrix of a domain of category Cat::Matrix

x

An identifier

Return Values

Polynomial of the domain `Dom::DistributedPolynomial([x],R)`, where `R` is the component ring of `A`.

Algorithms

`linalg::charpoly` implements Hessenberg's algorithm to compute the characteristic polynomial of a square matrix A. See: Henri Cohen: *A Course in Computational Algebraic Number Theory*, GTM 138, Springer Verlag.

This algorithm works for any field and requires only $O(n^3)$ field operations, in contrast to $O(n^4)$ when computing the determinant of the characteristic matrix of A.

Since the size of the components of A in intermediate computations of Hessenberg's algorithm can swell extremely, it is only applied for matrices over Dom::Float and Dom::IntegerMod.

For any other component ring, the characteristic polynomial is computed using the Berkowitz algorithm.

linalg::charmatlinalg::detlinalg::hessenberglinalg::minpoly

linalg::col

Purpose

Extract columns of a matrix

Syntax

```
linalg::col(A, c)
linalg::col(A, c1 .. c2)
linalg::col(A, list)
```

Description

`linalg::col(A, c)` extracts the *c*-th column vector of the matrix *A*.

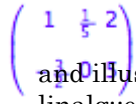
`linalg::col(A, c1.. c2)` returns a list of column vectors whose indices are in the range `c1.. c2`. If `c2< c1` then the empty list `[]` is returned.

`linalg::col(A, list)` returns a list of column vectors whose indices are contained in `list` (in the same order).

Examples

Example 1

We define a matrix over :
A := Dom::Matrix(Dom::Rational)([[1, 1/5, 2], [-3/2, 0, 5]]
)Dom::Matrix(Dom::Rational)([[1, 1/5, 2], [-3/2, 0, 5]])



and illustrate the three different input formats for `linalg::col`:
linalg::col(A, 2)Dom::Matrix(Dom::Rational)([[1/5], [0]])

linalg::col(A, [2, 1, 3])[Dom::Matrix(Dom::Rational)([[1/5], [0]]), Dom::Matrix(Dom::Rational)([[1], [-3/2]]), Dom::Matrix(Dom::Rational)([[2], [5]])]

$$\left[\begin{pmatrix}\frac{1}{5}\\0\end{pmatrix},\begin{pmatrix}1\\0\end{pmatrix},\begin{pmatrix}2\\5\end{pmatrix}\right]$$

linalg::col(A, 2..3)[Dom::Matrix(Dom::Rational)([[1/5], [0]]), Dom::Matrix(Dom::Rational)([[2], [5]])]

$$\left[\begin{pmatrix}\frac{1}{5}\\0\end{pmatrix},\begin{pmatrix}2\\5\end{pmatrix}\right]$$

Parameters

A

An *m n* matrix of a domain of category Cat::Matrix

c

The column index: a positive integer less or equal to *n*

c_1 .. c_2

A range of column indices (positive integers less or equal to *n*)

list

A list of column indices (positive integers less or equal to *n*)

Return Values

Single column vector or a list of column vectors; a column vector is an *m* 1 matrix of category Cat::Matrix(R), where *R* is the component ring of A.

See Also

linalg::rowlinalg::delCollinalg::delRowlinalg::setCollinalg::setRow

linalg::companion

Purpose

Companion matrix of a univariate polynomial

Syntax

```
linalg::companion(p, <x>)
```

Description

`linalg::companion(p)` returns the companion matrix associated with the polynomial *p*.

`p` must be monic and of degree one at least.

If `p` is a polynomial, i.e., an object of type DOM_POLY, then specifying `x` has no effect.

If `p` is a polynomial, then the component ring of the returned matrix is the coefficient ring of `p`, except in two cases for built-in coefficient rings: if the coefficient ring of `p` is `Expr` then the domain Dom::ExpressionField() is the component ring of the companion matrix. If it is `IntMod(m)` then the companion matrix is defined over the ring Dom::IntegerMod(m) (see "Example 2" on page 14-24).

If `p` is a polynomial expression, then the companion matrix is defined over `Dom::ExpressionField()`.

If `p` is a polynomial expression containing several symbolic indeterminates then `x` must be specified and distinguishes the indeterminate `x` from the other symbolic parameters.

Examples

Example 1

We start with the following polynomial expression:
delete a_0, a_1, a_2, a_3: p := x^4 + a_3*x^3 + a_2*x^2 + a_1*x + a_0x^4 + a_3*x^3 + a_2*x^2 + a_1*x + a_0

$$x^4 + a_3\,x^3 + a_2\,x^2 + a_1\,x + a_0$$

To compute the companion matrix of p with respect to x we must specify the second parameter x, because the expression `p` contains the indeterminates a_0, a_1, a_2, a_3 and x:

linalg::companion(p) Error: The polynomial expression is multivariate. Specify the indeterminate as second argument. [linalg::companion]
linalg::companion(p, x)matrix([[0, 0, 0, -a_0], [1, 0, 0, -a_1], [0, 1, 0, -a_2], [0, 0, 1, -a_3]])

$$\begin{pmatrix} 0 & 0 & 0 & -a_0 \\ 1 & 0 & 0 & -a_1 \\ 0 & 1 & 0 & -a_2 \\ 0 & 0 & 1 & -a_3 \end{pmatrix}$$

Of course, we can compute the companion matrix of p with respect to a_0 as well:
linalg::companion(p, a_0)matrix([[- x^4 - a_3*x^3 - a_2*x^2 - a_1*x]])

$$\begin{pmatrix} -x^4 - a_3\,x^3 - a_2\,x^2 - a_1\,x \end{pmatrix}$$

The following fails with an error message, because the polynomial p is not monic with respect to a_1:
linalg::companion(p, a_1) Error: Polynomial is not monic. [linalg::companion]

Example 2

If we enter a polynomial over the built-in coefficient domain `Expr`, then the companion matrix is defined over the standard component ring for matrices (the domain Dom::ExpressionField()):
C := linalg::companion(poly(x^2 + 10*x + PI, [x]))matrix([[0, -PI], [1, -10]])

$$\begin{pmatrix} 0 & -\pi \\ 1 & -10 \end{pmatrix}$$

domtype(C)Dom::Matrix()

Dom::Matrix()

If we define a polynomial over the build-in coefficient domain `IntMod(m)`, then the companion matrix is defined over the corresponding component ring `Dom::IntegerMod(m)`, as shown in the next example:
p := poly(x^2 + 10*x + 7, [x], IntMod(3))poly(x^2 + x + 1, [x], IntMod(3))

$$\text{poly}(x^2 + x + 1, [x], \text{IntMod}(3))$$

C := linalg::companion(p)Dom::Matrix(Dom::IntegerMod(3))([[0, -1], [1, -1]])

$$\begin{pmatrix} 0 \bmod 3 & 2 \bmod 3 \\ 1 \bmod 3 & 2 \bmod 3 \end{pmatrix}$$

domtype(C)Dom::Matrix(Dom::IntegerMod(3))

$$\text{Dom::Matrix(Dom::IntegerMod(3))}$$

Parameters

p

An univariate polynomial, or a polynomial expression

x

An identifier

Return Values

Matrix of the domain Dom::Matrix`(R)`.

Algorithms

The companion matrix of the polynomial $x^n + a_{n1}x^{n-1} + \ldots + a_1x + a_0$ is the matrix:

C=matrix([[0, Symbol::cdot, Symbol::cdot, Symbol::cdot, 0, -a[0]], [1, Symbol::cdot, “, “, “, -a[1]], [“, Symbol::cdot, Symbol::cdot, “, “, Symbol::cdot], [“, “, Symbol::cdot, Symbol::cdot, “, Symbol::cdot], [“, “, “, Symbol::cdot, 0, -a[(n-1)]], [“, “, “, “, 1, -a[n]]])

$$C = \begin{pmatrix} 0 & \cdots & 0 & -a_0 \\ 1 & \ddots & & -a_1 \\ & \ddots & & \vdots \\ & & 0 & -a_{n-1} \\ & & 1 & -a_n \end{pmatrix}$$

The companion matrix of a univariate polynomial p of degree n is an n n matrix C with $p_C = p$, where p_C is the characteristic polynomial of C.

linalg::concatMatrix

Purpose

Join matrices horizontally

Syntax

`linalg::concatMatrix(A, B1, <B2, >)`

Description

`linalg::concatMatrix(A, B1, B2, dots )` returns the matrix formed by joining the matrices A, B_1, B_2, ... horizontally.

The matrices `B1, B2, dots` are converted into the matrix domain `Dom::Matrix(R)`, where `R` is the component ring of `A`.

An error message is raised if one of these conversions fails, or if the matrices do not have the same number of rows as the matrix `A`.

A short form of `linalg::concatMatrix` is available through the dot operator ., i.e., instead of `linalg::concatMatrix(A, B)` one may use the short form `A . B`.

Examples

Example 1

We define the matrix:
A := matrix([[sin(x), x], [-x, cos(x)]])matrix([[sin(x), x], [-x, cos(x)]])

$$\begin{pmatrix} \sin(x) & x \\ -x & \cos(x) \end{pmatrix}$$

and append the 2 2 identity matrix to the right of `A`:
I2 := matrix::identity(2): linalg::concatMatrix(A, I2)matrix([[sin(x), x, 1, 0], [-x, cos(x), 0, 1]])

$$\begin{pmatrix} \sin(x) & x & 1 & 0 \\ -x & \cos(x) & 0 & 1 \end{pmatrix}$$

The short form for this operation is:
A . I2matrix([[sin(x), x, 1, 0], [-x, cos(x), 0, 1]])

$$\begin{pmatrix} \sin(x) & x & 1 & 0 \\ -x & \cos(x) & 0 & 1 \end{pmatrix}$$

Example 2

We define a matrix from the ring of 2 2 square matrices:
SqMatQ := Dom::SquareMatrix(2, Dom::Rational): A := SqMatQ([[1, 2], [3, 4]])Dom::SquareMatrix(2, Dom::Rational)([[1, 2], [3, 4]])

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$$

Note the following operation:
AA := A . ADom::Matrix(Dom::Rational)([[1, 2, 1, 2], [3, 4, 3, 4]])

$$\begin{pmatrix} 1 & 2 & 1 & 2 \\ 3 & 4 & 3 & 4 \end{pmatrix}$$

returns a matrix of a different domain type as the input matrix:
domtype(AA)Dom::Matrix(Dom::Rational)

Dom::Matrix(Dom::Rational)

Parameters

A

B_1

B_2, ...

Matrices of a domain of category Cat::Matrix

Return Values

Matrix of the domain type Dom::Matrix(R), where R is the component ring of A.

See Also

linalg::stackMatrix

linalg::cond

Purpose

Condition number of a matrix

Syntax

```
linalg::cond(M, <1 | 2 | Spectral | Infinity | Frobenius>)
```

Description

`linalg::cond(M)` computes the condition number of a matrix, defined by norm(M) * norm(M^(-1)) $\|M\|_\infty \left\|\frac{1}{M}\right\|_\infty$. By default the matrix norm Infinity is used by `linalg::cond`.

`linalg::cond(M)` is the short form of `linalg::cond(M, Infinity)`.

`linalg::cond(M, k)` computes the condition number of the matrix M, defined by norm(M, k) * norm(M^(-1), k) $\|M\|_k \left\|\frac{1}{M}\right\|_k$.

For further details see the help page of norm.

Examples

Example 1

We define the 3 3 matrix A.
A := matrix(3,3, [[1,0,3],[-4,2,0],[0,3,-2]])matrix([[1, 0, 3], [-4, 2, 0], [0, 3, -2]])

$$\begin{pmatrix} 1 & 0 & 3 \\ -4 & 2 & 0 \\ 0 & 3 & -2 \end{pmatrix}$$

Now we calculate the condition number of A for some matrix norms.
linalg::cond(A)33/10

$$\frac{33}{10}$$

linalg::cond(A, Infinity)33/10

$$\frac{33}{10}$$

linalg::cond(A, 1)3

3

linalg::cond(A, Frobenius)(sqrt(2)*sqrt(43)*sqrt(251))/40

$$\frac{\sqrt{2}\,\sqrt{43}\,\sqrt{251}}{40}$$

The result for the spectral norm is too complex, so we want the floating valuation. The tiny imaginary part is a rounding artifact:

linalg::cond(A, 2); float(%)sqrt(343/(9*(3970/27
+ (sqrt(27)*sqrt(910841)*I)/27)^(1/3)) +
(3970/27 + (sqrt(27)*sqrt(910841)*I)/27)^(1/3) +
43/3)*sqrt(11401/(5760000*(705851/13824000000 +
(sqrt(910841)*sqrt(176947200000000)*I)/176947200000000)^(1/3))
+ (705851/13824000000 +
(sqrt(910841)*sqrt(176947200000000)*I)/176947200000000)^(1/3)
+ 251/2400)

$$\sqrt{\frac{343}{9\left(\frac{3970}{27}+\frac{\sqrt{27}\,\sqrt{910841}\,i}{27}\right)^{1/3}}+\left(\frac{3970}{27}+\frac{\sqrt{27}\,\sqrt{910841}\,i}{27}\right)^{1/3}+\frac{43}{3}}$$

2.223147175 + 1.386849201e-18*I

$$2.223147175+1.386849201\,10^{-18}\,i$$

If *A* contains at least one floating-point number, the result will be computed numerically.

B := A: B[1,1] := float(B[1,1]): linalg::cond(B, 2)2.223147175

2.223147175

Example 2

We define the 2 2 matrix *C*.

C := matrix([[1,-2],[3,-4]])matrix([[1, -2], [3, -4]])

$$\begin{pmatrix} 1 & -2 \\ 3 & -4 \end{pmatrix}$$

Now we calculate the condition number of *C* for some matrix norms.
linalg::cond(C,1)21

21

linalg::cond(C,Infinity)21

21

linalg::cond(C,Frobenius); Simplify(%);(sqrt(2)*sqrt(15)*sqrt(30))/2

$$\frac{\sqrt{2}\,\sqrt{15}\,\sqrt{30}}{2}$$

15

15

Example 3

Hilbert matrices are very ill-conditioned:
linalg::cond(linalg::hilbert(3))748

748

linalg::cond(linalg::hilbert(5))943656

943656

linalg::cond(linalg::hilbert(7))1970389773/2

$$\frac{1970389773}{2}$$

Parameters

M

Square matrix of domain type Dom::Matrix

Options

Frobenius

Infinity

Spectral

The index of the matrix norm.

Return Values

Arithmetical expression.

See Also

norm

linalg::crossProduct

Purpose

Cross product of three-dimensional vectors

Syntax

```
linalg::crossProduct(u, v)
```

Description

`linalg::crossProduct(u, v)` computes the cross product of the three-dimensional vectors ‘u→‘$\vec{u}$ and ‘v→‘$\vec{v}$. This is the vector

‘u→‘ times ‘v→‘=matrix([[u[2] * v[3]-u[3] * v[2]], [u[3] * v[1]-u[1] * v[3]], [u[1] * v[2]-u[2] * v[1]]])

$$\vec{u} \times \vec{v} = \begin{pmatrix} u_2\, v_3 - u_3\, v_2 \\ u_3\, v_1 - u_1\, v_3 \\ u_1\, v_2 - u_2\, v_1 \end{pmatrix}$$

The vectors must be defined over the same component ring.

Examples

Example 1

We define two vectors:
a := matrix([[1, 2, 3]]); b := matrix([[-1, 0, 1]])matrix([[1, 2, 3]])

$$\begin{pmatrix} 1 & 2 & 3 \end{pmatrix}$$

matrix([[-1, 0, 1]])

$$\begin{pmatrix} -1 & 0 & 1 \end{pmatrix}$$

The cross product of these two vectors is a vector ‘c→‘$\vec{c}$ which is orthogonal to ‘a→‘$\vec{a}$ and ‘b→‘$\vec{b}$:
c:= linalg::crossProduct(a, b)matrix([[2, -4, 2]])

$$\begin{pmatrix} 2 & -4 & 2 \end{pmatrix}$$

linalg::scalarProduct(a, c), linalg::scalarProduct(b, c)0, 0

0, 0

Parameters

u

v

3-dimensional vectors, i.e., either two 3 1 or two 1 3 matrices of a domain of category Cat::Matrix

Return Values

Vector of the same domain type as u.

See Also

linalg::scalarProduct

linalg::curl

Purpose

Curl of a vector field

Syntax

```
linalg::curl(v, x)
linalg::curl(v, x, ogCoord, <c>)
```

Description

`linalg::curl(v, x)` computes the curl of the three-dimensional vector field ‘v→’$\vec{v}$ with respect to the three-dimensional vector ‘x→’$\vec{x}$ in Cartesian coordinates. This is the vector field

curl(‘v→’)= matrix([diff(v[3],x[2])-diff(v[2],x[3]), diff(v[1],x[3])-diff(v[3],x[1]), diff(v[2],x[1])-diff(v[1],x[2])])

$$\mathrm{curl}(\vec{v}) = \begin{pmatrix} \frac{\partial}{\partial x_2} v_3 - \frac{\partial}{\partial x_3} v_2 \\ \frac{\partial}{\partial x_3} v_1 - \frac{\partial}{\partial x_1} v_3 \\ \frac{\partial}{\partial x_1} v_2 - \frac{\partial}{\partial x_2} v_1 \end{pmatrix}$$

`linalg::curl` and curl are equivalent. See details and examples on the curl help page.

Parameters

v

A list of three arithmetical expressions, or a 3-dimensional vector (i.e., a 3 1 or 1 3 matrix of a domain of category Cat::Matrix)

x

A list of three (indexed) identifiers

ogCoord

The name of a 3 dimensional orthogonal coordinate system predefined in the table linalg::ogCoordTab, or a list of algebraic expressions representing the “scale parameters” of an orthogonal coordinate system.

c

The parameter of the coordinate systems EllipticCylindrical and Torus, respectively: an arithmetical expression. The default value is `c = 1`.

Return Values

Column vector.

linalg::delCol

Purpose

Delete matrix columns

Syntax

```
linalg::delCol(A, c)
linalg::delCol(A, c1 .. c2)
linalg::delCol(A, list)
```

Description

`linalg::delCol(A, c)` returns a copy of the matrix *A* in which the column with index *c* is deleted.

`linalg::delCol(A, c1.. c2)` deletes those columns whose indices are in the range `c1.. c2`. If `c2< c1` then the input matrix `A` is returned.

`linalg::delCol(A, list)` deletes those columns whose indices are contained in `list`.

If all columns are deleted then NIL is returned.

Examples

Example 1

We define the following matrix:
A := matrix([[1, 2, 3, 4], [5, 6, 7, 8]])matrix([[1, 2, 3, 4], [5, 6, 7, 8]])

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \end{pmatrix}$$

and demonstrate the three different input formats for `linalg::delCol`:
linalg::delCol(A, 2)matrix([[1, 3, 4], [5, 7, 8]])

$$\begin{pmatrix} 1 & 3 & 4 \\ 5 & 7 & 8 \end{pmatrix}$$

linalg::delCol(A, [1, 3])matrix([[2, 4], [6, 8]])

$$\begin{pmatrix} 2 & 4 \\ 6 & 8 \end{pmatrix}$$

linalg::delCol(A, 2..4)matrix([[1], [5]])

$$\begin{pmatrix} 1 \\ 5 \end{pmatrix}$$

Example 2

We compute the inverse of the 2 2 matrix:
MatQ := Dom::Matrix(Dom::Rational): A := MatQ([[3, 2], [5, -4]])Dom::Matrix(Dom::Rational)([[3, 2], [5, -4]])

$$\begin{pmatrix} 3 & 2 \\ 5 & -4 \end{pmatrix}$$

by appending the 2 2 identity matrix to the right side of *A* and applying the Gauss-Jordan algorithm provided by the function linalg::gaussJordan:
B := linalg::gaussJordan(A . MatQ::identity(2))Dom::Matrix(Dom::Rational)([[1, 0, 2/11, 1/11], [0, 1, 5/22, -3/22]])

$$\begin{pmatrix} 1 & 0 & \frac{2}{11} & \frac{1}{11} \\ 0 & 1 & \frac{5}{22} & -\frac{3}{22} \end{pmatrix}$$

We get the inverse of A by deleting the first two columns of the matrix B:
AI := linalg::delCol(B, 1..2)Dom::Matrix(Dom::Rational)([[2/11, 1/11], [5/22, -3/22]])

$$\begin{pmatrix} \frac{2}{11} & \frac{1}{11} \\ \frac{5}{22} & -\frac{3}{22} \end{pmatrix}$$

Finally, we check the result:
A * AI, AI * ADom::Matrix(Dom::Rational)([[1, 0], [0, 1]]), Dom::Matrix(Dom::Rational)([[1, 0], [0, 1]])

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

Note: The inverse of `A` can be computed directly by entering `1/A`.

Parameters

A

An m n matrix of a domain of category Cat::Matrix

c

The column index: a positive integer less or equal to n

c_1 .. c_2

A range of column indices (positive integers less or equal to n)

list

A list of column indices (positive integers less or equal to n)

Return Values

Matrix of a domain of category `Cat::Matrix(R)`, where `R` is the component ring of `A`, or NIL.

Concepts

- "Swap and Delete Rows and Columns"

linalg::delRow

Purpose

Delete matrix rows

Syntax

```
linalg::delRow(A, r)
linalg::delRow(A, r1 .. r2)
linalg::delRow(A, list)
```

Description

`linalg::delRow(A, r)` returns a copy of the matrix *A* in which the row with index *r* is deleted.

`linalg::delRow(A, r1.. r2)` deletes those rows whose indices are in the range `r1.. r2`. If `r2< r1` then the input matrix `A` is returned.

`linalg::delRow(A, list)` deletes those rows whose indices are contained in `list`.

If all rows are deleted then NIL is returned.

Examples

Example 1

We define the following matrix:
A := matrix([[1, 2], [3, 4], [5, 6], [7, 8]])matrix([[1, 2], [3, 4], [5, 6], [7, 8]])

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \\ 5 & 6 \\ 7 & 8 \end{pmatrix}$$

and illustrate the three different input formats for `linalg::delRow`:
linalg::delRow(A, 2)matrix([[1, 2], [5, 6], [7, 8]])

$$\begin{pmatrix} 1 & 2 \\ 5 & 6 \\ 7 & 8 \end{pmatrix}$$

linalg::delRow(A, [1, 4])matrix([[3, 4], [5, 6]])

$$\begin{pmatrix} 3 & 4 \\ 5 & 6 \end{pmatrix}$$

linalg::delRow(A, 2..4)matrix([[1, 2]])

```
(1 2)
```

Parameters

A

An m n matrix of a domain of category Cat::Matrix

r

The row index: a positive integer less or equal to m

r_1 .. r_2

A range of row indices (positive integers less or equal to m)

list

A list of row indices (positive integers less or equal to m)

Return Values

Matrix of a domain of category `Cat::Matrix(R)`, where `R` is the component ring of `A` or NIL.

linalg::det

Purpose

Determinant of a matrix

Syntax

```
linalg::det(A, options)
```

Description

`linalg::det(A)` computes the determinant of the square matrix *A*.

A floating-point approximation of the determinant is computed with numeric::det, if `A` is defined over the component ring Dom::Float. In this case, it is recommended to call `numeric::det` directly for a better efficiency.

The component ring of `A` must be a commutative ring, i.e., a domain of category Cat::CommutativeRing.

The `MinorExpansion` option is useful for small matrices (typically, matrices of dimension up to 10) containing many symbolic entries. By default, `linalg::det` tries to recognize matrices that can benefit from using `MinorExpansion`, and uses this option when computing their determinants. Nevertheless, `linalg::det` does not always recognize these matrices. Also, identifying that a matrix is small enough and contains many symbolic entries takes time. To improve performance, use the `MinorExpansion` option explicitly.

By default, `linalg::det` calls normal before returning results. This additional internal call ensures that the final result is normalized. This call can be computationally expensive. It also affects the result returned by `linalg::det` only if a matrix contains variables or exact expressions, such as `sqrt(5)` or `sin(PI/7)`.

To avoid this additional call, specify `Normal = FALSE`. In this case, `linalg::det` also can return normalized results, but does not guarantee such normalization. See “Example 2” on page 14-43 and “Example 3” on page 14-43.

Examples

Example 1

Compute the determinant of the following matrix:
A := matrix([[a11, a12], [a21, a22]])matrix([[a11, a12], [a21, a22]])

$$\begin{pmatrix} a11 & a12 \\ a21 & a22 \end{pmatrix}$$

`linalg::det` returns the well-known formula for the determinant of an arbitrary 2 2 matrix:
linalg::det(A)a11*a22 - a12*a21

$$a11\,a22 - a12\,a21$$

Example 2

If you use the `Normal` option, `linalg::det` calls the normal function for final results. This call ensures that `linalg::det` returns results in normalized form:
linalg::det(matrix([[x, x^2], [x/(x + 2), 1/x]]))(- x^3 + x + 2)/(x + 2)

$$\frac{-x^3 + x + 2}{x + 2}$$

If you specify `Normal = FALSE`, `linalg::det` does not call normal for the final result:
linalg::det(matrix([[x, x^2], [x/(x + 2), 1/x]]), Normal = FALSE)1 - x^3/(x + 2)

$$1 - \frac{x^3}{x + 2}$$

Example 3

Using `Normal` can significantly decrease the performance of `linalg::det`. For example, computing the determinant of this matrix takes a long time:
n := 5: det5 := linalg::det(matrix([[(x[i*j]^(i + j) + x[i+j]^j)/(i + j) $ j = 1..n] $ i = 1..n])):

For better performance, specify `Normal = FALSE`:
n := 5: det5 := linalg::det(matrix([[(x[i*j]^(i + j) + x[i+j]^j)/(i + j) $ j = 1..n] $ i = 1..n]), Normal = FALSE):

Parameters

A

Square matrix of a domain of category Cat::Matrix

Options

MinorExpansion

Compute the determinant by a recursive minor expansion along the first column.

Normal

Option, specified as `Normal = b`

Return normalized results. The value `b` must be TRUE or FALSE. By default, `Normal = TRUE`, meaning that `linalg::det` guarantees normalization of the returned results. Normalizing results can be computationally expensive.

Return Values

Element of the component ring of `A`.

Algorithms

For an n n matrix $A = (a_{i,j})_{1 \le i \le n,\ 1 \le j \le n}$ over a commutative ring its determinant is defined as:

det(A):=sum(sign(Symbol::sigma) * product(a[(Symbol::sigma(j), j)], j=1..n), Symbol::sigma in S[n])

$$\det A := \sum_{\sigma \in S_n} \operatorname{sign}(\sigma) \left(\prod_{j=1}^{n} a_{\sigma(j),\,j} \right)$$

(S_n is the symmetric group of all permutations of {1, …, n}.)

For a component ring of A that is an integral domain (i.e., a domain of category Cat::IntegralDomain) and not defined over the domain Dom::Float, Gaussian elimination is used to compute the determinant of A.

For any other commutative ring that is not an integral domain, a modification of the Berkowitz algorithm is used.

linalg::gaussElimlinalg::permanentlinalg::ranknumeric::det

linalg::divergence

Purpose

Divergence of a vector field

Syntax

```
linalg::divergence(v, x)
linalg::divergence(v, x, ogCoord, <c>)
```

Description

`linalg::divergence(v, x)` computes the divergence of the vector field 'v→'$\vec{v}$ with respect to 'x→'$\vec{x}$ in Cartesian coordinates. This is the sum 'div'('v→')=sum(diff(v[i],x[i]), i = 1..n)$\mathrm{div}(\vec{v}) = \sum_{i=1}^{n} \frac{\partial}{\partial x_i} v_i$.

`linalg::divergence` and divergence are equivalent. See details and examples on the divergence help page.

Parameters

v

A list of arithmetical expressions, or a vector (i.e., an n 1 or 1 n matrix of a domain of category Cat::Matrix)

x

A list of (indexed) identifiers

ogCoord

The name of a 3 dimensional orthogonal coordinate system predefined in the table linalg::ogCoordTab, or a list of algebraic expressions representing the "scale parameters" of an orthogonal coordinate system.

c

The parameter of the coordinate systems EllipticCylindrical and Torus, respectively: an arithmetical expression. The default value is `c` = 1.

Return Values

Arithmetical expression, or an element of the component ring of `v`.

linalg::eigenvalues

Purpose

Eigenvalues of a matrix

Syntax

```
linalg::eigenvalues(A, <Multiple>)
```

Description

`linalg::eigenvalues(A)` returns a list of the eigenvalues of the matrix *A*.

A floating-point approximation of the eigenvalues is computed with numeric::eigenvalues, if the matrix `A` is defined over the component ring Dom::Float (see "Example 1" on page 14-47). In this case it is recommended to call `numeric::eigenvalues` directly for a better efficiency.

The eigenvalues are obtained by computing the zeros of the characteristic polynomial of `A`. The solver solve must be able to compute the roots of the characteristic polynomial over the component ring of `A`.

Examples

Example 1

We compute the eigenvalues of the matrix

A=matrix([[1, 4, 2], [1, 4, 2], [2, 5, 3]])

$$A = \begin{pmatrix} 1 & 4 & 2 \\ 1 & 4 & 2 \\ 2 & 5 & 3 \end{pmatrix}$$

A := matrix([[1, 4, 2], [1, 4, 2], [2, 5, 3]]): linalg::eigenvalues(A){0, 4 - sqrt(15), sqrt(15) + 4}

$$\{0,\ 4 - \sqrt{15},\ \sqrt{15} + 4\}$$

If we consider the matrix over the domain `Dom::Float`, then the call of `linalg::eigenvalues(A)` results in a numerical computation of the eigenvalues of `A` via numeric::eigenvalues:
B := Dom::Matrix(Dom::Float)(A):
linalg::eigenvalues(B){-1.370431546e-15, 0.1270166538, 7.872983346}

$$\{-1.370431546\,10^{-15},\ 0.1270166538,\ 7.872983346\}$$

Example 2

With the option `Multiple` we get the information about the algebraic multiplicity of each eigenvalue:

```
C := Dom::Matrix(Dom::Rational)(4, 4, [[-3], [0, 6]])Dom::Matrix(Dom::Rational)([[-3, 0, 0, 0], [0, 6, 0, 0], [0, 0, 0, 0], [0, 0, 0, 0]])
```

$$\begin{pmatrix} -3 & 0 & 0 & 0 \\ 0 & 6 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

```
linalg::eigenvalues(C, Multiple)[[-3, 1], [0, 2], [6, 1]]
```

$$[[-3, 1], [0, 2], [6, 1]]$$

Parameters

A

A square matrix of a domain of category Cat::Matrix

Options

Multiple

Returns a list of sublists, where each sublist contains an eigenvalue of `A` and its algebraic multiplicity. Note that due to rounding errors, this may lead to wrong results in cases where multiple eigenvalues exist and `numeric::eigenvalues` is used.

Return Values

Set of the eigenvalues of `A`, or a list of inner lists when the option `Multiple` is given (see below).

linalg::eigenvectors

Purpose

Eigenvectors of a matrix

Syntax

```
linalg::eigenvectors(A)
```

Description

`linalg::eigenvectors(A)` computes the eigenvalues and eigenvectors of the matrix A.

A floating-point approximation of the eigenvalues and the eigenvectors is computed using numeric::eigenvectors, if the matrix `A` is defined over the component ring Dom::Float (see "Example 1" on page 14-49). In this case it is recommended to call `numeric::eigenvalues` directly for a better efficiency.

`linalg::eigenvectors` works as follows: For each eigenvalue λ of the n n matrix `A`, a basis for the kernel of (λI_n - A), the eigenspace of `A` with respect to the eigenvalue λ, is computed using the Gauss-Jordan algorithm (see linalg::gaussJordan). Here, I_n denotes the n n identity matrix.

The eigenvectors are of the domain Dom::Matrix(`R`), where `R` is the component ring of `A`.

The component ring of the matrix `A` must be a field, i.e., a domain of category Cat::Field, for which the solver solve is able to compute the zeros of a polynomial.

It can happen that a basis for the eigenspace of `A` with respect to a certain eigenvalue cannot be computed (e.g., if the component ring does not have a canonical representation of the zero element). In this case `linalg::eigenvectors` answers with a warning message and returns `FAIL`.

Examples

Example 1

We compute the eigenvalues and the eigenvectors of the matrix

A=matrix([[1, -3, 3], [6, -10, 6], [6, 6, 4]])

$$A = \begin{pmatrix} 1 & -3 & 3 \\ 6 & -10 & 6 \\ 6 & 6 & 4 \end{pmatrix}$$

A := Dom::Matrix(Dom::Rational)([[1, -3, 3], [6, -10, 6], [6, 6, 4]]): Ev:= linalg::eigenvectors(A)[[-11, 1, [Dom::Matrix(Dom::Rational)([[-7/10], [-9/5], [1]])]], [-2, 1, [Dom::Matrix(Dom::Rational)([[-1], [0], [1]])]], [8, 1, [Dom::Matrix(Dom::Rational)([[1/4], [5/12], [1]])]]

$$\left[\left[-11,\ 1,\ \left[\begin{pmatrix} -\frac{7}{10} \\ -\frac{9}{5} \\ 1 \end{pmatrix}\right]\right],\ \left[-2,\ 1,\ \left[\begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix}\right]\right],\ \left[8,\ 1,\ \left[\begin{pmatrix} \frac{1}{4} \\ \frac{5}{12} \\ 1 \end{pmatrix}\right]\right]\right]$$

The matrix A is diagonalizable. Hence, we extract the eigenvectors and combine them to a matrix P such that P^-1 * A * P is the diagonal matrix whose diagonal entries are given by the corresponding eigenvalues:

Eigenvectors:= Ev[1][3][1], Ev[2][3][1], Ev[3][3][1]Dom::Matrix(Dom::Rational)([[-7/10], [-9/5], [1]]), Dom::Matrix(Dom::Rational)([[-1], [0], [1]]), Dom::Matrix(Dom::Rational)([[1/4], [5/12], [1]])

$$\begin{pmatrix} -\frac{7}{10} \\ -\frac{9}{5} \\ 1 \end{pmatrix},\ \begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix},\ \begin{pmatrix} \frac{1}{4} \\ \frac{5}{12} \\ 1 \end{pmatrix}$$

P:= Eigenvectors[1].Eigenvectors[2].Eigenvectors[3]Dom::Matrix(Dom::Rational)([[-7/10, -1, 1/4], [-9/5, 0, 5/12], [1, 1, 1]])

$$\begin{pmatrix} -\frac{7}{10} & -1 & \frac{1}{4} \\ -\frac{9}{5} & 0 & \frac{5}{12} \\ 1 & 1 & 1 \end{pmatrix}$$

P^-1 * A * PDom::Matrix(Dom::Rational)([[-11, 0, 0], [0, -2, 0], [0, 0, 8]])

$$\begin{pmatrix} -11 & 0 & 0 \\ 0 & -2 & 0 \\ 0 & 0 & 8 \end{pmatrix}$$

A more skillful way of extracting the above eigenvectors from the output generated by `linalg::eigenvectors` is the following:
map(Ev, op@op, 3)[Dom::Matrix(Dom::Rational)([[-7/10], [-9/5], [1]]), Dom::Matrix(Dom::Rational)([[-1], [0], [1]]), Dom::Matrix(Dom::Rational)([[1/4], [5/12], [1]])]

$$\left[\begin{pmatrix} -\frac{7}{10} \\ -\frac{9}{5} \\ 1 \end{pmatrix}, \begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix}, \begin{pmatrix} \frac{1}{4} \\ \frac{5}{12} \\ 1 \end{pmatrix}\right]$$

If we consider the matrix `A` over the domain `Dom::Float`, the call of `linalg::eigenvectors(A)` results in a numerical computation of the eigenvalues and the eigenvectors of `A` via the function `numeric::eigenvectors`:
B := Dom::Matrix(Dom::Float)(A): linalg::eigenvectors(B)[[8.0, 1, [Dom::Matrix(Dom::Float)([[0.2248595067], [0.3747658445], [0.8994380268]])]], [-2.0, 1, [Dom::Matrix(Dom::Float)([[0.7071067812], [0], [-0.7071067812]])]], [-11.0, 1, [Dom::Matrix(Dom::Float)([[0.3218603429], [0.8276408818], [-0.4598004899]])]]]

$$\left[\left[8.0,\ 1,\ \left[\begin{pmatrix} 0.2248595067 \\ 0.3747658445 \\ 0.8994380268 \end{pmatrix}\right]\right],\ \left[-2.0,\ 1,\ \left[\begin{pmatrix} 0.7071067812 \\ 0.0 \\ -0.7071067812 \end{pmatrix}\right]\right],\ \left[-11.0,\ 1,\ \left[\begin{pmatrix} 0.3218603429 \\ 0.8276408818 \\ -0.4598004899 \end{pmatrix}\right]\right]\right]$$

Parameters

A

A square matrix of a domain of category Cat::Matrix

Return Values

List of sublists, where each sublist consists of an eigenvalue λ of `A`, its algebraic multiplicity and a basis for the eigenspace of λ. If a basis of an eigenspace cannot be computed, `FAIL` is returned.

See Also numeric::eigenvectorslinalg::eigenvalueslinalg::nullspace

Related Examples

- "Compute Eigenvalues and Eigenvectors Numerically"

linalg::expr2Matrix

Purpose

Construct a matrix from equations

Syntax

```
linalg::expr2Matrix(eqns, <vars, R>, <Include>)
```

Description

`linalg::expr2Matrix(eqns, vars)` constructs the extended coefficient matrix fenced(A, 'b→')$(A, \vec{b})$ of the system of m linear equations in `eqns` with respect to the n indeterminates in `vars`. The vector 'b→'$\vec{b}$ is the right-hand side of this system.

`linalg::expr2Matrix` returns the extended coefficient matrix M=fenced(A, 'b→')$M = (A, \vec{b})$. The right-hand side vector 'b→'$\vec{b}$ can be extracted from the matrix M by linalg::col`(M, n + 1)`.

The coefficient matrix A can be extracted by linalg::delCol`(M, n + 1)`.

Arithmetical expressions in `eqns` are considered as equations with right hand-sides zero.

If no variables are given, then the indeterminates of the equations are determined with the function indets and the option `PolyExpr`, i.e., the left-hand sides of the equations are considered as polynomial expressions.

If no component ring `R` is given then the standard domain Dom::ExpressionField`()` is chosen as the component ring of the extended coefficient matrix.

The coefficients of the linear equations are converted into elements of the component ring `R`. An error message is returned if this is not possible.

Examples

Example 1

The extended coefficient matrix of the system $x + y + z = 1$, $2y - z + 5 = 0$ of linear equations in the variables x, y, z is the following 2 4 matrix: delete x, y, z: Ab := linalg::expr2Matrix([x + y + z = 1, 2*y - z + 5], [x, y, z], Dom::Real)Dom::Matrix(Dom::Real)([[1, 1, 1, 1], [0, 2, -1, -5]])

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ 0 & 2 & -1 & -5 \end{pmatrix}$$

We use linalg::matlinsolve to compute the general solution of this system:
linalg::matlinsolve(Ab)[Dom::Matrix(Dom::Real)([[7/2], [-5/2], [0]]), [Dom::Matrix(Dom::Real)([[-3/2], [1/2], [1]])]]

$$\left[\begin{pmatrix} \frac{7}{2} \\ -\frac{5}{2} \\ 0 \end{pmatrix}, \left[\begin{pmatrix} -\frac{3}{2} \\ \frac{1}{2} \\ 1 \end{pmatrix}\right]\right]$$

The coefficient matrix or the right-hand side vector can be be extracted from the matrix `Ab` in the following way:
A := linalg::delCol(Ab, 4); b := linalg::col(Ab, 4)Dom::Matrix(Dom::Real)([[1, 1, 1], [0, 2, -1]])

$$\begin{pmatrix} 1 & 1 & 1 \\ 0 & 2 & -1 \end{pmatrix}$$

Dom::Matrix(Dom::Real)([[1], [-5]])

$$\begin{pmatrix} 1 \\ -5 \end{pmatrix}$$

Example 2

The following two inputs lead to different linear systems:
delete x, y, z: linalg::expr2Matrix([x + y + z = 1, 2*y - z + 5 = x]), linalg::expr2Matrix([x + y + z = 1, 2*y - z + 5 = x], [x, y])matrix([[1, 1, 1, 1], [-1, 2, -1, -5]]), matrix([[1, 1, 1 - z], [-1, 2, z - 5]])

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ -1 & 2 & -1 & -5 \end{pmatrix}, \begin{pmatrix} 1 & 1 & 1-z \\ -1 & 2 & z-5 \end{pmatrix}$$

Example 3

Note the difference between calling `linalg::expr2Matrix` with and without option `Include`:
delete x, y: linalg::expr2Matrix([x + y = 1, 2*x - y = 3], [x, y])matrix([[1, 1, 1], [2, -1, 3]])

$$\begin{pmatrix} 1 & 1 & 1 \\ 2 & -1 & 3 \end{pmatrix}$$

linalg::expr2Matrix([x + y = 1, 2*x - y = 3], [x, y], Include)matrix([[1, 1, -1], [2, -1, -3]])

$$\begin{pmatrix} 1 & 1 & -1 \\ 2 & -1 & -3 \end{pmatrix}$$

Parameters

eqns

The system of linear equations, i.e. a set or list of expressions of type `"_equal"`

vars

A set or list of indeterminates

R

A commutative ring, i.e., a domain of category Cat::CommutativeRing

Options

Include

Appends the negative of the right-hand side vector ‘b→’ $\vec{b}$ to the coefficient matrix A of the given system of linear equations. The result is the m (n + 1) matrix fenced(A, -‘b→’) $(A, -\vec{b})$.

Return Values

m (n + 1) matrix of the domain Dom::Matrix(`R`).

See Also linalg::matlinsolvelinsolveindets

linalg::factorCholesky

Purpose

The Cholesky decomposition of a matrix

Syntax

```
linalg::factorCholesky(A, <NoCheck>)
```

Description

`linalg::factorCholesky(A)` computes the Cholesky decomposition of a symmetric and positive definite matrix A and returns a lower triangular matrix R such that $RR^t = A$.

The Option `NoCheck` suppresses such errors (see “Example 2” on page 14-58).

The component ring of `A` must be a field, i.e., a domain of category Cat::Field.

`linalg::factorCholesky` returns `FAIL` if it fails to compute the matrix R over the component ring of `A` (the algorithm requires the computation of square roots of some elements in R).

Environment Interactions

Properties of identifiers are taken into account.

Examples

Example 1

We compute the Cholesky decomposition of the following matrix:
S := Dom::Matrix(Dom::Rational)([[4, -2, 4, 2], [-2, 10, -2, -7], [4, -2, 8, 4], [2, -7, 4, 7]])Dom::Matrix(Dom::Rational)([[4, -2, 4, 2], [-2, 10, -2, -7], [4, -2, 8, 4], [2, -7, 4, 7]])

$$\begin{pmatrix} 4 & -2 & 4 & 2 \\ -2 & 10 & -2 & -7 \\ 4 & -2 & 8 & 4 \\ 2 & -7 & 4 & 7 \end{pmatrix}$$

R := linalg::factorCholesky(S)Dom::Matrix(Dom::Rational)([[2, 0, 0, 0], [-1, 3, 0, 0], [2, 0, 2, 0], [1, -2, 1, 1]])

$$\begin{pmatrix} 2 & 0 & 0 & 0 \\ -1 & 3 & 0 & 0 \\ 2 & 0 & 2 & 0 \\ 1 & -2 & 1 & 1 \end{pmatrix}$$

and check the result:
R * linalg::transpose(R) = SDom::Matrix(Dom::Rational)([[4, -2, 4, 2], [-2, 10, -2, -7], [4, -2, 8, 4], [2, -7, 4, 7]]) = Dom::Matrix(Dom::Rational)([[4, -2, 4, 2], [-2, 10, -2, -7], [4, -2, 8, 4], [2, -7, 4, 7]])

$$\begin{pmatrix} 4 & -2 & 4 & 2 \\ -2 & 10 & -2 & -7 \\ 4 & -2 & 8 & 4 \\ 2 & -7 & 4 & 7 \end{pmatrix} = \begin{pmatrix} 4 & -2 & 4 & 2 \\ -2 & 10 & -2 & -7 \\ 4 & -2 & 8 & 4 \\ 2 & -7 & 4 & 7 \end{pmatrix}$$

Example 2

The option `NoCheck` can be helpful for matrices with symbolic components. For example, if we define the following matrix:
delete a, b: H := matrix([[a, b], [b, a]])matrix([[a, b], [b, a]])

$$\begin{pmatrix} a & b \\ b & a \end{pmatrix}$$

and have in mind that `a` and `b` are real, then `linalg::factorCholesky` is not able to check `H` to be positive definite:
linalg::factorCholesky(H) Error: Cannot check whether the matrix component is positive. [linalg::factorCholesky]

With the option `NoCheck` such errors are suppressed and `linalg::factorCholesky` continues the computation:
linalg::factorCholesky(H, NoCheck)matrix([[sqrt(a), 0], [b/sqrt(a), sqrt(a - b^2/a)]])

$$\begin{pmatrix} \sqrt{a} & 0 \\ \frac{b}{\sqrt{a}} & \sqrt{a - \frac{b^2}{a}} \end{pmatrix}$$

Of course, this result is only valid if $a > 0$ and $|b| < a$.

Parameters

A

A square matrix of a domain of category Cat::Matrix

Options

NoCheck

It is not checked whether A is symmetric and positive definite.

Return Values

Matrix of the same domain type as A, or the value FAIL.

Algorithms

The Cholesky decomposition of a positive definite n n matrix A is a decomposition of A in a product $RR^t = A$. such that R is lower triangular and has positive (real) entries on the main diagonal. R is called the "Cholesky factor" of A.

If $R = (r_{i,j})_{1 \le i \le n,\ 1 \le j \le n}$ is the Cholesky factor of A, then det(A)=fenced(product(r[(ii)], i=1..n))^2 $\det A = (\prod_{i=1}^{n} r_{ii})^2$.

linalg::factorLU

Purpose

LU-decomposition of a matrix

Syntax

```
linalg::factorLU(A)
```

Description

`linalg::factorLU(A)` computes an LU-decomposition of an m n matrix A, i.e., a decomposition of the A into an m m lower triangular matrix L and an m n upper triangular matrix U such that $PA = LU$, where P is a permutation matrix.

The diagonal entries of the lower triangular matrix L are equal to one (*Doolittle*-decomposition). The diagonal entries of U are the pivot elements used during the computation.

The matrices L and U are unique.

`pivindex` is a list `[ r1, r2, ...]` representing the row exchanges of A in the pivoting steps, i.e., $B = PA = LU$, where $b_{ij} = a_{r_i, j}$.

A floating-point approximation of the decomposition is computed using numeric::factorLU, if the matrix `A` is defined over the component ring Dom::Float. In this case it is recommended to call `numeric::factorLU` directly for a better efficiency.

The algorithm also works for singular A. In this case either L or U is singular.

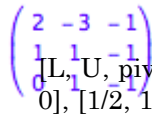
L and U are nonsingular if and only if A is nonsingular.

The component ring of the matrix `A` must be a field, i.e., a domain of category Cat::Field.

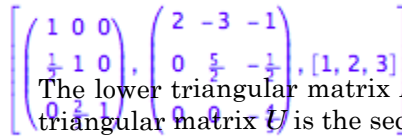
Examples

Example 1

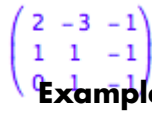
We compute an LU-decomposition of the real matrix:
A := Dom::Matrix(Dom::Real)([[2, -3, -1], [1, 1, -1], [0, 1, -1]]
)Dom::Matrix(Dom::Real)([[2, -3, -1], [1, 1, -1], [0, 1, -1]])



[L, U, pivlist] := linalg::factorLU(A)[Dom::Matrix(Dom::Real)([[1, 0, 0], [1/2, 1, 0], [0, 2/5, 1]]), Dom::Matrix(Dom::Real)([[2, -3, -1], [0, 5/2, -1/2], [0, 0, -4/5]]), [1, 2, 3]]

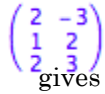


The lower triangular matrix L is the first element und the upper triangular matrix U is the second element of the list `LU`. The product of these two matrices is equal to the input matrix `A`:
L * UDom::Matrix(Dom::Real)([[2, -3, -1], [1, 1, -1], [0, 1, -1]])



Example 2

An LU-decomposition of the 3 2 matrix:
A := Dom::Matrix(Dom::Real)([[2, -3], [1, 2], [2, 3]])Dom::Matrix(Dom::Real)([[2, -3], [1, 2], [2, 3]])



gives a 3 3 lower triangular matrix and a 3 2 upper triangular matrix:
[L, U, pivlist] := linalg::factorLU(A)[Dom::Matrix(Dom::Real)([[1, 0, 0], [1/2, 1, 0], [1, 12/7, 1]]), Dom::Matrix(Dom::Real)([[2, -3], [0, 7/2], [0, 0]]), [1, 2, 3]]

$$\begin{bmatrix} \begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ 1 & \frac{12}{7} & 1 \end{pmatrix}, \begin{pmatrix} 2 & -3 \\ 0 & \frac{7}{2} \\ 0 & 0 \end{pmatrix}, [1, 2, 3] \end{bmatrix}$$

L * UDom::Matrix(Dom::Real)([[2, -3], [1, 2], [2, 3]])

$$\begin{pmatrix} 2 & -3 \\ 1 & 2 \\ 2 & 3 \end{pmatrix}$$

Example 3

To compute the LU-decomposition of the matrix:
A := matrix([[1, 2, -1], [0, 0, 3], [0, 2, -1]])matrix([[1, 2, -1], [0, 0, 3], [0, 2, -1]])

$$\begin{pmatrix} 1 & 2 & -1 \\ 0 & 0 & 3 \\ 0 & 2 & -1 \end{pmatrix}$$

one row interchange is needed, and we therefore get a non-trivial permutation list:
[L, U, pivlist] := linalg::factorLU(A)[matrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]]), matrix([[1, 2, -1], [0, 2, -1], [0, 0, 3]]), [1, 3, 2]]

$$\begin{bmatrix} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 2 & -1 \\ 0 & 2 & -1 \\ 0 & 0 & 3 \end{pmatrix}, [1, 3, 2] \end{bmatrix}$$

The corresponding permutation matrix is the following:
P := linalg::swapRow(matrix::identity(3), 3, 2)matrix([[1, 0, 0], [0, 0, 1], [0, 1, 0]])

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}$$

Hence, we have a decomposition of A into the product of the three matrices P^(-1), L and U as follows:
P^(-1) * L * Umatrix([[1, 2, -1], [0, 0, 3], [0, 2, -1]])

$$\begin{pmatrix} 1 & 2 & -1 \\ 0 & 0 & 3 \\ 0 & 2 & -1 \end{pmatrix}$$

Example 4

You may compute an LU-decomposition of a matrix with symbolic components, such as:
delete a, b, c, d: A := matrix([[a, b], [c, d]])matrix([[a, b], [c, d]])

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

The diagonal entries of the matrix U are the pivot elements used during the computation. They must be non-zero, if the inverse of U is needed:
[L, U, pivlist] := linalg::factorLU(A)[matrix([[1, 0], [c/a, 1]]), matrix([[a, b], [0, d - (b*c)/a]]), [1, 2]]

$$\left[\begin{pmatrix} 1 & 0 \\ \frac{c}{a} & 1 \end{pmatrix}, \begin{pmatrix} a & b \\ 0 & d - \frac{b\,c}{a} \end{pmatrix}, [1, 2]\right]$$

For example, if we use this decomposition to solve the linear system A * ‘x→‘=‘b→‘$A\,\vec{x} = \vec{b}$ for arbitrary vectors ‘b→‘=fenced(b[1], b[2])^t$\vec{b} = (b_1, b_2)^t$, then the following result is only correct for $a \neq 0$ and d-(b * c)/(a)<>0$d - \frac{b\,c}{a} \neq 0$:
delete b1, b2: linalg::matlinsolveLU(L, U, matrix([b1, b2]))matrix([[(b1 - (b*(a*b2 - b1*c))/(a*d - b*c))/a], [(a*b2 - b1*c)/(a*d - b*c)]])

$$\begin{pmatrix} \frac{b1 - \frac{b\,(a\,b2 - b1\,c)}{a\,d - b\,c}}{a} \\ \frac{a\,b2 - b1\,c}{a\,d - b\,c} \end{pmatrix}$$

Parameters

A

A matrix of a domain of category Cat::Matrix

Return Values

List `[L, U, pivindex]` with the two matrices L and U of the domain Dom::Matrix(`R`) and a list `pivindex` of positive integers. `R` is the component ring of `A`.

Algorithms

The following algorithm for solving the system A * ‘x→‘=‘b→‘$A\vec{x} = \vec{b}$ with a nonsingular matrix A uses LU-decomposition:

1. Compute a LU-decomposition of A: $A = LU$.
2. Solve ‘y→‘=L^(-1) * ‘b→‘$\vec{y} = \frac{\vec{b}}{L}$ by forward substitution.
3. Solve ‘x→‘=R^(-1) * ‘y→‘$\vec{x} = \frac{\vec{y}}{R}$ by backward substitution.

The LU-decomposition of a matrix A is useful for solving several systems of linear equations A * ‘x→‘=‘b→‘$A\vec{x} = \vec{b}$ with the same coefficient matrix A and several right-hand side vectors ‘b→‘$\vec{b}$, because then step one of the algorithm above needs to be done only once.

linalg::factorQR

Purpose

QR-decomposition of a matrix

Syntax

```
linalg::factorQR(A)
```

Description

`linalg::factorQR(A)` computes an QR-decomposition of an m n matrix A, i.e., a decomposition of A into an m m unitary matrix Q and an m n upper triangular matrix R such that $QR = A$.

`linalg::factorQR` uses Gram-Schmidt orthonormalization to compute the decomposition.

For a singular or non-square matrix `A` the QR-decomposition of `A` is not unique.

The columns of Q form an orthonormal basis with respect to the scalar product of two vectors, defined by linalg::scalarProduct, and the 2-norm of two vectors (see the method `"norm"` of the domain constructor Dom::Matrix).

If the component ring of `A` does not define the method `"conjugate"`, then the factor Q is orthogonal instead of unitary.

If the columns of `A` cannot be orthonormalized then `FAIL` is returned.

If `A` is a matrix over the domain Dom::Float and the computations are based on the standard scalar product, then the use of the corresponding function from the numeric library (numeric::factorQR) is recommended.

Even if `A` is defined over the real or the complex numbers the call of numeric::factorQR with the option `Symbolic` is recommended for better efficiency.

The component ring of the matrix `A` must be a field, i.e., a domain of category Cat::Field.

Examples

Example 1

We compute the QR-decomposition of a real matrix:

```
A := Dom::Matrix(Dom::Real)( [[2, -3, -1], [1, 1, -1], [0, 1, -1]]
)Dom::Matrix(Dom::Real)([[2, -3, -1], [1, 1, -1], [0, 1, -1]])
```

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

QR := linalg::factorQR(A)[Dom::Matrix(Dom::Real)([[(2*sqrt(5))/5, -sqrt(6)/6, -(sqrt(2)*sqrt(15))/30], [sqrt(5)/5, sqrt(6)/3, (sqrt(2)*sqrt(15))/15], [0, sqrt(6)/6, -(sqrt(2)*sqrt(15))/6]]), Dom::Matrix(Dom::Real)([[sqrt(5), -sqrt(5), -(3*sqrt(5))/5], [0, sqrt(6), -sqrt(6)/3], [0, 0, (2*sqrt(2)*sqrt(15))/15]])]

$$\left[\begin{pmatrix} \frac{2\sqrt{5}}{5} & -\frac{\sqrt{6}}{6} & -\frac{\sqrt{2}\sqrt{15}}{30} \\ \frac{\sqrt{5}}{5} & \frac{\sqrt{6}}{3} & \frac{\sqrt{2}\sqrt{15}}{15} \\ 0 & \frac{\sqrt{6}}{6} & -\frac{\sqrt{2}\sqrt{15}}{6} \end{pmatrix}, \begin{pmatrix} \sqrt{5} & -\sqrt{5} & -\frac{3\sqrt{5}}{5} \\ 0 & \sqrt{6} & -\frac{\sqrt{6}}{3} \\ 0 & 0 & \frac{2\sqrt{2}\sqrt{15}}{15} \end{pmatrix}\right]$$

The orthogonal matrix Q is the first element und the upper triangular matrix R is the second element of the list `QR`. The product of these two matrices is equal to the input matrix `A`:

QR[1] * QR[2]Dom::Matrix(Dom::Real)([[2, -3, -1], [1, 1, -1], [0, 1, -1]])

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

Example 2

The QR-decomposition of the 3 2 matrix:

B := Dom::Matrix(Dom::Real)([[2, -3], [1, 2], [2, 3]])Dom::Matrix(Dom::Real)([[2, -3], [1, 2], [2, 3]])

$$\begin{pmatrix} 2 & -3 \\ 1 & 2 \\ 2 & 3 \end{pmatrix}$$

yields a 3 3 orthogonal matrix and a 3 2 upper triangular matrix:

QR := linalg::factorQR(B)[Dom::Matrix(Dom::Real)([[2/3, -(31*sqrt(194))/582, sqrt(194)/194], [1/3, (8*sqrt(194))/291,

(6*sqrt(194))/97], [2/3, (23*sqrt(194))/582, -(7*sqrt(194))/194]]), Dom::Matrix(Dom::Real)([[3, 2/3], [0, sqrt(194)/3], [0, 0]])]

$$\left[\begin{pmatrix} \frac{2}{3} & -\frac{31\sqrt{194}}{582} & \frac{\sqrt{194}}{194} \\ \frac{1}{3} & \frac{8\sqrt{194}}{291} & \frac{6\sqrt{194}}{97} \\ \frac{2}{3} & \frac{23\sqrt{194}}{582} & -\frac{7\sqrt{194}}{194} \end{pmatrix}, \begin{pmatrix} 3 & \frac{2}{3} \\ 0 & \frac{\sqrt{194}}{3} \\ 0 & 0 \end{pmatrix}\right]$$

QR[1] * QR[2] Dom::Matrix(Dom::Real)([[2, -3], [1, 2], [2, 3]])

$$\begin{pmatrix} 2 & -3 \\ 1 & 2 \\ 2 & 3 \end{pmatrix}$$

For this example we may call numeric::factorQR(B, Symbolic) instead, which in general is faster than linalg::factorQR:
QR := numeric::factorQR(B, Symbolic)[matrix([[2/3, -(31*sqrt(194))/582, sqrt(194)/194], [1/3, (8*sqrt(194))/291, (6*sqrt(194))/97], [2/3, (23*sqrt(194))/582, -(7*sqrt(194))/194]]), matrix([[3, 2/3], [0, sqrt(194)/3], [0, 0]])]

Parameters

$$\left[\begin{pmatrix} \frac{2}{3} & -\frac{31\sqrt{194}}{582} & \frac{\sqrt{194}}{194} \\ \frac{1}{3} & \frac{8\sqrt{194}}{291} & \frac{6\sqrt{194}}{97} \\ \mathbf{A} & \frac{23\sqrt{194}}{582} & -\frac{7\sqrt{194}}{194} \end{pmatrix}, \begin{pmatrix} 3 & \frac{2}{3} \\ 0 & \frac{\sqrt{194}}{3} \\ 0 & 0 \end{pmatrix}\right]$$

A matrix of a domain of category Cat::Matrix

Return Values

List [Q, R] of the two matrices Q and R (of the same domain type as A), or the value FAIL.

Algorithms

The QR-decomposition can be used to generate a least square solution to an overdetermined system of linear equations. If A *

‘x→‘=‘b→‘$A\vec{x} = \vec{b}$, then R * ‘x→‘=Q^t * ‘b→‘$R\vec{x} = Q^t\vec{b}$ can be solved via backward substitution.

See Also linalg::factorLUlinalg::factorCholeskylllintnumeric::factorQR

Related Examples

- “Compute QR Factorization”

linalg::frobeniusForm

Purpose

Frobenius form of a matrix

Syntax

```
linalg::frobeniusForm(A, <All>)
```

Description

`linalg::frobeniusForm(A)` returns the Frobenius form of the matrix A, also called the Rational Canonical form of A.

`linalg::frobeniusForm(A, All)` computes the Frobenius form R of `A` and a transformation matrix P such that PRP^{-1}.

The Frobenius form as computed by `linalg::frobeniusForm` is unique (see below).

The component ring of `A` must be a field, i.e., a domain of category Cat::Field.

Examples

Example 1

The Frobenius form of the following matrix over :
A := Dom::Matrix(Dom::Complex)([[1, 2, 3], [4, 5, 6], [7, 8, 9]])Dom::Matrix(Dom::Complex)([[1, 2, 3], [4, 5, 6], [7, 8, 9]])

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

is the matrix:
R := linalg::frobeniusForm(A)Dom::Matrix(Dom::Complex)([[0, 0, 0], [1, 0, 18], [0, 1, 15]])

$$\begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 18 \\ 0 & 1 & 15 \end{pmatrix}$$

The transformation matrix P can be selected from the list `[R, P]`, which is the result of `linalg::frobeniusForm` with option `All`:
P := linalg::frobeniusForm(A, All)[2]Dom::Matrix(Dom::Complex)([[1, 1, 30], [0, 4, 66], [0, 7, 102]])

$$\begin{pmatrix} 1 & 1 & 30 \\ 0 & 4 & 66 \\ 0 & 7 & 102 \end{pmatrix}$$

We check the result:
P * R * P^(-1)Dom::Matrix(Dom::Complex)([[1, 2, 3], [4, 5, 6], [7, 8, 9]])

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

Parameters

A

A square matrix of a domain of category Cat::Matrix

Options

All

Returns the list `[R, P]` with the Frobenius form R of `A` and a transformation matrix P such that $A = PRP^{-1}$.

Return Values

Matrix of the same domain type as `A`, or the list `[R, P]` when the option `All` is given.

Algorithms

The Frobenius form of a square matrix A is the matrix

R= matrix([[R[1], “, “, “, “], [“, Symbol::centerdot, “, “, “], [“, “, Symbol::centerdot, “, “], [“, “, “, Symbol::centerdot, “], [“, “, “, “, R[r]]])

$$R = \begin{pmatrix} R_1 & & \\ & \ddots & \\ & & R_r \end{pmatrix}$$

where R_1, R_i, R_r are known as companion matrices and have the form:

R[i]=matrix([[0, Symbol::cdot, Symbol::cdot, Symbol::cdot, 0, -a[0]], [1, Symbol::cdot, “, “, “, -a[1]], [“, Symbol::cdot, Symbol::cdot, “, “, Symbol::cdot], [“, “, Symbol::cdot, Symbol::cdot, “, Symbol::cdot],

[“, “, “, Symbol::cdot, 0, Symbol::cdot], [“, “, “, “, 1, -a[n[i]-1]]]),
i=1,Symbol::hellip,r

$$R_i = \begin{pmatrix} 0 & \cdots & 0 & -a_0 \\ 1 & \ddots & & -a_1 \\ & \ddots & & \vdots \\ & & 1 & -a_{n_i-1} \end{pmatrix}, \quad i = 1, \ldots, r$$

In the last column of the companion matrix R_i, you see the coefficients of its minimal polynomial in ascending order, i.e., the polynomial $m_i := X^{n_i} + a_{n_i-1}X^{n_i-1} + \ldots + a_1X + a_0$ is the minimal polynomial of the matrix R_i. For these polynomials the following holds: m_{i+1} divides m_i for $i = 1, \ldots, r - 1$, and the product of all m_i for $i = 1, \ldots, r$ gives a factorization of the characteristic polynomial of the matrix A. The Frobenius form defined in this way is unique.

linalg::jordanFormlinalg::hermiteFormlinalg::smithFormlinalg::minpoly

linalg::gaussElim

Purpose

Gaussian elimination

Syntax

```
linalg::gaussElim(A, <All>)
```

Description

`linalg::gaussElim(A)` performs Gaussian elimination on the matrix A to reduce A to a similar matrix in upper row echelon form.

A row echelon form of `A` returned by `linalg::gaussElim` is not unique. See linalg::gaussJordan for computing the *reduced* row echelon form.

The component ring R of `A` must be an integral domain, i.e., a domain of category Cat::IntegralDomain.

If R is a field, i.e., a domain of category Cat::Field, ordinary Gaussian elimination is used. Otherwise, `linalg::gaussElim` applies fraction-free Gaussian elimination to `A`.

`linalg::gaussElim` serves as an interface function for the method `"gaussElim"` of the matrix domain of `A`, i.e., one may call `A::dom::gaussElim(A)` directly instead of `linalg::gaussElim(A, All)`

Refer to the help page of Dom::Matrix for details about the computation strategy of `linalg::gaussElim`.

Examples

Example 1

We apply Gaussian elimination to the following matrix:
A := Dom::Matrix(Dom::Rational)([[1, 2, 3, 4], [-1, 0, 1, 0], [3, 5, 6, 9]])Dom::Matrix(Dom::Rational)([[1, 2, 3, 4], [-1, 0, 1, 0], [3, 5, 6, 9]])

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -1 & 0 & 1 & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

which reduces `A` to the following row echelon form:
linalg::gaussElim(A)Dom::Matrix(Dom::Rational)([[1, 2, 3, 4], [0, 2, 4, 4], [0, 0, -1, -1]])

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 0 & 2 & 4 & 4 \\ 0 & 0 & -1 & -1 \end{pmatrix}$$

Example 2

We apply Gaussian elimination to the matrix:
B := Dom::Matrix(Dom::Integer)([[1, 2, -1], [1, 0, 1], [2, -1, 4]]
)Dom::Matrix(Dom::Integer)([[1, 2, -1], [1, 0, 1], [2, -1, 4]])

$$\begin{pmatrix} 1 & 2 & -1 \\ 1 & 0 & 1 \\ 2 & -1 & 4 \end{pmatrix}$$

and get the following result:
linalg::gaussElim(B, All)[Dom::Matrix(Dom::Integer)([[1, 2, -1], [0, -2,
2], [0, 0, -2]]), 3, -2, {1, 2, 3}]

$$\left[\begin{pmatrix} 1 & 2 & -1 \\ 0 & -2 & 2 \\ 0 & 0 & -2 \end{pmatrix}, 3, -2, \{1, 2, 3\}\right]$$

We see that $rank(B) = 3$ and det(B)=-2 $\det B = -2$.

Parameters

A

A matrix of a domain of category Cat::Matrix

Options

All

Returns a list [T, rank(A), det(A), {j[1], Symbol::hellip, j[r]}] $[T, \mathrm{rank}(A), \det A, \{j_1, \ldots, j_r\}]$ where T is a row echelon form of A and $\{j_1, \ldots, j_r\}$ is the set of characteristic column indices of T.

If A is not square, then the value FAIL is given instead of det(A) $\det A$.

Return Values

a matrix of the same domain type as `A`, or the list `[T, rank(A), det(A), {j_1,dots,j_r}]` when the option `All` is given (see below).

Algorithms

Let $T = (t_{i,j})_{1 \le i \le m,\ 1 \le j \le n}$ be an m n matrix. Then T is a matrix in an upper *row echelon form*, if r $\{0, 1, \ldots, n\}$ and indices $j_1, j_2, \ldots, j_r$ $\{1, \ldots, n\}$ exist with:

1 $j_1 < j_2 < \cdots < j_r$.

2 For each i $\{1, \ldots, r\}$: $t_{i,1} = t_{i,2} = \cdots = t_{i,j_i - 1} = 0$.

3 For each i $\{r + 1, \ldots, m\}$: $t_{i,j} = 0$ for each j $\{1, \ldots, n\}$.

The indices $j_1, j_2, \ldots, j_r$ are the *characteristic column indices* of the matrix T.

See Also

linalg::gaussJordanlllint

linalg::gaussJordan

Purpose

Gauss-Jordan elimination

Syntax

```
linalg::gaussJordan(A, <All>)
```

Description

`linalg::gaussJordan(A)` performs Gauss-Jordan elimination on the matrix A, i.e., it returns the reduced row echelon form of A.

The component ring R of `A` must be an integral domain, i.e., a domain of category Cat::IntegralDomain.

If R is a field, i.e., a domain of category Cat::Field, then the leading entries of the matrix T in reduced row echelon form are equal to one.

If R is a ring providing the method `"gcd"`, then the components of each row of T do not have a non-trivial common divisor.

If the component ring of `A` is a field, then the reduced row echelon form is unique.

Examples

Example 1

We apply Gauss-Jordan elimination to the following matrix:
A := Dom::Matrix(Dom::Rational)([[1, 2, 3, 4], [-5, 0, 3, 0], [3, 5, 6, 9]])Dom::Matrix(Dom::Rational)([[1, 2, 3, 4], [-5, 0, 3, 0], [3, 5, 6, 9]])

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -5 & 0 & 3 & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

linalg::gaussJordan(A, All)[Dom::Matrix(Dom::Rational)([[1, 0, 0, 1/2], [0, 1, 0, 1/2], [0, 0, 1, 5/6]]), 3, FAIL, {1, 2, 3}]

$$\left[\begin{pmatrix} 1 & 0 & 0 & \frac{1}{2} \\ 0 & 1 & 0 & \frac{1}{2} \\ 0 & 0 & 1 & \frac{5}{6} \end{pmatrix}, 3, \text{FAIL}, \{1, 2, 3\}\right]$$

We see that *rank*(*B*) = 3. Because the determinant of a matrix is only defined for square matrices, the third element of the returned list is the value FAIL.

Example 2

If we consider the matrix from "Example 1" on page 14-75 as an integer matrix and apply the Gauss-Jordan elimination we get the following matrix:
B := Dom::Matrix(Dom::Integer)([[1, 2, 3, 4], [-5, 0, 3, 0], [3, 5, 6, 9]]):
linalg::gaussJordan(B)Dom::Matrix(Dom::Integer)([[2, 0, 0, 1], [0, -2, 0, -1], [0, 0, -6, -5]])

$$\begin{pmatrix} 2 & 0 & 0 & 1 \\ 0 & -2 & 0 & -1 \\ 0 & 0 & -6 & -5 \end{pmatrix}$$

Parameters

A

A matrix of a domain of category Cat::Matrix

Options

All

Returns a list [T, rank(A), det(A), {j[1], Symbol::hellip, j[r]}][*T*, rank(*A*), det *A*, {j_1, ..., j_r}] where *T* is the reduced row echelon form of A and {j_1, ..., j_r} is the set of characteristic column indices of T.

If A is not square, then the value FAIL is given instead of det(A)det *A*.

Return Values

a matrix of the same domain type as A, or the list [T, rank(A), det(A), {j_1,dots,j_r}] when the option All is given (see below).

Algorithms

Let $T = (t_{i,j})_{1 \le i \le m,\ 1 \le j \le n}$ be an m n matrix. Then T is a matrix in *reduced row echelon form*, if r {0, 1, ..., n} and indices $j_1, j_2, \ldots, j_r$ {1, ..., n} exist with:

1. $j_1 < j_2 < \cdots < j_r$.
2. For each $i \in \{1, \ldots, r\}$: $t_{i,1} = t_{i,2} = \cdots = t_{i,j_i - 1} = 0$. In addition, if A is defined over a field: $t_{i,j_i} = 1$.
3. For each $i \in \{r + 1, \ldots, m\}$: $t_{i,j} = 0$ for each $j \in \{1, \ldots, n\}$.
4. For each $i \in \{1, \ldots, r\}$: $t_{k,j_i} = 0$ for each $k \in \{1, \ldots, i - 1\}$.

The indices $j_1, j_2, \ldots, j_r$ are the *characteristic column indices* of the matrix T.

linalg::gradient

Purpose

Vector gradient

Syntax

```
linalg::gradient(f, x)
linalg::gradient(f, x, ogCoord, <c>)
```

Description

`linalg::gradient(f, x)` computes the vector gradient of the scalar function f(‘x→’)$f(\vec{x})$ with respect to ‘x→’$\vec{x}$ in Cartesian coordinates. This is the vector grad(f)=fenced(diff(f,x[1]), Symbol::hellip, diff(f,x[n]))$\mathrm{grad}(f) = \left(\frac{\partial}{\partial x_1} f, \ldots, \frac{\partial}{\partial x_n} f\right)$.

`linalg::gradient`, linalg::grad, and gradient are equivalent. See details and examples on the gradient help page.

Parameters

f

An arithmetical expression in the variables given in `x`

x

A list of (indexed) identifiers

ogCoord

The name of a 3 dimensional orthogonal coordinate system predefined in the table linalg::ogCoordTab, or a list of algebraic expressions representing the “scale parameters” of an orthogonal coordinate system.

c

The parameter of the coordinate systems EllipticCylindrical and Torus, respectively: an arithmetical expression. The default value is `c` = 1.

Return Values

Column vector of the domain Dom::Matrix().

linalg::grad

Purpose

Vector gradient

Syntax

```
linalg::grad(f, x)
linalg::grad(f, x, ogCoord, <c>)
```

Description

`linalg::grad(f, x)` computes the vector gradient of the scalar function f(‘x→’)$f(\vec{x})$ with respect to ‘x→’$\vec{x}$ in Cartesian coordinates. This is the vector grad(f)=fenced(diff(f,x[1]), Symbol::hellip, diff(f,x[n]))$\mathrm{grad}(f) = \left(\frac{\partial}{\partial x_1} f, \ldots, \frac{\partial}{\partial x_n} f\right)$.

linalg::gradient and `linalg::grad` are equivalent.

In the case of three dimensions, `linalg::grad(f, x, ogCoord)` computes the gradient of `f` with respect to `x` in the orthogonally curvilinear coordinate system specified by `ogCoord`. The scaling factors of the specified coordinate system must be the value of the index `ogCoord` of the table linalg::ogCoordTab (see “Example 2” on page 14-79).

If `ogCoord` is an identifier then the scaling factors must be defined under the name of the identifier as an entry of the table linalg::ogCoordTab.

Examples

Example 1

We compute the vector gradient of the scalar function $f(x, y) = x^2 + y$ in Cartesian coordinates:

```
delete x, y: linalg::gradient(x^2 + y, [x, y])matrix([[2*x], [1]])
```

$$\begin{pmatrix} 2x \\ 1 \end{pmatrix}$$

Example 2

We compute the gradient of the function $f(r, \varphi, z) = r\cos(\varphi)z$ $(0 \le \varphi \le \pi)$ in cylindrical coordinates:

```
delete r, z, phi:  linalg::gradient(r*cos(phi)*z, [r, phi, z],
Cylindrical)matrix([[z*cos(phi)], [-z*sin(phi)], [r*cos(phi)]])
```

$$\begin{pmatrix} z\cos(\text{phi}) \\ -z\sin(\text{phi}) \\ r\cos(\text{phi}) \end{pmatrix}$$

Example 3

We want to compute the gradient of the function $f(r, \varphi, \theta) = rsin(\varphi)cos(\theta)$ in spherical coordinates given by

‘x→‘ = matrix([x, y, z]) = matrix([r*cos(Symbol::phi)*sin(Symbol::theta), r*sin(Symbol::phi)*sin(Symbol::theta), r*cos(Symbol::theta)])

$$\vec{x} = \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} r\cos(\phi)\sin(\theta) \\ r\sin(\phi)\sin(\theta) \\ r\cos(\theta) \end{pmatrix}$$

with $0 \le \varphi \le 2\pi$, $0 \le \theta \le \pi$.

The vectors

‘e→‘[r]= diff(‘x→‘, r) / abs(diff(‘x→‘, r)) =matrix([[cos(Symbol::phi) * sin(Symbol::theta)], [sin(Symbol::phi) * sin(Symbol::theta)], [cos(Symbol::theta)]]), ‘e→‘[Symbol::phi] =diff(‘x→‘, Symbol::phi) /abs(diff(‘x→‘, Symbol::phi)) =matrix([[-sin(Symbol::phi)], [cos(Symbol::phi)], [0]]), ‘e→‘[Symbol::theta] =diff(‘x→‘, Symbol::theta) /abs(diff(‘x→‘, Symbol::theta)) =matrix([[cos(Symbol::phi) * cos(Symbol::theta)], [sin(Symbol::phi) * cos(Symbol::theta)], [-sin(Symbol::theta)]])

$$\vec{e}_r = \frac{\frac{\partial}{\partial r}\vec{x}}{\left|\frac{\partial}{\partial r}\vec{x}\right|} = \begin{pmatrix} \cos(\phi)\sin(\theta) \\ \sin(\phi)\sin(\theta) \\ \cos(\theta) \end{pmatrix}, \quad \vec{e}_\varphi = \frac{\frac{\partial}{\partial \varphi}\vec{x}}{\left|\frac{\partial}{\partial \varphi}\vec{x}\right|} = \begin{pmatrix} -\sin(\phi) \\ \cos(\phi) \\ 0 \end{pmatrix}, \quad \vec{e}_\theta = \frac{\frac{\partial}{\partial \theta}\vec{x}}{\left|\frac{\partial}{\partial \theta}\vec{x}\right|} = \begin{pmatrix} \cos(\phi)\cos(\theta) \\ \sin(\phi)\cos(\theta) \\ -\sin(\theta) \end{pmatrix}$$

form an orthogonal system in spherical coordinates.

The scaling factors of the corresponding coordinate transformation (see linalg::ogCoordTab) are: g[1]=abs(‘e→‘[r])=1, g[2]=abs(‘e→‘[Symbol::phi])=r * sin(Symbol::theta), g[3]=abs(‘e→‘[Symbol::theta])=r

$g_1 = |\vec{e}_r| = 1,\ g_2 = |\vec{e}_\varphi| = r\sin(\theta),\ g_3 = |\vec{e}_\theta| = r$, which we use in the following example to compute the gradient of the function f in spherical coordinates:

delete r, phi, Theta: linalg::gradient(r*sin(phi)*cos(Theta), [r, phi, Theta], [1, r*sin(Theta), r])matrix([[cos(Theta)*sin(phi)], [(cos(Theta)*cos(phi))/sin(Theta)], [-sin(Theta)*sin(phi)]])

$$\begin{pmatrix} \cos(\Theta)\sin(\varphi) \\ \frac{\cos(\Theta)\cos(\varphi)}{\sin(\Theta)} \\ -\sin(\Theta)\sin(\varphi) \end{pmatrix}$$

Note that the spherical coordinates are already defined in linalg::ogCoordTab, i.e., the last result can also be achieved with the input `linalg::gradient(r*sin(phi)*cos(Theta), [r, phi, Theta], Spherical)`:

linalg::gradient(r*sin(phi)*cos(Theta), [r, phi, Theta], Spherical)matrix([[cos(Theta)*sin(phi)], [(cos(Theta)*cos(phi))/sin(Theta)], [-sin(Theta)*sin(phi)]])

$$\begin{pmatrix} \cos(\Theta)\sin(\varphi) \\ \frac{\cos(\Theta)\cos(\varphi)}{\sin(\Theta)} \\ -\sin(\Theta)\sin(\varphi) \end{pmatrix}$$

Parameters

f

An arithmetical expression in the variables given in `x`

x

A list of (indexed) identifiers

ogCoord

The name of a 3 dimensional orthogonal coordinate system predefined in the table linalg::ogCoordTab, or a list of algebraic expressions representing the “scale parameters” of an orthogonal coordinate system.

c

The parameter of the coordinate systems EllipticCylindrical and Torus, respectively: an arithmetical expression. The default value is `c = 1`.

Return Values

Column vector of the domain Dom::Matrix().

linalg::gradientlinalg::curllinalg::divergencelinalg::laplacianlinalg::ogCoordTablinalg::potentia

linalg::hermiteForm

Purpose

Hermite normal form of a matrix

Syntax

```
linalg::hermiteForm(A, <All>)
```

Description

`linalg::hermiteForm(A)` computes the Hermite normal form of a non-singular integer square matrix A. This is an upper-triangular matrix H such that $H_{jj} \geq 0$ and -(1)/(2) * H[(jj)]<H[(ij)]<=(1)/(2) * H[(jj)] $-\frac{H_{jj}}{2} < H_{ij} \leq \frac{H_{jj}}{2}$ for $j > i$. In the case, A is not a square matrix or a singular matrix, the matrix H is simply an upper-triangular matrix.

If the matrix `A` is not of the domain Dom::Matrix(Dom::Integer) then `A` is converted into a matrix of this domain for intermediate computations.

If this conversion fails, then an error message is returned.

`linalg::hermiteForm`(A, `All`) computes a transformation matrix U and a matrix H such that $H = UA$.

Examples

Example 1

We compute the Hermite normal form of the matrix:
A := Dom::Matrix(Dom::Rational)([[9, -36, 30], [-36, 192, -180], [30, -180, 180]])Dom::Matrix(Dom::Rational)([[9, -36, 30], [-36, 192, -180], [30, -180, 180]])

$$\begin{pmatrix} 9 & -36 & 30 \\ -36 & 192 & -180 \\ 30 & -180 & 180 \end{pmatrix}$$

linalg::hermiteForm(A)Dom::Matrix(Dom::Rational)([[3, 0, 30], [0, 12, 0], [0, 0, 60]])

$$\begin{pmatrix} 3 & 0 & 30 \\ 0 & 12 & 0 \\ 0 & 0 & 60 \end{pmatrix}$$

We may also compute the transformation matrix by giving the option `All`:

```
linalg::hermiteForm(A, All)[Dom::Matrix(Dom::Rational)([[3, 0, 30],
[0, 12, 0], [0, 0, 60]]), Dom::Matrix(Dom::Rational)([[13, 9, 7], [6, 4, 3],
[20, 15, 12]])]
```

$$\left[\begin{pmatrix} 3 & 0 & 30 \\ 0 & 12 & 0 \\ 0 & 0 & 60 \end{pmatrix}, \begin{pmatrix} 13 & 9 & 7 \\ 6 & 4 & 3 \\ 20 & 15 & 12 \end{pmatrix}\right]$$

Let us check the result:

```
U := linalg::hermiteForm(A, All)[2]:U *
ADom::Matrix(Dom::Rational)([[3, 0, 30], [0, 12, 0], [0, 0, 60]])
```

$$\begin{pmatrix} 3 & 0 & 30 \\ 0 & 12 & 0 \\ 0 & 0 & 60 \end{pmatrix}$$

Parameters

A

An integer matrix of category Cat::Matrix

Options

All

Returns the list `[H, U]` with the hermite normal form H of `A` and the corresponding transformation matrix U

Return Values

Either a matrix of the same domain type as `A` or the list `[H, U]` when the option `All` is given.

Algorithms

Let A be an n n matrix with coefficients in . Then there exists an n n matrix $H = (h_{ij})$ in Hermite normal form such that $H = AU$ with abs(U)=_outputSequence(Symbol::plusmn,1)$|U| = \pm 1$.

Note that H is unique, if A has full row rank. The matrix U is not unique. U may be computed by using the option `All`.

If A is a square matrix, then the product of the diagonal elements of its Hermite normal form is, up to the sign, the determinant of A.

See Also linalg::frobeniusFormlinalg::jordanFormlinalg::smithFormlllint

linalg::hessenberg

Purpose

Hessenberg matrix

Syntax

```
linalg::hessenberg(A, <All>)
```

Description

`linalg::hessenberg(A)` returns an (upper) Hessenberg matrix *H*.

`linalg::hessenberg` uses Gaussian elimination without pivoting. There is no special implementation for matrices with floating-point components.

The component ring of `A` must be a field, i.e., a domain of category Cat::Field.

Examples

Example 1

Consider the matrix:
A := Dom::Matrix(Dom::Rational)([[0, 1, 0, -1], [-4/3, 2/3, 5/3, -1/3], [-1, 2, 0, 0], [-5/3, 4/3, 1/3, 1/3]])Dom::Matrix(Dom::Rational)([[0, 1, 0, -1], [-4/3, 2/3, 5/3, -1/3], [-1, 2, 0, 0], [-5/3, 4/3, 1/3, 1/3]])

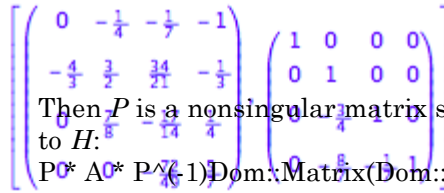
$$\begin{pmatrix} 0 & 1 & 0 & -1 \\ -\frac{4}{3} & \frac{2}{3} & \frac{5}{3} & -\frac{1}{3} \\ -1 & 2 & 0 & 0 \\ -\frac{5}{3} & \frac{4}{3} & \frac{1}{3} & \frac{1}{3} \end{pmatrix}$$

The following Hessenberg matrix is similar to *A*:
H := linalg::hessenberg(A)Dom::Matrix(Dom::Rational)([[0, -1/4, -1/7, -1], [-4/3, 3/2, 34/21, -1/3], [0, 7/8, -17/14, 1/4], [0, 0, -72/49, 5/7]])

$$\begin{pmatrix} 0 & -\frac{1}{4} & -\frac{1}{7} & -1 \\ -\frac{4}{3} & \frac{3}{2} & \frac{34}{21} & -\frac{1}{3} \\ 0 & \frac{7}{8} & -\frac{17}{14} & \frac{1}{4} \\ 0 & 0 & -\frac{72}{49} & \frac{5}{7} \end{pmatrix}$$

If the corresponding transformation matrix is needed as well, call `linalg::hessenberg` with option `All`:

```
[H, P] := linalg::hessenberg(A, All)[Dom::Matrix(Dom::Rational)([[0, -1/4, -1/7, -1], [-4/3, 3/2, 34/21, -1/3], [0, 7/8, -17/14, 1/4], [0, 0, -72/49, 5/7]]), Dom::Matrix(Dom::Rational)([[1, 0, 0, 0], [0, 1, 0, 0], [0, -3/4, 1, 0], [0, -8/7, -1/7, 1]])]
```

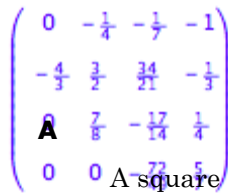


Then P is a nonsingular matrix such that the product PAP^{-1} is equal to H:

```
P* A* P^(-1)Dom::Matrix(Dom::Rational)([[0, -1/4, -1/7, -1], [-4/3, 3/2, 34/21, -1/3], [0, 7/8, -17/14, 1/4], [0, 0, -72/49, 5/7]])
```

Parameters

A



A square matrix of a domain of category Cat::Matrix

Options

All

Returns the list `[H, P]` with a Hessenberg matrix H similar to `A` and the corresponding nonsingular transformation matrix P such that $H = PAP^{-1}$.

Return Values

Matrix of the same domain type as `A`, or the list `[H, P]` when the option `All` is given.

Algorithms

An n n matrix $A = (a_{i,j})_{1 \le i \le n,\ 1 \le j \le n}$ is called an (upper) *Hessenberg matrix*, if the following holds: $a_{i,j} = 0$ for all i, j $\{1, \ldots, n\}$ with $i > j$.

For each square matrix A over a field there exists a Hessenberg matrix similar to A. In general, the upper Hessenberg matrix is not unique.

linalg::charpoly

linalg::hessian

Purpose

Hessian matrix of a scalar function

Syntax

```
linalg::hessian(f, x)
```

Description

`linalg::hessian(f, x)` computes the Hesse matrix (the Hessian) of the scalar function f(‘x→‘)$f(\vec{x})$ in Cartesian coordinates, i.e., the square matrix of second partial derivatives of f(‘x→‘)$f(\vec{x})$.

Examples

Example 1

The Hessian of the function $f(x, y, z) = xy + 2xz$ is the following matrix: delete x, y, z: linalg::hessian(x*y + 2*z*x, [x, y, z])matrix([[0, 1, 2], [1, 0, 0], [2, 0, 0]])

$$\begin{pmatrix} 0 & 1 & 2 \\ 1 & 0 & 0 \\ 2 & 0 & 0 \end{pmatrix}$$

Parameters

f

An arithmetical expression (the scalar function)

x

A list of (indexed) identifiers

Return Values

Matrix of the domain Dom::Matrix().

Algorithms

For a function _outputSequence(f, Symbol::colon, X, Symbol::rightarrow,R_)$f:X \to \mathbb{R}$, X a subset of (R_)^p$\mathbb{R}^p$, the p p matrix

H[f](‘x→‘) = matrix([[diff(f, x[1], x[1]), diff(f, x[2], x[1]), Symbol::hellip, diff(f, x[p], x[1])], [diff(f, x[1], x[2]), diff(f, x[2], x[2]), Symbol::hellip, diff(f, x[p], x[2])], [Symbol::cdot, Symbol::cdot, “, Symbol::cdot], [Symbol::cdot, Symbol::cdot, “, Symbol::cdot],

[Symbol::cdot, Symbol::cdot, “, Symbol::cdot], [diff(f, x[1], x[p]), diff(f, x[2], x[p]), Symbol::hellip, diff(f, x[p], x[p])]])

$H_f(\vec{x}) = \begin{pmatrix} \frac{\partial^2}{\partial x_1^2} f & \frac{\partial}{\partial x_1}\frac{\partial}{\partial x_2} f & \dots & \frac{\partial}{\partial x_1}\frac{\partial}{\partial x_p} f \\ \frac{\partial}{\partial x_2}\frac{\partial}{\partial x_1} f & \frac{\partial^2}{\partial x_2^2} f & \dots & \frac{\partial}{\partial x_2}\frac{\partial}{\partial x_p} f \\ \vdots & \vdots & & \vdots \\ \frac{\partial}{\partial x_p}\frac{\partial}{\partial x_1} f & \frac{\partial}{\partial x_p}\frac{\partial}{\partial x_2} f & \dots & \frac{\partial^2}{\partial x_p^2} f \end{pmatrix}$ is called the *Hesse matrix* of f.

See Also

difflinalg::gradient, linalg::jacobian

linalg::hilbert

Purpose

Hilbert matrix

Syntax

```
linalg::hilbert(n, <R>)
```

Description

`linalg::hilbert(n)` returns the n n Hilbert matrix $H = (h_{i,j})_{1 \le i \le m,\ 1 \le j \le n}$ defined by h[i,j]=fenced(i+j-1)^(-1) $h_{i,j} = \frac{1}{(i+j-1)}$.

The entries of Hilbert matrices are rational numbers. Note, however, that the returned matrix is not defined over the component domain Dom::Rational, but over the standard component domain `Dom::ExpressionField()`. Thus, no conversion is necessary when working with other functions that expect or return matrices over that component domain.

Use `linalg::hilbert(n, Dom::Rational)` to define the n n Hilbert matrix over the field of rational numbers.

Examples

Example 1

We construct the 3 3 Hilbert matrix:
H := linalg::hilbert(3)matrix([[1, 1/2, 1/3], [1/2, 1/3, 1/4], [1/3, 1/4, 1/5]])

$$\begin{pmatrix} 1 & \frac{1}{2} & \frac{1}{3} \\ \frac{1}{2} & \frac{1}{3} & \frac{1}{4} \\ \frac{1}{3} & \frac{1}{4} & \frac{1}{5} \end{pmatrix}$$

This is a matrix of the domain `Dom::Matrix()`.

If you prefer a different component ring, the matrix may be converted to the desired domain after construction (see coerce, for example). Alternatively, one can specify the component ring when creating the Hilbert matrix. For example, specification of the domain Dom::Float generates floating-point entries:
H := linalg::hilbert(3, Dom::Float)Dom::Matrix(Dom::Float)([[1.0, 0.5, 0.3333333333], [0.5, 0.3333333333, 0.25], [0.3333333333, 0.25, 0.2]])

$$\begin{pmatrix} 1.0 & 0.5 & 0.3333333333 \\ 0.5 & 0.3333333333 & 0.25 \\ 0.3333333333 & 0.25 & 0.2 \end{pmatrix}$$

domtype(H)Dom::Matrix(Dom::Float)

Dom::Matrix(Dom::Float)

Parameters

n

The dimension of the matrix: a positive integer

R

The component ring: a domain of category Cat::Rng; default: Dom::ExpressionField()

Return Values

n n matrix of the domain Dom::Matrix(R).

Algorithms

Hilbert matrices are symmetric and positive definite.

Hilbert matrices of large dimension are notoriously ill-conditioned challenging any numerical inversion scheme. However, their inverse can also be computed by a closed formula (see linalg::invhilbert).

linalg::invhilbertlinalg::invpascallinalg::invvandermondelinalg::pascallinalg::toeplitzlinalg::to

linalg::htranspose

Purpose

Hermitean transpose of a matrix

Syntax

```
linalg::htranspose(M)
```

Description

`linalg::htranspose(M)` computes the Hermitean transpose of the matrix *M*.

The Hermitean transpose of *M* is computed. The result is an *n m* matrix.

The [i, j]th element of the result is equal to the conjugate of the [j, i]th element of M.

Examples

Example 1

We define a 3 4 matrix:
A := matrix([[1, 2, 3, 4], [-I, 0, 1+I, 0], [3, 5, 6, 9]])matrix([[1, 2, 3, 4], [-I, 0, 1 + I, 0], [3, 5, 6, 9]])

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -i & 0 & 1+i & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

Then the Hermitean transpose of A is the 4 3 matrix:
linalg::htranspose(A)matrix([[1, I, 3], [2, 0, 5], [3, 1 - I, 6], [4, 0, 9]])

$$\begin{pmatrix} 1 & i & 3 \\ 2 & 0 & 5 \\ 3 & 1-i & 6 \\ 4 & 0 & 9 \end{pmatrix}$$

Parameters

M

m n matrix of domain Dom::Matrix

Return Values

n m matrix of domain Dom::Matrix.

Overloaded By

M

Algorithms

Let $A = (a_{i,j})_{1 \le i \le m,\ 1 \le j \le n}$ be an m n matrix. Then the Hermitean transpose of A is the n m matrix:

A^t = matrix([[conjugate(a[1,1]), conjugate(a[1,2]), Symbol::cdot, Symbol::cdot, Symbol::cdot, conjugate(a[m,1])], [conjugate(a[1,2]), conjugate(a[2,2]), Symbol::cdot, Symbol::cdot, Symbol::cdot, conjugate(a[m,2])], [Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot], [Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot], [Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot], [conjugate(a[1,n]), conjugate(a[1,n]), Symbol::cdot, Symbol::cdot, Symbol::cdot, conjugate(a[m,n])]])

$$A^t = \begin{pmatrix} \overline{a_{1,1}} & \overline{a_{1,2}} & \cdots & \overline{a_{m,1}} \\ \overline{a_{1,2}} & \overline{a_{2,2}} & \cdots & \overline{a_{m,2}} \\ \cdot & \cdot & \cdots & \cdot \\ \cdot & \cdot & \cdots & \cdot \\ \overline{a_{1,n}} & \overline{a_{1,n}} & \cdots & \overline{a_{m,n}} \end{pmatrix}$$

conjugate linalg::transpose

linalg::intBasis

Purpose

Basis for the intersection of vector spaces

Syntax

```
linalg::intBasis(S1, S2,  )
```

Description

`linalg::intBasis( S1, S2, ...)` returns a basis for the intersection of the vector spaces spanned by the vectors in S_1, S_2, ...

The domain type of the vectors of the returned set is the domain type of the first parameter S_1.

A basis for the zero-dimensional space is the empty set or empty list, respectively.

The given vectors must be defined over the same component ring which must be a field, i.e., a domain of category Cat::Field.

Examples

Example 1

We define three vectors ‘v→‘[1], ‘v→‘[2], ‘v→‘[3]$\vec{v}_1, \vec{v}_2, \vec{v}_3$ in ^{2}:
MatQ := Dom::Matrix(Dom::Rational): v1 := MatQ([[3, -2]]); v2 := MatQ([[1, 0]]); v3 := MatQ([[5, -3]])Dom::Matrix(Dom::Rational)([[3, -2]])

```
(3 -2)
```

Dom::Matrix(Dom::Rational)([[1, 0]])

```
(1 0)
```

Dom::Matrix(Dom::Rational)([[5, -3]])

```
(5 -3)
```

A basis for the vector space $V_1 \cap V_2 \cap V_3$ with

- V_1 generated by ‘v→‘[1],‘v→‘[2],‘v→‘[3]$\vec{v}_1, \vec{v}_2, \vec{v}_3$
- V_2 generated by ‘v→‘[1],‘v→‘[3]$\vec{v}_1, \vec{v}_3$

- V_3 generated by
  'v→'[1]+'v→'[2],'v→'[2],'v→'[1]+'v→'[3] $\vec{v}_1 + \vec{v}_2,\ \vec{v}_2,\ \vec{v}_1 + \vec{v}_3$

is:
linalg::intBasis([v1, v2, v3], [v1, v3], [v1 + v2, v2, v1 + v3])[Dom::Matrix(Dom::Rational)([[4, -2]]), Dom::Matrix(Dom::Rational)([[1, 0]])]

$$[(4\ \ -2),(1\ \ 0)]$$

Example 2

The intersection of the two vector spaces spanned by the vectors in S_1 and S_2, respectively:
S1 := {matrix([[1, 0, 1, 0]]), matrix([[0, 1, 0, 1]])}; S2 := {matrix([[1, 2, 1, 1]]), matrix([[-1, -2, 1, 0]])}{matrix([[0, 1, 0, 1]]), matrix([[1, 0, 1, 0]])}

$$\{(0\ 1\ 0\ 1),(1\ 0\ 1\ 0)\}$$

{matrix([[-1, -2, 1, 0]]), matrix([[1, 2, 1, 1]])}

$$\{(-1\ \ -2\ 1\ 0),(1\ 2\ 1\ 1)\}$$

is the zero-dimensional space:
linalg::intBasis(S1, S2){}

$$\varnothing$$

Parameters

S_1, S_2, ...

Either sets or lists of n-dimensional vectors (a vector is an n 1 or 1 n matrix of a domain of category Cat::Matrix)

Return Values

Set or a list of vectors, according to the domain type of the parameter S_1.

See Also linalg::basislinalg::sumBasis

linalg::inverseLU

Purpose

Computing the inverse of a matrix using LU-decomposition

Syntax

```
linalg::inverseLU(A)
linalg::inverseLU(L, U, pivindex)
```

Description

`linalg::inverseLU(A)` computes the inverse A^(-1) of the square matrix A using LU-decomposition.

`linalg::inverseLU(L, U, pivindex)` computes the inverse of the matrix $A = P^{-1}LU$ where `L`, `U` and `pivindex` are the result of an LU-deomposition of the (nonsingular) Matrix A, as computed by `linalg::factorLU`.

The matrix `A` must be nonsingular.

`pivindex` is a list `[r[1], r[2], ...]` representing a permutation matrix P such that $B = PA = LU$, where $b_{ij} = a_{r_i, j}$.

It is not checked whether `pivindex` has such a form.

The component ring of the input matrices must be a field, i.e., a domain of category Cat::Field.

Examples

Example 1

We compute the inverse of the matrix:
A := Dom::Matrix(Dom::Real)([[2, -3, -1], [1, 1, -1], [0, 1, -1]]
)Dom::Matrix(Dom::Real)([[2, -3, -1], [1, 1, -1], [0, 1, -1]])

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

using LU-decomposition:
Ai := linalg::inverseLU(A)Dom::Matrix(Dom::Real)([[0, 1, -1], [-1/4, 1/2, -1/4], [-1/4, 1/2, -5/4]])

$$\begin{pmatrix} 0 & 1 & -1 \\ -\frac{1}{4} & \frac{1}{2} & -\frac{1}{4} \\ -\frac{1}{4} & \frac{1}{2} & -\frac{5}{4} \end{pmatrix}$$

We check the result:
A^-1*Ai, Ai * ADom::Matrix(Dom::Real)([[1, 0, 0], [0, 1, 0], [0, 0, 1]]), Dom::Matrix(Dom::Real)([[1, 0, 0], [0, 1, 0], [0, 0, 1]])

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

We can also compute the inverse of A in the usual way:
1/ADom::Matrix(Dom::Real)([[0, 1, -1], [-1/4, 1/2, -1/4], [-1/4, 1/2, -5/4]])

$$\begin{pmatrix} 0 & 1 & -1 \\ -\frac{1}{4} & \frac{1}{2} & -\frac{1}{4} \\ -\frac{1}{4} & \frac{1}{2} & -\frac{5}{4} \end{pmatrix}$$

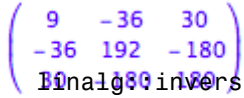
`linalg::inverseLU` should be used for efficiency reasons in the case where an LU decomposition of a matrix already is computed, as the next example illustrates.

Example 2

If we already have an LU decomposition of a (nonsingular) matrix, we can compute the inverse of the matrix $A = P^{-1}LU$ as follows:
LU := linalg::factorLU(linalg::hilbert(3))[matrix([[1, 0, 0], [1/2, 1, 0], [1/3, 1, 1]]), matrix([[1, 1/2, 1/3], [0, 1/12, 1/12], [0, 0, 1/180]]), [1, 2, 3]]

$$\left[\begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ \frac{1}{3} & 1 & 1 \end{pmatrix}, \begin{pmatrix} 1 & \frac{1}{2} & \frac{1}{3} \\ 0 & \frac{1}{12} & \frac{1}{12} \\ 0 & 0 & \frac{1}{180} \end{pmatrix}, [1, 2, 3]\right]$$

linalg::inverseLU(op(LU))matrix([[9, -36, 30], [-36, 192, -180], [30, -180, 180]])



`linalg::inverseLU` then only needs to perform forward and backward substitution to compute the inverse matrix (see also linalg::matlinsolveLU).

Parameters

A

L

U

A square matrix of a domain of category Cat::Matrix

pivindex

A list of positive integers

Return Values

Matrix of the same domain type as `A` or `L`, respectively.

See Also

_invertlinalg::factorLUlinalg::matlinsolveLU

linalg::invhilbert

Purpose

Inverse of a Hilbert matrix

Syntax

```
linalg::invhilbert(n, <R>)
```

Description

`linalg::invhilbert(n)` returns the inverse of the n n Hilbert matrix H. The n n Hilbert matrix $H = (h_{i,j})_{1 \le i \le m,\ 1 \le j \le n}$ is defined by h[i,j]=fenced(i+j-1)^(-1)$h_{i,j} = \frac{1}{(i+j-1)}$.

`linalg::invhilbert` uses an explicit formula for the inverse.

Note that the entries of the inverse of a Hilbert matrix are integers. But the returned matrix is defined over the standard component domain `Dom::ExpressionField()` so that no conversion is necessary when working with other functions that expect or return matrices over that component domain.

`linalg::invhilbert(n,Dom::Integer)` returns the inverse of the n n Hilbert matrix defined over the integers.

Examples

Example 1

We compute the inverse of the 3 3 Hilbert matrix:
A := linalg::invhilbert(3)matrix([[9, -36, 30], [-36, 192, -180], [30, -180, 180]])

$$\begin{pmatrix} 9 & -36 & 30 \\ -36 & 192 & -180 \\ 30 & -180 & 180 \end{pmatrix}$$

This is a matrix of the domain `Dom::Matrix()`.

If you prefer a different component ring, the matrix may be converted into the desired domain afterwards (see coerce, for example). Alternatively, one can specify the component ring when calling `linalg::invhilbert`, for example the domain Dom::Float:
A := linalg::invhilbert(3, Dom::Float)Dom::Matrix(Dom::Float)([[9.0, -36.0, 30.0], [-36.0, 192.0, -180.0], [30.0, -180.0, 180.0]])

$$\begin{pmatrix} 9.0 & -36.0 & 30.0 \\ -36.0 & 192.0 & -180.0 \\ 30.0 & -180.0 & 180.0 \end{pmatrix}$$

domtype(A):Dom::Matrix(Dom::Float)

Dom::Matrix(Dom::Float)

Parameters

n

The dimension of the matrix: a positive integer

R

The component ring: a domain of category Cat::Rng; default: Dom::ExpressionField()

Return Values

n n matrix of the domain Dom::Matrix(R).

Algorithms

Hilbert matrices of large dimension are notoriously ill-conditioned, challenging any numerical inversion scheme.

`linalg::invhilbert` uses the formula

fenced(H^-1)[i,j] = fenced(-1)^(i+j) * (c[i]*c[j])/(i+j-1)

$$\left(\frac{1}{H}\right)_{i,j} = \frac{(-1)^{i+j}(c_i\, c_j)}{i+j-1}$$

where

c[i] = fact(n+i-1)/(fact(n-i) * fenced(fact(i-1))^2)

$$c_i = \frac{(n+i-1)!}{(n-i)!\,((i-1)!)^2}$$

for the inverse of the n n Hilbert matrix H. All entries of H^(-1) are integers.

linalg::hilbertlinalg::invpascallinalg::invvandermondelinalg::pascallinalg::toeplitzlinalg::t

linalg::invpascal

Purpose

Inverse of a Pascal matrix

Syntax

```
linalg::invpascal(n, <R>)
```

Description

`linalg::invpascal(n)` returns the inverse of the n n Pascal matrix.

The entries of inverse Pascal matrices are integer numbers. Note, however, that the returned matrix is not defined over the component domain Dom::Integer, but over the standard component domain `Dom::ExpressionField()`. Thus, no conversion is necessary when working with other functions that expect or return matrices over that component domain.

The runtime to compute the inverse n n Pascal matrix via `linalg::invpascal` is $O(n^2)$. This is much faster than inverting the Pascal matrix by a generic inversion algorithm.

The Pascal matrices are provided by linalg::pascal.

Examples

Example 1

We construct the inverse 3 3 Pascal matrix:
linalg::invpascal(3)matrix([[3, -3, 1], [-3, 5, -2], [1, -2, 1]])

$$\begin{pmatrix} 3 & -3 & 1 \\ -3 & 5 & -2 \\ 1 & -2 & 1 \end{pmatrix}$$

This is a matrix of the domain `Dom::Matrix()`.

If you prefer a different component ring, the matrix may be converted to the desired domain after construction (see coerce, for example). Alternatively, one can specify the component ring when creating the inverse Pascal matrix. For example, specification of the domain Dom::Float generates floating-point entries:
linalg::invpascal(3, Dom::Float)Dom::Matrix(Dom::Float)([[3.0, -3.0, 1.0], [-3.0, 5.0, -2.0], [1.0, -2.0, 1.0]])

$$\begin{pmatrix} 3.0 & -3.0 & 1.0 \\ -3.0 & 5.0 & -2.0 \\ 1.0 & -2.0 & 1.0 \end{pmatrix}$$

domtype(%)Dom::Matrix(Dom::Float)

Dom::Matrix(Dom::Float)

Parameters

n

The dimension of the matrix: a positive integer

R

The component ring: a domain of category Cat::Rng; default: Dom::ExpressionField()

Return Values

n n matrix of the domain Dom::Matrix(R).

Algorithms

Pascal matrices and their inverses are symmetric and positive definite.

The determinant of a Pascal matrix and its inverse is 1.

The inverse of a Pascal matrix has integer entries.

If λ is an eigenvalue of a Pascal matrix/inverse Pascal matrix, then 1/Symbol::lambda$\frac{1}{\lambda}$ is also an eigenvalue of the matrix.

The entries Q_{ij} of the inverse *n n* Pascal matrix Q satisfy the linear relation

Q[i,j] = Q[i,j+1] + Q[i+1,j] + fenced(-1)^(i+j) * binomial(n,i) * binomial(n,j)

$$Q_{i,j} = Q_{i,j+1} + Q_{i+1,j} + (-1)^{i+j} \binom{n}{i} \binom{n}{j}$$

This relation is used by `linalg::invpascal` to compute the matrix.

See Also linalg::hilbertlinalg::invhilbertlinalg::invvandermondelinalg::pascallinalg::toeplitzlinalg::toepl

linalg::isHermitean

Purpose

Checks whether a matrix is Hermitean

Syntax

```
linalg::isHermitean(A)
```

Description

`linalg::isHermitean(A)` determines whether the matrix A is Hermitean, i.e., whether A = conjugate(A)^t$A = \overline{A}^t$, where conjugate(A)$\overline{A}$ denotes the conjugate matrix.

If the component ring of the matrix `A` does not provide the method `"conjugate"`, then `A` is tested for symmetry, i.e., `linalg::isHermitean` returns `TRUE` if and only if `A` satisfies the equation $A = A^t$.

Examples

Example 1

Here is an example of a Hermitean matrix:
A := Dom::Matrix(Dom::Complex)([[1, I], [-I, 1]])Dom::Matrix(Dom::Complex)([[1, I], [-I, 1]])

$$\begin{pmatrix} 1 & i \\ -i & 1 \end{pmatrix}$$

linalg::isHermitean(A)TRUE

TRUE

The following matrix is not Hermitean:
B := Dom::Matrix(Dom::Complex)([[1, -I], [-I, 1]])Dom::Matrix(Dom::Complex)([[1, -I], [-I, 1]])

$$\begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix}$$

linalg::isHermitean(B)FALSE

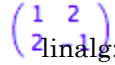
FALSE

The reason is the following:

linalg::transpose(conjugate(B)) <> BDom::Matrix(Dom::Complex)([[1, I], [I, 1]]) <> Dom::Matrix(Dom::Complex)([[1, -I], [-I, 1]])

Example 2

Here is an example of a symmetric matrix over the integers:
C := Dom::Matrix(Dom::Integer)([[1, 2], [2, -1]])Dom::Matrix(Dom::Integer)([[1, 2], [2, -1]])



linalg::isHermitean(C)TRUE

TRUE

Parameters

A

A square matrix of a domain of category Cat::Matrix

Return Values

Either TRUE or FALSE.

See Also

linalg::isPosDef

linalg::isPosDef

Purpose

Test a matrix for positive definiteness

Syntax

```
linalg::isPosDef(A)
```

Description

`linalg::isPosDef(A)` checks whether the matrix *A* is positive definite, so that ‘x→‘^t * A * ‘x→‘>0 $\vec{x}^t A \vec{x} > 0$ for arbitrary vectors ‘x→‘<>‘0→‘ $\vec{x} \neq \vec{0}$.

The component ring of `A` must be a field, i.e., a domain of category Cat::Field.

An error message is returned, if a result of an intermediate computation cannot be checked for being positive (which could happen, for example, if components of `A` are symbolic).

Environment Interactions

Properties of identifiers are taken into account.

Examples

Example 1

Here is an example of a positive definite matrix:
MatR := Dom::Matrix(Dom::Real): A := MatR([[14, 6, 9], [6, 17, -4], [9, -4, 13]])Dom::Matrix(Dom::Real)([[14, 6, 9], [6, 17, -4], [9, -4, 13]])

$$\begin{pmatrix} 14 & 6 & 9 \\ 6 & 17 & -4 \\ 9 & -4 & 13 \end{pmatrix}$$

linalg::isPosDef(A)TRUE

TRUE

The following matrix is not positive definite:
B := MatR([[1, 2, 3], [2, 3, 4], [5, 6, 7]])Dom::Matrix(Dom::Real)([[1, 2, 3], [2, 3, 4], [5, 6, 7]])

$$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 4 \\ 3 & 4 & 5 \end{pmatrix}$$
linalg::isPosDef(B)FALSE

FALSE

Example 2

`linalg::isPosDef` in general does not work for matrices with symbolic entries. It may respond with an error message (because the system in general cannot decide whether a symbolic component is positive), such as for the following matrix:
delete a, b: C := matrix([[a, b], [b, a]])matrix([[a, b], [b, a]])

$$\begin{pmatrix} a & b \\ b & a \end{pmatrix}$$
linalg::isPosDef(C) Error: Cannot check whether the matrix component is positive. [linalg::factorCholesky]

However, properties of identifiers are taken into account, so that, for example, `linalg::isPosDef` is able to perform the test correctly for the following matrix:
assume(a > 1): C := matrix([[a, 1], [1, a]]):linalg::isPosDef(C)TRUE

TRUE

Note that such computations depend on the power of the underlying property mechanism implemented in the `property` library.

Parameters

A

A matrix of a domain of category Cat::Matrix

Return Values

Either `TRUE` or `FALSE`.

See Also linalg::factorCholeskylinalg::isHermitean

linalg::isUnitary

Purpose

Test whether a matrix is unitary

Syntax

```
linalg::isUnitary(A)
```

Description

`linalg::isUnitary` tests whether the matrix A is a unitary matrix. An n n matrix A is unitary, if A * ‘A‾‘^t=‘&I;‘[n]$A\,\overline{A}^t = I_n$, where I_n is the n n identity matrix.

The square matrix `A` is a unitary matrix, if and only if the columns of `A` form an orthonormal basis with respect to the scalar product linalg::scalarProduct of two vectors.

The correctness of the result `FALSE` of `linalg::isUnitary` can only be guaranteed if the elements of the component ring R of the matrix `A` are canonically represented, i.e., if each element of R has only one unique representation.

The axiom Ax::canonicalRep states that a domain has this property. Hence, `linalg::isUnitary` returns `FALSE` or `UNKNOWN`, respectively, depending on whether the component ring of `A` has the axiom `Ax::canonicalRep`.

If the component ring of `A` does not define the method `"conjugate"` then it is checked whether `A` is an orthogonal matrix such that $AA^t = E_n$, where E_n is the n n identity matrix.

Examples

Example 1

The following matrix is unitary:
A := 1/sqrt(5) * matrix([[1, 2], [2, -1]])matrix([[sqrt(5)/5, (2*sqrt(5))/5], [(2*sqrt(5))/5, -sqrt(5)/5]])

$$\begin{pmatrix} \frac{\sqrt{5}}{5} & \frac{2\sqrt{5}}{5} \\ \frac{2\sqrt{5}}{5} & -\frac{\sqrt{5}}{5} \end{pmatrix}$$

linalg::isUnitary(A)TRUE

```
TRUE
```

Parameters

A

A square matrix of a domain of category Cat::Matrix

Return Values

Either `TRUE`, `FALSE`, or `UNKNOWN`.

See Also

linalg::orthoglinalg::scalarProduct

linalg::jacobian

Purpose

Jacobian matrix of a vector function

Syntax

```
linalg::jacobian(v, x)
```

Description

`linalg::jacobian(v, x)` computes the Jacobian matrix of the vector function ‘v→‘$\vec{v}$ with respect to ‘x→‘$\vec{x}$.

If `v` is a vector then the component ring of `v` must be a field (i.e., a domain of category Cat::Field) for which differentiation with respect to `x` is defined.

If `v` is given as a list of arithmetical expressions, then `linalg::jacobian` returns a matrix with the standard component ring Dom::ExpressionField`()`.

Examples

Example 1

The Jacobian matrix of the vector function ‘v→‘=matrix([[x^3], [x * z], [y+z]])$\vec{v} = \begin{pmatrix} x^3 \\ xz \\ y+z \end{pmatrix}$ is:

```
delete x, y, z: linalg::jacobian([x^3, x*z, y+z], [x, y, z])matrix([[3*x^2, 0, 0], [z, 0, x], [0, 1, 1]])
```

$$\begin{pmatrix} 3x^2 & 0 & 0 \\ z & 0 & x \\ 0 & 1 & 1 \end{pmatrix}$$

Parameters

v

A list of arithmetical expressions, or a vector (i.e., an n 1 or 1 n matrix of a domain of category Cat::Matrix)

x

A list of (indexed) identifiers

Return Values

Matrix of the domain Dom::Matrix(R), where R is the component ring of v or the domain Dom::ExpressionField().

Algorithms

For a vector function _outputSequence(‘v→‘,Symbol::colon, G, Symbol::rightarrow, R^m) $\vec{v}: G \to R^m$, where G is a subset of R_^n$\mathbb{R}^n$ the matrix

H[f](‘x→‘) = matrix([[diff(v[1], x[1]), diff(v[1], x[2]), Symbol::hellip, diff(v[1], x[n])], [diff(v[2], x[1]), diff(v[2], x[2]), Symbol::hellip, diff(v[2], x[n])], [Symbol::cdot, Symbol::cdot, “, Symbol::cdot], [Symbol::cdot, Symbol::cdot, “, Symbol::cdot], [Symbol::cdot, Symbol::cdot, “, Symbol::cdot], [diff(v[m], x[1]), diff(v[m], x[2]), Symbol::hellip, diff(v[m], x[n])]])

$H_f(\vec{x}) =$ is the *Jacobian matrix* of ‘v→‘$\vec{v}$.

$$\begin{pmatrix} \frac{\partial}{\partial x_1} v_1 & \frac{\partial}{\partial x_2} v_1 & \dots & \frac{\partial}{\partial x_n} v_1 \\ \frac{\partial}{\partial x_1} v_2 & \frac{\partial}{\partial x_2} v_2 & \dots & \frac{\partial}{\partial x_n} v_2 \\ \vdots & \vdots & & \vdots \\ \frac{\partial}{\partial x_1} v_m & \frac{\partial}{\partial x_2} v_m & \dots & \frac{\partial}{\partial x_n} v_m \end{pmatrix}$$

See Also

linalg::hessian, linalg::gradient

linalg::jordanForm

Purpose

Jordan normal form of a matrix

Syntax

```
linalg::jordanForm(A, <All>)
```

Description

`linalg::jordanForm(A)` returns the Jordan normal form J of the matrix A.

`linalg::jordanForm` computes a nonsingular transformation matrix P and a matrix J such that $A = PJP^{-1}$ with $J = diag(J_1, \ldots, J_r)$ and Jordan matrices $J_1, \ldots, J_r$.

The Jordan normal form of a square matrix A over a field F exists if the characteristic polynomial of A splits over F into linear factors. If this is not the case for the matrix `A`, then `linalg::jordanForm` returns `FAIL`.

The Jordan normal form is unique up to permutations of the Jordan matrices $J_1, \ldots, J_r$.

The implemented method computes the eigenvalues of `A`. It returns `FAIL` if this is not possible (see linalg::eigenvalues).

The component ring of `A` must be a field, i.e., a domain of category Cat::Field.

Examples

Example 1

The Jordan normal form of the matrix:
A := Dom::Matrix(Dom::Complex)([[1, 2], [4, 5]])Dom::Matrix(Dom::Complex)([[1, 2], [4, 5]])

$$\begin{pmatrix} 1 & 2 \\ 4 & 5 \end{pmatrix}$$

is the following matrix:
J := linalg::jordanForm(A)Dom::Matrix(Dom::Complex)([[3 - 2*sqrt(3), 0], [0, 2*sqrt(3) + 3]])

$$\begin{pmatrix} -2\sqrt{3}+3 & 0 \\ 0 & 2\sqrt{3}+3 \end{pmatrix}$$

The corresponding transformation matrix P can be obtained from the result `[J, P]` of `linalg::jordanForm` with the option `All`:

```
P := linalg::jordanForm(A, All)[2]Dom::Matrix(Dom::Complex)([[-
sqrt(3)/2 - 1/2, sqrt(3)/2 - 1/2], [1, 1]])
```

$$\begin{pmatrix} -\frac{\sqrt{3}}{2}-\frac{1}{2} & \frac{\sqrt{3}}{2}-\frac{1}{2} \\ 1 & 1 \end{pmatrix}$$

We check the result:

```
map(P * J * P^(-1), radsimp)Dom::Matrix(Dom::Complex)([[1, 2], [4, 5]])
```

$$\begin{pmatrix} 1 & 2 \\ 4 & 5 \end{pmatrix}$$

To get this result we must apply the function radsimp to each component of the matrix that is returned by the matrix product PJP^{-1}.

Parameters

A

A square matrix of a domain of category Cat::Matrix

Options

All

Returns the list `[J, P]` with the Jordan normal form J of `A` and the corresponding transformation matrix P such that $A = PJP^{-1}$.

Return Values

Either a matrix of the same domain type as `A`, the list `[J, P]` when the option `All` is given, or the value `FAIL`.

linalg::kroneckerProduct

Purpose

Kronecker product of matrices

Syntax

```
linalg::kroneckerProduct(A, <B,  >)
```

Description

`linalg::kroneckerProduct(A, B)` computes the Kronecker product of two matrices `A` and `B`.

The Kronecker product (direct matrix product) of an m n matrix `A` and a p q matrix `B` is the (mp) (nq) matrix _outputSequence(A,Symbol::otimes,B)$A \otimes B$ given in block form as

_outputSequence(A,Symbol::otimes,B) = matrix([[a[1,1] * B, Symbol::hellip, a[1,n] * B], [Symbol::cdot, “, Symbol::cdot], [Symbol::cdot, “, Symbol::cdot], [Symbol::cdot, “, Symbol::cdot], [a[m,1] * B, Symbol::hellip, a[m,n] * B]])

$$A \otimes B = \begin{pmatrix} a_{1,1} B & \dots & a_{1,n} B \\ \vdots & & \vdots \\ \vdots & & \vdots \end{pmatrix}$$

Componentwise: _outputSequence(A,Symbol::otimes,B)[‘I‘,J] = A[i,j] * B[k,l] with $(A \otimes B)_{I,J} = A_{i,j} B_{k,l}$ with $I = p(i - 1) + k$, $J = q(j - 1) + l$.

If `A` and `B` are matrices of the same matrix domain with the same component ring, the result is a matrix of the same type as `A` and `B`. If the domains or the component rings of `A` and `B` differ, `linalg::kroneckerProduct` tries to convert `B` into the domain type of `A` by `A::dom::coerce`. If this fails, conversion of `A` to the domain type of `B` is attempted. If no conversion is possible, an error is raised.

Note Note that the Kronecker product is only implemented for matrices over the domains Dom::Matrix, Dom::SquareMatrix or Dom::MatrixGroup. In particular, this includes matrices created by matrix.

A call with more than two arguments produces `linalg::kroneckerProduct(A, B, C) = linalg::kroneckerProduct(linalg::kroneckerProduct(A, B), C)` etc.

A call with only one argument is possible. It returns the input matrix.

Examples

Example 1

We consider two matrices `A` and `B` with symbolic components:
A:= matrix([[a11, a12], [a21, a22]]); B:= matrix([[b11, b12, b13], [b21, b22, b23]]);matrix([[a11, a12], [a21, a22]])

$$\begin{pmatrix} a11 & a12 \\ a21 & a22 \end{pmatrix}$$

matrix([[b11, b12, b13], [b21, b22, b23]])

$$\begin{pmatrix} b11 & b12 & b13 \\ b21 & b22 & b23 \end{pmatrix}$$

The Kronecker product of `A` and `B` is computed by multiplying the matrix `B` with each of the components of the matrix `A`. The resulting block matrix is returned as a matrix of larger dimension:
linalg::kroneckerProduct(A, B);matrix([[a11*b11, a11*b12, a11*b13, a12*b11, a12*b12, a12*b13], [a11*b21, a11*b22, a11*b23, a12*b21, a12*b22, a12*b23], [a21*b11, a21*b12, a21*b13, a22*b11, a22*b12, a22*b13], [a21*b21, a21*b22, a21*b23, a22*b21, a22*b22, a22*b23]])

$$\begin{pmatrix} a11\,b11 & a11\,b12 & a11\,b13 & a12\,b11 & a12\,b12 & a12\,b13 \\ a11\,b21 & a11\,b22 & a11\,b23 & a12\,b21 & a12\,b22 & a12\,b23 \\ a21\,b11 & a21\,b12 & a21\,b13 & a22\,b11 & a22\,b12 & a22\,b13 \\ a21\,b21 & a21\,b22 & a21\,b23 & a22\,b21 & a22\,b22 & a22\,b23 \end{pmatrix}$$

delete A, B:

Example 2

An n n matrix `H` with components in {- 1, 1} is called a *Hadamard matrix* if `H` multiplied with its transpose equals n times the n n identity matrix. The matrix `H` defined below is a Hadamard matrix:

```
H:= matrix([[1, 1], [1, -1]]); H * linalg::transpose(H) = 2 *
matrix::identity(2);matrix([[1, 1], [1, -1]])
```

$$\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$$

matrix([[2, 0], [0, 2]]) = matrix([[2, 0], [0, 2]])

$$\begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix} = \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix}$$

Hadamard matrices play a role in the field of error correcting codes. A basic property of this type of matrices is that the Kronecker product of two Hadamard matrices is again a Hadamard matrix. We verify this statement for the matrix `H`:

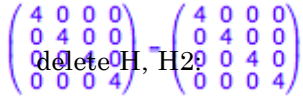
```
H2:= linalg::kroneckerProduct(H, H);matrix([[1, 1, 1, 1], [1, -1, 1, -1],
[1, 1, -1, -1], [1, -1, -1, 1]])
```

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & -1 & 1 & -1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}$$

Indeed, the matrix `H2` is a again a Hadamard matrix:

```
H2 * linalg::transpose(H2) = 4 * matrix::identity(4);matrix([[4, 0, 0, 0],
[0, 4, 0, 0], [0, 0, 4, 0], [0, 0, 0, 4]]) = matrix([[4, 0, 0, 0], [0, 4, 0, 0], [0,
0, 4, 0], [0, 0, 0, 4]])
```

delete H, H2:



Parameters

A

B, ...

Matrices of the domains Dom::Matrix, Dom::SquareMatrix or Dom::MatrixGroup

Return Values

Matrix of the same type as `A` or `B`.

linalg::laplacian

Purpose

The Laplacian

Syntax

```
linalg::laplacian(f, [x1, x2,  ])
linalg::laplacian(f, [x1, x2,  ], ogCoord, <c>)
```

Description

`linalg::laplacian(f, [ x1, x2, ...])` computes the Laplacian

_outputSequence(Symbol::Delta,f) = sum(diff(f,x[i],x[i]),i)$\Delta f = \sum_i \frac{\partial^2}{\partial x_i^2} f$ of the function `f`.

`linalg::laplacian` and laplacian are equivalent. See details and examples on the laplacian help page.

Parameters

f

An arithmetical expression in the variables x_1, x_2 etc.

x_1, x_2, ...

identifiers or indexed identifiers

ogCoord

The name of a 3 dimensional orthogonal coordinate system predefined in the table linalg::ogCoordTab, or a list of algebraic expressions representing the “scale parameters” of an orthogonal coordinate system.

c

The parameter of the coordinate systems EllipticCylindrical and Torus, respectively: an arithmetical expression. The default value is `c` = 1.

Return Values

Arithmetical expression.

linalg::matdim

Purpose

Dimension of a matrix

Syntax

```
linalg::matdim(A)
```

Description

`linalg::matdim(A)` returns the dimension of the matrix *A*, i.e., the number of rows and columns of *A*.

`linalg::matdim` is an interface function for the method `"matdim"` of the matrix domain of `A`, i.e., instead of `linalg::matdim(A)` one may call `A::dom::matdim(A)` directly.

Examples

Example 1

The dimension of the matrix:
A := matrix([[1, 2, 3, 4], [3, 1, 4], [5, 6]])matrix([[1, 2, 3, 4], [3, 1, 4, 0], [5, 6, 0, 0]])

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 3 & 1 & 4 & 0 \\ 5 & 6 & 0 & 0 \end{pmatrix}$$

can be determined by:
linalg::matdim(A)[3, 4]

[3, 4]

Parameters

A

An *m n* matrix of a domain of category Cat::Matrix

Return Values

List `[m, n]`, where `m` is the number of rows and `n` is the number of columns of `A`.

linalg::matlinsolve

Purpose

Solving systems of linear equations

Syntax

```
linalg::matlinsolve(A, b, <list>, options)
linalg::matlinsolve(A, B, options)
linalg::matlinsolve(A, options)
```

Description

`linalg::matlinsolve(A, b)` computes the general solution of the equation A * 'x→'='b→'$A\,\vec{x} = \vec{b}$.

`linalg::matlinsolve(A, b)` returns the solution vector 'x→'$\vec{x}$ of the system A * 'x→'='b→'$A\,\vec{x} = \vec{b}$ if it is a unique solution.

`linalg::matlinsolve(A, b)` returns a list ['w→', ['v→'[1], Symbol::hellip, 'v→'[r]]]$[\vec{w}, [\vec{v}_1, \ldots, \vec{v}_r]]$ if the system A * 'x→'='b→'$A\,\vec{x} = \vec{b}$ has more than one solution, where 'w→'$\vec{w}$ is one particular solution, i.e., A * 'w→'='b→'$A\,\vec{w} = \vec{b}$ and 'v→'[1], Symbol::hellip, 'v→'[r]$\vec{v}_1, \ldots, \vec{v}_r$ form a basis of the kernel of `A`, i.e., the solution space of the homogenous system A * 'x→'='(0→)'$A\,\vec{x} = (0)\vec{}$.

Each solution 'x→'$\vec{x}$ has the form 'x→'[s]+s[1] * 'v→'[1]+Symbol::hellip+s[r] * 'v→'[r]$\vec{x}_s + s_1\,\vec{v}_1 + \ldots + s_r\,\vec{v}_r (r \le n)$ with certain scalars $s_1, \ldots, s_r$.

A list of n scalars $[s_1, \ldots, s_n]$ may be passed as the additional parameter `list`. This extracts the solution 'x→'[s]+s[(i[1])] * 'v→'[1]+Symbol::hellip+s[(i[r])] * 'v→'[r]$\vec{x}_s + s_{i_1}\,\vec{v}_1 + \ldots + s_{i_r}\,\vec{v}_t$ with {i[1], Symbol::hellip, i[r]}={1, Symbol::hellip, n} minus {j[1],Symbol::hellip,j[l]}$\{i_1, \ldots, i_r\} = \{1, \ldots, n\} \setminus \{j_1, \ldots, j_l\}$ from the solution space of the system A * 'x→'='b→'$A\,\vec{x} = \vec{b}$, where $j_1, \ldots, j_l$ are the characteristic column indices of `A` (see linalg::gaussJordan).

The entries of `list` are converted to elements of the component ring of `A` (an error message is returned if this is not possible).

Note This option should only be used for exact and symbolic computations. In the case that `A` or `b` contains floating-point entries, it should not be used.

If the system A * 'x→'='b→'$A\vec{x} = \vec{b}$ has no solution, then the empty list `[]` is returned.

`linalg::matlinsolve(A)` solves the matrix equation C * 'x→'='b→'$C\vec{x} = \vec{b}$, where 'b→'$\vec{b}$ is the last column of `A` and C is `A` with the last column deleted.

`linalg::matlinsolve(A, B)` returns the solution X of the matrix equation $AX = B$, if it has exactly one solution. Otherwise the empty list `[]` is returned.

The vector `b` and the matrix `B` respectively, are converted into the domain Dom::Matrix`(R)`, where `R` is the component ring of `A`. Solution vectors also belong to this domain.

The component ring of `A` must be an integral domain, i.e., a domain of category Cat::IntegralDomain.

`linalg::matlinsolve` can compute the general solution for systems with more than one solution only over fields, i.e., component rings of category Cat::Field. If in this case the component ring of `A` does not have a canonical representation of the zero element, then it may happen that `linalg::matlinsolve` does not find a basis for the null space. In such a case, a wrong result is returned.

`linalg::matlinsolve` does exploit a sparse structure of `A`. (A matrix is *sparse* if it has many zero components). See "Example 5" on page 14-132.

Use the function numeric::matlinsolve to solve a linear system numerically.

Examples

Example 1

Solve the linear system:

matrix([[1, 2], [-1, 2]])*‘x→‘=matrix([[1], [-1]])

$$\begin{pmatrix} 1 & 2 \\ -1 & 2 \end{pmatrix} \vec{x} = \begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

over the reals. First, enter the coefficient matrix and the right side:
MatR := Dom::Matrix(Dom::Real): A := MatR([[1, 2], [-1, 2]]); b := MatR([1, -1])Dom::Matrix(Dom::Real)([[1, 2], [-1, 2]])

$$\begin{pmatrix} 1 & 2 \\ -1 & 2 \end{pmatrix}$$

Dom::Matrix(Dom::Real)([[1], [-1]])

$$\begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

Next, call `linalg::matlinsolve` to solve the system:
x := linalg::matlinsolve(A, b)Dom::Matrix(Dom::Real)([[1], [0]])

$$\begin{pmatrix} 1 \\ 0 \end{pmatrix}$$

The system has exactly one solution. The vector `x` satisfies the matrix equation given above:
A * xDom::Matrix(Dom::Real)([[1], [-1]])

$$\begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

Example 2

The system:

matrix([[1, 2], [-1, -2]])*‘x→‘=matrix([[1], [“]])

$$\begin{pmatrix} 1 & 2 \\ -1 & -2 \end{pmatrix} \vec{x} = \begin{pmatrix} 1 \end{pmatrix}$$

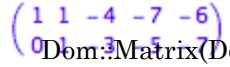
does not have a solution over (in fact, over no component domain):
MatR := Dom::Matrix(Dom::Real): A := MatR([[1, 2], [-1, -2]]): b := MatR([1, 0]): linalg::matlinsolve(A, b)[]

Example 3

Solve the linear system:

matrix([[1, 1, -4, -7, -6], [“, 1, -3, -5, -7]])*‘x→‘=matrix([[30], [17]])

over the rational numbers. First, enter the coefficient matrix and the right side:
MatQ := Dom::Matrix(Dom::Rational): A := MatQ([[1, 1, -4, -7, -6], [0, 1, -3, -5, -7]]); b := MatQ([30, 17])Dom::Matrix(Dom::Rational)([[1, 1, -4, -7, -6], [0, 1, -3, -5, -7]])



Dom::Matrix(Dom::Rational)([[30], [17]])

Next, call `linalg::matlinsolve` to solve the system:
sol:= linalg::matlinsolve(A, b)[Dom::Matrix(Dom::Rational)([[13], [17], [0], [0], [0]]), [Dom::Matrix(Dom::Rational)([[1], [3], [1], [0], [0]]), Dom::Matrix(Dom::Rational)([[2], [5], [0], [1], [0]]), Dom::Matrix(Dom::Rational)([[-1], [7], [0], [0], [1]])]

$$\left[\begin{pmatrix}13\\17\\0\\0\\0\end{pmatrix}, \left[\begin{pmatrix}1\\3\\1\\0\\0\end{pmatrix}, \begin{pmatrix}2\\5\\0\\1\\0\end{pmatrix}, \begin{pmatrix}-1\\7\\0\\0\\1\end{pmatrix}\right]\right]$$

The result is to be interpreted as follows: The first vector of the list `sol` is a particular solution of the linear system:
A * sol[1]Dom::Matrix(Dom::Rational)([[30], [17]])

$$\begin{pmatrix}30\\17\end{pmatrix}$$

The second entry of the list contains a basis for the null space of *A*, i.e., the solution space of the corresponding homogenous system A * ‘x→‘=‘(0→)‘$A\,\vec{x} = \vec{0}$ (the kernel of *A*). The basis returned is given as a list of vectors.

The following input checks this fact by computing the product A * ‘x→‘$A\,\vec{x}$ for each vector ‘x→‘$\vec{x}$ of the list `sol[2]`:
map(sol[2], x -> A * x)[Dom::Matrix(Dom::Rational)([[0], [0]]), Dom::Matrix(Dom::Rational)([[0], [0]]), Dom::Matrix(Dom::Rational)([[0], [0]])]

$$\left[\begin{pmatrix}0\\0\end{pmatrix}, \begin{pmatrix}0\\0\end{pmatrix}, \begin{pmatrix}0\\0\end{pmatrix}\right]$$

Any solution of the linear system can be represented as a sum of a particular solution (here: `sol[1]`) and a linear combination of the basis vectors of the kernel of *A*. Hence the input system has an infinite number of solutions.

For example, another solution of the system is given by:
x := sol[1] + 1*sol[2][1] + 1/2*sol[2][2] - 2*sol[2][3]Dom::Matrix(Dom::Rational)([[17], [17/2], [1], [1/2], [-2]])

$$\begin{pmatrix} 17 \\ \frac{17}{2} \\ \frac{1}{2} \end{pmatrix}$$

A * xDom::Matrix(Dom::Rational)([[30], [17]])

$$\begin{pmatrix} 30 \\ 17 \end{pmatrix}$$

If you identify the columns of the coefficient matrix A of the linear system with the variables x_1, x_2, x_3, x_4, x_5, then you see from the general solution that the variables x_3, x_4, x_5 act as free parameters. They can be assigned arbitrary rational values to obtain a unique solution.

By giving a list of values for these variables as a third parameter to `linalg::matlinsolve`, you can select a certain vector from the set of all solutions of the linear system. For example, to select the same vector `x` as chosen in the previous input, enter:
linalg::matlinsolve(A, b, [0, 0, 1, 1/2, -2])Dom::Matrix(Dom::Rational)([[17], [17/2], [1], [1/2], [-2]])

$$\begin{pmatrix} 17 \\ \frac{17}{2} \\ 1 \\ \frac{1}{2} \\ -2 \end{pmatrix}$$

If you are only interested in a particular solution and do not need the general solution of the linear system, enter:
linalg::matlinsolve(A, b, Special)Dom::Matrix(Dom::Rational)([[13], [17], [0], [0], [0]])

$$\begin{pmatrix} 13 \\ 17 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

This call suppresses the computation of the kernel of A.

Example 4

If the linear system is given in the form of equations the function linalg::expr2Matrix can be used to form the corresponding matrix equation:
delete x, y, z: Ab := linalg::expr2Matrix([x + y + z = 6, 2*x + y + 2*z = 10, x + 3*y + z = 10])matrix([[1, 1, 1, 6], [2, 1, 2, 10], [1, 3, 1, 10]])

$$\begin{pmatrix} 1 & 1 & 1 & 6 \\ 2 & 1 & 2 & 10 \\ 1 & 3 & 1 & 10 \end{pmatrix}$$

The result here is the extended coefficient matrix of the input system, that is, the right side vector 'b→' $\vec{b}$ is the 4th column vector of the matrix `Ab`. Since you did not specify a component ring for this matrix, the standard component ring for matrices, the domain Dom::ExpressionField(), was chosen.

To solve the linear system, call:
linalg::matlinsolve(Ab)[matrix([[4], [2], [0]]), [matrix([[-1], [0], [1]])]]

$$\left[\begin{pmatrix} 4 \\ 2 \\ 0 \end{pmatrix}, \left[\begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix}\right]\right]$$

The system has an infinite number of solutions. The third variable z acts as a free parameter and therefore can have any (complex) value.

To get the general solution in parameter form, you can use parameters for the variables x, y, z of the input system:
delete u, v, w: sol := linalg::matlinsolve(Ab, [u, v, w])matrix([[4 - w], [2], [w]])

$$\begin{pmatrix} 4 - w \\ 2 \\ w \end{pmatrix}$$

This is possible here because you perform the matrix computations over `Dom::ExpressionField()` which lets you compute with symbolical (arithmetical) expressions.

To select a certain vector from the set of solutions, for example, the solution for $w = 1$, enter:
x := subs(sol, w = 1)matrix([[3], [2], [1]])

$$\begin{pmatrix} 3 \\ 2 \\ 1 \end{pmatrix}$$

Example 5

Consider a system of linear equations with a sparse structure, that is, the coefficient matrix has many zero components:
eqs := {x1 + x5 = 0, x2 - x4 = 1, x3 + 2*x5 = 2, x4 - x5 = -1}: Ab := linalg::expr2Matrix(eqs, [x1, x2, x3, x4, x5])matrix([[1, 0, 0, 0, 1, 0], [0, 1, 0, -1, 0, 1], [0, 0, 1, 0, 2, 2], [0, 0, 0, 1, -1, -1]])

$$\begin{pmatrix} 1 & 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & -1 & 0 & 1 \\ 0 & 0 & 1 & 0 & 2 & 2 \\ 0 & 0 & 0 & 1 & -1 & -1 \end{pmatrix}$$

`linalg::matlinsolve` exploits the sparsity of the coefficient matrix if it is passed as a matrix of type Dom::Matrix. Alternatively, you can use the function linsolve which allows sparse input and output via symbolic equations:
linsolve(eqs)[x1 = -x5, x2 = x5, x3 = 2 - 2*x5, x4 = x5 - 1]

$$[x1 = -x5,\ x2 = x5,\ x3 = 2 - 2\,x5,\ x4 = x5 - 1]$$

You also can use the function numeric::matlinsolve with the option `Symbolic` instead of `linalg::matlinsolve`:

```
A := linalg::delCol(Ab, 6): b := linalg::col(Ab, 6): numeric::matlinsolve(A,
b, Symbolic)[matrix([[0], [0], [2], [-1], [0]]), matrix([[-1], [1], [-2], [1], [1]])]
```

$$\left[\begin{pmatrix} 0 \\ 0 \\ 2 \\ -1 \\ 0 \end{pmatrix}, \begin{pmatrix} -1 \\ 1 \\ -2 \\ 1 \\ 1 \end{pmatrix}\right]$$

Note that the function `numeric::matlinsolve` always works over a subfield of the complex numbers and does not let you specify the domain of computation. Without the option `Symbolic`, `numeric::matlinsolve` converts input data to floating-point numbers.

Example 6

Check whether the matrix equation

matrix([[1, 2], [-2, 3]])*‘x→‘=matrix([[4, 2], [6, 3]])

$$\begin{pmatrix} 1 & 2 \\ -2 & 3 \end{pmatrix} \vec{x} = \begin{pmatrix} 4 & 2 \\ 6 & 3 \end{pmatrix}$$

has a unique solution over the integers.

Start by entering the coefficient matrix and the right side matrix:

```
MatZ := Dom::Matrix(Dom::Integer): A := MatZ([[1, 2], [-2, 3]]); B :=
MatZ([[4, 2], [6, 3]])Dom::Matrix(Dom::Integer)([[1, 2], [-2, 3]])
```

$$\begin{pmatrix} 1 & 2 \\ -2 & 3 \end{pmatrix}$$

Dom::Matrix(Dom::Integer)([[4, 2], [6, 3]])

$$\begin{pmatrix} 4 & 2 \\ 6 & 3 \end{pmatrix}$$

Next, solve the matrix equation:

```
X := linalg::matlinsolve(A, B)Dom::Matrix(Dom::Integer)([[0, 0], [2, 1]])
```

$$\begin{pmatrix} 0 & 0 \\ 2 & 1 \end{pmatrix}$$

The equation indeed has a unique solution (otherwise the answer of `linalg::matlinsolve` would be the empty list `[]`). Check the result:
A * XDom::Matrix(Dom::Integer)([[4, 2], [6, 3]])

$$\begin{pmatrix} 4 & 2 \\ 6 & 3 \end{pmatrix}$$

Example 7

If you use the `Normal` option, `linalg::matlinsolve` calls the normal function for final results. This call ensures that `linalg::matlinsolve` returns results in normalized form:
A := matrix([[1, s], [t, -1]]): b := matrix([s + 1, t - 1]): x := linalg::matlinsolve(A, b)matrix([[1], [1]])

$$\begin{pmatrix} 1 \\ 1 \end{pmatrix}$$

If you specify `Normal = FALSE`, `linalg::matlinsolve` does not call normal for the final result:
x := linalg::matlinsolve(A, b, Normal = FALSE)matrix([[s - (s*(t*(s + 1) - t + 1))/(s*t + 1) + 1], [(t*(s + 1) - t + 1)/(s*t + 1)]])

$$\begin{pmatrix} s - \frac{s\,(t\,(s+1)-t+1)}{s\,t+1} + 1 \\ \frac{t\,(s+1)-t+1}{s\,t+1} \end{pmatrix}$$

Example 8

Solve this system:
A := matrix([[1, s], [1, t]]): b := matrix([1, 1]):linalg::matlinsolve(A, b)matrix([[1], [0]])

$$\begin{pmatrix} 1 \\ 0 \end{pmatrix}$$

Note that more solutions exist for `t = s`. `linalg::matlinsolve` omits these solutions because it makes some additional assumptions on symbolic parameters of this system. To see the assumptions that `linalg::matlinsolve` made while solving this system, use the `ShowAssumptions` option:
linalg::matlinsolve(A, b, ShowAssumptions)[matrix([[1], [0]]), [], [], [t - s <> 0]]

Parameters

A

m n matrix of a domain of category Cat::Matrix

B

m k matrix of a domain of category `Cat::Matrix`

b

m-dimensional column vector, i.e., a *m* 1 matrix of a domain of category `Cat::Matrix`

list

List of *n* elements of the component ring of `A`

Options

Normal

Option, specified as `Normal = b`

Return normalized results. The value `b` must be TRUE or FALSE. By default, `Normal = TRUE`, meaning that `linalg::matlinsolve` guarantees normalization of the returned results. Normalizing results can be computationally expensive.

By default, `linalg::matlinsolve` calls normal before returning results. This additional internal call ensures that the final result is normalized. This call can be computationally expensive. This

option affects the output only if the solution contains variables or exact expressions, such as `sqrt(5)` or `sin(PI/7)`.

To avoid this additional call, specify `Normal = FALSE`. In this case, `linalg::matlinsolve` also can return normalized results, but does not guarantee such normalization. See "Example 7" on page 14-134.

ShowAssumptions

Return information about internal assumptions that `linalg::matlinsolve` made on symbolic parameters in `eqs`.

With `ShowAssumptions`, `linalg::matlinsolve` returns a list `[S, KernelBasis, Constraints, Pivots]`. The lists `Constraints` and `Pivots` contain equations and inequalities involving symbolic parameters in `A` and `b` (or `B`). Internally, these were assumed to hold true when solving the system. See "Example 8" on page 14-134.

When Gaussian elimination produces an equation `0 = c` with nonzero `c`, `linalg::matlinsolve` without `ShowAssumptions` returns `[]`. If `c` involves symbolic parameters, try using `linalg::matlinsolve` with `ShowAssumptions` to solve such systems. If the system is solvable, you will get the solution. In this case, an equation `0 = c` is returned in the `Constraints` list. If the system is not solvable, `linalg::matlinsolve` with `ShowAssumptions` returns `[[], [], [], []]`.

Special

Only one particular solution `w` of the system A * 'x→'='b→' $A\vec{x} = \vec{b}$ is returned. This supresses the computation of a basis for the kernel of `A`.

Unique

Checks whether the system has a unique solution and returns it. The return value `NIL` means that the system has more than one solution.

Return Values

Without `ShowAssumptions`, `linalg::matlinsolve` can return a vector or a list `[S, KernelBasis]` (possibly empty), where `S` is a solution vector and `KernelBasis` is a list of basis vectors for the kernel of `A`. It also can return a matrix or the value `NIL`.

The matrix and the vectors, respectively, are of the domain type `Dom::Matrix(R)`, where `R` is the component ring of `A`.

With `ShowAssumptions`, `linalg::matlinsolve` returns a list `[S, KernelBasis, Constraints, Pivots]`. The lists `Constraints` and `Pivots` contain equations and inequalities involving symbolic parameters in `A` and `b` (or `B`). Internally, these were assumed to hold true when solving the system. If the system is not solvable, `linalg::matlinsolve` with `ShowAssumptions` returns `[[], [], [], []]`.

Algorithms

Let A be an m n matrix with components from a field F and 'b→'$\vec{b}$ an m-dimensional vector over F. Let fenced(A, 'b→')$(A, \vec{b})$ be the extended coefficient matrix of the linear system A * 'x→'='b→'$A\,\vec{x} = \vec{b}$.

Then the following holds:

- The linear system A * 'x→'='b→'$A\,\vec{x} = \vec{b}$ has a solution, if and only if rank(A, 'b→')=rank(A)$\mathrm{rank}(A, \vec{b}) = \mathrm{rank}(A)$.
- It has exactly one solution, if and only if rank(A, 'b→')=rank(A)=n$\mathrm{rank}(A, \vec{b}) = \mathrm{rank}(A) = n$.
- If 'x→'[s]$\vec{x}_s$ is a solution of the system A * 'x→'='b→'$A\,\vec{x} = \vec{b}$and {'v→'[1], Symbol::hellip, 'v→'[r]}$\{\vec{v}_1, \ldots, \vec{v}_r\}$ a basis of the kernel of A, then

  L(A, 'b→') = ImageSet('w→' + Symbol::lambda[1] * 'v→'[1] + Symbol::lambda[2] * 'v→'[2] + Symbol::cdots + Symbol::lambda[r] * 'v→'[r], Symbol::lambda[1], dots, Symbol::lambda[r] in K)

$$L(A, \vec{b}) = \{\vec{w} + \lambda_1 \vec{v}_1 + \lambda_2 \vec{v}_2 + \cdots + \lambda_r \vec{v}_r \mid \lambda_1, \ldots, \lambda_r \in K\}$$

is the set of all solutions of the linear system A * ‘x→‘=‘b→‘$A \vec{x} = \vec{b}$, the *general solution* of the (inhomogeneus) linear system.

The *kernel of the matrixA* is defined as:

ker(A) = ImageSet(‘w→‘, A * ‘w→‘ = ‘0→‘)

$$\ker(A) = \{\vec{w} \mid A\vec{w} = \vec{0}\}$$

The kernel of A is a vector space over F of dimension n - $rank(A)$.

Concepts

- “Solve Algebraic Systems”

linalg::matlinsolveLU

Purpose

Solving the linear system given by an LU decomposition

Syntax

```
linalg::matlinsolveLU(L, U, b)
linalg::matlinsolveLU(L, U, B)
```

Description

`linalg::matlinsolveLU(L, U, b)` solves the linear system L * U * ‘x→‘=‘b→‘$L\,U\,\vec{x} = \vec{b}$, where the matrices L and U form an LU-decomposition, as computed by `linalg::factorLU`.

If the third parameter is an n k matrix `B` then the result is an n k matrix X satisfying the matrix equation $LUX = B$.

The system to be solved always has a unique solution.

The diagonal entries of the lower diagonal matrix `L` must be equal to one (*Doolittle*-decomposition, see linalg::factorLU).

`linalg::matlinsolveLU` expects `L` and `U` to be nonsingular.

`linalg::matlinsolveLU` does not check on any of the required properties of `L` and `U`.

The component ring of the matrices `L` and `U` must be a field, i.e., a domain of category Cat::Field.

The parameters must be defined over the same component ring.

Examples

Example 1

We solve the system

matrix([[2, -3, -1], [1, 1, -1], [“, 1, -1]]) * X=matrix([[1, “, “], [“, 1, “], [“, “, 1]])

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ & 1 & -1 \end{pmatrix} X = \begin{pmatrix} 1 & & \\ & 1 & \\ & & 1 \end{pmatrix}$$

```
MatR := Dom::Matrix(Dom::Real): A := MatR([[2, -3, -1], [1, 1, -1], [0,
1, -1]]); I3 := MatR::identity(3)Dom::Matrix(Dom::Real)([[2, -3, -1], [1,
1, -1], [0, 1, -1]])
```

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

```
Dom::Matrix(Dom::Real)([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

We start by computing an LU-decomposition of A:

```
LU := linalg::factorLU(A)[Dom::Matrix(Dom::Real)([[1, 0, 0], [1/2, 1,
0], [0, 2/5, 1]]), Dom::Matrix(Dom::Real)([[2, -3, -1], [0, 5/2, -1/2], [0, 0,
-4/5]]), [1, 2, 3]]
```

$$\left[\begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ 0 & \frac{2}{5} & 1 \end{pmatrix}, \begin{pmatrix} 2 & -3 & -1 \\ 0 & \frac{5}{2} & -\frac{1}{2} \\ 0 & 0 & -\frac{4}{5} \end{pmatrix}, [1, 2, 3]\right]$$

Now we solve the system $AX = I_3$, which gives us the inverse of A:

```
Ai := linalg::matlinsolveLU(LU[1], LU[2],
I3)Dom::Matrix(Dom::Real)([[0, 1, -1], [-1/4, 1/2, -1/4], [-1/4, 1/2, -5/4]])
```

$$\begin{pmatrix} 0 & 1 & -1 \\ -\frac{1}{4} & \frac{1}{2} & -\frac{1}{4} \\ -\frac{1}{4} & \frac{1}{2} & -\frac{5}{4} \end{pmatrix}$$

```
A*Ai, Ai * ADom::Matrix(Dom::Real)([[1, 0, 0], [0, 1, 0], [0, 0, 1]]),
Dom::Matrix(Dom::Real)([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

Parameters

L

An n n lower triangular matrix of a domain of category Cat::Matrix

U

An n n upper triangular form matrix of the same domain as `L`

B

An n k matrix of a domain of category `Cat::Matrix`

b

An n-dimensional column vector, i.e., an n 1 matrix of a domain of category `Cat::Matrix`

Return Values

n-dimensional solution vector or n k dimensional solution matrix, respectively, of the domain type `Dom::Matrix(R)`, where `R` is the component ring of `A`.

See Also

linalg::factorLULinalg::inverseLULinalg::matlinsolve

linalg::minpoly

Purpose

Minimal polynomial of a matrix

Syntax

```
linalg::minpoly(A, x)
```

Description

`linalg::minpoly(A, x)` computes the minimal polynomial of the square matrix A in x, i.e., the monic polynomial of lowest degree annihilating the matrix A.

The minimal polynomial of `A` divides the characteristic polynomial of `A`, by Cayley-Hamilton theorem.

If the matrix is defined over Dom::Float, then due to numerical errors the computed polynomial can have a degree higher than the dimension of the matrix. In such cases, `linalg::minpoly` returns the value FAIL. See “Example 3” on page 14-143.

The component ring of `A` must be a field, i.e., a domain of category Cat::Field.

Examples

Example 1

We define the following matrix over the rational numbers:
A := Dom::Matrix(Dom::Rational)([[0, 2, 0], [0, 0, 2], [2, 0, 0]]
)Dom::Matrix(Dom::Rational)([[0, 2, 0], [0, 0, 2], [2, 0, 0]])

$$\begin{pmatrix} 0 & 2 & 0 \\ 0 & 0 & 2 \\ 2 & 0 & 0 \end{pmatrix}$$

The minimal polynomial of the matrix A in the variable x is then given by:
delete x: linalg::minpoly(A, x)x^3 - 8

$$x^3 - 8$$

In this case, the minimal polynomial is in fact equal to the characteristic polynomial of A:
linalg::charpoly(A, x)x^3 - 8

$$x^3 - 8$$

Example 2

The minimal polynomial of the matrix:
B := matrix([[0, 1, 0], [0, 0, 0], [0, 0, 0]])matrix([[0, 1, 0], [0, 0, 0], [0, 0, 0]])

$$\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

is a polynomial of degree 2:
m := linalg::minpoly(B, x)x^2

$$x^2$$

The characteristic polynomial of *B* has degree 3 and is divided by the minimal polynomial of *B*:
p := linalg::charpoly(B, x)x^3

$$x^3$$

p / mx

$$x$$

Example 3

For the following example, MuPAD is not able to compute the minimal polynomial, and thus FAIL is returned:
C := Dom::Matrix(Dom::Float)([[7, 0, 0, 0, 0], [1, 0, 0, 0, 0], [1, 2, 0, 0, 0], [1, 2, 3, 0, 0], [1, 2, 3, 4, 7]])Dom::Matrix(Dom::Float)([[7.0, 0, 0, 0, 0], [1.0, 0, 0, 0, 0], [1.0, 2.0, 0, 0, 0], [1.0, 2.0, 3.0, 0, 0], [1.0, 2.0, 3.0, 4.0, 7.0]])

$$\begin{pmatrix} 7.0 & 0.0 & 0.0 & 0.0 & 0.0 \\ 1.0 & 0.0 & 0.0 & 0.0 & 0.0 \\ 1.0 & 2.0 & 0.0 & 0.0 & 0.0 \\ 1.0 & 2.0 & 3.0 & 0.0 & 0.0 \\ 1.0 & 2.0 & 3.0 & 4.0 & 0.0 \end{pmatrix}$$

delete x: linalg::minpoly(C, x) Warning: Cannot compute the minimal polynomial. [linalg::minpoly] FAIL

FAIL

In fact, for this example MuPAD is not able to check for zero equivalence during Gaussian elimination and therefore chose a wrong pivot element.

If you perform the computation over the coefficient domainDom::ExpressionField(`normal`) instead, then in most cases the minimal polynomial can be computed:
C := matrix([[7, 0, 0, 0, 0], [1, 0, 0, 0, 0], [1, 2, 0, 0, 0], [1, 2, 3, 0, 0], [1, 2, 3, 4, 7]])matrix([[7, 0, 0, 0, 0], [1, 0, 0, 0, 0], [1, 2, 0, 0, 0], [1, 2, 3, 0, 0], [1, 2, 3, 4, 7]])

$$\begin{pmatrix} 7 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 1 & 2 & 0 & 0 & 0 \\ 1 & 2 & 3 & 0 & 0 \\ 1 & 2 & 3 & 4 & 7 \end{pmatrix}$$

linalg::minpoly(C, x)x^5 - 14*x^4 + 49*x^3

$$x^5 - 14\,x^4 + 49\,x^3$$

However, in general this problem regarding zero recognition cannot be avoided.

Parameters

A

A square matrix of a domain of category Cat::Matrix

x

An indeterminate

Return Values Polynomial of the domain `Dom::DistributedPolynomial([x],R)`, where `R` is the component ring of `A`, or the value FAIL.

See Also linalg::charpolylinalg::frobeniusForm

linalg::multCol

Purpose

Multiply columns with a scalar

Syntax

```
linalg::multCol(A, c, s)
linalg::multCol(A, c1 .. c2, s)
linalg::multCol(A, list, s)
```

Description

`linalg::multCol(A, c, s)` returns a copy of the matrix *A* resulting from *A* by multiplying the *c*-th column of *A* with the scalar *s*.

`linalg::multCol(A, c1.. c2, s)` returns a copy of the matrix `A` obtained from `A` by multiplying those columns whose indices are in the range `c1.. c2` with the scalar `s`.

`linalg::multCol(A, list, s)` returns a copy of the matrix `A` obtained from matrix `A` by multiplying those columns whose indices are contained in `list` with the scalar `s`.

The scalar `s` is converted into an element of the component ring of the matrix `A`. An error message is returned if the conversion fails.

Examples

Example 1

We define the following matrix:
A := matrix([[1, 2, 3], [4, 5, 6], [7, 8, 9]])matrix([[1, 2, 3], [4, 5, 6], [7, 8, 9]])

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

and illustrate the three different input formats for `linalg::multCol`:
linalg::multCol(A, 2, -1)matrix([[1, -2, 3], [4, -5, 6], [7, -8, 9]])

$$\begin{pmatrix} 1 & -2 & 3 \\ 4 & -5 & 6 \\ 7 & -8 & 9 \end{pmatrix}$$

linalg::multCol(A, 1..2, 2)matrix([[2, 4, 3], [8, 10, 6], [14, 16, 9]])

$$\begin{pmatrix} 2 & 4 & 3 \\ 8 & 10 & 6 \\ 14 & 16 & 9 \end{pmatrix}$$

linalg::multCol(A, [3, 1], 0)matrix([[0, 2, 0], [0, 5, 0], [0, 8, 0]])

$$\begin{pmatrix} 0 & 2 & 0 \\ 0 & 5 & 0 \\ 0 & 8 & 0 \end{pmatrix}$$

Parameters

A

An m n matrix of a domain of category Cat::Matrix

c

The column index: a positive integer less or equal to n

c_1 .. c_2

A range of column indices (positive integers less or equal to n)

list

A list of column indices (positive integers less or equal to n)

Return Values

Matrix of the same domain type as A.

See Also

linalg::addCollinalg::addRowlinalg::multRow

linalg::multRow

Purpose

Multiply rows with a scalar

Syntax

```
linalg::multRow(A, r, s)
linalg::multRow(A, r1 .. r2, s)
linalg::multRow(A, list, s)
```

Description

`linalg::multRow(A, r, s)` returns a copy of the matrix *A* resulting from *A* by multiplying the *r*-th row of *A* with the scalar *s*.

`linalg::multRow(A, r1.. r2, s)` returns a copy of the matrix `A` obtained from `A` by multiplying those rows whose indices are in the range `r1.. r2` with the scalar `s`.

`linalg::multRow(A, list, s)` returns a copy of the matrix `A` obtained from matrix `A` by multiplying those rows whose indices are contained in `list` with the scalar `s`.

The scalar `s` is converted into an element of the component ring of the matrix `A`. An error message is returned if the conversion fails.

Examples

Example 1

We define the following matrix:
A := matrix([[1, 2, 3], [4, 5, 6], [7, 8, 9]])matrix([[1, 2, 3], [4, 5, 6], [7, 8, 9]])

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

and illustrate the three different input formats for `linalg::multRow`:
linalg::multRow(A, 2, -1)matrix([[1, 2, 3], [-4, -5, -6], [7, 8, 9]])

$$\begin{pmatrix} 1 & 2 & 3 \\ -4 & -5 & -6 \\ 7 & 8 & 9 \end{pmatrix}$$

linalg::multRow(A, 1..2, 2)matrix([[2, 4, 6], [8, 10, 12], [7, 8, 9]])

$$\begin{pmatrix} 2 & 4 & 6 \\ 8 & 10 & 12 \\ 7 & 8 & 9 \end{pmatrix}$$

linalg::multRow(A, [3, 1], 0)matrix([[0, 0, 0], [4, 5, 6], [0, 0, 0]])

$$\begin{pmatrix} 0 & 0 & 0 \\ 4 & 5 & 6 \\ 0 & 0 & 0 \end{pmatrix}$$

Parameters

A

An m n matrix of a domain of category Cat::Matrix

r

The row index: a positive integer less or equal to m

r_1 .. r_2

A range of row indices (positive integers less or equal to m)

list

A list of row indices (positive integers less or equal to m)

Return Values

Matrix of the same domain type as A.

See Also

linalg::addCollinalg::addRowlinalg::multCol

linalg::ncols

Purpose

Number of columns of a matrix

Syntax

```
linalg::ncols(A)
```

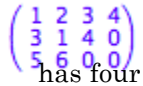
Description

`linalg::ncols(A)` returns the number of columns of the matrix *A*.

Examples

Example 1

The matrix:
A:= matrix([[1, 2, 3, 4], [3, 1, 4], [5, 6]])matrix([[1, 2, 3, 4], [3, 1, 4, 0], [5, 6, 0, 0]])



has four columns:
linalg::ncols(A)4

4

Parameters

A

A matrix of a domain of category Cat::Matrix

Return Values

Positive integer.

See Also

linalg::matdimlinalg::nrowslinalg::vecdim

linalg::nonZeros

Purpose

Number of non-zero elements of a matrix

Syntax

```
linalg::nonZeros(A)
```

Description

`linalg::nonZeros(A)` returns the number of non-zero components of the matrix *A*.

Examples

Example 1

The matrix
MZ7 := Dom::Matrix(Dom::IntegerMod(7)): A := MZ7([[18, -1], [4, 81]])Dom::Matrix(Dom::IntegerMod(7))([[-3, -1], [-3, -3]])

$$\begin{pmatrix} 4 \bmod 7 & 6 \bmod 7 \\ 4 \bmod 7 & 4 \bmod 7 \end{pmatrix}$$

has four non-zero entries:
linalg::nonZeros(A)4

$$4$$

The matrix:
B := MZ7([[21, 2], [-1, 14]])Dom::Matrix(Dom::IntegerMod(7))([[0, 2], [-1, 0]])

$$\begin{pmatrix} 0 \bmod 7 & 2 \bmod 7 \\ 6 \bmod 7 & 0 \bmod 7 \end{pmatrix}$$

has only two non-zero entries:
linalg::nonZeros(B)2

$$2$$

Parameters

A

A matrix of a domain of category Cat::Matrix

Return Values

Nonnegative integer

linalg::normalize

Purpose

Normalize a vector

Syntax

```
linalg::normalize(v)
```

Description

`linalg::normalize(v)` normalizes the vector ‘v→’$\vec{v}$ with respect to the 2-norm (norm(‘v→’,2)=sqrt(linalg::scalarProduct(‘v→’,‘v→’))$\|\vec{v}\|_2 = \sqrt{\langle \vec{v}, \vec{v} \rangle}$).

The result of `linalg::normalize(v)` is a vector that has norm 1 and the same direction as `v`.

The scalar product linalg::scalarProduct(‘v→’, ‘v→’)$\langle \vec{v}, \vec{v} \rangle$ for a vector ‘v→’$\vec{v}$ is implemented by the function linalg::scalarProduct.

The norm of a vector is computed with the function norm, which is overloaded for vectors. See the method `"norm"` of the domain constructor Dom::Matrix for details.

If the norm is an object that cannot be converted into an element of the component ring of `v`, then an error occurs (see “Example 2” on page 14-154).

Examples

Example 1

We define the following vector:
u := matrix([[1, 2]])matrix([[1, 2]])

$$\begin{pmatrix} 1 & 2 \end{pmatrix}$$

Then the vector of norm 1 with the same direction as `u` is given by:
linalg::normalize(u)matrix([[sqrt(5)/5, (2*sqrt(5))/5]])

$$\begin{pmatrix} \frac{\sqrt{5}}{5} & \frac{2\sqrt{5}}{5} \end{pmatrix}$$

Example 2

The following computation fails because the vector (1, 2) cannot be normalized over the rationals:

```
v := Dom::Matrix(Dom::Rational)([[1, 2]]): linalg::normalize(v)
Error: Cannot normalize the given vector over its component ring.
[linalg::normalize]
```

If we define v over the real numbers, then we get the normalized vector of v as follows:

```
w := Dom::Matrix(Dom::Real)(v):
linalg::normalize(w)Dom::Matrix(Dom::Real)([[sqrt(5)/5, (2*sqrt(5))/5]])
```

Parameters

v

A vector, i.e., an n 1 or 1 n matrix of a domain of category Cat::Matrix

Return Values

Vector of the same domain type as v.

See Also

normlinalg::scalarProduct

linalg::nrows

Purpose

Number of rows of a matrix

Syntax

```
linalg::nrows(A)
```

Description

`linalg::nrows(A)` returns the number of rows of the matrix *A*.

Examples

Example 1

The matrix:
A := matrix([[1, 2, 3, 4], [3, 1, 4], [5, 6]])matrix([[1, 2, 3, 4], [3, 1, 4, 0], [5, 6, 0, 0]])

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 3 & 1 & 4 & 0 \\ 5 & 6 & 0 & 0 \end{pmatrix}$$

has three rows:
linalg::nrows(A)3

3

Parameters

A

A matrix of a domain of category Cat::Matrix

Return Values

Positive integer.

See Also

linalg::matdimlinalg::ncolslinalg::vecdim

linalg::nullspace

Purpose

Basis for the null space of a matrix

Syntax

```
linalg::nullspace(A)
```

Description

`linalg::nullspace(A)` returns a basis for the null space of the matrix *A*, i.e., a list *B* of linearly independent vectors such that A * ‘x→‘=‘0→‘$A\,\vec{x} = \vec{0}$ if and only if ‘x→‘$\vec{x}$ is a linear combination of the vectors in *B*.

The component ring of the matrix `A` must be a field, i.e., a domain of category Cat::Field.

If the component ring of `A` does not have a canonical representation of the zero element, it can happen that `linalg::nullspace` does not find a basis for the null space. In such a case, a wrong result is returned.

Examples

Example 1

The kernel of the matrix:
A := Dom::Matrix(Dom::Real)([[3^(1/2)*2 - 2, 2], [4, 3^(1/2)*2 + 2]])Dom::Matrix(Dom::Real)([[2*sqrt(3) - 2, 2], [4, 2*sqrt(3) + 2]])

$$\begin{pmatrix} 2\sqrt{3}-2 & 2 \\ 4 & 2\sqrt{3}+2 \end{pmatrix}$$

is one-dimensional, and a basis is {matrix([[-(1)/(sqrt(3)-1)], [1]])}$\left\{\begin{pmatrix} -\frac{1}{\sqrt{3}-1} \\ 1 \end{pmatrix}\right\}$:
linalg::nullspace(A)[Dom::Matrix(Dom::Real)([[-1/(sqrt(3) - 1)], [1]])]

$$\left[\begin{pmatrix} -\frac{1}{\sqrt{3}-1} \\ 1 \end{pmatrix}\right]$$

Parameters

A

A matrix of a domain of category Cat::Matrix

Return Values

List of (column) vectors of the domain Dom::Matrix(R), where R is the component ring of A.

linalg::ogCoordTab

Purpose

Table of orthogonal coordinate transformations

Syntax

```
linalg::ogCoordTab[ogName](u1, u2, u3, <c>)
linalg::ogCoordTab[ogName,
  Transformation](u1, u2, u3, <c>)
linalg::ogCoordTab[ogName,
  InverseTransformation](u1, u2, u3, <c>)
linalg::ogCoordTab[ogName,
  UnitVectors](u1, u2, u3, <c>)
linalg::ogCoordTab[ogName,
  Scales](u1, u2, u3, <c>)
linalg::ogCoordTab[ogName, Ranges](<c>)
linalg::ogCoordTab[ ogName , Dimension]
```

Description

`linalg::ogCoordTab` is a table of predefined orthogonal coordinate transformations in R_^3$\mathbb{R}^3$.

The entry associated with `ogName` defines a coordinate transformation ‘x→‘=‘x→‘(‘u→‘)$\vec{x} = \vec{x}(\vec{u})$ which maps the orthogonal parameters ‘u→‘=fenced(u[1], u[2], u[3])$\vec{u} = (u_1, u_2, u_3)$ to a vector ‘x→‘=fenced(x[1], x[2], x[3])$\vec{x} = (x_1, x_2, x_3)$ in cartesian coordinates.

The coordinate systems `EllipticCylindrical` and `Torus` are defined with a constant parameter `c` which has to be passed as an additional argument. See “Example 2” on page 14-162.

The following coordinate transformations are stored in `linalg::ogCoordTab`. They are invertible for the indicated parameter values:

- `Cartesian`:

  u_1 , u_2 , u_3 :

  x[1]=u[1], x[2] = u[2], x[3] = u[3]

$$x_1 = u_1,\ x_2 = u_2,\ x_3 = u_3$$

- `Spherical`:

  $0 < u_1 < \infty$, $0 \le u_2 < 2\pi$, $0 \le u_3 < \pi$:

  x[1]=u[1] * cos(u[2]) * sin(u[3]), x[2] = u[1] * sin(u[2]) * sin(u[3]), + x[3] = u[1] * cos(u[3])

$$x_1 = u_1 \cos(u_2) \sin(u_3),\ x_2 = u_1 \sin(u_2) \sin(u_3),\ x_3 = u_1 \cos(u_3)$$

- `Cylindrical`:

  $0 < u_1 < \infty$, $0 \le u_2 < 2\pi$, u_3 :

  x[1]=u[1] * cos(u[2]), x[2] = u[1] * sin(u[2]),x[3] = u[3]

$$x_1 = u_1 \cos(u_2),\ x_2 = u_1 \sin(u_2),\ x_3 = u_3$$

- `EllipticCylindrical`:

  $0 < u_1 < \infty$, $0 \le u_2 < 2\pi$, u_3 (with a real constant c):

  x[1]=c*cos(u[1]) * cos(u[2]), x[2] = c * sinh(u_1) * sin(u_2), x[3] = u[3]

$$x_1 = c \cos(u_1) \cos(u_2),\ x_2 = c \sinh(u_1) \sin(u_2),\ x_3 = u_3$$

- `ParabolicCylindrical`:

  $0 < u_1 < \infty$, u_2 , u_3 :

  x[1]=1/2 * fenced(u[1]^2-u[2]^2), x[2] = u[1] * u[2], x[3] = u[3]

$$x_1 = \frac{\left(u_1^{\,2} - u_2^{\,2}\right)}{2},\ x_2 = u_1\, u_2,\ x_3 = u_3$$

- `RotationParabolic`:

$0 < u_1 < \infty$, $0 < u_2 < \infty$, $0 \le u_3 < 2\pi$:

x[1]=u[1] * u[2] * cos(u[3]), x[2] = u[1] * u[2] * sin(u[3]), + x[3] = 1/2 * fenced(u[1]^2 - u[2]^2)

$$x_1 = u_1\, u_2 \cos(u_3),\ x_2 = u_1\, u_2 \sin(u_3),\ x_3 = \frac{(u_1^2 - u_2^2)}{2}$$

- `Torus`:

  $0 < u_1 < c$, $0 \le u_2 < 2\pi$, $0 \le u_3 < 2\pi$ (with a positive constant c):

  x[1]= (c - u[1] * cos(u[2])) * cos(u[3]), x[2] = (c - u[1] * cos(u[2])) * sin(u[3]), + x[3] = u[1] * sin(u[2])

$$x_1 = (c - u_1 \cos(u_2)) \cos(u_3),\ x_2 = (c - u_1 \cos(u_2)) \sin(u_3),\ x_3 = u_1 \sin(u_2)$$

`linalg::ogCoordTab` is used by functions such as linalg::curl, linalg::divergence, linalg::gradient, and linalg::laplacian to perform computations in non-cartesian coordinates.

Examples

Example 1

The following call returns the cartesian vector 'x→'=[x, y, z] $\vec{x} = [x, y, z]$ in terms of spherical coordinates 'u→'=[u[1], u[2], u[3]] $\vec{u} = [u_1, u_2, u_3]$:
linalg::ogCoordTab[Spherical, Transformation](u1, u2, u3)[u1*cos(u2)*sin(u3), u1*sin(u2)*sin(u3), u1*cos(u3)]

$$[u1 \cos(u2) \sin(u3),\ u1 \sin(u2) \sin(u3),\ u1 \cos(u3)]$$

The spherical coordinates expressed by the cartesian coordinates: linalg::ogCoordTab[Spherical, InverseTransformation](x, y, z)[sqrt(x^2 + y^2 + z^2), arccos(x/sqrt(x^2 + y^2)) + sign(y)*(sign(y) - 1)*(PI - arccos(x/sqrt(x^2 + y^2))), arccos(z/sqrt(x^2 + y^2 + z^2))]

$$\left[\sqrt{x^2+y^2+z^2},\ \arccos\left(\frac{x}{\sqrt{x^2+y^2}}\right)+\operatorname{sign}(y)\,(\operatorname{sign}(y)-1)\left(\pi-\arccos\left(\frac{x}{\sqrt{x^2+y^2}}\right)\right),\ \arccos\left(\frac{z}{\sqrt{x^2+}\right.\right.$$

Note the `sign(y)` in the expression for u_2. This ensures that the correct angle is returned for any value of y:

```
assume(y > 0): linalg::ogCoordTab[Spherical, InverseTransformation](x,
y, z)[sqrt(x^2 + y^2 + z^2), arccos(x/sqrt(x^2 + y^2)), arccos(z/sqrt(x^2
+ y^2 + z^2))]
```

$$\left[\sqrt{x^2+y^2+z^2},\ \arccos\left(\frac{x}{\sqrt{x^2+y^2}}\right),\ \arccos\left(\frac{z}{\sqrt{x^2+y^2+z^2}}\right)\right]$$

```
linalg::ogCoordTab[Spherical, InverseTransformation](1, 1, 0),
linalg::ogCoordTab[Spherical, InverseTransformation](-1, 0, 1),
linalg::ogCoordTab[Spherical, InverseTransformation](1, 0, 2),
linalg::ogCoordTab[Spherical, InverseTransformation](1, -1, 3)[sqrt(2),
PI/4, PI/2], [sqrt(2), PI, PI/4], [sqrt(5), 0, arccos((2*sqrt(5))/5)], [sqrt(11),
(7*PI)/4, arccos((3*sqrt(11))/11)]
```

$$\left[\sqrt{2},\ \frac{\pi}{4},\ \frac{\pi}{2}\right],\ \left[\sqrt{2},\ \pi,\ \frac{\pi}{4}\right],\ \left[\sqrt{5},\ 0,\ \arccos\left(\frac{2\sqrt{5}}{5}\right)\right],\ \left[\sqrt{11},\ \frac{7\pi}{4},\ \arccos\left(\frac{3\sqrt{11}}{11}\right)\right]$$

These parameter values are from the following ranges:

```
linalg::ogCoordTab[Spherical, Ranges]()[0..infinity, 0..2*PI, 0..PI]
```

$$[0..\infty,\ 0..2\,\pi,\ 0..\pi]$$

The following orthonormal vectors are tangent to the spherical parameter lines:

```
linalg::ogCoordTab[Spherical, UnitVectors](u1, u2, u3)[[cos(u2)*sin(u3),
sin(u2)*sin(u3), cos(u3)], [-sin(u2), cos(u2), 0], [cos(u2)*cos(u3),
cos(u3)*sin(u2), -sin(u3)]]
```

$$[[\cos(u2)\sin(u3),\ \sin(u2)\sin(u3),\ \cos(u3)],\ [-\sin(u2),\ \cos(u2),\ 0],\ [\cos(u2)\cos(u3),\ \cos(u3)\sin(u2$$

The ‘scaling factors’ are:
linalg::ogCoordTab[Spherical,Scales](u1, u2, u3)[1, u1*sin(u3), u1]

$$[1,\ u1\ \sin(u3),\ u1]$$

There is the following relationship between the Jacobian of the transformation ‘u→‘ -> ‘x→‘$\vec{u} \to \vec{x}$ from the orthogonal coordinates to the cartesian coordinates:
xyz:= linalg::ogCoordTab[Spherical,Transformation](u1, u2, u3):
unitvectors:= linalg::ogCoordTab[Spherical, UnitVectors](u1, u2, u3): scales:= linalg::ogCoordTab[Spherical, Scales](u1, u2, u3):linalg::transpose(linalg::jacobian(xyz, [u1, u2, u3])) = matrix(3, 3, scales, Diagonal)* matrix(unitvectors)matrix([[cos(u2)*sin(u3), sin(u2)*sin(u3), cos(u3)], [-u1*sin(u2)*sin(u3), u1*cos(u2)*sin(u3), 0], [u1*cos(u2)*cos(u3), u1*cos(u3)*sin(u2), -u1*sin(u3)]]) = matrix([[cos(u2)*sin(u3), sin(u2)*sin(u3), cos(u3)], [-u1*sin(u2)*sin(u3), u1*cos(u2)*sin(u3), 0], [u1*cos(u2)*cos(u3), u1*cos(u3)*sin(u2), -u1*sin(u3)]])

$$\begin{pmatrix} \cos(u2)\sin(u3) & \sin(u2)\sin(u3) & \cos(u3) \\ -u1\sin(u2)\sin(u3) & u1\cos(u2)\sin(u3) & 0 \\ u1\cos(u2)\cos(u3) & u1\cos(u3)\sin(u2) & -u1\sin(u3) \end{pmatrix} = \begin{pmatrix} \cos(u2)\sin(u3) & \sin(u2)\sin(u3) & \\ -u1\sin(u2)\sin(u3) & u1\cos(u2)\sin(u3) & \\ u1\cos(u2)\cos(u3) & u1\cos(u3)\sin(u2) & - \end{pmatrix}$$

delete y, xyz, unitvectors, scales:

Example 2

The following call returns the cartesian vector ‘x→‘=[x, y, z]$\vec{x} = [x, y, z]$ in terms of elliptic cylindrical coordinates ‘u→‘=[u, v, w]$\vec{u} = [u, v, w]$ involving a parameter *c*:
linalg::ogCoordTab[EllipticCylindrical, Transformation](u, v, z, c)[c*cosh(u)*cos(v), c*sinh(u)*sin(v), z]

$$[c\cosh(u)\cos(v),\ c\sinh(u)\sin(v),\ z]$$

We compute the gradient of the function $f(u, v, w) = x(u, v, w)$ in elliptic cylindrical coordinates ‘u→‘=[u, v, w]$\vec{u} = [u, v, w]$.

f:= (c*cos(v)*cosh(u))^2:

For computing the components of the gradient with respect to an orthogonal system, it is sufficient to know the 'scale parameters': linalg::ogCoordTab[EllipticCylindrical, Scales](u, v, w, c)[c*sqrt(cosh(u)^2 - cos(v)^2), c*sqrt(cosh(u)^2 - cos(v)^2), 1]

$$\left[c\sqrt{\cosh(u)^2-\cos(v)^2},\ c\sqrt{\cosh(u)^2-\cos(v)^2},\ 1\right]$$

gradf := linalg::gradient(f, [u, v, w], %)matrix([[(2*c*cosh(u)*cos(v)^2*sinh(u))/sqrt(cosh(u)^2 - cos(v)^2)], [-(2*c*cosh(u)^2*cos(v)*sin(v))/sqrt(cosh(u)^2 - cos(v)^2)], [0]])

$$\begin{pmatrix} \frac{2\,c\cosh(u)\cos(v)^2\sinh(u)}{\sqrt{\cosh(u)^2-\cos(v)^2}} \\ -\frac{2\,c\cosh(u)^2\cos(v)\sin(v)}{\sqrt{\cosh(u)^2-\cos(v)^2}} \\ 0 \end{pmatrix}$$

These are the coefficients of the gradient with respect to the orthonormal basis 'e→'[u], 'e→'[v], 'e→'[w] $\vec{e}_u, \vec{e}_v, \vec{e}_w$ returned via the option `UnitVectors`:

[e_u, e_v, e_w] := linalg::ogCoordTab[EllipticCylindrical, UnitVectors](u, v, w, c)[[(cos(v)*sinh(u))/sqrt(cosh(u)^2 - cos(v)^2), (cosh(u)*sin(v))/sqrt(cosh(u)^2 - cos(v)^2), 0], [-(cosh(u)*sin(v))/sqrt(cosh(u)^2 - cos(v)^2), (cos(v)*sinh(u))/sqrt(cosh(u)^2 - cos(v)^2), 0], [0, 0, 1]]

$$\left[\left[\frac{\cos(v)\sinh(u)}{\sqrt{\cosh(u)^2-\cos(v)^2}},\ \frac{\cosh(u)\sin(v)}{\sqrt{\cosh(u)^2-\cos(v)^2}},\ 0\right],\left[-\frac{\cosh(u)\sin(v)}{\sqrt{\cosh(u)^2-\cos(v)^2}},\ \frac{\cos(v)\sinh(u)}{\sqrt{\cosh(u)^2-\cos(v)^2}},\ 0\right],[0,\ 0,\ 1]\right]$$

We convert the lists e_u, e_v, e_w into column vectors via matrix. Thus, in the standard basis of ^{3}, the gradient vector field is:

G := gradf[1]*matrix(e_u) + gradf[2]*matrix(e_v) + gradf[3]*matrix(e_w)matrix([[(2*c*cosh(u)*cos(v)^3*sinh(u)^2)/(cosh(u)^2

- cos(v)^2) + (2*c*cosh(u)^3*cos(v)*sin(v)^2)/(cosh(u)^2 - cos(v)^2)], [0], [0]])

$$\begin{pmatrix} \frac{2\,c\,\cosh(u)\,\cos(v)^3\,\sinh(u)^2}{\cosh(u)^2-\cos(v)^2} + \frac{2\,c\,\cosh(u)^3\,\cos(v)\,\sin(v)^2}{\cosh(u)^2-\cos(v)^2} \\ 0 \\ 0 \end{pmatrix}$$

matrix([[(2*c*cosh(u)*cos(v)^3*sinh(u)^2)/(cosh(u)^2 - cos(v)^2) + (2*c*cosh(u)^3*cos(v)*sin(v)^2)/(cosh(u)^2 - cos(v)^2)], [0], [0]])

$$\begin{pmatrix} \frac{2\,c\,\cosh(u)\,\cos(v)^3\,\sinh(u)^2}{\cosh(u)^2-\cos(v)^2} + \frac{2\,c\,\cosh(u)^3\,\cos(v)\,\sin(v)^2}{\cosh(u)^2-\cos(v)^2} \\ 0 \\ 0 \end{pmatrix}$$

matrix([[(2*c*cosh(u)*cos(v)^3*sinh(u)^2)/(cosh(u)^2 - cos(v)^2) + (2*c*cosh(u)^3*cos(v)*sin(v)^2)/(cosh(u)^2 - cos(v)^2)], [0], [0]])

$$\begin{pmatrix} \frac{2\,c\,\cosh(u)\,\cos(v)^3\,\sinh(u)^2}{\cosh(u)^2-\cos(v)^2} + \frac{2\,c\,\cosh(u)^3\,\cos(v)\,\sin(v)^2}{\cosh(u)^2-\cos(v)^2} \\ 0 \\ 0 \end{pmatrix}$$

We simplify this expression using the identities $sin^2(v) = 1 - cos^2(v)$, $sin(h)^2(u) = cos(h)^2(u) - 1$:
normal(subs(G, sin(v)^2 = 1 - cos(v)^2, sinh(u)^2 = cosh(u)^2 - 1))matrix([[2*c*cosh(u)*cos(v)], [0], [0]])

$$\begin{pmatrix} 2\,c\,\cosh(u)\,\cos(v) \\ 0 \\ 0 \end{pmatrix}$$

This is the gradient of the function $f(x, y, z) = x^2$ with x expressed by elliptic cylindrical coordinates:
G := linalg::gradient(x^2, [x, y, z])matrix([[2*x], [0], [0]])

$$\begin{pmatrix} 2\,x \\ 0 \\ 0 \end{pmatrix}$$

[x, y, z] := linalg::ogCoordTab[EllipticCylindrical, Transformation](u, v, w, c)[c*cosh(u)*cos(v), c*sinh(u)*sin(v), w]

$$[c\cosh(u)\cos(v),\ c\sinh(u)\sin(v),\ w]$$

map(G, eval)matrix([[2*c*cosh(u)*cos(v)], [0], [0]])

$$\begin{pmatrix} 2\,c\cosh(u)\cos(v) \\ 0 \\ 0 \end{pmatrix}$$

delete f, gradf, e_u, e_v, e_w, G, x, y, z:

Parameters

ogName

The name of a predefined coordinate system. The following 3 dimensional coordinate systems are available: `Cartesian`, `Spherical`, `Cylindrical`, `EllipticCylindrical`, `ParabolicCylindrical`, `RotationParabolic`, `Torus`.

u_1

u_2

u_3

The coordinates of the orthogonal system: identifiers, indexed identifiers, or arithmetical expressions.

x_1

x_2

x_3

Cartesian coordinates: identifiers, indexed identifiers, or arithmetical expressions.

c

An arithmetical expression. The default value is `c = 1`.

Options

Transformation

`linalg::ogCoordTab [ogName, Transformation]( u1, u2, u3 c )` returns a list of arithmetical expressions `[ x1( u1, u2, u3), x2( u1, u2, u3), x3( u1, u2, u3)]` defining the transformation from the orthogonal coordinates u_i to the cartesian coordinates x_j. The transformation is invertible if the coordinates u_i are from the range $a_i < u_i < b_i$ where `[a1..b1, a2..b2, a3..b3] = linalg::ogCoordTab [ogName, Ranges]( c )`.

InverseTransformation

`linalg::ogCoordTab [ogName, InverseTransformation]( x1, x2, x3 c )` returns a list of arithmetical expressions `[ u1( x1, x2, x3), u2( x1, x2, x3), u3( x1, x2, x3)]` defining the inverse transformation. The inverse transformation produces parameter values u_i in the range $a_i \le u_i \le b_i$ given by `[a1..b1, a2..b2, a3..b3] = linalg::ogCoordTab [ogName, Ranges]( c )`.

UnitVectors

`linalg::ogCoordTab [ogName, UnitVectors]( u1, u2, u3 c )` returns a list of orthonormal vectors [‘e→‘[1], ‘e→‘[2], ‘e→‘[3]][$\vec{e}_1, \vec{e}_2, \vec{e}_3$], where each vector is represented by a list of three arithmetical expressions. These vectors ‘e→‘[i]=(1)/(s[i])*diff(‘x→‘,u[i]) $\vec{e}_i = \frac{1}{s_i}\frac{\partial}{\partial u_i}\vec{x}$ with s[i]=abs(diff(‘x→‘,u[i])) $s_i = \left|\frac{\partial}{\partial u_i}\vec{x}\right|$ are the unit vectors tangent to the parameter lines u_i.

Scales

`linalg::ogCoordTab [ogName, Scales]( u1, u2, u3 c )` returns a list `[ s1, s2, s3]` of “scaling factors” of the transformation ‘u→‘ -> ‘x→‘ $\vec{u} \to \vec{x}$. The “scales” are the

Euclidean lengths s[i]=abs(diff(‘x→‘,u[i])) $s_i = \left|\frac{\partial}{\partial u_i}\vec{x}\right|$ of the vectors diff(‘x→‘,u[i]) $\frac{\partial}{\partial u_i}\vec{x}$ tangent to the parameter lines u_i.

Return Values

Most of the entries in `linalg::ogCoordTab` are functions:

`linalg::ogCoordTab [ogName, Transformation]( u1, u2, u3, c )` returns a list of arithmetical expressions `[ x1( u1, u2, u3), x2( u1, u2, u3), x3( u1, u2, u3)]` defining the transformation from the orthogonal coordinates u_i to the cartesian coordinates x_j.

`linalg::ogCoordTab [ogName, InverseTransformation]( x1, x2, x3, c )` returns a list of arithmetical expressions `[ u1( x1, x2, x3), u2( x1, x2, x3), u3( x1, x2, x3)]` defining the inverse transformation.

`linalg::ogCoordTab [ogName, UnitVectors]( u1, u2, u3, c )` returns a list of orthogonal unit “vectors.” The “vectors” are given as lists of arithmetical expressions.

`linalg::ogCoordTab [ogName, Scales]( u1, u2, u3, c )` returns a list of arithmetical expressions.

`linalg::ogCoordTab [ogName, Ranges]( c )` returns a list of ranges `[ a1.. b1, a2.. b2, a3.. b3]`. The transformation is invertible for parameter values $a_i < u_i < b_i$.

`linalg::ogCoordTab [ogName, Dimension]` yields the dimension of the space parametrized by the orthogonal coordinates. Presently, all predefined systems parametrize ^{3}, i.e., the dimension is 3 in all cases.

The call `linalg::ogCoordTab [ogName]( u1, u2, u3, c )` is identical to the call `linalg::ogCoordTab [ogName, UnitVectors]( u1, u2, u3, c )`.

linalg::curllinalg::divergencelinalg::gradientlinalg::hessianlinalg::jacobianlinalg::laplacian

linalg::orthog

Purpose

Orthogonalization of vectors

Syntax

```
linalg::orthog(S)
```

Description

`linalg::orthog(S)` orthogonalizes the vectors in *S* using the Gram-Schmidt orthogonalization algorithm.

The vectors in `S` are orthogonalized with respect to the scalar product linalg::scalarProduct.

If *O* is the returned set, then the vectors of *O* span the same subspace as the vectors in `S`, and they are pairwise orthogonal, i.e.: ‘v→’*‘w→’=0$\vec{v}\ \vec{w} = 0$ for all ‘v→’, ‘w→’ in O$\vec{v}, \vec{w} \in O$ with ‘v→’<>‘w→’$\vec{v} \neq \vec{w}$.

The vectors returned are not normalized. To normalize them use `map(O, linalg::normalize)`.

For an ordered set of orthogonal vectors, `S` should be a list.

The vectors in `S` must be defined over the same component ring.

The component ring of the vectors in `S` must be a field, i.e., a domain of category Cat::Field.

Examples

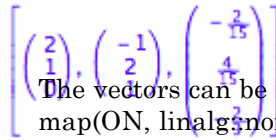
Example 1

The following list of vectors is a basis of the vector space ^{3}:
MatR := Dom::Matrix(Dom::Real): S := [MatR([2, 1, 0]), MatR([-3, 1, 1]), MatR([-1, -1, -1])][Dom::Matrix(Dom::Real)([[2], [1], [0]]), Dom::Matrix(Dom::Real)([[-3], [1], [1]]), Dom::Matrix(Dom::Real)([[-1], [-1], [-1]])]

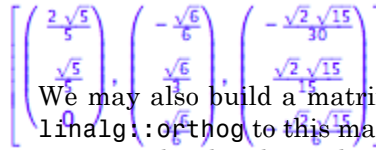
$$\left[\begin{pmatrix}2\\1\\0\end{pmatrix}, \begin{pmatrix}-3\\1\\1\end{pmatrix}, \begin{pmatrix}-1\\-1\\-1\end{pmatrix}\right]$$

The Gram-Schmidt algorithm then returns an orthogonal basis for ^{3}. We get an orthonormal basis with the following input:

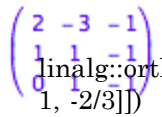
ON:= linalg::orthog(S)[Dom::Matrix(Dom::Real)([[2], [1], [0]]), Dom::Matrix(Dom::Real)([[-1], [2], [1]]), Dom::Matrix(Dom::Real)([[-2/15], [4/15], [-2/3]])]



The vectors can be normalized using linalg::normalize:
map(ON, linalg::normalize)[Dom::Matrix(Dom::Real)([[(2*sqrt(5))/5], [sqrt(5)/5], [0]]), Dom::Matrix(Dom::Real)([[-sqrt(6)/6], [sqrt(6)/3], [sqrt(6)/6]]), Dom::Matrix(Dom::Real)([[-(sqrt(2)*sqrt(15))/30], [(sqrt(2)*sqrt(15))/15], [-(sqrt(2)*sqrt(15))/6]])]



We may also build a matrix from the vectors in `S` an apply `linalg::orthog` to this matrix. The result is the matrix whose columns are given by the above elements of the list `ON`:
A:= S[1].S[2].S[3]Dom::Matrix(Dom::Real)([[2, -3, -1], [1, 1, -1], [0, 1, -1]])



linalg::orthog(A)Dom::Matrix(Dom::Real)([[2, -1, -2/15], [1, 2, 4/15], [0, 1, -2/3]])

$$\begin{pmatrix} 2 & -1 & -\frac{2}{15} \\ 1 & 2 & \frac{4}{15} \\ 0 & 1 & -\frac{4}{3} \end{pmatrix}$$

Example 2

The orthogonalization of the vectors:
T := {matrix([[-2, 5, 3]]), matrix([[0, 2, 1]])}{matrix([[0, 2, 1]]), matrix([[-2, 5, 3]])}

$$\{(0\ 2\ 1), (-2\ 5\ 3)\}$$

gives:
linalg::orthog(T){matrix([[0, 2, 1]]), matrix([[-2, -1/5, 2/5]])}

$$\{(0\ 2\ 1), (-2\ -\frac{1}{5}\ \frac{2}{5})\}$$

Example 3

The result of `linalg::orthog` is a list or set of linearly independent vectors, even if the input contains linearly dependent vectors:
MatQ := Dom::Matrix(Dom::Rational): S := [MatQ([2, 1]), MatQ([3, 4]), MatQ([-1, 1])][Dom::Matrix(Dom::Rational)([[2], [1]]), Dom::Matrix(Dom::Rational)([[3], [4]]), Dom::Matrix(Dom::Rational)([[-1], [1]])]

$$\left[\begin{pmatrix} 2 \\ 1 \end{pmatrix}, \begin{pmatrix} 3 \\ 4 \end{pmatrix}, \begin{pmatrix} -1 \\ 1 \end{pmatrix}\right]$$

linalg::orthog(S)[Dom::Matrix(Dom::Rational)([[2], [1]]), Dom::Matrix(Dom::Rational)([[-1], [2]])]

$$\left[\begin{pmatrix} 2 \\ 1 \end{pmatrix}, \begin{pmatrix} -1 \\ 2 \end{pmatrix}\right]$$

Parameters **s**

A set or list of vectors of the same dimension (a vector is an n 1 or 1 n matrix of a domain of category Cat::Matrix) or a matrix

Return Values Set or a list of vectors, respectively.

See Also linalg::factorQRlinalg::isUnitarylinalg::normalizelinalg::scalarProductlllintnorm

linalg::pascal

Purpose

Pascal matrix

Syntax

```
linalg::pascal(n, <R>)
```

Description

`linalg::pascal(n)` returns the n n Pascal matrix P given by

P[i,j]=binomial(i+j-2, i-1)$P_{i,j} = \binom{i+j-2}{i-1}$, $1 \le i, j \le n$.

The entries of Pascal matrices are integer numbers. Note, however, that the returned matrix is not defined over the component domain Dom::Integer, but over the standard component domain `Dom::ExpressionField()`. Thus, no conversion is necessary when working with other functions that expect or return matrices over that component domain.

Use `linalg::pascal(n, Dom::Integer)` to define the n n Pascal matrix over the ring of integer numbers.

Inverse Pascal matrices are provided by linalg::invpascal.

Examples

Example 1

We construct the 3 3 Pascal matrix:
linalg::pascal(3)matrix([[1, 1, 1], [1, 2, 3], [1, 3, 6]])

$$\begin{pmatrix} 1 & 1 & 1 \\ 1 & 2 & 3 \\ 1 & 3 & 6 \end{pmatrix}$$

This is a matrix of the domain `Dom::Matrix()`.

If you prefer a different component ring, the matrix may be converted to the desired domain after construction (see coerce, for example). Alternatively, one can specify the component ring when creating the Pascal matrix. For example, specification of the domain Dom::Float generates floating-point entries:
linalg::pascal(3, Dom::Float)Dom::Matrix(Dom::Float)([[1.0, 1.0, 1.0], [1.0, 2.0, 3.0], [1.0, 3.0, 6.0]])

$$\begin{pmatrix} 1.0 & 1.0 & 1.0 \\ 1.0 & 2.0 & 3.0 \\ 1.0 & 3.0 & 6.0 \end{pmatrix}$$

domtype(%)Dom::Matrix(Dom::Float)

Dom::Matrix(Dom::Float)

Example 2

The Cholesky factor of a Pascal matrix consists of the elements of Pascal's triangle:
linalg::factorCholesky(linalg::pascal(4))matrix([[1, 0, 0, 0], [1, 1, 0, 0], [1, 2, 1, 0], [1, 3, 3, 1]])

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 1 & 2 & 1 & 0 \\ 1 & 3 & 3 & 1 \end{pmatrix}$$

Parameters

n

The dimension of the matrix: a positive integer

R

The component ring: a domain of category Cat::Rng; default: Dom::ExpressionField()

Return Values

n *n* matrix of the domain Dom::Matrix(R).

Algorithms

Pascal matrices are symmetric and positive definite.

The determinant of a Pascal matrix is 1.

The inverse of a Pascal matrix has integer entries.

If λ is an eigenvalue of a Pascal matrix, then 1/Symbol::lambda$_1$ is also an eigenvalue of the matrix.

See Also linalg::hilbertlinalg::invhilbertlinalg::invpascallinalg::invvandermondelinalg::toeplitzlinalg::to

linalg::permanent

Purpose

Permanent of a matrix

Syntax

```
linalg::permanent(A)
```

Description

`linalg::permanent(A)` computes the permanent of the square matrix *A*.

The component ring of the matrix `A` must be a commutative ring, i.e., a domain of category Cat::CommutativeRing.

Examples

Example 1

We compute the permanent of the following matrix:
delete a11, a12, a21, a22: A := matrix([[a11, a12], [a21, a22]])matrix([[a11, a12], [a21, a22]])

$$\begin{pmatrix} a11 & a12 \\ a21 & a22 \end{pmatrix}$$

which gives us the general formula for the permanent of an arbitrary 2 2 matrix:
linalg::permanent(A)a11*a22 + a12*a21

$$a11\,a22 + a12\,a21$$

Example 2

The permanent of a matrix can be computed over arbitrary commutative rings. Let us create a random matrix defined over the ring $_6$, the integers modulo 6:
B := linalg::randomMatrix(5, 5, Dom::IntegerMod(6))Dom::Matrix(Dom::IntegerMod(6))([[3, 2, 3, -1, -2], [2, -1, 2, 1, 1], [1, 3, 3, 2, 2], [1, 0, 3, 3, -1], [0, 0, 0, 1, 3]])

$$\begin{pmatrix} 3 \bmod 6 & 2 \bmod 6 & 3 \bmod 6 & 5 \bmod 6 & 4 \bmod 6 \\ 2 \bmod 6 & 5 \bmod 6 & 2 \bmod 6 & 1 \bmod 6 & 1 \bmod 6 \\ 1 \bmod 6 & 3 \bmod 6 & 3 \bmod 6 & 2 \bmod 6 & 2 \bmod 6 \\ 1 \bmod 6 & 0 \bmod 6 & 3 \bmod 6 & 3 \bmod 6 & 5 \bmod 6 \\ 0 \bmod 6 & 1 \bmod 6 & 0 \bmod 6 & 1 \bmod 6 & 3 \bmod 6 \end{pmatrix}$$

The permanent of this matrix is:
linalg::permanent(B)4 mod 6

4 mod 6

Its determinant is:
linalg::det(B)0 mod 6

0 mod 6

Parameters

A

A square matrix of a domain of category Cat::Matrix

Return Values

Element of the component ring of A.

Algorithms

The permanent of an n n matrix $A = (a_{i,j})_{1 \le i \le n,\ 1 \le j \le n}$ is defined similary as the determinant of A, only the signs of the permutations do not enter the definition:

perm(A):=sum(product(a[(Symbol::sigma(j), j)], j=1..n), Symbol::sigma in S[n])

$$\mathrm{perm}(A) := \sum_{\sigma \in S_n} \prod_{j=1}^{n} a_{\sigma(j),\,j}$$

(S_n is the symmetric group of all permutations of {1, …, n}.)

In contrast to the computation of the determinant, the computation of the permanent takes time $O(n^2 2^n)$.

See Also linalg::det

linalg::potential

Purpose

The (scalar) potential of a gradient field

Syntax

```
linalg::potential(f, [x1, x2,  ], <[y1, y2,  ]>, <Test>)
```

Description

`linalg::potential(f, x)` determines whether the vector field 'f→'='f→'('x→') $\vec{f} = \vec{f}(\vec{x})$ is a gradient field 'f→'('x→')=grad(p('x→')) $\vec{f}(\vec{x}) = \mathrm{grad}(p(\vec{x}))$ of some scalar potential p with respect to the variables 'x→' $\vec{x}$, and computes that potential if it exists.

`linalg::potential` and potential are equivalent. See details and examples on the potential help page.

Parameters

f

The vector field: a list of arithmetical expressions, or a vector of such expressions. A vector is an n 1 or 1 n matrix of a domain of category Cat::Matrix.

x_1, x_2, ...

The variables: identifiers or indexed identifiers

y_1, y_2, ...

The components of the "base point:" arithmetical expressions. If a base point 'y→' $\vec{y}$ is specified, the returned potential p satisfies p('y→')=0 $p(\vec{y}) = 0$.

Options

Test

`linalg::potential` only checks whether the vector field has a potential and returns `TRUE` or `FALSE`, respectively.

Return Values

Arithmetical expression or a Boolean value.

linalg::pseudoInverse

Purpose

Moore-Penrose inverse of a matrix

Syntax

```
linalg::pseudoInverse(A)
```

Description

`linalg::pseudoInverse(A)` computes the Moore-Penrose inverse of *A*.

If the Moore-Penrose inverse of `A` does not exist, then `FAIL` is returned.

The component ring of the matrix `A` must be a field, i.e., a domain of category Cat::Field.

Examples

Example 1

The Moore-Penrose inverse of the 2 3 matrix:
A := Dom::Matrix(Dom::Complex)([[1, I, 3], [1, 3, 2]])Dom::Matrix(Dom::Complex)([[1, I, 3], [1, 3, 2]])

$$\begin{pmatrix} 1 & i & 3 \\ 1 & 3 & 2 \end{pmatrix}$$

is the 3 2 matrix:
Astar := linalg::pseudoInverse(A)Dom::Matrix(Dom::Complex)([[7/96 + (1/32)*I, 1/24 - (1/32)*I], [- 7/32 - (5/96)*I, 5/16 + (7/96)*I], [7/24 + (1/16)*I, 1/96 - (3/32)*I]])

$$\begin{pmatrix} \frac{7}{96} + \frac{1}{32} i & \frac{1}{24} - \frac{1}{32} i \\ -\frac{7}{32} - \frac{5}{96} i & \frac{5}{16} + \frac{7}{96} i \\ \frac{7}{24} + \frac{1}{16} i & \frac{1}{96} - \frac{3}{32} i \end{pmatrix}$$

Note that in this example, only:
A * AstarDom::Matrix(Dom::Complex)([[1, 0], [0, 1]])

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

yields the identity matrix, but not (see “Backgrounds” below):

```
Astar * ADom::Matrix(Dom::Complex)([[11/96, 3/32 - (1/48)*I, 29/96
+ (1/32)*I], [3/32 + (1/48)*I, 95/96, - 1/32 - (1/96)*I], [29/96 - (1/32)*I,
- 1/32 + (1/96)*I, 43/48]])
```

Parameters

A

A matrix of category Cat::Matrix

Return Values

Matrix of the same domain type as `A`, or the value `FAIL`.

Algorithms

For an invertible matrix A, the Moore-Penrose inverse A^* of A coincides with the inverse of A. In general, only $AA^*A = A$ and $A^*AA^* = A^*$ holds.

If A is of dimension m n, then A^* is of dimension n m.

The computation of the Moore-Penrose inverse requires the existence of a scalar product on the vector space K^n, where K is the coefficient field of the matrix A. This is only the case for some fields K in theory, but linalg::scalarProduct works also for vectors over other fields (e.g. finite fields). The computation of a Moore-Penrose inverse may fail in such cases.

_invert

linalg::randomMatrix

Purpose

Generate a random matrix

Syntax

```
linalg::randomMatrix(m, n, <R>, <bound>,
<Diagonal | Unimodular>)
```

Description

The call `linalg::randomMatrix(m, n)` returns a random m n matrix over the default component ring for matrices, i.e., over the domain `Dom::ExpressionField()`.

The matrix components are generated by the method `"random"` of the domain `R` (see “Example 2” on page 14-182).

The parameter `bound` is given as a parameter to the method `"random"` of the domain `R` in order to bound the size of the components of the random matrix. The correct type of `bound` is determined by the method `"random"`. The parameter has no effect if the slot `"random"` does not have a size argument.

Examples

Example 1

We create a random square matrix over the integers. Because the matrix is random the created matrix can vary:

```
linalg::randomMatrix(2,  2,
Dom::Integer)Dom::Matrix(Dom::Integer)([[824, -65], [-814, -741]])
```

$$\begin{pmatrix} 824 & -65 \\ -814 & -741 \end{pmatrix}$$

If you want to bound the size of its components, say between -2 and 2, enter:

```
linalg::randomMatrix(2,  2,  Dom::Integer,
-2..2)Dom::Matrix(Dom::Integer)([[-1, 1], [-2, 1]])
```

$$\begin{pmatrix} -1 & 1 \\ -2 & 1 \end{pmatrix}$$

Example 2

The following input creates a random vector over the component ring `Dom::FloatIV` of floating-point intervals. Because the vector is random the created vector can vary:

```
v := linalg::randomMatrix(1, 4,
Dom::FloatIV)Dom::Matrix(Dom::FloatIV)([[0.2703581655 ...
0.8310371789, 0.1531565159 ... 0.994812781, 0.1801642275 ...
0.2662729023, 0.4520830548 ... 0.6787819564]])
```

$$\left(\begin{array}{cccccc} 0.2703581654 \ldots 0.831037179 & 0.1531565158 \ldots 0.9948127811 & 0.1801642274 \ldots 0.2662729024 & 0 \end{array}\right)$$

```
domtype(v)Dom::Matrix(Dom::FloatIV)
```

$$\text{Dom::Matrix(Dom::FloatIV)}$$

The components of this matrix are random floating-point intervals created by the `"random"` method of the domain constructor Dom::FloatIV.

Example 3

To create a random diagonal matrix over the rationals we enter, for example:

```
linalg::randomMatrix(3, 3, Dom::Rational,
Diagonal)Dom::Matrix(Dom::Rational)([[229/220, 0, 0], [0, -535/617, 0],
[0, 0, -245/597]])
```

$$\begin{pmatrix} \frac{229}{220} & 0 & 0 \\ 0 & -\frac{535}{617} & 0 \\ 0 & 0 & -\frac{245}{597} \end{pmatrix}$$

Example 4

The following command creates a random unimodular matrix over the integers so that its determinant is either 1 or -1:

A := linalg::randomMatrix(3, 3, Dom::Integer, Unimodular)Dom::Matrix(Dom::Integer)([[-1, -8, 4], [4, 0, -5], [-3, 5, 2]])

$$\begin{pmatrix} -1 & -8 & 4 \\ 4 & 0 & -5 \\ -3 & 5 & 2 \end{pmatrix}$$

linalg::det(A)-1

$$-1$$

We can bound the size of the components. The following input returns a unimodular matrix $A = (a_{ij})$ with $|a_{ij}| \leq 2$ for $i, j = 1, 2, 3$:
A := linalg::randomMatrix(3, 3, 2, Unimodular)matrix([[0, -1, 0], [1, 0, 2], [1, 0, 1]])

$$\begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 2 \\ 1 & 0 & 1 \end{pmatrix}$$

Since we did not specifiy the component ring, the matrix is defined over the standard component ring for matrices (the domain `Dom::ExpressionField()`):
domtype(A)Dom::Matrix()

Dom::Matrix()

Parameters

m

n

Positive integers

R

The component ring, i.e., a domain of category Cat::Rng; default: Dom::ExpressionField()

bound

An arithmetical expression

Options

Diagonal

Creates a random *m n* diagonal matrix over `R`.

Unimodular

Creates a random *m m* unimodular matrix over `R`, so that its determinant is a unit in `R`.

Note Note that this option is only available for square matrices.

The norm of each component of the matrix returned does not exceed `bound`, which must be a positive integer, if specified. The default value of `bound` is 10.

Return Values

Matrix of the domain Dom::Matrix(`R`).

References

For generating random unimodular matrices, see Jürgen Hansen: *Generating Problems in Linear Algebra*, MapleTech, Volume 1, No.2, 1994.

Dom::Matrixrandom

linalg::rank

Purpose

Rank of a matrix

Syntax

```
linalg::rank(A)
linalg::rank(S)
```

Description

`linalg::rank(A)` computes the rank of the matrix *A*.

`linalg::rank(S)` computes the rank of the matrix whose columns are the vectors in *S*.

The row rank of a matrix is the maximal number of linearly independent row vectors of that matrix. The column rank of a matrix is the maximal number of linearly independent column vectors of that matrix. For each matrix, its row rank is equal to its column rank. This number is called the rank of a matrix.

The component ring of `A` or of the vectors given in `S` must be an integral domain (a domain of category Cat::IntegralDomain).

`linalg::rank` replaces symbolic elements of a matrix by random integer numbers between 1 and 10^{10}. Then the function computes the rank of the resulting numeric matrix by Gaussian elimination (see linalg::gaussElim). This approach introduces a tiny chance of getting a wrong result.

Note `linalg::rank` does not simplify special functions and algebraic numbers. For some matrices, this approach leads to wrong results. See "Example 3" on page 14-186.

Examples

Example 1

Define the following matrix `A` over :
MatZ := Dom::Matrix(Dom::Integer): A := MatZ([[1, 2, 3, 4], [-1, 0, 1, 0], [3, 5, 6, 9]])Dom::Matrix(Dom::Integer)([[1, 2, 3, 4], [-1, 0, 1, 0], [3, 5, 6, 9]])

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -1 & 0 & 1 & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

Compute the rank of the matrix A:
linalg::rank(A)3

3

Example 2

Use the three vectors matrix([0,1,1]), matrix([0,1,0]),

matrix([0,0,1]) $\begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}$, $\begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}$, $\begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}$ to define the columns of the matrix A.
Compute the rank of A:
MatZ := Dom::Matrix(Dom::Integer): S:= { MatZ([0,1,1]), MatZ([0,1,0]), MatZ([0,0,1]) }: linalg::rank(S)2

2

Example 3

The `linalg::rank` function does not use any simplification rules for special functions, algebraic numbers (radicals), and so on. If `linalg::rank` computes intermediate expressions that can be simplified to zero, the function can return incorrect results. For example, create the following matrices:
A := matrix([[exp(x + y), exp(x)], [exp(y), 1]]); B := matrix([[sin(x)^2 + cos(x)^2, 1], [1, 1]]); C := matrix([[sqrt(6), sqrt(2)], [sqrt(3), 1]])matrix([[exp(x + y), exp(x)], [exp(y), 1]])

$$\begin{pmatrix} e^{x+y} & e^{x} \\ e^{y} & 1 \end{pmatrix}$$

matrix([[cos(x)^2 + sin(x)^2, 1], [1, 1]])

$$\begin{pmatrix} \cos(x)^2 + \sin(x)^2 & 1 \end{pmatrix}$$

matrix([[sqrt(6), sqrt(2)], [sqrt(3), 1]])

$$\begin{pmatrix} \sqrt{6} & \sqrt{2} \\ \sqrt{3} & 1 \end{pmatrix}$$

There is only one independent row in each of these matrices. The rank of the matrices `A`, `B`, and `C` is 1. The `linalg::rank` function returns 2 because it does not simplify the expressions exp(x + y) - exp(x)*exp(y) $e^{x+y} - e^x e^y$, $sin^2 + cos^2$ - 1, and sqrt(2)*sqrt(3) - sqrt(6) $\sqrt{2}\sqrt{3} - \sqrt{6}$:
linalg::rank(A), linalg::rank(B), linalg::rank(C)2, 2, 2

2, 2, 2

Parameters

A

A matrix of a domain of category Cat::Matrix

S

A list or set of column vectors of the same dimension (a column vector is an n 1 matrix of a domain of category Cat::Matrix)

Return Values

Nonnegative integer

See Also

linalg::detlinalg::gaussElim

Related Examples

- “Compute Rank of a Matrix”

linalg::row

Purpose

Extract rows of a matrix

Syntax

```
linalg::row(A, r)
linalg::row(A, r1 .. r2)
linalg::row(A, list)
```

Description

`linalg::row(A, r)` extracts the *r*-th row vector of the matrix *A*.

`linalg::row(A, r1.. r2)` returns a list of row vectors whose indices are in the range `r1.. r2`. If `r2< r1` then the empty list `[]` is returned.

`linalg::row(A, list)` returns a list of row vectors whose indices are contained in `list` (in the same order).

Examples

Example 1

We define a matrix over :
A := Dom::Matrix(Dom::Rational)([[1, 1/5], [-3/2, 5], [2, -3]]
)Dom::Matrix(Dom::Rational)([[1, 1/5], [-3/2, 5], [2, -3]])

$$\begin{pmatrix} 1 & \frac{1}{5} \\ -\frac{3}{2} & 5 \\ 2 & -3 \end{pmatrix}$$

and illustrate the three different input formats for the function `linalg::row`:
linalg::row(A, 2)Dom::Matrix(Dom::Rational)([[-3/2, 5]])

$$\begin{pmatrix} -\frac{3}{2} & 5 \end{pmatrix}$$

linalg::row(A, [2, 1, 3])[Dom::Matrix(Dom::Rational)([[-3/2, 5]]), Dom::Matrix(Dom::Rational)([[1, 1/5]]), Dom::Matrix(Dom::Rational)([[2, -3]])]

$$\left[\begin{pmatrix} -\frac{3}{2} & 5 \end{pmatrix}, \begin{pmatrix} 1 & \frac{1}{5} \end{pmatrix}, \begin{pmatrix} 2 & -3 \end{pmatrix}\right]$$

```
linalg::row(A, 2..3)[Dom::Matrix(Dom::Rational)([[-3/2, 5]]),
Dom::Matrix(Dom::Rational)([[2, -3]])]
```

$$[(-\frac{3}{2}\ 5),(2\ -3)]$$

Parameters

A

An m n matrix of a domain of category Cat::Matrix

r

The row index: a positive integer less or equal to m

r_1 .. r_2

A range of row indices (positive integers less or equal to m)

list

A list of row indices (positive integers less or equal to m)

Return Values

Single row vector or a list of row vectors; a row vector is a 1 n matrix of category Cat::Matrix(R), where R is the component ring of A.

See Also

linalg::collinalg::delCollinalg::delRowlinalg::setCollinalg::setRow

linalg::scalarProduct

Purpose

Scalar product of vectors

Syntax

```
linalg::scalarProduct(u, v, <Real>)
```

Description

`linalg::scalarProduct(u, v)` computes the scalar product of the vectors ‘u→‘=fenced(u[1], Symbol::hellip, u[n]) $\vec{u} = (u_1, \ldots, u_n)$ and ‘v→‘=fenced(v[1], Symbol::hellip, v[n]) $\vec{v} = (v_1, \ldots, v_n)$ with respect to the standard basis, i.e., the sum u[1] * conjugate(v[1]) +Symbol::hellip+u[n] * conjugate(v[n]) $u_1\,\overline{v_1} + \ldots + u_n\,\overline{v_n}$.

The scalar product is also called “inner product” or “dot product”.

If the component ring of the vectors `u` and `v` does not define the entry `"conjugate"` or if the option `Real` is specified, then `linalg::scalarProduct` uses the definition $u_1 v_1 + \ldots + u_n v_n$ of the scalar product.

The vectors `u` and `v` must be defined over the same component ring.

`linalg::scalarProduct` can be redefined to a different scalar product. This also affects the behaviour of functions such as linalg::angle, linalg::factorQR, linalg::isUnitary, norm (for vectors and matrices), linalg::orthog and linalg::pseudoInverse depend on the definition of `linalg::scalarProduct`. See “Example 3” on page 14-191.

Environment Interactions

Properties of identifiers are taken into account.

Examples

Example 1

We compute the scalar product of the vectors (*i*, 1) and (1, - *i*): MatC := Dom::Matrix(Dom::Complex): u := MatC([I, 1]): v := MatC([1, -I]): linalg::scalarProduct(u, v)2*I

$$2\,i$$

Example 2

We compute the scalar product of the vectors ‘u→‘=fenced(u[1], u[2])$\vec{u} = (u_1, u_2)$ and ‘v→‘=fenced(v[1], v[2])$\vec{v} = (v_1, v_2)$ with the symbolic entries u_1, u_2, v_1, v_2 over the standard component ring for matrices:
delete u1, u2, v1, v2: u := matrix([u1, u2]): v := matrix([v1, v2]):
linalg::scalarProduct(u, v)u1*conjugate(v1) + u2*conjugate(v2)

$$u1\,\overline{v1} + u2\,\overline{v2}$$

You can use assume to tell the system that the symbolic components are to represent real numbers:
assume([u1, u2, v1, v2], Type::Real):

Then the scalar product of ‘u→‘$\vec{u}$ and ‘v→‘$\vec{v}$ simplifies to:
linalg::scalarProduct(u, v)u1*v1 + u2*v2

$$u1\,v1 + u2\,v2$$

Alternatively, the option `Real` can be specified:
unassume(u1, u2, v1, v2): linalg::scalarProduct(u, v, Real)u1*v1 + u2*v2

$$u1\,v1 + u2\,v2$$

Example 3

One particular scalar product in the real vector space of continuous functions on the interval [0, 1] is defined by

fenced(f, g)=int(f(t) * g(t), t=0..1)

$$(f, g) = \int_0^1 f(t)\,g(t)\,\mathrm{d}\,t$$

To compute an orthogonal basis corresponding to the polynomial basis 1, t, t^2, t^3, … with respect to this scalar product, we replace the standard scalar product by the following procedure:

```
standardScalarProduct := linalg::scalarProduct: unprotect(linalg):
linalg::scalarProduct := proc(u, v) local F, f, t; begin // (0) f := expr(u[1] *
v[1]); // (1) t := indets(f); if t = {} then t := genident("t") else t := op(t, 1)
end_if; // (2) F := int(f, t = 0..1); // (3) u::dom::coeffRing::coerce(F) end:
```

We start with step `(0)` to convert $f(t)g(t)$ to an expression of a basic domain type, such that the system function int in step `(2)` can handle its input (this is not necessary if the elements of the component ring of the vectors are already represented by elements of basic domains).

Step `(1)` extracts the indeterminate of the polynomials, step `(2)` computes the scalar product as defined above and step `(3)` converts the result back to an element of the component ring of vectors `u` and `v`.

Note that we need to unprotect the write protected identifier `linalg`, otherwise the assignment would lead to an error message.

We next create the matrix which consists of the first five of the above polynomials:

```
P := matrix([[1, t, t^2, t^3, t^4]])matrix([[1, t, t^2, t^3, t^4]])
```

$$\begin{pmatrix} 1 & t & t^2 & t^3 & t^4 \end{pmatrix}$$

If we now perform the Gram-Schmidt orthogonalization procedure on the columns of `P` with the function linalg::orthog, we get:

```
S := linalg::orthog(linalg::col(P, 1..4))[matrix([[1]]), matrix([[t - 1/2]]),
matrix([[t^2 - t + 1/6]]), matrix([[t^3 - (3*t^2)/2 + (3*t)/5 - 1/20]])]
```

$$\left[\begin{pmatrix} 1 \end{pmatrix}, \begin{pmatrix} t-\frac{1}{2} \end{pmatrix}, \begin{pmatrix} t^2-t+\frac{1}{6} \end{pmatrix}, \begin{pmatrix} t^3-\frac{3\,t^2}{2}+\frac{3\,t}{5}-\frac{1}{20} \end{pmatrix}\right]$$

Each vector in `S` is orthogonal to the other vectors in `S` with respect to the modified scalar product. We check this for the first vector:

```
linalg::scalarProduct(S[1], S[j]) $ j = 2..nops(S)0, 0, 0
```

$$0,\ 0,\ 0$$

Finally, we undo the redefinition of the scalar product, so as not to run into trouble with subsequent computations:

linalg::scalarProduct := standardScalarProduct: protect(linalg, Error):

Parameters

u

v

Vectors of the same dimension (a vector is an n 1 or 1 n matrix of a domain of category Cat::Matrix)

Options

Real

Use $u_1v_1 + \ldots + u_nv_n$ as the definition of the scalar product, i.e., suppress the use of conjugate.

Return Values

Element of the component ring of u and v.

See Also

linalg::anglelinalg::crossProductlinalg::isUnitarylinalg::factorQRlinalg::orthognorm

linalg::setCol

Purpose

Change a column of a matrix

Syntax

```
linalg::setCol(A, p, c)
```

Description

`linalg::setCol(A, p, c)` returns a copy of matrix A with the p-th column replaced by the column vector ‘c→’$\vec{c}$.

If `c` is a list with at most m elements, then `c` is converted into a column vector. An error message is returned if the conversion is not possible (e.g., if an element of the list cannot be converted into an object of the component ring of `A`; see “Example 2” on page 14-194).

Examples

Example 1

We define a matrix over the rationals:
MatQ := Dom::Matrix(Dom::Rational): A := MatQ([[1, 2], [3, 2]])Dom::Matrix(Dom::Rational)([[1, 2], [3, 2]])

$$\begin{pmatrix} 1 & 2 \\ 3 & 2 \end{pmatrix}$$

and replace the 2nd column by the 2 1 zero vector:
linalg::setCol(A, 2, MatQ([0, 0]))Dom::Matrix(Dom::Rational)([[1, 0], [3, 0]])

$$\begin{pmatrix} 1 & 0 \\ 3 & 0 \end{pmatrix}$$

Example 2

We create the 2 2 zero matrix over $_6$:
B := Dom::Matrix(Dom::IntegerMod(6))(2, 2)Dom::Matrix(Dom::IntegerMod(6))([[0, 0], [0, 0]])

$$\begin{pmatrix} 0 \bmod 6 & 0 \bmod 6 \\ 0 \bmod 6 & 0 \bmod 6 \end{pmatrix}$$

and replace the 2nd column by the vector matrix([[1], [-1]])$\begin{pmatrix} 1 \\ -1 \end{pmatrix}$. We give the column vector in form of a list. Its elements are converted implicitly into objects of the component ring of `B`:
linalg::setCol(B, 2, [1, -1])Dom::Matrix(Dom::IntegerMod(6))([[0, 1], [0, -1]])

$\begin{pmatrix} 0 \bmod 6 & 1 \bmod 6 \\ 0 \bmod 6 & 5 \bmod 6 \end{pmatrix}$

The following input leads to an error message because the number `1/3` can not be converted into an object of type `Dom::IntegerMod(6)`:
linalg::setCol(B, 1, [1/3, 0]) Error: The column vector is invalid. [linalg::setCol]

Parameters

A

An m n matrix of a domain of category Cat::Matrix

c

A column vector, or a list that can be converted into a column vector of the domain `Dom::Matrix(R)`, where `R` is the component ring of `A` (a column vector is an m 1 matrix)

Return Values

Matrix of the same domain type as `A`.

See Also

linalg::collinalg::delCollinalg::delRowlinalg::rowlinalg::setRow

linalg::setRow

Purpose

Change a row of a matrix

Syntax

```
linalg::setRow(A, p, r)
```

Description

`linalg::setRow(A, p, r)` returns a copy of the matrix A with the p-th row replaced by the row vector 'r→'$\vec{r}$.

If `r` is a list with at most n elements, then `r` is converted into a row vector. An error message is returned if the conversion is not possible (e.g., if an element of the list cannot be converted into an object of the component ring of `A`; see "Example 2" on page 14-196).

Examples

Example 1

We define a matrix over the rationals:
MatQ := Dom::Matrix(Dom::Rational): A := MatQ([[1, 2], [3, 2]])Dom::Matrix(Dom::Rational)([[1, 2], [3, 2]])

$$\begin{pmatrix} 1 & 2 \\ 3 & 2 \end{pmatrix}$$

and replace the 2nd row by the 1 2 zero vector:
linalg::setRow(A, 2, MatQ(1, 2, [0, 0]))Dom::Matrix(Dom::Rational)([[1, 2], [0, 0]])

$$\begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix}$$

Example 2

We create the 2 4 zero matrix over $_6$:
B := Dom::Matrix(Dom::IntegerMod(6))(2, 4)Dom::Matrix(Dom::IntegerMod(6))([[0, 0, 0, 0], [0, 0, 0, 0]])

$$\begin{pmatrix} 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 \\ 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 \end{pmatrix}$$

and replace the 2nd row by the vector (1, - 1, 1, - 1). We give the row vector in form of a list. Its elements are converted implicitly into objects of the component ring of `B`:
linalg::setRow(B, 2, [1, -1, 1, -1])Dom::Matrix(Dom::IntegerMod(6))([[0, 0, 0, 0], [1, -1, 1, -1]])

$$\begin{pmatrix} 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 \\ 1 \bmod 6 & 5 \bmod 6 & 1 \bmod 6 & 5 \bmod 6 \end{pmatrix}$$

The following input leads to an error message because the number $(1)/(3)$ can not be converted into an object of type `Dom::IntegerMod(6)`:
linalg::setRow(B, 1, [1/3, 0, 1, 0]) Error: The row vector is invalid. [linalg::setRow]

Parameters

A

An m n matrix of a domain of category Cat::Matrix

r

A row vector or a list that can be converted into a row vector the domain `Dom::Matrix(R)`, where `R` is the component ring of `A` (a row vector is a 1 n matrix)

Return Values

Matrix of the same domain type as `A`.

See Also

linalg::collinalg::delCollinalg::delRowlinalg::rowlinalg::setCol

linalg::smithForm

Purpose

Smith canonical form of a matrix

Syntax

```
linalg::smithForm(A)
```

Description

`linalg::smithForm(A)` computes the Smith canonical form of the n-dimensional square matrix A, i.e., an n n diagonal matrix S such that $S_{i-1,i-1}$ divides $S_{i,i}$ for $i = 2, \ldots, n$.

The Smith canonical form of a matrix `A` is unique.

The component ring of `A` must be a Euclidean ring, i.e., a domain of category Cat::EuclideanDomain.

Examples

Example 1

We define a matrix over the integers:

```
MatZ := Dom::Matrix(Dom::Integer): A := MatZ([[9, -36, 30], [-36, 192, -180], [30, -180, 180]])
```

Dom::Matrix(Dom::Integer)([[9, -36, 30], [-36, 192, -180], [30, -180, 180]])

$$\begin{pmatrix} 9 & -36 & 30 \\ -36 & 192 & -180 \\ 30 & -180 & 180 \end{pmatrix}$$

The Smith canonical form of `A` is then given by:

```
linalg::smithForm(A)
```

Dom::Matrix(Dom::Integer)([[3, 0, 0], [0, 12, 0], [0, 0, 60]])

$$\begin{pmatrix} 3 & 0 & 0 \\ 0 & 12 & 0 \\ 0 & 0 & 60 \end{pmatrix}$$

Example 2

We compute the Smith canonical form of a matrix over a ring of polynomials:

```
MatPoly := Dom::Matrix(Dom::DistributedPolynomial([x], Dom::Rational)):  B := MatPoly( [[-(x - 3)^2*(x - 2),(x -
```

3)*(x - 2)*(x - 4)], [(x - 3)*(x - 2)*(x - 4),-(x - 3)^2*(x - 4)]
])Dom::Matrix(Dom::DistributedPolynomial([x], Dom::Rational,
LexOrder))([[Dom::DistributedPolynomial([x], Dom::Rational,
LexOrder)(- 21*x + 8*x^2 - x^3 + 18), Dom::DistributedPolynomial([x],
Dom::Rational, LexOrder)(26*x - 9*x^2 + x^3 - 24)],
[Dom::DistributedPolynomial([x], Dom::Rational, LexOrder)(26*x -
9*x^2 + x^3 - 24), Dom::DistributedPolynomial([x], Dom::Rational,
LexOrder)(- 33*x + 10*x^2 - x^3 + 36)]])

$$\begin{pmatrix} -x^3+8x^2-21x+18 & x^3-9x^2+26x-24 \\ x^3-9x^2+26x-24 & -x^3+10x^2-33x+36 \end{pmatrix}$$

The Smith canonical form of the matrix `B` is the following matrix:
linalg::smithForm(B)Dom::Matrix(Dom::DistributedPolynomial([x],
Dom::Rational, LexOrder))([[Dom::DistributedPolynomial([x],
Dom::Rational, LexOrder)(x - 3), Dom::DistributedPolynomial([x],
Dom::Rational, LexOrder)(0)], [Dom::DistributedPolynomial([x],
Dom::Rational, LexOrder)(0), Dom::DistributedPolynomial([x],
Dom::Rational, LexOrder)(26*x - 9*x^2 + x^3 - 24)]])

$$\begin{pmatrix} x-3 & 0 \\ 0 & x^3-9x^2+26x-24 \end{pmatrix}$$

Parameters

A

A square matrix of a domain of category Cat::Matrix

Return Values

Matrix of the same domain type as `A`.

Algorithms

An n n matrix $S = (s_{ij})$ with coefficients in a Euclidean ring is said to be in Smith canonical form if S is a diagonal matrix (with nonnegative coefficients in case of the ring) such that $s_{i,\,i}$ divides $s_{i+1,\,i+1}$ for all $i < n$.

See Also linalg::frobeniusFormlinalg::hermiteFormlinalg::jordanForm

linalg::sqrtMatrix

Purpose

Square root of a matrix

Syntax

```
linalg::sqrtMatrix(A, <sqrtfunc>)
```

Description

`linalg::sqrtMatrix(A)` returns the square root of the matrix *A*.

The matrix *A* must have a Jordan canonical form (see also linalg::jordanForm for the computation of the Jordan canonical form in MuPAD). Furthermore, *A* must not have eigenvalue 0 of geometric multiplicity higher than 1 (in this situation the square root of *A* cannot be computed).

Examples

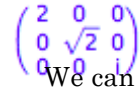
Example 1

A square root of a diagonal matrix is given by the diagonal matrix, whose diagonal entries are just the square roots of the original matrix.

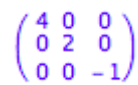
We compute the square root of the matrix

A=matrix([[4, 0, 0], [0, 2, 0], [0, 0, -1]])

A := matrix([[4, 0, 0], [0, 2, 0], [0, 0, -1]]): S := linalg::sqrtMatrix(A)matrix([[2, 0, 0], [0, sqrt(2), 0], [0, 0, I]])



We can easily check the correctness of the result:
S^2matrix([[4, 0, 0], [0, 2, 0], [0, 0, -1]])



Example 2

We compute the square root of the matrix

A=matrix([[2, -2, 0], [-1, 3, 0], [-1/3, 5/3, 2]])

$$A := \begin{pmatrix} 2 & -2 & 0 \\ -1 & 3 & 0 \\ -\frac{1}{3} & \frac{5}{3} & 2 \end{pmatrix}$$

A := matrix([[2, -2, 0], [-1, 3, 0], [-1/3, 5/3, 2]]): S := linalg::sqrtMatrix(A)matrix([[4/3, -2/3, 0], [-1/3, 5/3, 0], [(2*sqrt(2))/3 - 1, 1 - sqrt(2)/3, sqrt(2)]])

$$\begin{pmatrix} \frac{4}{3} & -\frac{2}{3} & 0 \\ -\frac{1}{3} & \frac{5}{3} & 0 \\ \frac{2\sqrt{2}}{3} - 1 & 1 - \frac{\sqrt{2}}{3} & \sqrt{2} \end{pmatrix}$$

If we compute the square of the matrix `S` and simplify the result, we obtain the matrix `A`:

simplify(S^2)matrix([[2, -2, 0], [-1, 3, 0], [-1/3, 5/3, 2]])

$$\begin{pmatrix} 2 & -2 & 0 \\ -1 & 3 & 0 \\ -\frac{1}{3} & \frac{5}{3} & 2 \end{pmatrix}$$

Using the function `x -> -sqrt(x)` as second argument for the computation of the square root of the matrix `A`, we obtain a different matrix, whose components are just the negative components of the original square root computed above:

S:= linalg::sqrtMatrix(A, x -> -sqrt(x)): S, simplify(S^2);matrix([[-4/3, 2/3, 0], [1/3, -5/3, 0], [1 - (2*sqrt(2))/3, sqrt(2)/3 - 1, -sqrt(2)]]), matrix([[2, -2, 0], [-1, 3, 0], [-1/3, 5/3, 2]])

Parameters

$$\left(\begin{array}{ccc} -\frac{4}{3} & \frac{2}{3} & 0 \\ \frac{1}{3} & -\frac{5}{3} & 0 \\ -\frac{2\sqrt{2}}{3} & \frac{\sqrt{2}}{3}-1 & -\sqrt{2} \end{array}\right), \left(\begin{array}{ccc} 2 & -2 & 0 \\ -1 & 3 & 0 \\ -\frac{1}{3} & \frac{5}{3} & 2 \end{array}\right)$$

A

A square matrix of a domain of category Cat::Matrix

sqrtfunc

A function satisfying $sqrtfunc(a)^2 = a$ for every element a of the coefficient ring of A (i.e. the square root function of the coefficient domain of A).

Return Values

Matrix B with $B^2 = A$ such that the eigenvalues of B are the square roots of the eigenvalues of A or FAIL if the square root of the matrix does not exist

See Also

linalg::eigenvalueslinalg::eigenvectorslinalg::jordanFormnumeric::eigenvaluesnumeric::ei

linalg::stackMatrix

Purpose

Join matrices vertically

Syntax

```
linalg::stackMatrix(A, <B_1, B_2,  >)
```

Description

`linalg::stackMatrix(A, B_1, B_2, ...)` returns the matrix formed by joining the matrices `A, B_1, B_2, ...` vertically.

The matrices `B_1, B_2, ...` are converted into the matrix domain `Dom::Matrix(R)`, where `R` is the component ring of `A`.

An error message is raised if one of these conversions fails, or if the matrices do not have the same number of columns as the matrix `A`.

Examples

Example 1

We define a matrix:
A:= matrix([[sin(x),x], [-x,cos(x)]])matrix([[sin(x), x], [-x, cos(x)]])

$$\begin{pmatrix} \sin(x) & x \\ -x & \cos(x) \end{pmatrix}$$

and append the 2 2 identity matrix to the lower end of the matrix `A`:
linalg::stackMatrix(A, matrix::identity(2))matrix([[sin(x), x], [-x, cos(x)], [1, 0], [0, 1]])

$$\begin{pmatrix} \sin(x) & x \\ -x & \cos(x) \\ 1 & 0 \\ 0 & 1 \end{pmatrix}$$

Example 2

We define a matrix from the ring of 2 2 square matrices:
SqMatQ := Dom::SquareMatrix(2,Dom::Rational): A := SqMatQ([[1, 2], [3, 4]])Dom::SquareMatrix(2, Dom::Rational)([[1, 2], [3, 4]])

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$$

Note that the following operation:
AA := linalg::stackMatrix(A, A)Dom::Matrix(Dom::Rational)([[1, 2], [3, 4], [1, 2], [3, 4]])

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \\ 1 & 2 \\ 3 & 4 \end{pmatrix}$$

returns a matrix of a different domain type as the input matrix:
domtype(AA)Dom::Matrix(Dom::Rational)

Dom::Matrix(Dom::Rational)

Parameters

A, <B_1, B_2, ...>

Matrices of a domain of category Cat::Matrix

Return Values

Matrix of the domain type Dom::Matrix(R), where R is the component ring of A.

See Also

linalg::concatMatrix

linalg::submatrix

Purpose

Extract a submatrix or a subvector from a matrix or a vector, respectively

Syntax

```
linalg::submatrix(A, r1 .. r2, c1 .. c2)
linalg::submatrix(A, rlist, clist)
linalg::submatrix(v, i1 .. i2)
linalg::submatrix(v, list)
```

Description

`linalg::submatrix(A, r1.. r2, c1.. c2)` returns a copy of the submatrix of the matrix A obtained by selecting the rows r_1, $r_1 + 1$, ..., r_2 and the columns c_1, $c_1 + 1$, ..., c_2.

`linalg::submatrix(v, i1.. i2)` returns a copy of the subvector of the vector 'v→' obtained by selecting the components with indices i_1, $i_1 + 1$, ..., i_2.

The index notation `A[ r1.. r2, c1.. c2]` and `v[ i1.. i2]`, respectively, can be used instead of `linalg::submatrix(A, r1.. r2, c1.. c2)` and `linalg::submatrix(v, i1.. i2)`.

`linalg::submatrix(A,rlist,clist)` returns the submatrix of the matrix `A` whose (i, j)-th component is $a_{rlist_i,\ clist_j}$.

`linalg::submatrix(v,list)` returns the subvector of the vector `v` whose i-th component is v_{list_i}.

If `v` is a row vector or a column vector, then `linalg::submatrix(v, 1..1, i1.. i2)` and `linalg::submatrix(v, i1.. i2, 1..1)`, respectively, are valid inputs, and they both are equivalent to the call `linalg::submatrix(v, i1.. i2)`.

Examples

Example 1

We define the following matrix:
A := matrix([[1, x, 0], [0, x^2, 1]])matrix([[1, x, 0], [0, x^2, 1]])

$$\begin{pmatrix} 1 & x & 0 \\ 0 & x^2 & 1 \end{pmatrix}$$

The submatrix $(a_{1,j})_{1 \le j \le 2}$ of A is given by:
linalg::submatrix(A, 1..1, 1..2)matrix([[1, x]])

$$\begin{pmatrix} 1 & x \end{pmatrix}$$

Equivalent to the use of the index operator we obtain:
A[1..1, 1..2]matrix([[1, x]])

$$\begin{pmatrix} 1 & x \end{pmatrix}$$

We extract the first and the third column of A and get the 2 2 identity matrix:
linalg::submatrix(A, [1, 2], [1, 3])matrix([[1, 0], [0, 1]])

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

Example 2

Vector components can be accessed by a single index or a range of indices. For example, to extract the first two components of the following vector:
v := matrix([1, 2, 3])matrix([[1], [2], [3]])

$$\begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix}$$

just enter the command:
v[1..2]matrix([[1], [2]])

$$\begin{pmatrix} 1 \\ 2 \end{pmatrix}$$

Of course, the same subvector can be extracted with the command `linalg::submatrix(v, 1..2)`.

The following input returns the vector comprising the first and the third component of `v`:
linalg::submatrix(v, [1, 3])matrix([[1], [3]])

$$\begin{pmatrix} 1 \\ 3 \end{pmatrix}$$

Parameters

`A`

An m n matrix of a domain of category Cat::Matrix

`v`

A vector with k components, i.e., a k 1 or 1 k matrix of a domain of category Cat::Matrix

r_1 .. r_2

c_1 .. c_2

Ranges of row/column indices: positive integers less or equal to m and n, respectively

`rlist`

`clist`

Lists of row/column indices: positive integers less or equal to m and n, respectively

i_1 .. i_2

A range of vector indices: positive integers less or equal to k

`list`

A list of vector indices: positive integers less or equal to k

Return Values

Matrix of the same domain type as `A` or a vector of the same domain type as `v`, respectively.

See Also linalg::collinalg::rowlinalg::substitute

linalg::substitute

Purpose

Replace a part of a matrix by another matrix

Syntax

```
linalg::substitute(B, A, m, n)
```

Description

`linalg::substitute(B, A, m, n)` returns a copy of the matrix `B`, where entries starting at position [m, n] are replaced by the entries of the matrix `A`, i.e., B_{mn} is A_{11}.

If the matrices are defined over different component domains, then the entries of `A` are converted into elements of the component domain of the matrix `B`. If one of these conversions fails, then an error message is returned.

Examples

Example 1

We define the following matrix:
B := matrix([[1, 2, 3, 4], [5, 6, 7, 8], [9, 10, 11, 12], [13, 14, 15, 16]])matrix([[1, 2, 3, 4], [5, 6, 7, 8], [9, 10, 11, 12], [13, 14, 15, 16]])

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 9 & 10 & 11 & 12 \\ 13 & 14 & 15 & 16 \end{pmatrix}$$

and copy the 2 2 zero matrix into the matrix `B`, beginning at position [3, 3]:
A := matrix(2, 2): linalg::substitute(B, A, 3, 3)matrix([[1, 2, 3, 4], [5, 6, 7, 8], [9, 10, 0, 0], [13, 14, 0, 0]])

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 9 & 10 & 0 & 0 \\ 13 & 14 & 0 & 0 \end{pmatrix}$$

Matrix entries out of range are ignored:
linalg::substitute(B, A, 4, 4)matrix([[1, 2, 3, 4], [5, 6, 7, 8], [9, 10, 11, 12], [13, 14, 15, 0]])

Parameters

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 9 & 10 & 11 & 12 \\ 13 & 14 & 15 & 0 \end{pmatrix}$$

A

B

Matrices of a domain of category Cat::Matrix

m

n

Positive integers

Return Values

Matrix of the same domain type as `B`.

See Also

linalg::submatrixlinalg::concatMatrixlinalg::setCollinalg::setRowlinalg::stackMatrix

linalg::sumBasis

Purpose

Basis for the sum of vector spaces

Syntax

`linalg::sumBasis(`S_1`, `S_2`, )`

Description

`linalg::sumBasis( `S_1`, `S_2`, ...)` returns a basis of the vector space $V_1 + V_2 + \ldots$, where V_i denotes the vector space spanned by the vectors in S_i.

To obtain an ordered basis, S_1, S_2, ... should be given as lists of vectors.

A basis of the zero-dimensional space is the empty set or list, respectively.

The given vectors must be defined over the same component ring, which must be a field, i.e., a domain of category Cat::Field.

Examples

Example 1

We define three vectors ‘v→‘[1], ‘v→‘[2], ‘v→‘[3]$\vec{v}_1, \vec{v}_2, \vec{v}_3$ over :
MatQ := Dom::Matrix(Dom::Rational): v1 := MatQ([[3, -2]]); v2 := MatQ([[1, 0]]); v3 := MatQ([[5, -3]])Dom::Matrix(Dom::Rational)([[3, -2]])

```
(3 -2)
```

Dom::Matrix(Dom::Rational)([[1, 0]])

```
(1 0)
```

Dom::Matrix(Dom::Rational)([[5, -3]])

```
(5 -3)
```

A basis of the vector space $V_1 + V_2 + V_3$ with

- V_1 generated by ‘v→‘[1],‘v→‘[2],‘v→‘[3]$\vec{v}_1, \vec{v}_2, \vec{v}_3$

- V_2 generated by ‘v→‘[1],‘v→‘[3] $\vec{v}_1, \vec{v}_3$
- V_3 generated by ‘v→‘[1]+‘v→‘[2],‘v→‘[2],‘v→‘[1]+‘v→‘[3] $\vec{v}_1 + \vec{v}_2, \vec{v}_2, \vec{v}_1 + \vec{v}_3$

is:
linalg::sumBasis([v1, v2, v3], [v1, v3], [v1 + v2, v2, v1 + v3])[Dom::Matrix(Dom::Rational)([[3, -2]]), Dom::Matrix(Dom::Rational)([[1, 0]])]

$$[(3\ \ -2), (1\ \ 0)]$$

Example 2

The following set of two vectors:
MatQ := Dom::Matrix(Dom::Rational): S1 := {MatQ([1, 2, 3]), MatQ([-1, 0, 2])}{Dom::Matrix(Dom::Rational)([[-1], [0], [2]]), Dom::Matrix(Dom::Rational)([[1], [2], [3]])}

$$\left\{\begin{pmatrix} -1 \\ 0 \\ 2 \end{pmatrix}, \begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix}\right\}$$

is a basis of a two-dimensional subspace of ^{3}:
linalg::rank(S1)2

$$2$$

The same holds for the following set:
S2 := {MatQ([0, 2, 3]), MatQ([2, 4, 6])};
linalg::rank(S2){Dom::Matrix(Dom::Rational)([[0], [2], [3]]), Dom::Matrix(Dom::Rational)([[2], [4], [6]])}

$$\left\{\begin{pmatrix} 0 \\ 2 \\ 3 \end{pmatrix}, \begin{pmatrix} 2 \\ 4 \\ 6 \end{pmatrix}\right\}$$

2

2

The sum of the corresponding two subspaces is the vector space ^{3}:
Q3 := linalg::sumBasis(S1, S2){Dom::Matrix(Dom::Rational)([[-1], [0], [2]]), Dom::Matrix(Dom::Rational)([[0], [2], [3]]), Dom::Matrix(Dom::Rational)([[1], [2], [3]])}

$$\left\{\begin{pmatrix}-1\\0\\2\end{pmatrix}, \begin{pmatrix}0\\2\\3\end{pmatrix}, \begin{pmatrix}1\\2\\3\end{pmatrix}\right\}$$

Parameters

S_1, S_2, ...

A set or list of vectors of the same dimension (a vector is a n 1 or 1 n matrix of a domain of category Cat::Matrix)

Return Values

Set or a list of vectors, according to the domain type of the parameter S_1.

See Also

linalg::basislinalg::intBasislinalg::rank

linalg::swapCol

Purpose

Swap two columns in a matrix

Syntax

```
linalg::swapCol(A, c1, c2)
linalg::swapCol(A, c1, c2, r1 .. r2)
```

Description

`linalg::swapCol(A, c1, c2)` returns a copy of the matrix *A* with the columns with indices `c1` and `c2` interchanged.

The effect of `linalg::swapCol(A, c1, c2, r1.. r2)` is that only the components from row `r1` to row `r2` of column `c1` are interchanged with the corresponding components of column `c2`.

Examples

Example 1

We consider the following matrix:
A := matrix(3, 3, (i, j) -> 3*(i - 1) + j)matrix([[1, 2, 3], [4, 5, 6], [7, 8, 9]])

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

The following command interchanges the first and the second column of `A`. The result is the following matrix:
linalg::swapCol(A, 1, 2)matrix([[2, 1, 3], [5, 4, 6], [8, 7, 9]])

$$\begin{pmatrix} 2 & 1 & 3 \\ 5 & 4 & 6 \\ 8 & 7 & 9 \end{pmatrix}$$

If only the components in the first two rows should be affected, we enter:
linalg::swapCol(A, 1, 2, 1..2)matrix([[2, 1, 3], [5, 4, 6], [7, 8, 9]])

$$\begin{pmatrix} 2 & 1 & 3 \\ 5 & 4 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

The third row remains unchanged.

Parameters

A

An m n matrix of a domain of category Cat::Matrix

c_1

c_2

The column indices: positive integers less or equal to n

r_1 .. r_2

A range of row indices (positive integers less or equal to m)

Return Values

Matrix of the same domain type as A.

See Also

linalg::collinalg::delCollinalg::delRowlinalg::rowlinalg::setCollinalg::setRowlinalg::swapRow

Concepts

- "Swap and Delete Rows and Columns"

linalg::swapRow

Purpose

Swap two rows in a matrix

Syntax

```
linalg::swapRow(A, r1, r2)
linalg::swapRow(A, r1, r2, c1 .. c2)
```

Description

`linalg::swapRow(A, r1, r2)` returns a copy of the matrix *A* with the rows with indices r_1 and r_2 interchanged.

The effect of `linalg::swapRow(A, r1, r2, c1.. c2)` is that only the components from column c_1 to column c_2 of row r_1 are interchanged with the corresponding components of row r_2.

Examples

Example 1

We consider the following matrix:
A := matrix(3, 3, (i, j) -> 3*(i - 1) + j)matrix([[1, 2, 3], [4, 5, 6], [7, 8, 9]])

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

The following command interchanges the first and the second row of `A`. The result is the following matrix:
linalg::swapRow(A, 1, 2)matrix([[4, 5, 6], [1, 2, 3], [7, 8, 9]])

$$\begin{pmatrix} 4 & 5 & 6 \\ 1 & 2 & 3 \\ 7 & 8 & 9 \end{pmatrix}$$

If only the components in the first two columns should be affected, we enter:
linalg::swapRow(A, 1, 2, 1..2)matrix([[4, 5, 3], [1, 2, 6], [7, 8, 9]])

$$\begin{pmatrix} 4 & 5 & 3 \\ 1 & 2 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

The third column remains unchanged.

Parameters

A

An m n matrix of a domain of category Cat::Matrix

r_1

r_2

The row indices: positive integers less or equal to m

c_1 .. c_2

A range of column indices (positive integers less or equal to n)

Return Values

Matrix of the same domain type as A.

linalg::sylvester

Purpose

Sylvester matrix of two polynomials

Syntax

```
linalg::sylvester(p, q)
linalg::sylvester(f, g, x)
```

Description

`linalg::sylvester(p, q)` returns the Sylvester matrix of the two polynomials p and q.

If no variable is specified, then the polynomials `p` and `q` must be either of the domain `DOM_POLY` or from a domain of category Cat::Polynomial. Polynomial expressions are not allowed.

If the polynomials `p` and `q` are of the domain `DOM_POLY`, then they must be univariate polynomials. The component ring of the Sylvester matrix is the common coefficient ring R of `p` and `q`, except in the following two cases for built-in coefficient rings: If R is `Expr` then the domain Dom::ExpressionField() is the component ring of the Sylvester matrix. If R is `IntMod(m)`, then the Sylvester matrix is defined over the ring Dom::IntegerMod(m) (see "Example 2" on page 14-220).

Otherwise, if the polynomials `p` and `q` are from a domain of category `Cat::Polynomial`, then the Sylvester matrix is computed with respect to the main variable of `p` and `q` (see the method `"mainvar"` of the category Cat::Polynomial). In the case of univariate polynomials the Sylvester matrix is defined over the common coefficient ring of `p` and `q`. In the case of multivariate polynomials, the Sylvester matrix is defined over the component ring Dom::DistributedPolynomial(ind, R), where `ind` is the list of all variables of `p` and `q` except `x`, and `R` is the common coefficient ring of the polynomials.

If `f` and `g` are polynomial expressions or multivariate polynomials of type `DOM_POLY`, then you must specifiy the variable `x`.

In the case of polynomial expressions, the component ring of the Sylvester matrix is the domain `Dom::ExpressionField()` (see "Example 3" on page 14-221).

In the case of multivariate polynomials the Sylvester matrix is defined over the component ring `Dom::DistributedPolynomial(ind, R)`, where `ind` is the list of all variables of `f` and `g` except `x`, and `R` is the common coefficient ring of the polynomials (see “Example 4” on page 14-221).

At least one of the input polynomials must have positive degree with respect to the main variable or `x`, respectively, but it is not necessary that both of them have positive degree.

Examples

Example 1

The Sylvester matrix of the two polynomials $p = x^2 + 2x - 1$ and $q = x^4 + 1$ over is the following 6 6 matrix:
delete x: Z := Dom::Integer: S := linalg::sylvester(poly(x^2 + 2*x - 1, Z), poly(x^4 + 1, Z))Dom::Matrix(Dom::Integer)([[1, 2, -1, 0, 0, 0], [0, 1, 2, -1, 0, 0], [0, 0, 1, 2, -1, 0], [0, 0, 0, 1, 2, -1], [1, 0, 0, 0, 1, 0], [0, 1, 0, 0, 0, 1]])

$$\begin{pmatrix} 1 & 2 & -1 & 0 & 0 & 0 \\ 0 & 1 & 2 & -1 & 0 & 0 \\ 0 & 0 & 1 & 2 & -1 & 0 \\ 0 & 0 & 0 & 1 & 2 & -1 \\ 1 & 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 & 1 \end{pmatrix}$$

Example 2

If the polynomials have the built-in coefficient ring `IntMod(m)`, then the Sylvester matrix is defined over the domain Dom::IntegerMod(m):
delete x: S:= linalg::sylvester(poly(x + 1, IntMod(7)), poly(x^2 - 2*x + 2, IntMod(7)))Dom::Matrix(Dom::IntegerMod(7))([[1, 1, 0], [0, 1, 1], [1, -2, 2]])

$$\begin{pmatrix} 1 \bmod 7 & 1 \bmod 7 & 0 \bmod 7 \\ 0 \bmod 7 & 1 \bmod 7 & 1 \bmod 7 \\ 1 \bmod 7 & 5 \bmod 7 & 2 \bmod 7 \end{pmatrix}$$

domtype(S)Dom::Matrix(Dom::IntegerMod(7))

```
Dom::Matrix(Dom::IntegerMod(7))
```

Example 3

The Sylvester matrix of the following two polynomial expressions with respect to the variable x is:

```
delete x, y: S := linalg::sylvester(x + y^2, 2*x^3 - 1, x)matrix([[1, y^2, 0, 0], [0, 1, y^2, 0], [0, 0, 1, y^2], [2, 0, 0, -1]])
```

$$\begin{pmatrix} 1 & y^2 & 0 & 0 \\ 0 & 1 & y^2 & 0 \\ 0 & 0 & 1 & y^2 \\ 2 & 0 & 0 & -1 \end{pmatrix}$$

```
domtype(S)Dom::Matrix()
```

```
Dom::Matrix()
```

The Sylvester matrix of these two polynomials with respect to y is the following 2 2 matrix:

```
linalg::sylvester(x + y^2, 2*x^3 - 1, y)matrix([[2*x^3 - 1, 0], [0, 2*x^3 - 1]])
```

$$\begin{pmatrix} 2x^3 - 1 & 0 \\ 0 & 2x^3 - 1 \end{pmatrix}$$

Example 4

Here is an example for computing the Sylvester matrix of multivariate polynomials:

```
delete x, y: Q := Dom::Rational: T := linalg::sylvester(poly(x^2 - x + y, Q), poly(x + 2, Q), x)Dom::Matrix(Dom::DistributedPolynomial([y], Dom::Rational, LexOrder))([[Dom::DistributedPolynomial([y], Dom::Rational, LexOrder)(1), Dom::DistributedPolynomial([y], Dom::Rational, LexOrder)(-1), Dom::DistributedPolynomial([y],
```

Dom::Rational, LexOrder)(y)], [Dom::DistributedPolynomial([y], Dom::Rational, LexOrder)(1), Dom::DistributedPolynomial([y], Dom::Rational, LexOrder)(2), Dom::DistributedPolynomial([y], Dom::Rational, LexOrder)(0)], [Dom::DistributedPolynomial([y], Dom::Rational, LexOrder)(0), Dom::DistributedPolynomial([y], Dom::Rational, LexOrder)(1), Dom::DistributedPolynomial([y], Dom::Rational, LexOrder)(2)]])

$$\begin{pmatrix} 1 & -1 & y \\ 1 & 2 & 0 \\ 0 & 1 & 2 \end{pmatrix}$$

domtype(T)Dom::Matrix(Dom::DistributedPolynomial([y], Dom::Rational, LexOrder))

Dom::Matrix(Dom::DistributedPolynomial([y], Dom::Rational, LexOrder))

The Sylvester matrix of these two multivariate polynomials with respect to y is:
linalg::sylvester(poly(x^2 - x + y, Q), poly(x + 2, Q), y)Dom::Matrix(Dom::DistributedPolynomial([x], Dom::Rational, LexOrder))([[Dom::DistributedPolynomial([x], Dom::Rational, LexOrder)(x + 2)]])

$$(x+2)$$

Parameters

p

q

Polynomials

f

g

Polynomials or polynomial expressions of positive degree

x

A variable

Return Values Matrix of the domain Dom::Matrix(R), where R is the coefficient domain of the polynomials (see below).

See Also polylib::discrimpolylib::resultant

linalg::tr

Purpose

Trace of a matrix

Syntax

```
linalg::tr(A)
```

Description

`linalg::tr(A)` returns the trace of the square matrix *A*, i.e., the sum of the diagonal elements of *A*.

Examples

Example 1

We compute the trace of the following matrix:

```
A := Dom::Matrix(Dom::Integer) (3, 3, (i, j) -> 3*(i - 1) +
j)Dom::Matrix(Dom::Integer)([[1, 2, 3], [4, 5, 6], [7, 8, 9]])
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

```
linalg::tr(A)15
```

$$15$$

Parameters

A

A square matrix of a domain of category Cat::Matrix

Return Values

Element of the component ring of `A`.

linalg::det

Concepts

- “Compute Determinants and Traces of Square Matrices”

linalg::toeplitz

Purpose

Toeplitz matrix

Syntax

```
linalg::toeplitz(m, n, [t_k,  ,t_-k], <R>)
linalg::toeplitz(n, [t_k,  ,t_-k], <R>)
```

Description

`linalg::toeplitz(m, n, [ t_k, ..., t_1, t_0, t_-1, ..., t_-k])` returns the m n Toeplitz matrix

matrix([[t_0, t_1, t_2, Symbol::cdot,Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, t_k], [‘{t}_{-1}‘, t_0, t_1, t_2, Symbol::cdot, Symbol::cdot,Symbol::cdot, Symbol::cdot, ‘{t}_{k - 1}‘], [‘{t}_{-2}‘, ‘{t}_{-1}‘, t_0, t_1, t_2, Symbol::cdot,Symbol::cdot, Symbol::cdot, ‘{t}_{k - 2}‘], [Symbol::cdot, " ", Symbol::cdot, Symbol::cdot, Symbol::cdot, " ", " ", " ", Symbol::cdot], [Symbol::cdot, " ", " ", Symbol::cdot, Symbol::cdot, Symbol::cdot, " ", " ", Symbol::cdot], [Symbol::cdot, " ", " ", " ", Symbol::cdot, Symbol::cdot, Symbol::cdot, " ", Symbol::cdot], [Symbol::cdot, " ", " ", " ", " ", Symbol::cdot, t_0, t_1, t_2], [Symbol::cdot, " ", " ", " ", " ", Symbol::cdot, ‘{t}_{-1}‘, t_0, t_1], [‘{t}_{-k}‘,Symbol::cdot, Symbol::cdot, Symbol::cdot,Symbol::cdot,Symbol::cdot,‘{t}_{-2}‘,‘{t}_{-1}‘, t_0]])

$$\begin{pmatrix} t_0 & t_1 & t_2 & \cdot & \cdot & \cdot & \cdot & t_k \\ t_{-1} & t_0 & t_1 & t_2 & \cdot & \cdot & \cdot & t_{k-1} \\ t_{-2} & t_{-1} & t_0 & t_1 & t_2 & \cdot & \cdot & t_{k-2} \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & t_0 & t_1 & t_2 & \cdot & \cdot \\ \cdot & \cdot & \cdot & t_{-1} & t_0 & t_1 & \cdot & \cdot \\ t_{-k} & \cdot & \cdot & \cdot & t_{-2} & t_{-1} & t_0 & \cdot \end{pmatrix}$$

`linalg::toeplitz(n, [ t_k, ..., t_-k])` returns the square Toeplitz matrix of dimension n n.

An odd number $2k + 1$ of entries $[t_k, ..., t_{-k}]$ must be specified. There must be at least k diagonal bands above the diagonal and k diagonal bands below the diagonal: k must satisfy $k \le min(m, n) - 1$. Entries with matrix indices (i, j) satisfying $|i - j| > k$ are set to 0.

Toeplitz matrices of dimension n n can be inverted with $O(n^2)$ operations. See linalg::toeplitzSolve.

Examples

Example 1

We construct a 4 4 Toeplitz matrix with 3 bands:
linalg::toeplitz(4, [-1, 2, 1])matrix([[2, 1, 0, 0], [-1, 2, 1, 0], [0, -1, 2, 1], [0, 0, -1, 2]])

$$\begin{pmatrix} 2 & 1 & 0 & 0 \\ -1 & 2 & 1 & 0 \\ 0 & -1 & 2 & 1 \\ 0 & 0 & -1 & 2 \end{pmatrix}$$

We construct a 3 5 Toeplitz matrix with symbolic entries:
linalg::toeplitz(3, 5, [a, b, c])matrix([[b, c, 0, 0, 0], [a, b, c, 0, 0], [0, a, b, c, 0]])

$$\begin{pmatrix} b & c & 0 & 0 & 0 \\ a & b & c & 0 & 0 \\ 0 & a & b & c & 0 \end{pmatrix}$$

Parameters

m

n

The row, respectively column dimension of the matrix: positive integers

t_k, ..., t_{-k}

arithmetical expressions or elements of the component ring `R`

R

The component ring: a domain of category Cat::Rng. The default ring is Dom::ExpressionField`()`.

Return Values

Matrix of the domain Dom::Matrix`(R)`.

See Also linalg::hilbertlinalg::invhilbertlinalg::invpascallinalg::invvandermondelinalg::pascallinalg

linalg::toeplitzSolve

Purpose

Solve a linear Toeplitz system

Syntax

```
linalg::toeplitzSolve(t, y)
```

Description

`linalg::toeplitzSolve(t, y)` returns the solution ‘x→’$\vec{x}$ of the linear Toeplitz system sum(t[i-j]*x[j], j = 1..n) = y[i]$\sum_{j=1}^{n} t_{i-j} x_j = y_i$ with $i = 1, \ldots, n$.

`linalg::toeplitzSolve(t, y)` with `t` = [t_k, …, t_0, …, t_{-k}] and `y` = [y_1, …, y_n] solves the n n Toeplitz system

_outputSequence(matrix([[t[0], t[-1], Symbol::cdot, Symbol::cdot, Symbol::cdot, t[-k],“,“,“,“,“], [t[1], t[0], t[-1], Symbol::cdot, Symbol::cdot,t[-k],“,“,“,“,“], [Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot,“,“,“,“,“], [Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot,“,“,“,“,“], [Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot,“,“,“,“,“], [t[k], t[k-1], Symbol::cdot, Symbol::cdot, Symbol::cdot, t[-k],“,“,“,“,“], [“,t[k], t[k-1], Symbol::cdot, Symbol::cdot, Symbol::cdot, t[-k],“,“,“,“], [“,“,t[k], t[k-1], Symbol::cdot, Symbol::cdot, Symbol::cdot, t[-k],“,“,“], [“,“,“, Symbol::cdot, Symbol::cdot,Symbol::cdot,Symbol::cdot,Symbol::cdot,“,“], [“,“,“,“, Symbol::cdot, Symbol::cdot,Symbol::cdot,Symbol::cdot,“,Symbol::cdot,“], [“,“,“,“, Symbol::cdot, Symbol::cdot,Symbol::cdot,Symbol::cdot,“,“,Symbol::cdot]]), matrix([x[1],x[2],‘.’,‘.’,‘.’,x[n]])) = matrix([y[1],y[2],‘.’,‘.’,‘.’,y[n]])

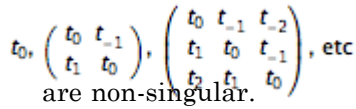
$$\begin{pmatrix} t_0 & t_{-1} & \cdot & \cdot & \cdot & t_{-k} & & \\ t_1 & t_0 & t_{-1} & \cdot & \cdot & t_{-k} & & \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & & \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & & \\ t_k & t_{k-1} & \cdot & \cdot & \cdot & t_{-k} & & \\ & t_k & t_{k-1} & \cdot & \cdot & \cdot & t_{-k} & \\ & & t_k & t_{k-1} & \cdot & \cdot & \cdot & t_{-k} \\ & & & & \cdot & \cdot & \cdot & \cdot \\ & & & & \cdot & \cdot & \cdot & \cdot \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix} = \begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix}$$

with $2k + 1$ bands.

`linalg::toeplitzSolve` implements the Levinson algorithm. It uses $O(n^2)$ elementary operations to solve the Toeplitz system. The memory requirements are $O(n)$. For dense Toeplitz systems, it is faster than the general solver solve and the linear solvers linsolve, numeric::linsolve, linalg::matlinsolve and numeric::matlinsolve.

Note Note that the Levinson algorithm requires that all principal minors

t[0], matrix([[t[0],t[-1]],[t[1],t[0]]]),
matrix([[t[0],t[-1],t[-2]],[t[1],t[0],t[-1]],[t[2],t[1],t[0]]]), etc



are non-singular.

If `linalg::toeplitzSolve` does not manage to find the solution due to this limitation, or if the system is very sparse with k smaller than sqrt(n)$\sqrt{n}$, we recommend to generate the corresponding Toeplitz matrix via linalg::toeplitz and compute the solution via linalg::matlinsolve or numeric::matlinsolve, respectively. Cf. “Example 2” on page 14-230

`linalg::toeplitzSolve` can solve Toeplitz systems over arbitrary coefficient rings. Just make sure that both the Toeplitz entries t as well as the components of the 'right hand side' y are elements of the desired coefficient ring. Cf. “Example 3” on page 14-231.

Examples

Example 1

The Toeplitz entries t and the right hand side y of the linear system are entered as row vectors:
t := matrix([4, 2, 1, 3, 5]): y := matrix([y1, y2, y3]):

The solution of the Toeplitz system is returned as a vector of the same type as the input vector *y*:

```
x := linalg::toeplitzSolve(t, y): x, domtype(x)matrix([[(7*y2)/25 - y1/5
+ (4*y3)/25], [(2*y1)/5 - (19*y2)/25 + (7*y3)/25], [(2*y2)/5 - y3/5]]),
Dom::Matrix()
```

$$\begin{pmatrix} \frac{7\,y2}{25} - \frac{y1}{5} + \frac{4\,y3}{25} \\ \frac{2\,y1}{5} - \frac{19\,y2}{25} + \frac{7\,y3}{25} \\ \frac{2\,y2}{5} - \frac{y3}{5} \end{pmatrix}, \text{Dom::Matrix()}$$

If the input vector is a list, the output is a list, too:

```
x := linalg::toeplitzSolve(t, [y1, y2, y3]): x, domtype(x)[(7*y2)/25 - y1/5 +
(4*y3)/25, (2*y1)/5 - (19*y2)/25 + (7*y3)/25, (2*y2)/5 - y3/5], DOM_LIST
```

$$\left[\frac{7\,y2}{25} - \frac{y1}{5} + \frac{4\,y3}{25},\ \frac{2\,y1}{5} - \frac{19\,y2}{25} + \frac{7\,y3}{25},\ \frac{2\,y2}{5} - \frac{y3}{5}\right], \text{DOM\_LIST}$$

delete t, y, x:

Example 2

The Levinson algorithm cannot solve the following Toeplitz system because the first principal minor of the Toeplitz matrix (the central element of the Toeplitz entries) vanishes:

```
linalg::toeplitzSolve([1, 0, 1], [y1, y2, y3, y4])FAIL
```

FAIL

This does not necessarily imply that the Toeplitz system is not solvable. We generate the corresponding Toeplitz matrix and use a generic linear solver such as linalg::matlinsolve:

```
T := linalg::toeplitz(4, 4, [1, 0, 1])matrix([[0, 1, 0, 0], [1, 0, 1, 0], [0, 1, 0,
1], [0, 0, 1, 0]])
```

$$\begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}$$

linalg::matlinsolve(T, matrix([y1, y2, y3, y4]))matrix([[y2 - y4], [y1], [y4], [y3 - y1]])

$$\begin{pmatrix} y2 - y4 \\ y1 \\ y4 \\ y3 - y1 \end{pmatrix}$$

Example 3

We solve a Toeplitz system over the field $_7$ (the integers modulo 7) represented by the domain Dom::IntegerMod(7):
R := Dom::IntegerMod(7): t := [R(5), R(3), R(2), R(5), R(1)]: y := [R(1), R(2), R(3)]: linalg::toeplitzSolve(t, y)[1 mod 7, 5 mod 7, 2 mod 7]

[1 mod 7, 5 mod 7, 2 mod 7]

delete R, t, y:

Parameters

t

A vector or a list with $2k + 1$ elements. (A vector is a $(2k + 1)$ 1 or a 1 $(2k + 1)$ matrix of category Cat::Matrix).

y

A vector or a list with n elements

Return Values

Vector or list with n elements of the same domain type as the elements of y. FAIL is returned if the algorithm does not succeed in finding a solution.

See Also

linalg::hilbertlinalg::invhilbertlinalg::invpascallinalg::invvandermondelinalg::matlinsolvel

linalg::transpose

Purpose

Transpose of a matrix

Syntax

```
linalg::transpose(A)
```

Description

`linalg::transpose(A)` returns the transpose A^t of the matrix A.

`linalg::transpose` is an interface function for the method `"transpose"` of the matrix domain of `A`, i.e., instead of `linalg::transpose(A)` one may call `A::dom::transpose(A)` directly.

Examples

Example 1

We define a 3 4 matrix:
A := matrix([[1, 2, 3, 4], [-1, 0, 1, 0], [3, 5, 6, 9]])matrix([[1, 2, 3, 4], [-1, 0, 1, 0], [3, 5, 6, 9]])

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -1 & 0 & 1 & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

Then the transpose of `A` is the 4 3 matrix:
linalg::transpose(A)matrix([[1, -1, 3], [2, 0, 5], [3, 1, 6], [4, 0, 9]])

$$\begin{pmatrix} 1 & -1 & 3 \\ 2 & 0 & 5 \\ 3 & 1 & 6 \\ 4 & 0 & 9 \end{pmatrix}$$

Parameters

A

A matrix of a domain of category Cat::Matrix

Return Values

Matrix of the same domain type as `A`.

Algorithms

Let $A = (a_{i,j})_{1 \le i \le m,\ 1 \le j \le n}$ be an m n matrix. Then the transpose of A is the n m matrix:

A^t = matrix([[a[1,1], a[1,2], Symbol::cdot, Symbol::cdot, Symbol::cdot, a[m,1]], [a[1,2], a[2,2], Symbol::cdot, Symbol::cdot, Symbol::cdot, a[m,2]], [Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot], [Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot], [Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot], [a[1,n], a[1,n], Symbol::cdot, Symbol::cdot, Symbol::cdot, a[m,n]]])

$$A^t = \begin{pmatrix} a_{1,1} & a_{1,2} & \cdots & a_{m,1} \\ a_{1,2} & a_{2,2} & \cdots & a_{m,2} \\ \vdots & \vdots & \cdots & \vdots \\ a_{1,n} & a_{1,n} & \cdots & a_{m,n} \end{pmatrix}$$

linalg::vandermonde

Purpose

Vandermonde matrices and their inverses

Syntax

```
linalg::vandermonde([v1, v2,  ], <R>)
```

Description

`linalg::vandermonde( v1, v2, ... , vn)` returns the n n Vandermonde matrix V with entries $V_{ij} = v_i^{j-1}$.

Use `linalg::vandermonde([ v1, ..., vn], R)` to define the n n Vandermonde matrix over the field `R`. Note that the Vandermonde nodes v_i must be elements of `R` or must be convertible to elements of `R`. The same holds true for the inverse Vandermonde matrix.

Vandermonde matrices of dimension n n can be inverted with $O(n^2)$ operations. Linear equations with a Vandermonde coefficient matrix can be solved via linalg::vandermondeSolve.

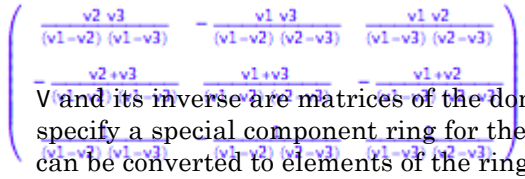
Examples

Example 1

We construct a 3 3 Vandermonde matrix:
V := linalg::vandermonde([v1, v2, v3])matrix([[1, v1, v1^2], [1, v2, v2^2], [1, v3, v3^2]])

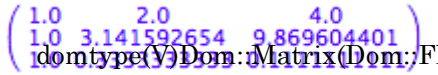
$$\begin{pmatrix} 1 & v1 & v1^2 \\ 1 & v2 & v2^2 \\ 1 & v3 & v3^2 \end{pmatrix}$$

The inverse of this matrix is:
linalg::invvandermonde([v1, v2, v3])matrix([[(v2*v3)/((v1 - v2)*(v1 - v3)), -(v1*v3)/((v1 - v2)*(v2 - v3)), (v1*v2)/((v1 - v3)*(v2 - v3))], [-(v2 + v3)/((v1 - v2)*(v1 - v3)), (v1 + v3)/((v1 - v2)*(v2 - v3)), -(v1 + v2)/((v1 - v3)*(v2 - v3))], [1/((v1 - v2)*(v1 - v3)), -1/((v1 - v2)*(v2 - v3)), 1/((v1 - v3)*(v2 - v3))]])



V and its inverse are matrices of the domain `Dom::Matrix()`. One can specify a special component ring for the matrices, provided the nodes can be converted to elements of the ring. For example, specification of the domain Dom::Float generates floating-point entries:

```
V := linalg::vandermonde([2, PI, 1/3],
Dom::Float)Dom::Matrix(Dom::Float)([[1.0, 2.0, 4.0], [1.0, 3.141592654,
9.869604401], [1.0, 0.3333333333, 0.1111111111]])
```

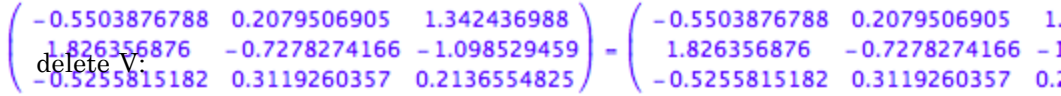


```
domtype(V)Dom::Matrix(Dom::Float)
```

```
Dom::Matrix(Dom::Float)
```

It is faster to compute the inverse via linalg::invvandermonde than inverting the Vandermonde matrix by a generic inversion algorithm (as implemented by `V^(-1)`):

```
V^(-1) = linalg::invvandermonde([2, PI, 1/3],
Dom::Float)Dom::Matrix(Dom::Float)([[-0.5503876788,
0.2079506905, 1.342436988], [1.826356876, -0.7278274166,
-1.098529459], [-0.5255815182, 0.3119260357, 0.2136554825]])
= Dom::Matrix(Dom::Float)([[-0.5503876788, 0.2079506905,
1.342436988], [1.826356876, -0.7278274166, -1.098529459],
[-0.5255815182, 0.3119260357, 0.2136554825]])
```



```
delete V:
```

Parameters

v_1, v_2, ...

The Vandermonde nodes: arithmetical expressions

R

The component ring: a domain of category Cat::Rng; default: Dom::ExpressionField()

Return Values

n *n* matrix of the domain Dom::Matrix(R).

Algorithms

Vandermonde matrices are notoriously ill-conditioned. The inverses of large floating-point Vandermonde matrices are subject to severe round-off effects.

See Also

linalg::invvandermondelinalg::hilbertlinalg::invhilbertlinalg::invpascallinalg::pascallinalg::toe

linalg::invvandermonde

Purpose

Vandermonde matrices and their inverses

Syntax

```
linalg::invvandermonde([v1, v2,  ], <R>)
```

Description

`linalg::invvandermonde( v1, v2, ... , vn)` returns the inverse of the Vandermonde matrix with nodes v_i.

Use `linalg::vandermonde([ v1, ..., vn], R)` to define the n n Vandermonde matrix over the field `R`. Note that the Vandermonde nodes v_i must be elements of `R` or must be convertible to elements of `R`. The same holds true for the inverse Vandermonde matrix.

Vandermonde matrices of dimension n n can be inverted with $O(n^2)$ operations. Linear equations with a Vandermonde coefficient matrix can be solved via linalg::vandermondeSolve.

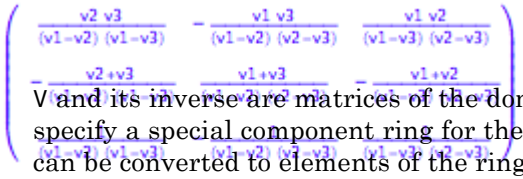
Examples

Example 1

We construct a 3 3 Vandermonde matrix:
V := linalg::vandermonde([v1, v2, v3])matrix([[1, v1, v1^2], [1, v2, v2^2], [1, v3, v3^2]])

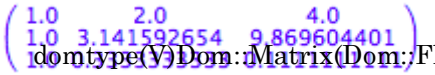
$$\begin{pmatrix} 1 & v1 & v1^2 \\ 1 & v2 & v2^2 \\ 1 & v3 & v3^2 \end{pmatrix}$$

The inverse of this matrix is:
linalg::invvandermonde([v1, v2, v3])matrix([[(v2*v3)/((v1 - v2)*(v1 - v3)), -(v1*v3)/((v1 - v2)*(v2 - v3)), (v1*v2)/((v1 - v3)*(v2 - v3))], [-(v2 + v3)/((v1 - v2)*(v1 - v3)), (v1 + v3)/((v1 - v2)*(v2 - v3)), -(v1 + v2)/((v1 - v3)*(v2 - v3))], [1/((v1 - v2)*(v1 - v3)), -1/((v1 - v2)*(v2 - v3)), 1/((v1 - v3)*(v2 - v3))]])



V and its inverse are matrices of the domain `Dom::Matrix()`. One can specify a special component ring for the matrices, provided the nodes can be converted to elements of the ring. For example, specification of the domain Dom::Float generates floating-point entries:

```
V := linalg::vandermonde([2, PI, 1/3],
Dom::Float)Dom::Matrix(Dom::Float)([[1.0, 2.0, 4.0], [1.0, 3.141592654,
9.869604401], [1.0, 0.3333333333, 0.1111111111]])
```

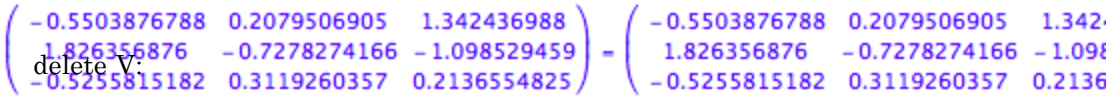


```
domtype(V)Dom::Matrix(Dom::Float)
```

```
Dom::Matrix(Dom::Float)
```

It is faster to compute the inverse via `linalg::invvandermonde` than inverting the Vandermonde matrix by a generic inversion algorithm (as implemented by `V^(-1)`):

```
V^(-1) = linalg::invvandermonde([2, PI, 1/3],
Dom::Float)Dom::Matrix(Dom::Float)([[-0.5503876788,
0.2079506905, 1.342436988], [1.826356876, -0.7278274166,
-1.098529459], [-0.5255815182, 0.3119260357, 0.2136554825]])
= Dom::Matrix(Dom::Float)([[-0.5503876788, 0.2079506905,
1.342436988], [1.826356876, -0.7278274166, -1.098529459],
[-0.5255815182, 0.3119260357, 0.2136554825]])
```



```
delete V:
```

Parameters

v_1, v_2, ...

The Vandermonde nodes: arithmetical expressions

R

The component ring: a domain of category Cat::Rng; default: Dom::ExpressionField()

Return Values

n n matrix of the domain Dom::Matrix(R).

Algorithms

Vandermonde matrices are notoriously ill-conditioned. The inverses of large floating-point Vandermonde matrices are subject to severe round-off effects.

linalg::vandermondeSolve

Purpose

Solve a linear Vandermonde system

Syntax

```
linalg::vandermondeSolve(v, y, <Transposed>)
```

Description

`linalg::vandermondeSolve(v, y)` returns the solution ‘x→‘$\vec{x}$ of the linear Vandermonde system sum(v[i]^(j-1)*x[j], j = 1..n) = y[i]$\sum_{j=1}^{n} v_i^{j-1} x_j = y_i$ with $i = 1, \ldots, n$.

`linalg::vandermondeSolve` uses $O(n^2)$ elementary operations to solve the Vandermonde system. It is faster than the general solver solve and the linear solvers linsolve, numeric::linsolve, linalg::matlinsolve and numeric::matlinsolve.

The solution ‘x→‘=fenced(x[1], Symbol::hellip, x[n])$\vec{x} = (x_1, \ldots, x_n)$ returned by `linalg::vandermondeSolve([v[i] $ i=1..n], [y[i] $ i=1..n])` yields the coefficients of the polynomial $p(v) = x_1 + x_2 v + \cdots + x_n v^{n-1}$ interpolating the data table $(v_1, y_1), \ldots, (v_n, y_n)$, i.e.,

p(v[1])=y[1], Symbol::hellip, p(v[n])=y[n]

$p(v_1) = y_1, \ldots, p(v_n) = y_n$

See “Example 1” on page 14-240.

Examples

Example 1

The Vandermonde points v and the right hand side y of the linear system are entered as vectors:
delete y0, y1, y2: v := matrix([[0, 1, 2]]); y := matrix([[y0, y1, y2]])matrix([[0, 1, 2]])

```
(0 1 2)
```

matrix([[y0, y1, y2]])

```
(y0 y1 y2)
```

The solution vector is:
x := linalg::vandermondeSolve(v, y)matrix([[y0, 2*y1 - (3*y0)/2 - y2/2, y0/2 - y1 + y2/2]])

$$\left(\begin{matrix} y0 & 2\,y1 - \frac{3\,y0}{2} - \frac{y2}{2} & \frac{y0}{2} - y1 + \frac{y2}{2} \end{matrix}\right)$$

The solution yields the coefficients of the interpolating polynomial:
P := v -> _plus(x[i+1]*v^i $ i=0..2):

through the points $(0, y_0)$, $(1, y_1)$, $(2, y_2)$:
P(v[1]), P(v[2]), P(v[3])y0, y1, y2

$$y0,\ y1,\ y2$$

With the optional argument `Transposed`, the linear system with the transposed Vandermonde matrix corresponding to `v` is solved:
linalg::vandermondeSolve(v, y, Transposed)matrix([[y0 - (3*y1)/2 + y2/2, 2*y1 - y2, y2/2 - y1/2]])

$$\left(\begin{matrix} y0 - \frac{3\,y1}{2} + \frac{y2}{2} & 2\,y1 - y2 & \frac{y2}{2} - \frac{y1}{2} \end{matrix}\right)$$

delete v, y, x, P:

Example 2

The Vandermonde points v and the right hand side y of the linear system are entered as 2 1 matrices:
Mat := Dom::Matrix(Dom::ExpressionField(normal)):delete v1, v2, y1, y2: v := Mat([v1, v2]): y := Mat([y1, y2]):

We define the vectors over the domain Dom::ExpressionField`(normal)` in order to simplify intermediate computations.

Next, we compute the solution of the corresponding Vandermonde system:
x := linalg::vandermondeSolve(v, y)Dom::Matrix(Dom::ExpressionField(normal, iszero@normal))([[(v1*y2 - v2*y1)/(v1 - v2)], [(y1 - y2)/(v1 - v2)]])

$$\begin{pmatrix} \frac{v1\ y2 - v2\ y1}{v1 - v2} \\ \frac{y2 - y1}{v1 - v2} \end{pmatrix}$$

We construct the Vandermonde matrix `V` and verify the result:
V := Mat([[1, v[1]], [1, v[2]]])Dom::Matrix(Dom::ExpressionField(normal, iszero@normal))([[1, v1], [1, v2]])

$$\begin{pmatrix} 1 & v1 \\ 1 & v2 \end{pmatrix}$$

V * xDom::Matrix(Dom::ExpressionField(normal, iszero@normal))([[y1], [y2]])

$$\begin{pmatrix} y1 \\ y2 \end{pmatrix}$$

delete Mat, v, y, x, V:

Example 3

We solve a Vandermonde system over the field $_7$ (the integers modulo 7) represented by the domain `Dom::IntegerMod(7)`:
MatZ7 := Dom::Matrix(Dom::IntegerMod(7)): v := MatZ7([1, 2, 3]): y := MatZ7([0, 1, 2]):linalg::vandermondeSolve(v, y)Dom::Matrix(Dom::IntegerMod(7))([[-1], [1], [0]])

$$\begin{pmatrix} 6 \bmod 7 \\ 1 \bmod 7 \\ 0 \bmod 7 \end{pmatrix}$$

delete MatZ7, v, y:

Parameters

`v`

A vector with distinct elements (a vector is an n 1 or 1 n matrix of category Cat::Matrix). Alternatively, a list with n distinct elements is also accepted.

`y`

A vector of the same dimension and domain type as `v`. Alternatively, a list with n elements is also accepted.

Options

Transposed

Returns the solution ‘x→‘$\vec{x}$ of the transposed system sum(v[j]^(i-1)*x[j], j = 1..n) = y[i] $\sum_{j=1}^{n} v_j^{i-1} x_j = y_i$ with $i = 1, \ldots, n$.

Return Values

Vector of the same domain type as `y`.

Algorithms

The Vandermonde matrix

V=matrix([[1, v[1], v[1]^2, Symbol::hellip, v[1]^(n-1)], [1, v[2], v[2]^2, Symbol::hellip, v[2]^(n-1)], [Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot], [Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot], [Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot, Symbol::cdot], [1, v[n], v[n]^2, Symbol::hellip, v[n]^(n-1)]])

$$V = \begin{pmatrix} 1 & v_1 & v_1^2 & \ldots & v_1^{n-1} \\ 1 & v_2 & v_2^2 & \ldots & v_2^{n-1} \\ . & . & . & . & . \\ . & . & . & . & . \\ . & . & . & . & . \\ 1 & v_n & v_n^2 & \ldots & v_n^{n-1} \end{pmatrix}$$

generated by $v = [v_1, \ldots, v_n]$ is invertible if and only if the v_i are distinct.

The vector ‘x→‘$\vec{x}$ returned by `linalg::vandermondeSolve(x, y)` is the unique solution of V * ‘x→‘=‘y→‘$V\vec{x} = \vec{y}$.

The vector x returned by `linalg::vandermondeSolve(x, y, Transposed)` is the unique solution of V^t * ‘x→‘=‘y→‘$V^t\vec{x} = \vec{y}$.

interpolatelinalg::invhilbertlinalg::invpascallinalg::invvandermondelinalg::matlinsolvelina

linalg::vecdim

Purpose

Number of components of a vector

Syntax

```
linalg::vecdim(v)
```

Description

`linalg::vecdim(v)` returns the number of elements of the vector ‘v→’$\vec{v}$.

Examples

Example 1

We define a column vector with two elements and a row vector with four elements:
v1 := matrix([1, 0]); v2 := matrix([[1, 2, 3, 4]])matrix([[1], [0]])

$$\begin{pmatrix} 1 \\ 0 \end{pmatrix}$$

matrix([[1, 2, 3, 4]])

$$(1\ 2\ 3\ 4)$$

`linalg::vecdim` gives us the number of elements, i.e., the dimension of these vectors:
linalg::vecdim(v1), linalg::vecdim(v2)2, 4

2, 4

In contrast, the function linalg::matdim returns the number of rows and columns of these vectors:
linalg::matdim(v1), linalg::matdim(v2)[2, 1], [1, 4]

[2, 1], [1, 4]

Parameters

v

A vector, i.e., an n 1 or 1 n matrix of a domain of category Cat::Matrix

Return Values Positive integer.

See Also linalg::matdimlinalg::ncolslinalg::nrows

linalg::vectorOf

Purpose

Type specifier for vectors

Syntax

```
linalg::vectorOf(R)
linalg::vectorOf(R, n)
```

Description

`linalg::vectorOf(R)` is a type specifier representing all objects of a domain of category Cat::Matrix with component ring `R` and number of rows or number of columns equal to one.

`linalg::vectorOf(R,n)` is a type specifier representing all objects of a domain of category Cat::Matrix with component ring `R` and number of rows equal to `n` and number of columns equal to one, or vice versa.

`linalg::vectorOf(Type::AnyType,n)` is a type specifier representing all objects of a domain of category Cat::Matrix with an arbitrary component ring `R` and number of rows equal to `n` and number of columns equal to one, or vice versa.

Examples

Example 1

`linalg::vectorOf` can be used together with testtype to check whether a MuPAD object is a vector:
MatZ := Dom::Matrix(Dom::Integer): v := MatZ([1, 0, -1])Dom::Matrix(Dom::Integer)([[1], [0], [-1]])

$$\begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix}$$

The following yields `FALSE` because `v` is 3-dimensional vector:
testtype(v, linalg::vectorOf(Dom::Integer, 4))FALSE

FALSE

The following yields `FALSE` because `v` is defined over the integers:
testtype(v, linalg::vectorOf(Dom::Rational))FALSE

```
FALSE
```

Of course, `v` can be converted into a vector over the rationals, as shown by the following call:
bool(coerce(v, Dom::Matrix(Dom::Rational)) <> FAIL)TRUE

```
TRUE
```

This shows that `testtype` in conjunction with `linalg::vectorOf(R)` does not check whether an object can be converted into a vector over the specified component ring `R`. It checks only if the object is a vector whose component ring is `R`.

The following test returns `TRUE` because `v` is a 3-dimensional vector:
testtype(v, linalg::vectorOf(Type::AnyType, 3))TRUE

```
TRUE
```

Example 2

`linalg::vectorOf` can also be used for checking parameters of procedures. The following procedure computes the orthogonal complement of a 2-dimensional vector:
orth := proc(v:linalg::vectorOf(Type::AnyType, 2)) begin [v[1], v[2]] := [-v[2],v[1]]; return(v) end: u := matrix([[1, 2]]); u_ := orth(u)matrix([[1, 2]])

```
[ 1  2 ]
```
matrix([[-2, 1]])

```
[ -2  1 ]
```

Calling the procedure `orth` with an invalid parameter leads to an error message:

orth([1, 2]) Error: The type of argument number 1 must be 'slot(Type, vectorOf)(Type::AnyType, 2)'. The object '[1, 2]' is incorrect. Evaluating: orth

Parameters

R

The component ring: a library domain

n

A positive integer

Return Values

Type expression of the domain type Type.

See Also

testtype

linalg::vectorPotential

Purpose

Vector potential of a three-dimensional vector field

Syntax

```
linalg::vectorPotential(j, [x1, x2, x3], <Test>)
```

Description

`linalg::vectorPotential(j, x)` returns the vector potential of the vector field 'j→'('x→') $\vec{j}(\vec{x})$ with respect to 'x→' $\vec{x}$. This is a vector field 'v→' $\vec{v}$ with curl['v→']('x→') = 'j→' $\mathrm{curl}_{\vec{v}}(\vec{x}) = \vec{j}$.

`linalg::vectorPotential` and vectorPotential are equivalent. See details and examples on the vectorPotential help page.

Parameters

j

A list of three arithmetical expressions, or a 3-dimensional vector (i.e., a 3 1 or 1 3 matrix of a domain of category Cat::Matrix)

x_1

x_2

x_3

(indexed) identifiers

Options

Test

`linalg::vectorPotential` only checks whether the vector field `j` has a vector potential and returns `TRUE` or `FALSE`, respectively.

Return Values

Vector with three components, i.e., an 3 1 or 1 *n* matrix of a domain of category Cat::Matrix, or a boolean value.

linalg::wiedemann

Purpose

Solving linear systems by Wiedemann's algorithm

Syntax

```
linalg::wiedemann(A, b, <mult>, <prob>)
```

Description

`linalg::wiedemann(A, b, mult, ...)` tries to find a vector 'x→'$\vec{x}$ that satisfies the equation A * 'x→'='b→'$A\,\vec{x} = \vec{b}$ by using Wiedemann's algorithm.

The parameter `mult` must be a function such that the result of `mult(A,y)` equals A * 'y→'$A\,\vec{y}$ for every n-dimensional column vector 'y→'$\vec{y}$. The parameter `y` is of the same domain type as `A`. The argument `mult` does not need to handle other types of parameters, nor does it need to handle other matrices than `A`.

`linalg::wiedemann` uses a probabilistic algorithm. For a deterministic variant enter `FALSE` for the optional parameter `prob`.

If the system A * 'x→'='b→'$A\,\vec{x} = \vec{b}$ does not have a solution, then `linalg::wiedemann` returns `FAIL`.

If the system A * 'x→'='b→'$A\,\vec{x} = \vec{b}$ has more than one solution, then a random one is returned.

Due to the probabilistic nature of Wiedemann's algorithm, the computation may fail with small probability. In this case `FAIL` is returned. If the deterministic variant is chosen, then the algorithm may be slower for a small number of matrices.

The vector `b` must be defined over the component ring of `A`.

The coefficient ring of `A` must be a field, i.e., a domain of category Cat::Field.

It is recommended to use `linalg::wiedemann` only if `mult` uses significantly less than $O(n^2)$ field operations.

Examples

Example 1

We define a matrix and a column vector over the finite field with 29 elements:

MatZ29 := Dom::Matrix(Dom::IntegerMod(29)): A := MatZ29([[1, 2, 3], [4, 7, 8], [9, 12, 17]]); b := MatZ29([1, 2, 3])Dom::Matrix(Dom::IntegerMod(29))([[1, 2, 3], [4, 7, 8], [9, 12, -12]])

$$\begin{pmatrix} 1 \bmod 29 & 2 \bmod 29 & 3 \bmod 29 \\ 4 \bmod 29 & 7 \bmod 29 & 8 \bmod 29 \\ 9 \bmod 29 & 12 \bmod 29 & 17 \bmod 29 \end{pmatrix}$$

Dom::Matrix(Dom::IntegerMod(29))([[1], [2], [3]])

$$\begin{pmatrix} 1 \bmod 29 \\ 2 \bmod 29 \\ 3 \bmod 29 \end{pmatrix}$$

Since A does not have a special form that would allow a fast matrix-vector multiplication, we simply use _mult. Wiedemann's algorithm works in this case, although it is less efficient than Gaussian elimination:
linalg::wiedemann(A, b, _mult)[Dom::Matrix(Dom::IntegerMod(29))([[-5], [-8], [-12]]), TRUE]

$$\left[\begin{pmatrix} 24 \bmod 29 \\ 21 \bmod 29 \\ 17 \bmod 29 \end{pmatrix}, \text{TRUE}\right]$$

Example 2

Now let us define another matrix that has a special form:
MatZ29 := Dom::Matrix(Dom::IntegerMod(29)): A := MatZ29([[1, 0, 0], [0, 1, 2], [0, 0, 1]]); b := MatZ29(3, 1, [1, 2, 3]):Dom::Matrix(Dom::IntegerMod(29))([[1, 0, 0], [0, 1, 2], [0, 0, 1]])

$$\begin{pmatrix} 1 \bmod 29 & 0 \bmod 29 & 0 \bmod 29 \\ 0 \bmod 29 & 1 \bmod 29 & 2 \bmod 29 \\ 0 \bmod 29 & 0 \bmod 29 & 1 \bmod 29 \end{pmatrix}$$

For this particular matrix, it is easy to define an efficient multiplication method:
mult := proc(dummy, y) begin y[2]:=y[2]+2*y[3]; y end:
linalg::wiedemann(A, b, mult)[Dom::Matrix(Dom::IntegerMod(29))([[1], [-4], [3]]), TRUE]

$$\left[\begin{pmatrix} 1 \bmod 29 \\ 25 \bmod 29 \\ 3 \bmod 29 \end{pmatrix}, \text{TRUE}\right]$$

Parameters

A

An n n matrix of a domain of category Cat::Matrix

b

An n-dimensional column vector, i.e., an n 1 matrix of a domain of category `Cat::Matrix`

mult

A matrix-vector multiplication method: function or functional expression; default: _mult

prob

`TRUE` or `FALSE` (default: `TRUE`)

Return Values

Either the list `[x, TRUE]` if a solution for the system A * ‘x→‘=‘b→‘$A\,\vec{x} = \vec{b}$ has been found, or the list `[x, FALSE]` if a non-zero solution for the corresponding homogeneous system A * ‘x→‘=‘0→‘$A\,\vec{x} = \vec{0}$ has been found, or the value `FAIL` (see below).

Algorithms

The expected running time for the probabilistic algorithm is $O(n^2 + nM)$, and the running time for the deterministic variant is $O(n^2M)$ in the worst case, but only $O(n^2 + nM)$ on average. Here, M is the number of field operations that the matrix-vector multiplication routine `mult` uses.

The basic idea of the algorithm is to solve a linear system A * ‘x→‘=‘b→‘$A\,\vec{x} = \vec{b}$ by finding the minimal polynomial $f(y)$ that solves f(A) * ‘b→‘=‘0→‘$f(A)\,\vec{b} = \vec{0}$. If the constant coefficient $c = f(0)$ is non-zero and $g(y) := f(y) - c$, the equality g(A) * ‘b→‘=-c * ‘b→‘$g(A)\,\vec{b} = -c\,\vec{b}$ implies that ‘x→‘=-1/c * fenced(g/y)(A)$\vec{x} = -\frac{1}{c}\left(\frac{g}{y}\right)(A)$ is the solution.

The polynomial f is found by looking for the minimal polynomial h satisfying ‘u→‘ * h(A) * ‘b→‘=‘0→‘$\vec{u}\,h(A)\,\vec{b} = \vec{0}$ for some randomly chosen row vector ‘u→‘$\vec{u}$. This may yield $h \neq f$ in unlucky cases, but in general the probability for this is small.

linopt – Linear Optimization

==REFNAME==

linopt::corners

Purpose

Return the feasible corners of a linear program

Syntax

```
linopt::corners([constr, obj], vars, <All>, <Logic>)
linopt::corners([constr, obj, <NonNegative>, <seti>],
vars, <All>, <Logic>)
linopt::corners([constr, obj, <NonNegative>, <All>],
vars, <All>, <Logic>)
linopt::corners([constr, obj, <setn>, <seti>],
vars, <All>, <Logic>)
linopt::corners([constr, obj, <setn>, <All>],
vars, <All>, <Logic>)
```

Description

`linopt::corners([constr, obj], vars)` returns all valid corners of the linear program.

`linopt::corners([constr, obj], vars, All)` returns all corners of the linear program.

[`constr`, `obj`] is a linear program of the same structure like in linopt::maximize. The second parameter `vars` specifies the order in which the components of the corners found are printed; if e.g. {x=1, y=2} is a corner and [x,y] was entered, [1,2] will be returned.

As options, for finding the corners, one may use `All` and/or `Logic`. `All` causes the output of non-feasible corners, too, `Logic` allows the algorithm to search for corners in planes like x=0, too, although $x \geq 0$ is not part of the input. This guarantees that for all non-empty feasible regions a corner will be found.

As the result of `linopt::corners` a triple consisting of the set of corners, the maximal objective function value found and the corner associated to it is returned. If there is no feasible corner found, only the empty set is returned.

Examples

Example 1

We compute all valid corners of a small linear program:

```
k := [{4 <= 2*x + 2*y, -2 <= 4*y - 2*x, -8 <= y - 2*x, y - 2*x <= -2, y <=
6}, x + y]: linopt::corners(k, [x, y])[{[4/3, 2/3], [5/3, 1/3], [4, 6], [5, 2],
[7, 6]}, 13, [7, 6]]
```

$$\left[\left\{\left[\frac{4}{3}, \frac{2}{3}\right], \left[\frac{5}{3}, \frac{1}{3}\right], [4, 6], [5, 2], [7, 6]\right\}, 13, [7, 6]\right]$$

Now we compute all corners, also the ones which are not valid. We see that we now get e.g. also the corner which is given by the cut of $-2x + 4y = 2$ and $-2x + y \leq -2$. Here we see that the invalid corner (13,6) has the maximal objective function value 19:

```
k := [{4 <= 2*x + 2*y, -2 <= 4*y - 2*x, -8 <= y - 2*x, y - 2*x <= -2, y <= 6},
x + y]: linopt::corners(k, [x, y], All)[{[-4, 6], [1, 0], [4/3, 2/3], [5/3, 1/3],
[10/3, -4/3], [4, 6], [5, 2], [7, 6], [13, 6]}, 19, [13, 6]]
```

$$\left[\left\{[-4, 6], [1, 0], \left[\frac{4}{3}, \frac{2}{3}\right], \left[\frac{5}{3}, \frac{1}{3}\right], \left[\frac{10}{3}, -\frac{4}{3}\right], [4, 6], [5, 2], [7, 6], [13, 6]\right\}, 19, [13, 6]\right]$$

delete k:

Example 2

As one can see the linear program given by the constraints $x + y \geq -1$ and $x + y \leq 3$ and the linear objective function $x + 2y$ has no corners:

```
l := [{-1 <= x + y, x + y <= 3}, x + 2*y]: linopt::corners(l,[x,y]),
linopt::corners(l,[x,y], All)[{}, {}
```

$$\varnothing, \varnothing$$

If one also assumes a cut with a coordinate plane as a corner, some corners exist. One can use linopt::plot_data to visualize this problem:

```
linopt::corners(l, [x,y], Logic)[{[-1, 0], [0, 0], [0, -1], [0, 3], [3, 0]}, 6, [0, 3]]
```

$$[\{[-1, 0], [0, 0], [0, -1], [0, 3], [3, 0]\}, 6, [0, 3]]$$

delete l:

Parameters

constr

A set or list of linear constraints

obj

A linear expression

seti

A set which contains identifiers interpreted as indeterminants

setn

A set which contains identifiers interpreted as indeterminants

vars

A list containing the variables of the linear program described by `constr` and `obj` and the existing options

Options

All

This option can appear at two different places in the call of `linopt::corners`. If it is part of the linear program it means that all variables are constrained to be integers. If it appears as the third or forth argument of the call it means that all corners, not only the valid ones should be computed by `linopt::corners`.

NonNegative

All variables are constrained to be nonnegative

Logic

This allows the algorithm to search for corners in planes like x=0 too, although $x \geq 0$ is not part of the linear program.

Return Values

Set or a list with 3 elements.

linopt::maximize

Purpose

Maximize a linear or mixed-integer program

Syntax

```
linopt::maximize([constr, obj], <DualPrices>)
linopt::maximize([constr, obj, <NonNegative>, <seti>])
linopt::maximize([constr, obj, <NonNegative>, <All>])
linopt::maximize([constr, obj, <setn>, <seti>])
linopt::maximize([constr, obj, <setn>, <All>])
linopt::maximize([constr, obj, <NonNegative>], DualPrices)
linopt::maximize([constr, obj, <set>], DualPrices)
```

Description

`linopt::maximize([constr, obj])` returns the solution of the linear or mixed-integer program given by the constraints `constr` and the linear objective function `obj` which should be maximized.

The expression `obj` is the linear objective function to be maximized subject to the linear constraints `constr`. The function `linopt::maximize` returns a triple consisting of the state of the output, `OPTIMAL`, `EMPTY` or `UNBOUNDED`, a set of equations which describes the optimal solution of the specified linear program, which is empty or depends on a free variable Φ subject to the state, and finally the maximal objective function value, which can be either a number, `-infinity` or a linear function in Φ.

The states `OPTIMAL`, `EMPTY` or `UNBOUNDED` have the following meanings. `OPTIMAL` means an optimal solution for the linear program was found. If the state is `EMPTY` no optimal solution was found and if it is `UNBOUNDED` then the solution has no upper bound.

If the option `NonNegative` is used all variables are constrained to be nonnegative. If instead of `NonNegative` a set `setn` is given then only the variables from `setn` are constrained to be nonnegative.

If the option `All` is used all variables are constrained to be integers. If instead of `All` a set `seti` is given, then only the variables from `seti` are constrained to be integers.

As a second parameter for `linopt::maximize` the option `DualPrices` is provided for the linear case (the first parameter therefore must not

have more than three elements). This option causes the output of the dual-prices in addition to the solution-tripel. In this case the result of `linopt::maximize` is a sequence of a list containing the solution-tripel and a set containing the dual prices. See “Example 4” on page 15-8.

Examples

Example 1

We try to solve the linear program

eqsys(2*c[1] <= 1, 2*c[2] <=1)

$$2\,c_1 \le 1$$

$$2\,c_2 \le 1$$

with the linear objective function $c_1 + 2c_2$:
linopt::maximize([{2*c1 <= 1, 2*c2 <= 1}, c1 + 2*c2])[OPTIMAL, {c1 = 1/2, c2 = 1/2}, 3/2]

$$\left[\text{OPTIMAL}, \left\{c1 = \frac{1}{2}, c2 = \frac{1}{2}\right\}, \frac{3}{2}\right]$$

Example 2

Now let’s have a look at the linear program

eqsys(3*x+4*y-3*z <= 23, 5*x-4*y-3*z <= 10, 7*x+4*y+11*z <= 30)

$$3\,x + 4\,y - 3\,z \le 23$$

$$5\,x - 4\,y - 3\,z \le 10$$

$$7\,x + 4\,y + 11\,z \le 30$$

with the linear objective function $-x + y + 2z$. If we make no restriction to the variables the result is unbounded:
c := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10, 7*x + 4*y + 11*z <= 30}, -x + y + 2*z]: linopt::maximize(c)[UNBOUNDED, {x = -PHI1, y = 0, z = (7*PHI1)/11 + 30/11}, (25*PHI1)/11 + 60/11]

$$\left[\text{UNBOUNDED}, \left\{x = -\text{PHI1}, y = 0, z = \frac{7\,\text{PHI1}}{11} + \frac{30}{11}\right\}, \frac{25\,\text{PHI1}}{11} + \frac{60}{11}\right]$$

But if all variables are constrained to be nonnegative, we get a result. That's also the case if only x and y are constrained to be nonnegative:
linopt::maximize(append(c, NonNegative)); linopt::maximize(append(c, {x, y}))[OPTIMAL, {x = 0, y = 49/8, z = 1/2}, 57/8]

$$\left[\text{OPTIMAL}, \left\{x = 0, y = \frac{49}{8}, z = \frac{1}{2}\right\}, \frac{57}{8}\right]$$

[OPTIMAL, {x = 0, y = 49/8, z = 1/2}, 57/8]

$$\left[\text{OPTIMAL}, \left\{x = 0, y = \frac{49}{8}, z = \frac{1}{2}\right\}, \frac{57}{8}\right]$$

delete c:

Example 3

The following linear program do not have a solution:
linopt::maximize([{x <= -1, x >= 0}, x])[EMPTY, {}, -infinity]

$$[\text{EMPTY}, \varnothing, -\infty]$$

Example 4

The output of the dual prices can be enforced with the option `DualPrices`:
linopt::maximize([{2*c1 <= 1, 2*c2 <= 1},c1 + 2*c2], DualPrices)[OPTIMAL, {c1 = 1/2, c2 = 1/2}, 3/2], {[c1 <= 1/2, 1], [c2 <= 1/2, 2]}

$$\left[\text{OPTIMAL}, \left\{c1 = \frac{1}{2}, c2 = \frac{1}{2}\right\}, \frac{3}{2}\right], \left\{\left[c1 \le \frac{1}{2}, 1\right], \left[c2 \le \frac{1}{2}, 2\right]\right\}$$

Example 5

We have a look at the knapsack problem with *x1*, *x2*, *x3*, *x4* {0, 1}:

```
c := {20*x1 + 15*x2 + 20*x3 + 5*x4 <= 25}: c := c union {x1 <= 1, x2 <= 1,
x3 <= 1, x4 <= 1}: f := 10*x1 + 15*x2 + 16*x3 + x4: linopt::maximize([c,
f, NonNegative, All])[OPTIMAL, {x1 = 0, x2 = 0, x3 = 1, x4 = 1}, 17]
```

```
[OPTIMAL, {x1 = 0, x2 = 0, x3 = 1, x4 = 1}, 17]
```

```
delete c, f:
```

Parameters

constr

A set or list of linear constraints

obj

A linear expression

seti

A set which contains identifiers interpreted as indeterminates

setn

A set which contains identifiers interpreted as indeterminates

Options

All

All variables are constrained to be integers

NonNegative

All variables are constrained to be nonnegative

DualPrices

This option is only available in the linear case. It causes the output of the dual-prices in addition to the solution-triple.

Return Values

List or a sequence of a list and a set containing the solution of the linear or mixed-integer program.

linopt::minimize

Purpose

Minimize a linear or mixed-integer program

Syntax

```
linopt::minimize([constr, obj], <DualPrices>)
linopt::minimize([constr, obj, <NonNegative>, <seti>])
linopt::minimize([constr, obj, <NonNegative>, <All>])
linopt::minimize([constr, obj, <setn>, <seti>])
linopt::minimize([constr, obj, <setn>, <All>])
linopt::minimize([constr, obj, <NonNegative>], DualPrices)
linopt::minimize([constr, obj, <set>], DualPrices)
```

Description

`linopt::minimize([constr, obj])` returns the solution of the linear or mixed-integer program given by the constraints `constr` and the linear objective function `obj` which should be minimized.

The expression `obj` is the linear objective function to be minimized subject to the linear constraints `constr`. The function `linopt::minimize` returns a triple consisting of the state of the output, `OPTIMAL`, `EMPTY` or `UNBOUNDED`, a set of equations which describes the optimal solution of the specified linear program, which is empty or depends on a free variable Φ subject to the state, and finally the minimal objective function value, which can be either a number, `infinity` or a linear function in Φ.

The states `OPTIMAL`, `EMPTY` or `UNBOUNDED` have the following meanings. `OPTIMAL` means an optimal solution for the linear program was found. If the state is `EMPTY` no optimal solution was found and if it is `UNBOUNDED` then the solution has no upper bound.

If the option `NonNegative` is used all variables are constrained to be nonnegative. If instead of `NonNegative` a set `setn` is given then only the variables from `setn` are constrained to be nonnegative.

If the option `All` is used all variables are constrained to be integers. If instead of `All` a set `seti` is given, then only the variables from `seti` are constrained to be integers.

As a second parameter for `linopt::minimize` the option `DualPrices` is provided for the linear case (the first parameter therefore must not

have more than three elements). This option causes the output of the dual-prices in addition to the solution-tripel. In this case the result of `linopt::minimize` is a sequence of a list containing the solution-tripel and a set containing the dual prices. See “Example 4” on page 15-13.

Examples

Example 1

We try to solve the linear program

eqsys(c[1] + c[2] <= 3, c[2] <= 9)

$$c_1 + c_2 \le 3$$
$$c_2 \le 9$$

with the linear objective function - c_1 - c_2:
linopt::minimize([{c1 + c2 <= 3, c2 <= 9}, -c1 - c2])[OPTIMAL, {c1 = 0, c2 = 3}, -3]

[OPTIMAL, {c1 = 0, c2 = 3}, −3]

Example 2

Now let’s have a look at the linear program

eqsys(3*x+4*y-3*z <= 23, 5*x-4*y-3*z <= 10, 7*x+4*y+11*z <= 30)

$$3x + 4y - 3z \le 23$$
$$5x - 4y - 3z \le 10$$
$$7x + 4y + 11z \le 30$$

with the linear objective function - $x + y + 2z$. If we make no restriction to the variables the result is unbounded:
c := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10, 7*x + 4*y + 11*z <= 30}, -x + y + 2*z]: linopt::minimize(c)[UNBOUNDED, {y = -PHI1, x = -4*PHI1 - 13/2, z = - (16*PHI1)/3 - 85/6}, - (23*PHI1)/3 - 131/6]

$$\left[\text{UNBOUNDED}, \left\{y = -\text{PHI1}, x = -4\,\text{PHI1} - \frac{13}{2}, z = -\frac{16\,\text{PHI1}}{3} - \frac{85}{6}\right\}, -\frac{23\,\text{PHI1}}{3} - \frac{131}{6}\right]$$

But if all variables are constrained to be nonnegative, we get a result. That's also the case if only x and y are constrained to be nonnegative: linopt::minimize(append(c, NonNegative)); linopt::minimize(append(c, {x, y}))[OPTIMAL, {x = 2, y = 0, z = 0}, -2]

$$[\text{OPTIMAL}, \{x = 2, y = 0, z = 0\}, -2]$$

[OPTIMAL, {x = 0, y = 13/8, z = -11/2}, -75/8]

$$\left[\text{OPTIMAL}, \left\{x = 0, y = \frac{13}{8}, z = -\frac{11}{2}\right\}, -\frac{75}{8}\right]$$

delete c:

Example 3

The following linear program does not have a solution: linopt::minimize([{x <= -1, x >= 0}, x])[EMPTY, {}, infinity]

$$[\text{EMPTY}, \varnothing, \infty]$$

Example 4

The output of the dual prices can be enforced with the option `DualPrices`: linopt::minimize([{c1 + c2 <= 3, c2 <= 9}, -c1 - c2], DualPrices)[OPTIMAL, {c1 = 0, c2 = 3}, -3], {[c1 + c2 <= 3, 1], [c2 <= 9, 0]}

$$[\text{OPTIMAL}, \{c1 = 0, c2 = 3\}, -3], \{[c1 + c2 \le 3, 1], [c2 \le 9, 0]\}$$

Parameters

constr

A set or list of linear constraints

obj

A linear expression

seti

S set which contains identifiers interpreted as indeterminates

setn

A set which contains identifiers interpreted as indeterminates

Options

All

All variables are constrained to be integer

NonNegative

All variables are constrained to be nonnegative

DualPrices

This option is only available in the linear case. It causes the output of the dual-prices in addition to the solution-tripel.

Return Values

List or a sequence of a list and a set containing the solution of the linear or mixed-integer program.

See Also linopt::maximizelinopt::plot_datalinopt::corners

linopt::plot_data

Purpose

Plot the feasible region of a linear program

Syntax

```
linopt::plot_data([constr, obj, <NonNegative>,
<seti>], vars)
linopt::plot_data([constr, obj, <NonNegative>,
<All>], vars)
linopt::plot_data([constr, obj, <setn>, <seti>], vars)
linopt::plot_data([constr, obj, <setn>, <All>], vars)
```

Description

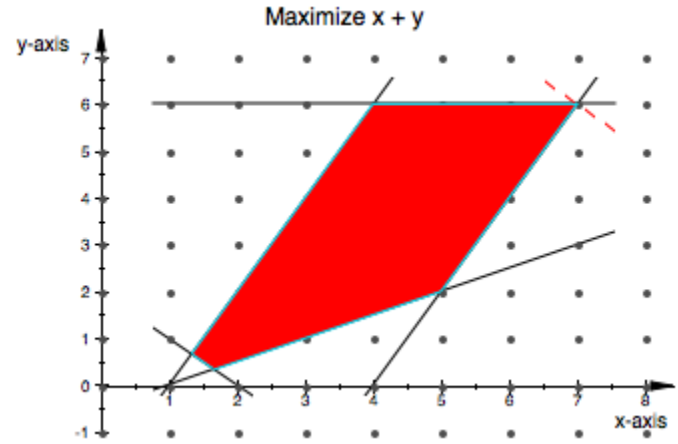
`linopt::plot_data([constr, obj], vars)` returns a graphical description of the feasible region of the linear program [constr, obj], and the line vertical to the objective function vector through the corner with the maximal objective function value found.

[`constr`, `obj`] is a linear program with exactly two variables. The problem has the same structure like in linopt::maximize. The second parameter `vars` specifies which variable belongs to the horizontal and vertical axis.

Examples

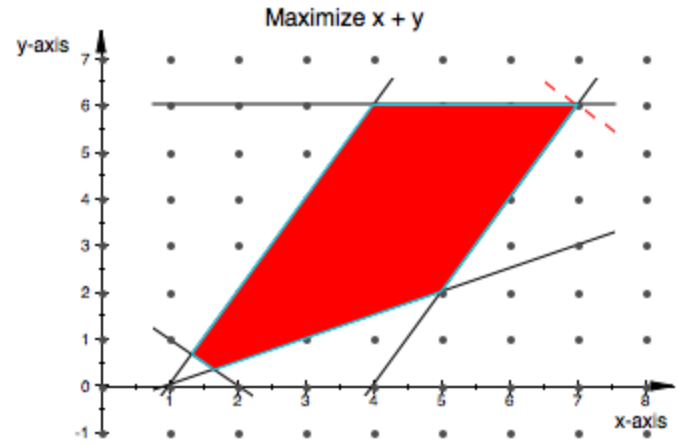
Example 1

We plot the feasible region of the given linear program. Here the valid corners of the linear program are easy to see:
k := [{2*x + 2*y >= 4, -2*x + 4*y >= -2, -2*x + y >= -8, -2*x + y <= -2, y <= 6}, x + y, NonNegative]: g := linopt::plot_data(k, [x, y]): plot(g):



In this example there is no difference if the Option `NonNegative` is given for the linear program or not:

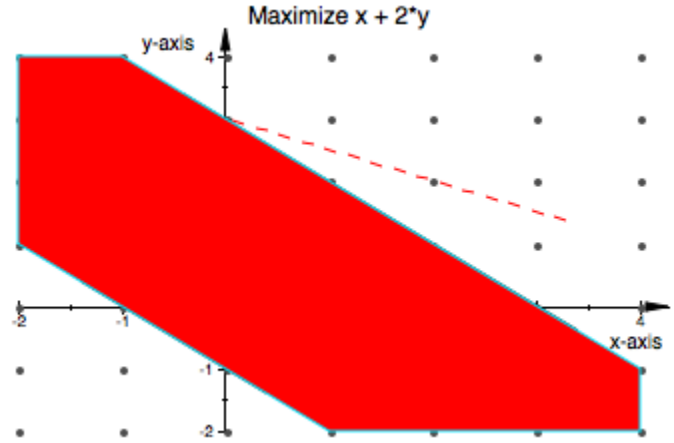
```
k := [{2*x + 2*y >= 4, -2*x + 4*y >= -2, -2*x + y >= -8, -2*x + y <= -2, y <= 6}, x + y]: g := linopt::plot_data(k, [x, y]): plot(g):
```



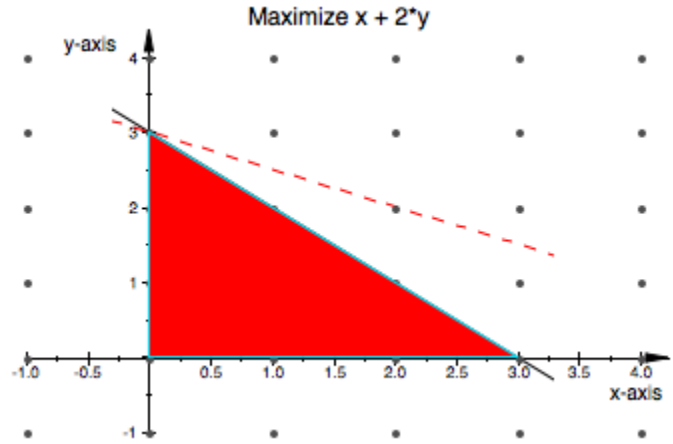
```
delete k, g:
```

Example 2

Now we give an example where one can see a difference if the variables are constrained to be nonnegative:
k := [{x + y >= -1, x + y <= 3}, x + 2*y]: g := linopt::plot_data(k, [x, y]): plot(g):



k := [{x + y >= -1, x + y <= 3}, x + 2*y, NonNegative]: g := linopt::plot_data(k, [x, y]): plot(g):



delete k, g:

Parameters

constr

A set or list of linear constraints

obj

A linear expression

seti

A set which contains identifiers interpreted as indeterminates

setn

A set which contains identifiers interpreted as indeterminates

vars

A list containing the two variables of the linear program described by `constr` and `obj` and the existing options

Options

All

All variables are constrained to be integer

NonNegative

All variables are constrained to be nonnegative

Return Values

Expression describing a graphical object which can be used by plot.

linopt::maximizelinopt::minimizelinopt::corners

linopt::Transparent

Purpose

Return the ordinary simplex tableau of a linear program

Syntax

```
linopt::Transparent([constr, obj, <NonNegative>, <seti>])
linopt::Transparent([constr, obj, <NonNegative>, <All>])
linopt::Transparent([constr, obj, <setn>, <seti>])
linopt::Transparent([constr, obj, <setn>, <All>])
```

Description

`linopt::Transparent([constr, obj])` returns the ordinary simplex tableau of the given linear program given by the constraints `constr` and the linear objective function `obj`.

[`constr`, `obj`] is a Linear Optimization Problem of the same structure like in linopt::maximize. As the result the ordinary simplex tableau of the given problem is returned; this means that equations will be replaced by two unequations and unbounded variables will be replaced by two new variables.

Internally the tableau returned consists of more information than viewable on the screen. Therefore linopt::Transparent::convert is provided to perform the transduction into the structure of the screen-tableau. (This can be necessary if the returned tableau shall serve as an input-parameter for another function — e.g. a user defined procedure for the selection of pivot elements.) If an ordinary simplex with two phases is wished, the next step should be the call of linopt::Transparent::phaseI_tableau.

All functions of the linopt library using the tableau returned by `linopt::Transparent` try to minimize the problem! Therefore it can be necessary to multiply the objective function with -1 first.

In the simplex tableau returned a special notation is used. "linopt" stands for the tableau them self, "obj" describes the linear objective function, "restr" stands for the vector of restrictions, slk[1], slk[2], ... are the slack variables and the names of the other variables stand for themselves. Variables which are given as row labels indicate that they are part of the base.

Examples

Example 1

First a small example, returning the ordinary simplex tableau of the given linear program. One can see that the slack variables are forming the basis:

```
k := [{x + y >= -1, x + y <= 3}, x + 2*y, NonNegative]:
linopt::Transparent(k)array(1..4, 1..6, [["linopt", "restr", slk[1], slk[2], y, x], ["obj", 0, 0, 0, 2, 1], [slk[1], 1, 1, 0, -1, -1], [slk[2], 3, 0, 1, 1, 1]])
```

"linopt"	"restr"	slk_1	slk_2	y	x
"obj"	0	0	0	2	1
slk_1	1	1	0	−1	−1
slk_2	3	0	1	1	1

It follows a little bit larger example:

```
k := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10, 7*x + 4*y + 11*z <= 30}, -x + y + 2*z, NonNegative]: linopt::Transparent(k)array(1..5, 1..8, [["linopt", "restr", slk[1], slk[2], slk[3], y, x, z], ["obj", 0, 0, 0, 0, 1, -1, 2], [slk[1], 23, 1, 0, 0, 4, 3, -3], [slk[2], 10, 0, 1, 0, -4, 5, -3], [slk[3], 30, 0, 0, 1, 4, 7, 11]])
```

"linopt"	"restr"	slk_1	slk_2	slk_3	y	x	z
"obj"	0	0	0	0	1	−1	2
slk_1	23	1	0	0	4	3	−3
slk_2	10	0	1	0	−4	5	−3
slk_3	30	0	0	1	4	7	11

The result of `linopt::Transparent` is of domain type `linopt::Transparent`. So it can be used as input for other `linopt::Transparent::*` function, e.g. for linopt::Transparent::suggest:

```
k := [{x + y >= -1, x + y <= 3}, x + 2*y, NonNegative]: t := linopt::Transparent(k): domtype(t), linopt::Transparent::suggest(t)‘linopt::Transparent‘, OPTIMAL
```

```
linopt::Transparent, OPTIMAL
delete k, t:
```

Parameters

constr

A set or list of linear constraints

obj

A linear expression

seti

A set which contains identifiers interpreted as indeterminates

setn

A set which contains identifiers interpreted as indeterminates

Options

All

All variables are constrained to be integer

NonNegative

All variables are constrained to be nonnegative

Return Values

Simplex tableau of domain type `linopt::Transparent`.

See Also linopt::Transparent::autosteplinopt::Transparent::coercelinopt::Transparent::dual_priceslinop

linopt::Transparent::autostep

Purpose

Perform the next simplex step

Syntax

```
linopt::Transparent::autostep(tableau)
```

Description

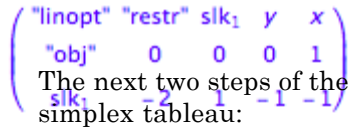
`linopt::Transparent::autostep(tableau)` performs the next step of the simplex algorithm. This is the same step that linopt::Transparent::suggest would suggest for the given simplex tableau `tableau`.

Normally `linopt::Transparent::autostep` returns the next simplex tableau. If the calculation of the simplex algorithm is finished `linopt::Transparent::autostep` returns a set containing a solution of the given linear program described by `tableau`.

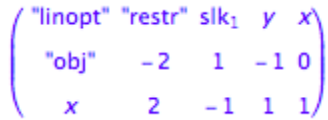
Examples

Example 1

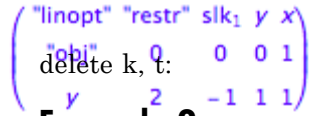
The ordinary simplex tableau of a given linear program is created:
k := [{x + y >= 2}, x, NonNegative]: t := linopt::Transparent(k)array(1..3, 1..5, [["linopt", "restr", slk[1], y, x], ["obj", 0, 0, 0, 1], [slk[1], -2, 1, -1, -1]])



The next two steps of the simplex algorithm are executed for the given simplex tableau:
linopt::Transparent::autostep(t);
linopt::Transparent::autostep(%)array(1..3, 1..5, [["linopt", "restr", slk[1], y, x], ["obj", -2, 1, -1, 0], [x, 2, -1, 1, 1]])



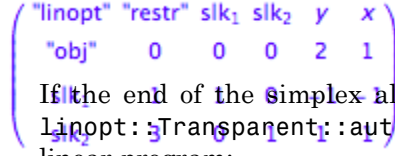
array(1..3, 1..5, [["linopt", "restr", slk[1], y, x], ["obj", 0, 0, 0, 1], [y, 2, -1, 1, 1]])



delete k, t:

Example 2

The ordinary simplex tableau of a given linear program is created:
k := [{x + y >= -1, x + y <= 3}, x + 2*y, NonNegative]: t := linopt::Transparent(k)array(1..4, 1..6, [["linopt", "restr", slk[1], slk[2], y, x], ["obj", 0, 0, 0, 2, 1], [slk[1], 1, 1, 0, -1, -1], [slk[2], 3, 0, 1, 1, 1]])



If the end of the simplex algorithm is reached, `linopt::Transparent::autostep` returns a solution of the given linear program:
linopt::Transparent::suggest(t),
linopt::Transparent::autostep(t)OPTIMAL, {x = 0, y = 0}

delete k, t:

Parameters

tableau

A simplex tableau of domain type `linopt::Transparent`

Return Values

Simplex tableau of domain type `linopt::Transparent` or a set which contains the solution of the linear program.

linopt::Transparentlinopt::Transparent::convertlinopt::Transparent::dual_priceslinopt::Tr

linopt::Transparent::clean_basis

Purpose

Delete all slack variables of the first phase from the basis

Syntax

```
linopt::Transparent::clean_basis(tableau)
```

Description

`linopt::Transparent::clean_basis(tableau)` removes the additional slack variables of the phase one of the simplex algorithm from the optimal basic (described by `tableau`) calculated by linopt::Transparent::phaseI_tableau and linopt::Transparent::simplex.

At the end of the phase one of the 2-phase simplex algorithm, explicitly started by using linopt::Transparent::phaseI_tableau, it is necessary to eliminate all artificial variables from the optimal basis before phase two can be started by using linopt::Transparent::phaseII_tableau. `linopt::Transparent::clean_basis` performs some pivot steps until all phase one slack variables do not occur in the basis any longer.

Examples

Example 1

In this example we first compute an optimal basis for the first phase of the simplex algorithm:
t := linopt::Transparent([{x <= 1,y <= 1,x + y >= 2}, 0,NonNegative]): t := linopt::Transparent::phaseI_tableau(t):
t := linopt::Transparent::simplex(t)array(1..5, 1..10, [["linopt", "restr", slk[4], slk[5], slk[6], slk[1], slk[2], slk[3], y, x], ["obj", 0, 2, 2, 0, 1, 1, 1, 0, 0], [x, 1, 1, 0, 0, 1, 0, 0, 0, 1], [y, 1, 0, 1, 0, 0, 1, 0, 1, 0], [slk[6], 0, -1, -1, 1, -1, -1, -1, 0, 0]])

"linopt"	"restr"	slk_4	slk_5	slk_6	slk_1	slk_2	slk_3	y	x
"obj"	0	2	2	0	1	1	1	0	0
x	1	1	0	0	1	0	0	0	1
y	1	0	1	0	0	1	0	1	0
slk_6	0	−1	−1	1	−1	−1	−1	0	0

As we can see the artificial slack variable slk[6] is an element of the optimal basis. An error message is returned if we apply

linopt::Transparent::phaseII_tableau or linopt::Transparent::simplex to this simplex tableau:
linopt::Transparent::phaseII_tableau(t); Error: Clean the basis from phase I slack variables first. [linopt::Transparent::phaseII_tableau]

So we have to use `linopt::Transparent::clean_basis` before continuing with the appropriate function:
t := linopt::Transparent::clean_basis(t);
linopt::Transparent::phaseII_tableau(t)array(1..5, 1..10, [["linopt", "restr", slk[4], slk[5], slk[6], slk[1], slk[2], slk[3], y, x], ["obj", 0, 1, 1, 1, 0, 0, 0, 0, 0], [x, 1, 0, -1, 1, 0, -1, -1, 0, 1], [y, 1, 0, 1, 0, 0, 1, 0, 1, 0], [slk[1], 0, 1, 1, -1, 1, 1, 1, 0, 0]])

"linopt"	"restr"	slk_4	slk_5	slk_6	slk_1	slk_2	slk_3	y	x
"obj"	0	1	1	1	0	0	0	0	0
x	1	0	−1	1	0	−1	−1	0	1
y	1	0	1	0	1	0	1	0	0
slk_1	0	1	1	−1	1	1	1	0	0

array(1..5, 1..7, [["linopt", "restr", slk[1], slk[2], slk[3], y, x], ["obj", 0, 0, 0, 0, 0, 0], [x, 1, 0, 0, -1, -1, 0, 1], [y, 1, 0, 1, 0, 1, 0, 0], [slk[1], 0, 1, 1, 1, 0, 0]])

"linopt"	"restr"	slk_1	slk_2	slk_3	y	x
"obj"	0	0	0	0	0	0
x	1	0	−1	−1	0	1
y	1	0	1	0	1	0
slk_1	0	1	1	1	0	0

delete t:

Parameters

tableau

A simplex tableau of domain type `linopt::Transparent`

Return Values

Simplex tableau of domain type `linopt::Transparent`.

linopt::Transparentlinopt::Transparent::autosteplinopt::Transparent::convertlinopt::Transpar

linopt::Transparent::convert

Purpose

Transform the given tableau into a structure printable on screen

Syntax

```
linopt::Transparent::convert(tableau)
```

Description

`linopt::Transparent::convert` converts `tableau` into a two dimensional array which corresponds with the screen-tableau. One can now access the element in the *i*-th row and *j*-th column of the simplex tableau by accessing the corresponding element of the array.

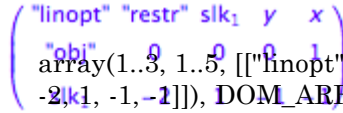
Internally the given `tableau` of domain type linopt::Transparent contains a lot of more information than the simplex tableau which is printed by some functions of the `linopt` library, e.g. linopt::Transparent::simplex, and which is visible on the screen. Furthermore it is not possible to access the element in the *i*-th row and *j*-th column of `tableau` to get the corresponding element from the simplex tableau which is visible on the screen.

While the internal structure of `tableau` is not known the structure of the two dimensional array is well defined. So it can be easily used in own procedures. See “Example 2” on page 15-32.

Examples

Example 1

We convert a simplex tableau of domain type `linopt::Transparent` into a two dimensional array:
k := [{x + y >= 2}, x, NonNegative]: t := linopt::Transparent(k): a := linopt::Transparent::convert(t): t, domtype(t); a, domtype(a)array(1..3, 1..5, [["linopt", "restr", slk[1], y, x], ["obj", 0, 0, 0, 1], [slk[1], -2, 1, -1, -1]]), linopt::Transparent



array(1..3, 1..5, [["linopt", "restr", slk[1], y, x], ["obj", 0, 0, 0, 1], [slk[1], -2, 1, -1, -1]]), DOM_ARRAY

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & slk_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ slk_1 & -2 & 1 & -1 & -1 \end{pmatrix}, \text{DOM\_ARRAY}$$

delete a, k, t:

Example 2

We will write another simplex routine `mysimplex` for solving a linear program. For this we define the function `eigenpivot` for finding the pivot element of a given simplex tableau. `eigenpivot` assumes that the simplex tableau is given as a two dimensional array.

Here is the procedure `eigenpivot`, which is not coded in every detail, e.g., the error checking isn't implemented completely:

```
eigenpivot := proc(T: DOM_ARRAY) local i,j,m,n,k,l,mini; begin m
:= op(T,[0,2,2]): n := op(T,[0,3,2]): k := 0: l := 0: mini := unbesetzt:
for j from 3 to n do if T[2,j] < 0 then l := j: break end_if: end_for:
if l=0 then return(OPTIMAL) end_if: for i from 3 to m do if T[i,l]
> 0 and (mini=unbesetzt or T[i,2]/T[i,l] < mini) then k := i: mini :=
T[k,2]/T[k,l] end_if end_for: if k=0 then return(UNBOUNDED) end_if:
return(T[k,1],T[1,l]): end_proc:
```

This is the new simplex algorithm `mysimplex` which uses `eigenpivot` and some function from the `linopt` library:

```
mysimplex := proc(P) local T; begin T := linopt::Transparent(P):
T := linopt::Transparent::phaseI_tableau(T): piv :=
eigenpivot(linopt::Transparent::convert(T)): while piv <> OPTIMAL
and piv <> UNBOUNDED do T := linopt::Transparent::userstep(T,piv):
piv := eigenpivot(linopt::Transparent::convert(T)) end_while: if piv =
UNBOUNDED then error(" Phase I unbounded ?!?") end_if: if T[2,2] <>
0 then return(EMPTY) end_if: T := linopt::Transparent::clean_basis(T):
T := linopt::Transparent::phaseII_tableau(T): piv :=
eigenpivot(linopt::Transparent::convert(T)): while piv <> OPTIMAL
and piv <> UNBOUNDED do T := linopt::Transparent::userstep(T,piv):
piv := eigenpivot(linopt::Transparent::convert(T)) end_while: if
piv = OPTIMAL then return(linopt::Transparent::result(T)) else
return(UNBOUNDED) end_if end_proc:
```

We now apply `mysimplex` to a linear program:
k := [{2*x + 2*y >= 4, -2*x + 4*y >= -2, -2*x + y>= -8, -2*x + y <= -2, y <= 6}, -x - y]: k := append(k, NonNegative): mysimplex(k);{x = 7, y = 6}

$\{x = 7, y = 6\}$

delete k, eigenpivot, mysimplex:

Parameters

tableau

A simplex tableau of domain type

Return Values

Two dimensional array, representing the given simplex tableau `tableau`.

linopt::Transparentlinopt::Transparent::autosteplinopt::Transparent::phaseI_tableaulinop

linopt::Transparent::dual_prices

Purpose

Get the dual solution belonging to the given tableau

Syntax

```
linopt::Transparent::dual_prices(tableau)
```

Description

`linopt::Transparent::dual_prices(tableau)` returns the dual solution of the linear optimization problem given by `tableau`.

This procedure returns the dual solution belonging to the given tableau in form of a set of lists containing two elements, the first one is a restriction and the second one is the value belonging to the slack variable connected to the restriction in the dual solution.

Examples

Example 1

Here it is demonstrated that the dual solution of the final tableau is similar to the second element of the result of linopt::minimize using the option `DualPrices`:

First we compute the final tableau of the simplex algorithm:
k := [{x <= 2, y <= 2, x + 2*y >= 4}, - x + y, NonNegative]: t := linopt::Transparent(k): t := linopt::Transparent::simplex(t)array(1..5, 1..7, [["linopt", "restr", slk[1], slk[2], slk[3], y, x], ["obj", 1, 3/2, 0, 1/2, 0, 0], [x, 2, 1, 0, 0, 0, 1], [slk[2], 1, 1/2, 1, 1/2, 0, 0], [y, 1, -1/2, 0, -1/2, 1, 0]])

"linopt"	"restr"	slk_1	slk_2	slk_3	y	x
"obj"	1	$\frac{3}{2}$	0	$\frac{1}{2}$	0	0
x	2	1	0	0	0	1
slk_2	1	$\frac{1}{2}$	1	$\frac{1}{2}$	0	0
y	1	$-\frac{1}{2}$	0	$-\frac{1}{2}$	1	0

Now we compute the solutions:
linopt::Transparent::dual_prices(t); linopt::minimize(k, DualPrices)[2]{[4 <= x + 2*y, 1/2], [0 <= x, 0], [x <= 2, 3/2], [0 <= y, 0], [y <= 2, 0]}

$$\left\{\left[4 \le x + 2\,y,\ \frac{1}{2}\right],\ [0 \le x,\ 0],\ \left[x \le 2,\ \frac{3}{2}\right],\ [0 \le y,\ 0],\ [y \le 2,\ 0]\right\}$$

{[4 <= x + 2*y, 1/2], [0 <= x, 0], [x <= 2, 3/2], [0 <= y, 0], [y <= 2, 0]}

$$\left\{\left[4 \le x + 2\,y,\ \frac{1}{2}\right],\ [0 \le x,\ 0],\ \left[x \le 2,\ \frac{3}{2}\right],\ [0 \le y,\ 0],\ [y \le 2,\ 0]\right\}$$

delete k, t:

Example 2

We compute the dual solution of another linear program:
k := [{x <= 2, y <= 2, x + 2*y >= 4}, -x + y, NonNegative]: t := linopt::Transparent(k); linopt::Transparent::dual_prices(t)array(1..5, 1..7, [["linopt", "restr", slk[1], slk[2], slk[3], y, x], ["obj", 0, 0, 0, 0, 1, -1], [slk[1], 2, 1, 0, 0, 0, 1], [slk[2], 2, 0, 1, 0, 1, 0], [slk[3], -4, 0, 0, 1, -2, -1]])

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 0 & 1 & -1 \\ \text{slk}_1 & 2 & 1 & 0 & 0 & 0 & 1 \\ \text{slk}_2 & 2 & 0 & 1 & 0 & 1 & 0 \end{pmatrix}$$

{[4 <= x + 2*y, 0], [0 <= x, -1], [x <= 2, 0], [0 <= y, 1], [y <= 2, 0]}

$$\{[4 \le x + 2\,y,\ 0],\ [0 \le x,\ -1],\ [x \le 2,\ 0],\ [0 \le y,\ 1],\ [y \le 2,\ 0]\}$$

delete k, t:

Parameters

tableau

A simplex tableau of domain type `linopt::Transparent`

Return Values

Set of lists, each containing 2 elements.

See Also linopt::Transparentlinopt::Transparent::result

linopt::Transparent::phaseI_tableau

Purpose

Start an ordinary phase one of a 2-phase simplex algorithm

Syntax

```
linopt::Transparent::phaseI_tableau(tableau)
```

Description

`linopt::Transparent::phaseI_tableau` explicitly starts an (ordinary) phase one of the simplex algorithm , i.e. rows associated with infeasible basic variables are multiplied with -1 and another identity matrix with new slack variables is added to the given tableau. As soon as an optimal tableau with relative costs 0 is found the calculation can be continued with linopt::Transparent::clean_basis and the second phase of the simplex algorithm (linopt::Transparent::phaseII_tableau).

Examples

Example 1

The first simplex tableau is created and the first phase of the simplex algorithm is started:
t := linopt::Transparent([{x + y >= 2}, x, NonNegative]); t := linopt::Transparent::phaseI_tableau(t)array(1..3, 1..5, [["linopt", "restr", slk[1], y, x], ["obj", 0, 0, 0, 1], [slk[1], -2, 1, -1, -1]])

"linopt"	"restr"	slk_1	y	x
"obj"	0	0	0	1
slk_1	2	1	−1	−1

array(1..3, 1..6, [["linopt", "restr", slk[2], slk[1], y, x], ["obj", -2, 0, 1, -1, -1], [slk[2], 2, 1, -1, -1, -1]])

"linopt"	"restr"	slk_2	slk_1	y	x
"obj"	−2	0	1	−1	−1
slk_2	2	1	−1	−1	−1

We can see that a new slack variable, slk_2, was added to the tableau. And if we now execute linopt::Transparent::simplex we can see that we have just finished the first phase of the simplex algorithm:

linopt::Transparent::suggest(t); t := linopt::Transparent::simplex(t):
linopt::Transparent::suggest(t)slk[2], y

slk_2, y

"linopt::Transparent::phaseII_tableau"

"linopt::Transparent::phaseII_tableau"

We continue the simplex algorithm by executing linopt::Transparent::clean_basis, linopt::Transparent::phaseII_tableau and linopt::Transparent::simplex. Observe in this special case linopt::Transparent::clean_basis is not necessary:
t := linopt::Transparent::clean_basis(t): t
:= linopt::Transparent::phaseII_tableau(t):
t := linopt::Transparent::simplex(t);
linopt::Transparent::suggest(t)array(1..3, 1..5, [["linopt", "restr", slk[1], y, x], ["obj", 0, 0, 0, 1], [y, 2, -1, 1, 1]])

"linopt"	"restr"	slk_1	y	x
"obj"	0	0	0	1
y	2	−1	1	1

OPTIMAL

OPTIMAL

linopt::Transparentlinopt::Transparent::autosteplinopt::Transparent::convertlinopt::Trans

linopt::Transparent::phaseII_tableau

Purpose

Start phase two of a 2-phase simplex algorithm

Syntax

```
linopt::Transparent::phaseII_tableau(tableau)
```

Description

`linopt::Transparent::phaseII_tableau(tableau)` starts the second phase of the simplex algorithm on the given simplex tableau `tableau`.

After the explicitly started first phase of the simplex algorithm (see linopt::Transparent::phaseI_tableau) terminated with an optimal tableau with associated costs 0 and no phase one slack variables in the basis (see linopt::Transparent::clean_basis) this procedure can be used to start phase II. The procedure eliminates all artificial variables of phase I and their associated columns and reenters the old objective function modified for the new basis.

Examples

Example 1

The first simplex tableau is created and the first phase of the simplex algorithm is finished:
t := linopt::Transparent([{x + y >= 2}, x,
NonNegative]): t := linopt::Transparent::simplex(
linopt::Transparent::phaseI_tableau(t))array(1..3, 1..6, [["linopt",
"restr", slk[2], slk[1], y, x], ["obj", 0, 1, 0, 0, 0], [y, 2, 1, -1, 1, 1]])

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_2 & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 1 & 0 & 0 & 0 \\ y & 2 & 1 & -1 & 1 & 1 \end{pmatrix}$$

One sees that the artificial slack variable slk[2] of the first phase is removed by `linopt::Transparent::phaseII_tableau`. In this example it is not necessary to use linopt::Transparent::clean_basis for cleaning the basis:
linopt::Transparent::phaseII_tableau(t)array(1..3, 1..5, [["linopt",
"restr", slk[1], y, x], ["obj", 0, 0, 0, 1], [y, 2, -1, 1, 1]])

"linopt"	"restr"	slk_1	y	x
"obj"	0	0	0	1
y	2	−1	1	1

delete t:

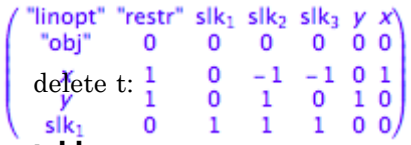
Example 2

Again the first simplex tableau is created and the first phase of the simplex algorithm is finished:
t := linopt::Transparent([{x <= 1, y <= 1, x + y >= 2}, 0, NonNegative]): t := linopt::Transparent::phaseI_tableau(t): t := linopt::Transparent::simplex(t)array(1..5, 1..10, [["linopt", "restr", slk[4], slk[5], slk[6], slk[1], slk[2], slk[3], y, x], ["obj", 0, 2, 2, 0, 1, 1, 1, 0, 0], [x, 1, 1, 0, 0, 1, 0, 0, 0, 1], [y, 1, 0, 1, 0, 0, 1, 0, 1, 0], [slk[6], 0, -1, -1, 1, -1, -1, -1, 0, 0]])

"linopt"	"restr"	slk_4	slk_5	slk_6	slk_1	slk_2	slk_3	y	x
"obj"	0	2	2	0	1	1	1	0	0
x	1	1	0	0	1	−0	0	0	1
y	1	0	1	0	0	1	0	1	0
[illegible]	0	1	1	1	1	1	1	0	0

In this example the artificial slack variable `slk[6]` is an element of the optimal basis. So we have to use linopt::Transparent::clean_basis before continuing with `linopt::Transparent::phaseII_tableau`, otherwise we will get an error message:
linopt::Transparent::phaseII_tableau(t) Error: Clean the basis from phase I slack variables first. [linopt::Transparent::phaseII_tableau]
t := linopt::Transparent::clean_basis(t):
linopt::Transparent::phaseII_tableau(t)array(1..5, 1..7, [["linopt", "restr", slk[1], slk[2], slk[3], y, x], ["obj", 0, 0, 0, 0, 0, 0], [x, 1, 0, -1, -1, 0, 1], [y, 1, 0, 1, 0, 1, 0], [slk[1], 0, 1, 1, 1, 0, 0]])

delete t:



Parameters

tableau

A simplex tableau of domain type `linopt::Transparent`

Return Values

Simplex tableau of domain type `linopt::Transparent`.

linopt::Transparentlinopt::Transparent::autosteplinopt::Transparent::convertlinopt::Transpar

linopt::Transparent::result

Purpose

Get the basic feasible solution belonging to the given simplex tableau

Syntax

```
linopt::Transparent::result(tableau)
```

Description

`linopt::Transparent::result(tableau)` returns the basic feasible solution belonging to the given simplex tableau `tableau`.

Only the user defined variables are taken into account - the dual prices can be achieved by use of linopt::Transparent::dual_prices.

Examples

Example 1

We first compute an edge for an initial simplex tableau:
k := [{x <= 1, y <= 1, x + y >= 2}, 0, NonNegative]: t := linopt::Transparent(k): linopt::Transparent::result(t){x = 0, y = 0}

$\{x = 0, y = 0\}$

Now we compute the edge for the final tableau, which is identical to the optimal solution of the linear program given by `k`. We get the final simplex tableau by using linopt::Transparent::simplex:
t := linopt::Transparent(k): t := linopt::Transparent::simplex(t): linopt::Transparent::result(t){x = 1, y = 1}

$\{x = 1, y = 1\}$

linopt::minimize(k)[OPTIMAL, {x = 1, y = 1}, 0]

$[\mathrm{OPTIMAL}, \{x = 1, y = 1\}, 0]$

delete k, t:

Parameters

tableau

A simplex tableau of domain type `linopt::Transparent`

Return Values

Set containing the values of the user defined variables for the feasible solution.

See Also linopt::Transparentlinopt::Transparent::dual_prices

linopt::Transparent::simplex

Purpose

Finish the current phase of the 2-phase simplex algorithm

Syntax

```
linopt::Transparent::simplex(tableau)
```

Description

`linopt::Transparent::simplex` runs the current phase of the 2-phase simplex algorithm until the end, i.e. if phase I was explicitly started (see linopt::Transparent::phaseI_tableau) the first phase will lead the optimal tableau. Sometimes it can be necessary to eliminate some slack variables of phase one by using linopt::Transparent::clean_basis.

If there was no phase I started by the user, `(linopt::Transparent)::simplex` returns the last optimal tableau or the empty set if there was no feasible solution found.

Examples

Example 1

We apply `linopt::Transparent::simplex` to an ordinary simplex tableau of a linear program and we get the optimal tableau:
k := [{x + y >= 2}, x, NonNegative]: t := linopt::Transparent(k); t := linopt::Transparent::simplex(t)array(1..3, 1..5, [["linopt", "restr", slk[1], y, x], ["obj", 0, 0, 0, 1], [slk[1], -2, 1, -1, -1]])

"linopt"	"restr"	slk_1	y	x
"obj"	0	0	0	1
slk_1	2	1	1	1

array(1..3, 1..5, [["linopt", "restr", slk[1], y, x], ["obj", 0, 0, 0, 1], [y, 2, 1, 1, 1]])

"linopt"	"restr"	slk_1	y	x
"obj"	0	0	0	1
y	2	−1	1	1

Let us proof the obtained result:
linopt::Transparent::suggest(t)OPTIMAL

OPTIMAL

delete k, t:

Example 2

If the first phase of the simplex algorithm was started explicitly,`linopt::Transparent::simplex` returns only the optimal tableau of the first phase:

k := [{x + y >= 2}, y, NonNegative]: t := linopt::Transparent(k): t := linopt::Transparent::phaseI_tableau(t); t := linopt::Transparent::simplex(t)array(1..3, 1..6, [["linopt", "restr", slk[2], slk[1], y, x], ["obj", -2, 0, 1, -1, -1], [slk[2], 2, 1, -1, 1, 1]])

"linopt"	"restr"	slk_2	slk_1	y	x
"obj"	-2	0	1	-1	-1
slk_2	2	1	-1	1	1

array(1..3, 1..6, [["linopt", "restr", slk[2], slk[1], y, x], ["obj", 0, 1, 0, 0, 0], [slk[2], 2, 1, -1, 1, 1]])

"linopt"	"restr"	slk_2	slk_1	y	x
"obj"	0	1	0	0	0
y	2	1	-1	1	1

The next step of the simplex algorithm is computed:

linopt::Transparent::suggest(t)"linopt::Transparent::phaseII_tableau"

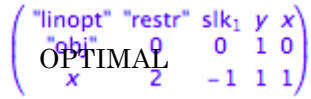
"linopt::Transparent::phaseII_tableau"

With linopt::Transparent::autostep we execute the first step of the second phase of the simplex algorithm. One can see that the simplex algorithm is not finished yet:

t := linopt::Transparent::autostep(t): linopt::Transparent::suggest(t);y, x

y, x

If we then apply `linopt::Transparent::simplex` again we get the optimal solution. Here we don't had to use linopt::Transparent::clean_basis, before using `linopt::Transparent::autostep`, because there are no artificial variables in the basis computed by the first `linopt::Transparent::simplex` call above:
t := linopt::Transparent::simplex(t);
linopt::Transparent::suggest(t)array(1..3, 1..5, [["linopt", "restr", slk[1], y, x], ["obj", 0, 0, 1, 0], [x, 2, -1, 1, 1]])



OPTIMAL

OPTIMAL
delete k, t:

Parameters

tableau

A simplex tableau of domain type `linopt::Transparent`

Return Values

Simplex tableau of domain type `linopt::Transparent` or the empty set if there was no feasible solution found.

linopt::Transparent::suggest

Purpose

Suggest the next step in the simplex algorithm

Syntax

```
linopt::Transparent::suggest(tableau)
```

Description

`linopt::Transparent::suggest(tableau)` suggests the next step in the simplex algorithm for the given simplex tableau `tableau`.

Normally this suggestion will be a pivot element, i.e. a sequence of a basic and a non-basic variable. If a phase I of the 2-phase simplex algorithm was started explicitly (see linopt::Transparent::phaseI_tableau) and the current tableau belongs to a feasible solution the suggestion will be the string `"linopt::Transparent::phaseII_tableau"`. At the end of the calculation the 'suggestion' is the identifier `OPTIMAL`.

The result of `linopt::Transparent::suggest` can be influenced if the global identifier `OPTIMAL` has a value. For this reason the identifier `OPTIMAL` is protected.

Examples

Example 1

We have a look at a linear program where the ordinary simplex tableau of the given problem is not the last tableau during the computation of the simplex algorithm. Looking at the ordinary simplex tableau we see that the element of the slk[2]-labeled row and the x-labeled column is a pivot element:

```
k := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10, 7*x + 4*y + 11*z
<= 30}, -x + y + 2*z, NonNegative]:  t := linopt::Transparent(k);
linopt::Transparent::suggest(t)array(1..5, 1..8, [["linopt", "restr", slk[1],
slk[2], slk[3], y, x, z], ["obj", 0, 0, 0, 0, 1, -1, 2], [slk[1], 23, 1, 0, 0, 4, 3,
-3], [slk[2], 10, 0, 1, 0, -4, 5, -3], [slk[3], 30, 0, 0, 1, 4, 7, 11]])
```

"linopt"	"restr"	slk_1	slk_2	slk_3	y	x	z
"obj"	0	0	0	0	1	−1	2
slk_1	23	1	0	0	4	3	−3
slk_2	10	0	1	0	−4	5	−3
slk_3	30	0	0	1	4	7	11

slk[2], x

slk_2, x

delete k, t:

Example 2

Here the ordinary simplex tableau still contains the solution of the linear program if the linear objective function is to minimize (see linopt::Transparent for more information):

```
k := [{x+y>=-1, x+y<=3}, x+2*y, NonNegative]:  t :=
linopt::Transparent(k); linopt::Transparent::suggest(t)array(1..4, 1..6,
[["linopt", "restr", slk[1], slk[2], y, x], ["obj", 0, 0, 0, 2, 1], [slk[1], 1, 1, 0,
-1, -1], [slk[2], 3, 0, 1, 1, 1]])
```

"linopt"	"restr"	slk_1	slk_2	y	x
"obj"	0	0	0	2	1
slk_1	1	1	0	−1	−1
slk_2	3	0	1	1	1

OPTIMAL

OPTIMAL

delete k, t:

Example 3

Here we explicitly start the first phase of the simplex algorithm. If we want a solution of the original linear program we have to apply the second phase of the simplex algorithm:

```
k := [{3*x + 4*y - 3*z <= 23, 5*x -4*y -3*z <= 10, 7*x
+ 4*y + 11*z <= 30}, -x + y + 2*z, NonNegative]: t :=
linopt::Transparent(k): t := linopt::Transparent::phaseI_tableau(t):
t := linopt::Transparent::simplex(t):
linopt::Transparent::suggest(t)"linopt::Transparent::phaseII_tableau"

"linopt::Transparent::phaseII_tableau"
delete k, t:
```

Parameters

tableau

A simplex tableau of domain type `linopt::Transparent`

Return Values

Sequence of 2 identifiers, the identifier `OPTIMAL` or the string `"linopt::Transparent::phaseII_tableau"`.

linopt::Transparentlinopt::Transparent::autosteplinopt::Transparent::convertlinopt::Trans

linopt::Transparent::userstep

Purpose

Perform a user defined simplex step

Syntax

```
linopt::Transparent::userstep(tableau, basvar, nonbasbar)
```

Description

`linopt::Transparent::userstep(tableau, basvar, nonbasbar)` performs a user defined simplex step in the `tableau` with the pivot element defined by `basvar` and `nonbasvar`.

Examples

Example 1

We execute the simplex step given by the pivot element `(slk[1],x)`:
k := [{x + y >= 2}, x, NonNegative]: t:= linopt::Transparent(k);
linopt::Transparent::userstep(t, slk[1], x)array(1..3, 1..5, [["linopt", "restr", slk[1], y, x], ["obj", 0, 0, 0, 1], [slk[1], -2, 1, -1, -1]])

"linopt"	"restr"	slk_1	y	x
"obj"	0	0	0	1
slk_1	1	−1	−1	2

array(1..3, 1..5, [["linopt", "restr", slk[1], y, x], ["obj", -2, 1, -1, 0], [x, 2, 1, 1, 1]])

"linopt"	"restr"	slk_1	y	x
"obj"	−2	1	−1	0
x	−1	1	1	1

Example 2

If we specify a wrong pivot element, we will get an error message:
k := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10, 7*x + 4*y + 11*z <= 30}, -x + y + 2*z, NonNegative]: t:= linopt::Transparent(k);
linopt::Transparent::userstep(t, x, y)array(1..5, 1..8, [["linopt", "restr", slk[1], slk[2], slk[3], y, x, z], ["obj", 0, 0, 0, 0, 1, -1, 2], [slk[1], 23, 1, 0, 0, 4, 3, -3], [slk[2], 10, 0, 1, 0, -4, 5, -3], [slk[3], 30, 0, 0, 1, 4, 7, 11]])

"linopt"	"restr"	slk_1	slk_2	slk_3	y	x	z
"obj"	0	0	0	0	1	−1	2
slk_1	20	1	0	0	4	3	2
slk_2	10	0	1	0	−4	5	−3
slk_3	30	0	0	1	4	7	11

Error: The pivot element is not specified or specified incorrectly.
[linopt::Transparent::userstep] delete k, t:

Parameters

tableau

A simplex tableau of domain type `linopt::Transparent`

basvar

A basic variable represented by an identifier that has to leave the basis

nonbasvar

A non-basic variable represented by an identifier that has to enter the basis

Return Values

Simplex tableau of domain type `linopt::Transparent`.

listlib – Manipulating Lists

==REFNAME==

listlib::insert

Purpose

Insert an element into a list

Syntax

```
listlib::insert(list, element, <function>)
```

Description

`listlib::insert(list, element)` inserts `element` into `list`.

With the function `listlib::insert` any element can be inserted into any list.

With the third optional argument a function can be given that compare the elements of the list with the element to insert and therewith determines the position, the element is inserted. The given function is called with two elements and have to return `TRUE`, if the two elements are in the right order, otherwise `FALSE` (see next paragraph).

The given function is called step by step with an element of the list as first argument and the given element as second argument, until it returns FALSE. Then the given element is inserted into the list in *front* of the last proved element (see “Example 2” on page 16-3).

Note The list must be ordered with regard to the order function, otherwise the element could be inserted at the wrong place.

If no third argument is given the function _less is used. If no order of the elements with regard to _less is defined, a function must be given, otherwise an error appears. The system function sysorder always can be used.

Examples

Example 1

Insert `3` into the given ordered list:
listlib::insert([1, 2, 4, 5, 6], 3)[1, 2, 3, 4, 5, 6]

```
[1, 2, 3, 4, 5, 6]
```

Insert 3 into the given descending ordered list. The insert function represents and preserves the order of the list:
listlib::insert([6, 5, 4, 2, 1], 3, _not@_less)[6, 5, 4, 3, 2, 1]

[6, 5, 4, 3, 2, 1]

Because identifiers cannot be ordered by _less, another function must be given, e.g., the function that represents the systems internal order:
listlib::insert([a, b, d, e, f], c, sysorder)[a, b, c, d, e, f]

[a, b, c, d, e, f]

Example 2

Because no function is given as third argument, the function _less is used. _less is called: `_less(1, 3)`, `_less(2, 3)`, `_less(4, 3)` and then 3 is inserted in front of 4:
listlib::insert([1, 2, 4], 3)[1, 2, 3, 4]

[1, 2, 3, 4]

If the list is not ordered right, then the insert position could be wrong:
listlib::insert([4, 1, 2], 3)[3, 4, 1, 2]

[3, 4, 1, 2]

Example 3

The following example shows, how expressions can be ordered by a user defined priority. This order is given by the function named `priority`, which returns a smaller number, when the expression has a type with higher priority:
priority := X -> contains(["_power", "_mult", "_plus"], type(X)):
priority(x^2), priority(x + 2)1, 3

1, 3

The function `sortfunc` returns TRUE, if the both given arguments are in the right order, i.e., the first argument has a higher (or equal) priority than the second argument:
sortfunc := (X, Y) -> bool(priority(Y) > priority(X)): sortfunc(x^2, x + 2), sortfunc(x + 2, x*2)TRUE, FALSE

TRUE, FALSE

Now the expression `x*2` is inserted at the “right” place in the list:
listlib::insert([x^y, x^2, x*y, -y, x + y], x*2, sortfunc)[x^y, x^2, 2*x, x*y, -y, x + y]

$$[x^y,\ x^2,\ 2\,x,\ x\,y,\ -y,\ x+y]$$

Parameters

list

MuPAD list

element

MuPAD expression to insert

function

Function that determines the insert position

Return Values

Given list enlarged with the inserted element

See Also

_concatappendlistlib::insertAt

listlib::insertAt

Purpose

Insert an element into a list at a given position

Syntax

```
listlib::insertAt(list, element, <pos>)
```

Description

`listlib::insertAt(list, element, pos)` inserts `element` into `list` at position `pos`.

With the function `listlib::insertAt` any element can be inserted into any list at a specified place.

The third argument (the “insert index”) determines the place to insert the element into the given list.

If the insert index is less than `1` the element is inserted in front of the list. If the insertion index is greater than `nops(list)` the element is appended to the list. To append an element to a list the kernel function append is faster.

If no third argument is given, the given element is inserted in front of the list.

If the argument `element` is a list too, the elements of this list will be inserted (or appended) instead of the whole list by preserving the order.

Examples

Example 1

Insertion `2` at the third place of the given list:
listlib::insertAt([1, 1, 1], 2, 3)[1, 1, 2, 1]

```
[1, 1, 2, 1]
```

Insertion of an element in front of a list. The third argument is optional in this case:
listlib::insertAt([1, 1, 3, 1], 2, 0), listlib::insertAt([1, 1, 3, 1], 2)[2, 1, 1, 3, 1], [2, 1, 1, 3, 1]

```
[2, 1, 1, 3, 1], [2, 1, 1, 3, 1]
```

Appending of an element. This could be done faster with append: listlib::insertAt([1, 2, 3], 4, 1000), append([1, 2, 3], 4)[1, 2, 3, 4], [1, 2, 3, 4]

```
[1, 2, 3, 4], [1, 2, 3, 4]
```

Parameters

list

A list

element

Any MuPAD object

pos

Any integer

Return Values

Given list enlarged with the inserted element

See Also

listlib::insertappend_concat

listlib::merge

Purpose

Merging two ordered lists

Syntax

```
listlib::merge(list1, list2, <function>)
```

Description

`listlib::merge(list1, list2)` merges both lists into one list.

With the third optional argument a function can be given that compare the elements of the lists and therewith determines the order of the elements. The given function is called with two elements and have to return `TRUE`, if the two elements are in the right order, otherwise `FALSE` (see next paragraph).

The given function is called step by step with an element of the first list as first argument and an element of the second list as second argument, until it returns FALSE. Then the element of the second list is inserted into the first list in *front* of the last proved element (see "Example 2" on page 16-8).

Note The lists must be ordered with regard to the order function, otherwise the elements could be inserted at the wrong place.

If no third argument is given the function _less is used. If no order of the elements with regard to _less is defined, a function must be given, otherwise an error appears. The system function sysorder always can be used.

Examples

Example 1

Merging two ascending ordered lists:
listlib::merge([1, 3, 5, 7], [2, 4, 6, 8])[1, 2, 3, 4, 5, 6, 7, 8]

```
[1, 2, 3, 4, 5, 6, 7, 8]
```

Merging two descending ordered lists:
listlib::merge([7, 5, 3, 1], [8, 6, 4, 2], _not@_less)[8, 7, 6, 5, 4, 3, 2, 1]

[8, 7, 6, 5, 4, 3, 2, 1]

Example 2

The following example shows, how expressions can be ordered by a user defined priority. This order is given by the function named `priority`, which returns a smaller number, when the expression has a type with higher priority:
priority := X -> contains(["_power", "_mult", "_plus"], type(X)):
priority(x^2), priority(x + 2)1, 3

1, 3

The function `sortfunc` returns TRUE, if the both given arguments are in the right order, i.e., the first argument has a higher (or equal) priority than the second argument:
sortfunc := (X, Y) -> bool(priority(Y) > priority(X)): sortfunc(x^2, x + 2), sortfunc(x + 2, x*2)TRUE, FALSE

TRUE, FALSE

Now the both lists are merged with regard to the given priority:
listlib::merge([x^y, x*2, -y], [x^2, x*y, x + y], sortfunc)[x^y, x^2, 2*x, -y, x*y, x + y]

$[x^y, x^2, 2\,x, -y, x\,y, x + y]$
delete priority, sortfunc:

Parameters

list1

list2

A MuPAD list

function

A function that determines the merging order

Return Values Ordered list that contains the elements of both lists

See Also listlib::singleMergelistlib::insert_concatzip

listlib::removeDuplicates

Purpose

Removes duplicate entries

Syntax

```
listlib::removeDuplicates(list, <KeepOrder>)
```

Description

`listlib::removeDuplicates(list)` removes all duplicates of each entry of the list `list`. The new list is build up from right to left with the order of the *last* occurence of each entry in `list`. Cf. “Example 1” on page 16-10.

A faster possibibliy to remove duplicate entries is to convert the list into a set and back into a list. You will loose the order of the list entries in this case. Cf. “Example 3” on page 16-10.

Examples

Example 1

Per default `listlib::removeDuplicates` removes duplicate entries in reverse order:
list:= [1, 1, 1, 3, 1, 5, 5, 1, 3, 3, 1, 7]: listlib::removeDuplicates(list)[5, 3, 1, 7]

```
[5, 3, 1, 7]
```

Example 2

With option `KeepOrder` entries are selected in the order of their occurence:
list:= [1, 1, 1, 3, 1, 5, 5, 1, 3, 3, 1, 7]: listlib::removeDuplicates(list, KeepOrder)[1, 3, 5, 7]

```
[1, 3, 5, 7]
```

Example 3

If you don’t need the order of list entries any more, you may convert the list into a set and back into a list, this is much faster:
list:= [1, 1, 1, 3, 1, 5, 5, 1, 3, 3, 1, 7]: [op({op(list)})][1, 3, 5, 7]

```
[1, 3, 5, 7]
```

Parameters

list

A MuPAD list

Options

KeepOrder

`listlib::removeDuplicates(list, KeepOrder)` returns a list of the entries of `list` in the order of their *first* occurrence. The list is build up from left to right. See “Example 2” on page 16-10.

Return Values

List that contains each entry only once

See Also

DOM_LISTlistlib::removeDupSorted

listlib::removeDupSorted

Purpose

Remove duplicates of any element from ordered lists

Syntax

```
listlib::removeDupSorted(list)
```

Description

`listlib::removeDupSorted(list)` removes all duplicates of any element of the ordered list `list`.

`listlib::removeDupSorted` does the same as listlib::removeDuplicates, but it assumes that the list is sorted and therefor it is faster. A notable gain will only occur, if there are only few duplicates in a long list.

Examples

Example 1

`listlib::removeDupSorted` removes all duplicates from the given list: listlib::removeDupSorted([1, 1, 1, 3, 5, 5, 5, 5, 5, 5, 5, 7, 7, 7])[1, 3, 5, 7]

```
[1, 3, 5, 7]
```

If the list is not ordered, `listlib::removeDupSorted` fails: listlib::removeDupSorted([1, 3, 5, 7, 1, 3, 5, 7, 1, 3, 5, 7])[1, 3, 5, 7, 1, 3, 5, 7, 1, 3, 5, 7]

```
[1, 3, 5, 7, 1, 3, 5, 7, 1, 3, 5, 7]
```

Parameters

list

An ordered MuPAD list

Return Values

List that contains every element only once

See Also

listlib::removeDuplicates

listlib::setDifference

Purpose

Remove elements from a list

Syntax

```
listlib::setDifference(list1, list2)
```

Description

`listlib::setDifference(list1, list2)` removes all elements from `list1`, that are given by `list2`.

Note The order of the list is not preserved.

Examples

Example 1

`listlib::setDifference` removes `2`, `4`, `6` and `8` from the given list:
listlib::setDifference([1, 2, 3, 4, 5, 6, 7, 8], [2, 4, 6, 8])[1, 3, 5, 7]

```
[1, 3, 5, 7]
```

Parameters

list1

list2

A MuPAD list

Return Values

First list without all elements of the second list

See Also

minus

listlib::singleMerge

Purpose

Merging of two ordered lists without duplicates

Syntax

```
listlib::singleMerge(list1, list2, <function>)
```

Description

`listlib::singleMerge(list1, list2)` merges the both lists into one list. It is assumed that the lists are “disjunct”, no element appears in both lists. Otherwise such elements are inserted only once in the result list.

With the third optional argument a function can be given that compare the elements of the lists and therewith determines the order of the elements. The given function is called with two elements and have to return `TRUE`, if the two elements are in the right order, otherwise `FALSE` (see next paragraph).

The given function is called step by step with an element of the first list as first argument and an element of the second list as second argument, until it returns FALSE. Then the element of the second list is inserted into the first list in *front* of the last proved element (see “Example 3” on page 16-15).

Note The lists must be ordered with regard to the order function, otherwise the elements could be inserted at the wrong place.

If no third argument is given the function _less is used. If no order of the elements with regard to _less is defined, a function must be given, otherwise an error appears. The system function sysorder always can be used.

Examples

Example 1

Merging two ascending ordered lists:
listlib::singleMerge([1, 3, 5, 7], [2, 4, 6, 8])[1, 2, 3, 4, 5, 6, 7, 8]

[1, 2, 3, 4, 5, 6, 7, 8]

Merging two descending ordered lists:
listlib::singleMerge([7, 5, 3, 1], [8, 6, 4, 2], _not@_less)[8, 7, 6, 5, 4, 3, 2, 1]

[8, 7, 6, 5, 4, 3, 2, 1]

Example 2

Merging two ascending ordered lists with duplicates:
listlib::singleMerge([1, 2, 5, 7], [2, 5, 6, 8])[1, 2, 5, 6, 7, 8]

[1, 2, 5, 6, 7, 8]

But the following lists does not contain mutual equal elements:
listlib::singleMerge([1, 1, 3, 3], [2, 2, 4, 4])[1, 1, 2, 2, 3, 3, 4, 4]

[1, 1, 2, 2, 3, 3, 4, 4]

Example 3

The following example shows, how expressions can be ordered by a user defined priority. This order is given by the function named `priority`, which returns a smaller number when the expression has a type with higher priority:
priority := X -> contains(["_power", "_mult", "_plus"], type(X)):
priority(x^2), priority(x + 2)1, 3

1, 3

The function `sortfunc` returns TRUE, if the both given arguments are in the right order, i.e., the first argument has a higher (or equal) priority than the second argument:
sortfunc := (X, Y) -> bool(priority(Y) > priority(X)): sortfunc(x^2, x + 2), sortfunc(x + 2, x*2)TRUE, FALSE

TRUE, FALSE

Now the both lists are merged with regard to the given priority:
listlib::singleMerge([x^y, x*2, -y], [x^2, x*y, x + y], sortfunc)[x^y, x^2, 2*x, -y, x*y, x + y]

$[x^y, x^2, 2\,x, -y, x\,y, x+y]$

delete priority, sortfunc:

Parameters

list1

list2

A MuPAD list

function

A function that determines the merging order

Return Values

Ordered list that contains the elements of both lists

See Also

listlib::mergelistlib::insert_concatzip

listlib::sublist

Purpose

Search sublists

Syntax

```
listlib::sublist(list1, list2, <index>, <Consecutive>)
```

Description

`listlib::sublist(list1, list2)` determines, whether the list `list1` contains another list `list2`.

With `listlib::sublist` the position of the first appearance of a list in another list can be determined.

The position that was found is returned as integer. If the given list does not contain the given `sublist`, the number `0` is returned.

If an index is given, the search starts at this position. There with multiple occurrence of a sublist can be determined.

With the option `Consecutive`, the list must contain the sublist in one piece without elements in between.

Examples

Example 1

The sublist is a part of the list, but not in one piece:
listlib::sublist([1, 2, 3, 4, 5, 6, 7, 8], [2, 3, 5, 6])2

```
2
```

listlib::sublist([1, 2, 3, 4, 5, 6, 7, 8], [2, 3, 5, 6], Consecutive)0

```
0
```

The list contains the sublist, coherent and incoherent:
listlib::sublist([1, 2, 3, 4, 5, 1, 3, 5], [1, 3, 5])1

```
1
```

listlib::sublist([1, 2, 3, 4, 5, 1, 3, 5], [1, 3, 5], Consecutive)6

```
6
```

Example 2

Find the last occurence of the sublist inside of the list:

```
POS:= 0: while listlib::sublist([1, 2, 3, 1, 3, 1, 2, 3], [1, 2, 3], POS + 1)
> 0 do POS:= listlib::sublist([1, 2, 3, 1, 3, 1, 2, 3], [1, 2, 3], POS + 1)
end_while: POS6
```

```
6
```

delete POS:

Parameters

list1

list2

MuPAD list

index

Integer that determines the first search position

Options

Consecutive

Determines that the sublist `list2` is containing coherent in `list1`

Return Values

Position of the first element of the containing sublist or zero

See Also

containsop

misc – Miscellanea

==REFNAME==

misc::breakmap

Purpose

Stops the mapping currently done by maprec

Syntax

```
misc::breakmap()
```

Description

`misc::breakmap`() stops the recursive application of a function to all subexpressions of an expression that misc::maprec is just working on.

`misc::breakmap` is useful as a command inside the procedure mapped by misc::maprec in case we know that we are finished with our work and the remaining recursive mapping is not necessary.

Examples

Example 1

We want to know whether a given expression contains a particular type `t`. As soon as we have found the first occurence of `t`, we can terminate our search.
myfound := FALSE: misc::maprec(hold(((23+5.0)/3+4*I)*PI), {DOM_COMPLEX}=proc() begin myfound := misc::breakmap(); args() end_proc): myfoundTRUE

TRUE

What did we do? We told misc::maprec just to go down the expression tree and look for subexpressions of type DOM_COMPLEX; and, whenever such subexpression should be found, to apply a certain procedure to it. That procedure stops the recursive mapping, remembers that we have found the type we had searched for, and returns exactly its argument such that the result returned by misc::maprec equals the input. In the example below, we test whether our given expression contains the type DOM_POLY.
myfound := FALSE: misc::maprec(hold(((23+5.0)/3+4*I)*PI), {DOM_POLY}=proc() begin myfound := misc::breakmap(); args() end_proc): myfoundFALSE

FALSE

Note that you do not need to use this method when searching for subexpressions of a given type; calling hastype is certainly more convenient.

Return Values

`misc::breakmap` always returns TRUE.

See Also

misc::maprec

misc::genassop

Purpose

Generates an n-ary associative operator from a binary one

Syntax

```
misc::genassop(binaryop, zeroelement)
```

Description

`misc::genassop(binaryop, zeroelement)` generates an n-ary associative operator from the binary operator `binaryop`, where `zeroelement` is a neutral element for `binaryop`.

`binaryop` must be a function taking two arguments (no matter of what kind) and returning a valid argument to itself. It must satisfy the associative law `binaryop(binaryop(a, b), c) = binaryop(a, binaryop(b, c))`.

`zeroelement` is an object such that `binaryop(a, zeroelement) = a` holds for every `a`.

`misc::genassop` returns a procedure which returns `zeroelement` if it is called without arguments and the argument if it is called with one argument.

Note `misc::genassop` doesn't check whether `binaryop` is really associative and whether `zeroelement` is really a neutral element for `binaryop`.

Examples

Example 1

We know that _plus is an n-ary operator anyway, but let us assume that _plus was only a binary operator. We can create an own n-ary addition as follows:
myplus := misc::genassop(_plus, 0)‘proc genericAssop() ... end‘

```
proc genericAssop() ... end
```

Now we make `myplus` add some values.
myplus(3, 4, 8), myplus(-5), myplus()15, -5, 0

```
15, -5, 0
```

As mentioned in the "Details" section, `myplus` returns the argument if is called with exactly one argument, and it returns the `zeroelement` `0` if it is called without arguments.

Parameters

binaryop

A function

zeroelement

An object

Return Values

`misc::genassop` returns a procedure `f`. That procedure accepts an arbitrary number of arguments of the same kind `binaryop` does; it returns `zeroelement` if it is called without argument, and its only argument if it is called with one argument; its value on *n* arguments is inductively defined by `f(x1, ..., xn)=f(binaryop(x1,x2), x3,...,xn)`.

operator

misc::maprec

Purpose

Map a function to subexpressions of an expression

Syntax

```
misc::maprec(ex, selector = funci,  , <PreMap | PostMap>,
<NoOperators>, <Unsimplified>)
```

Description

`misc::maprec(ex, selector=funci)` maps the function `funci` to all subexpressions of the expression `ex` that satisfy a given criterion (defined by `selector`) and replaces each selected subexpression `s` by `funci(s)`.

Several different functions may be mapped to subexpressions satisfying different selection criteria.

$\texttt{misc::maprec(ex, selector}_1\texttt{ = funci}_1\texttt{, , selector}_n\texttt{ = funci}_n\texttt{)}$ does two steps: it tests whether `ex` meets a selection criterion defined by some selector `selector_k` (and, if yes, replaces `ex` by `funci_k(ex)`); and it applies itself recursively to all operands of `ex`. The order of these steps is determined by the options `PreMap` and `PostMap`.

Selectors are applied from left to right; if the expression meets some selection criterion, no further selectors are tried.

`selector` can have two forms. It can be a set $\{t_1, \ldots, t_n\}$. Here a subexpression `s` of `ex` is selected if type(s1) is one of the types $t_1, \ldots, t_n$. If it is not a set, a subexpression `s` of `ex` is selected if `p`(s) returns TRUE. As every MuPAD object may be applied as a function to `s`, `p` may be of any type in the latter case.

In order not to select a subexpression, the selector need not return FALSE; it suffices that it does not return TRUE.

If neither the option `PreMap` nor the option `PostMap` is given, then `PreMap` is used.

Use a misc::breakmap command inside `funci` in order to stop the recursive mapping. See the help page of misc::breakmap for an example.

Note Only subexpressions of domain type DOM_ARRAY, DOM_EXPR, DOM_LIST, DOM_SET, and DOM_TABLE are mapped recursively, as well as domain elements of a domain `T` for which a slot `T::enableMaprec` exists and equals `TRUE`; a slot `T::map` working properly must then exist, too. To subexpressions of other types, `selector` is applied, but `misc::maprec` is not mapped to their operands. (This is to avoid unwanted substitutions.) If you want to recurse on them, either add an `enableMaprec`-slot, or use a `selector` that selects such subexpressions, and make `funci` initiate another recursive mapping.

`misc::maprec` is overloadable. If the domain of a subexpression has a method `"maprec"`, then this method is called with the subexpression and the other arguments of the call.

Note The subexpression is replaced by the result, but `misc::maprec` is not mapped to its operands; such recursive mapping must be done by the domain method if desired.

Note The operators of expressions (`op(expression, 0)`) are also mapped recursively like all the other operands. Use `NoOperators` to switch this off.

Examples

Example 1

In the following example every integer of the given expression `a+3+4` is substituted by the value 10. Since `10(n)` returns `10` for every integer `n`, it suffices to write `10` instead of `n -> 10` here.

```
misc::maprec(hold(a+3+4), {DOM_INT} = 10)a + 20
```

$$a + 20$$

In the example above, we used hold to suppress the evaluation of the expression because otherwise `a+3+4` is evaluated to `a+7` and we get the result:
misc::maprec(a+3+4, {DOM_INT} = 10)a + 10

$$a + 10$$

The simplification of the resulting `10 + 10` to `20` can be avoided by using the option `Unsimplified`:
misc::maprec(hold(a+3+4), {DOM_INT} = 10, Unsimplified)a + 10 + 10

$$a + 10 + 10$$

Example 2

Now we give an example where the `selector` is a function. We want to eleminate all the prime numbers from an expression.
misc::maprec(hold(_plus)(i $ i=1..20), isprime= null(), PostMap)133

$$133$$

Here isprime returns TRUE for every prime number between 1 and 20. Every prime number between 1 and 20 is replaced by null() (since `null()(p)` gives `null()`) which means the above call computes the sum of all non-prime numbers between 1 and 20.

Example 3

Normally, `misc::maprec` recurses also into the operators of subexpressions. This may be unwanted in many cases:
misc::maprec(a+b, {DOM_IDENT}= (x -> x.1))_plus1(a1, b1)

$$_{p}\mathrm{lus1}(a1, b1)$$

We just wanted to replace the summands, but not the operator. Using the option `NoOperators` helps:
misc::maprec(a+b, {DOM_IDENT}= (x -> x.1), NoOperators)a1 + b1

```
a1 + b1
```

Parameters

ex

Any MuPAD object

selector

Any MuPAD object

funci

Any MuPAD object

Options

PreMap

For each subexpressions `s` of `ex`, the selector is applied to it *after* visiting all of its subexpressions; `s` may have changed at that time due to substitutions in the subexpressions.

PostMap

For each subexpressions `s` of `ex`, the selector is applied to it *before* visiting its subexpressions. If `s` is selected by `selector`, it is replaced by `funci(s)`, and `misc::maprec` is *not* recursively applied to the operands of `funci(s)`; otherwise, `misc::maprec` is recursively applied to the operands of `s`.

NoOperators

The selector is not applied to the operator of `ex`.

Unsimplified

The resulting expressions are not further simplified.

Return Values

`misc::maprec` may return any MuPAD object.

Overloaded By

`ex`

See Also mapmapcoeffsmisc::breakmap

misc::pslq

Purpose

Heuristic detection of relations between real numbers

Syntax

```
misc::pslq(numberlist, precision)
```

Description

`misc::pslq(numberlist, precision)` returns a list of integers `[k1, ..., kn]` such that — denoting the elements of `numberlist` by `a1, ..., an` — the absolute value of sum(a[i] * k[i], i=0..n) $\sum_{i=0}^{n} a_i k_i$ is less than 10^(-precision) $\frac{1}{precision}$ times the Euclidean norm of `numberlist`, or `FAIL` if such integers could not be detected.

This method can be used to get an idea about linear dependencies, before proving them.

Environment Interactions

`misc::pslq` is *not* affected by the current value of DIGITS. Numerical computations are carried out with more significant digits such that the output meets the specification given above.

Examples

Example 1

Does π satisfy a polynomial equation of degree at most 2 ?
misc::pslq([1, PI, PI^2], 20)FAIL

```
FAIL
```

Example 2

Having forgotten the relation between sine and cosine, we can try the heuristic way.
misc::pslq([1, sin(0.32), sin(0.32)^2, cos(0.32), cos(0.32)^2], 10)matrix([[1, 0, -1, 0, -1]])

```
(1  0  -1  0  -1)
```

Parameters

numberlist

List of real numbers or objects that can be converted to real numbers by the function float.

precision

Positive integer

Return Values

List of integers, or `FAIL`

Algorithms

This function has been written by Raymond Manzoni.

The algorithm has been taken from Bailey and Plouffe, *Recognizing numerical constants*. See also Helaman R.P. Ferguson and David Bailey, *A Polynomial Time, Numerically Stable Integer Relation Algorithm*, RNR Technical Report RNR-92-032.

18

module – Dynamic Modules

module

module::age

Purpose

Module aging

Note Dynamic modules for MuPAD will be removed in a future release.

Syntax

```
module::age()
module::age(maxtime)
module::age(maxtime, interval)
```

Description

`module::age(maxtime)` sets the maximum number of seconds that the machine code of an inactive dynamic module resides in the main memory. A module is called inactive, if its machine code is currently not executed or used in any other sense.

`module::age()` returns the current maximum age of dynamic modules. This is the maximum number of seconds the machine code of a dynamic module resides in MuPAD kernel process before it is displaced from the main memory. The return value 0 indicates that module aging is deactivated.

`module::age(maxtime)` sets a new maximum age of dynamic modules and returns this value.

`module::age(0)` deactivates the module aging. This is the default value.

`module::age(maxtime,interval)` also sets the maximum number of seconds between two successive checks whether any inactive dynamic module has to be displaced.

Parameters

maxtime

Maximum number of seconds before module displacement takes place: integer of range 0..3600

interval

Maximum number of seconds between two checks for module displacement: integer of range 1..60

Return Values

Integer of range 0..3600 is returned.

Algorithms

`module::age` uses the module function `stdmod::age` to get and set the maximum age.

This kind of module resource management is called module aging.

The Aging algorithm is called periodically during the evaluation as well as directly before the functions module, module::displace and external are executed.

Beside module aging, the maximum number of modules which simultaneously reside in main memory can be limited with the function module::max.

The function module::stat displays information about the dynamic module which are currently loaded in the main memory.

Purpose

module::displace

Unloads a module

Note Dynamic modules for MuPAD will be removed in a future release.

Syntax

```
module::displace(modname, <Force>)
module::displace()
```

Description

`module::displace(modname)` unloads a dynamic module.

Environment Interactions

The machine code of modules is unloaded transparently to the user. It especially does not affect the module domains. The machine code is reloaded automatically if it is needed later.

The function reset unloads all dynamic modules.

Parameters

modname

Module name: character string, identifier or module domain

Options

Force

Forces the module manager to unload a static module.

Return Values

Void object of type DOM_NULL.

module::func

Purpose

Creates a module function environment

Note Dynamic modules for MuPAD will be removed in a future release.

Syntax

```
module::func(mname, <fname>)
```

Description

In some cases it is not necessary to access a whole module but one only wants to call a specific module function. This can be done by creating a module function environment and assigning it to a variable. With this neither the module machine code is loaded nor the module domain will be created. The corresponding machine code is loaded on demand when this module function is executed.

`module(mname,fname)` is an abbreviation for `module::func(name,fname)`.

`module::func(name,fname)` uses the kernel function external to create a module function environment.

Parameters

mname

Module name: character string, identifier or module domain

fname

Function name: character string or identifier

Return Values

Function environment function environment of type DOM_FUNC_ENV.

module::help

Purpose

Displays module online documentation

Note Dynamic modules for MuPAD will be removed in a future release.

Syntax

```
module::help(mname)
module::help(mname, fname)
```

Description

`module::help(mname)` displays plain text module online documentation.

The online documentation of a dynamic module usually consists of a brief introduction page about the features of the module followed by help pages for all functions of the module.

`module::help(mname,fname)` displays the plain text help page of the module function `mname::fname`. This online documentation may be provided with the file `mname.mdh` which must then be located in the same directory as the module file `mname.mdm`.

The online documentation of the module `mname` respectively of the module function `mname::fname` can be displayed in a more convenient way using the module function `mname::doc()` respectively `mname::doc("fname")`.

Parameters

mname

Module name: character string

fname

Function name: character string

Return Values

Void object of type DOM_NULL.

Algorithms

`module::help` uses the module function `stdmod::help` to find and read the module online documentation file.

The search paths for the module online documentation is equal to those used for dynamic module files. Additional information are given with the kernel function `loadmod`.

References

Reference: Dynamic Modules - User's Manual and Programming Guide for MuPAD 1.4, Andreas Sorgatz, Oct 1998, Springer Verlag, Heidelberg, with CD-ROM, ISBN 3-540-65043-1. Section 3.4 describes the file format of the module online documentation file.

See Also

modulemodule::stat

module::load

Purpose

Loads a module

Note Dynamic modules for MuPAD will be removed in a future release.

Syntax

```
module::load(mname)
```

Description

`module::load(mname)` loads a dynamic module and creates a corresponding module domain.

`module(mname)` is an abbreviation for `module::load(mname)`.

Environment Interactions

If `module::load(mname)` successfully loads a dynamic modules, it creates a corresponding module domain and assigns it to the identifier `mname`.

Parameters

mname

Module name: character string or identifier

Return Values

Module domain of type DOM_DOMAIN.

module::max

Purpose

Simultaneously loadable modules

Note Dynamic modules for MuPAD will be removed in a future release.

Syntax

```
module::max()
module::max(maxnum)
```

Description

`module::max(maxnum)` sets the maximum number of dynamic modules which may reside in the main memory simultaneously.

`module::max(maxnum)` sets a new maximum number and returns this value.

Parameters

maxnum

Maximum number of dynamic modules which simultaneously reside in the main memory: integer less than or equal to 256 and greater than or equal to 1 respectively the number of currently loaded modules

Return Values

Integer in the range 1..256.

Algorithms

`module::max` uses the module function `stdmod::max` to get and set the maximum number of simultaneously loadable modules.

If the maximum number of simultaneously loadable modules is reached, for any new dynamic module that is to be loaded at least one previously loaded module is displaced from the main memory with respect to the least-recently-used strategy. Thus, the actual number of simultaneously usable modules is not limited.

Module displacement is transparent to the user. The machine code is reloaded automatically if it is needed later.

The maximum number of seconds that the machine code of an inactive dynamic module resides in the main memory can be limited with the function module::age.

The function module::stat displays information about the dynamic module which are currently loaded in the main memory.

Purpose

Loads a module

Note Dynamic modules for MuPAD will be removed in a future release.

Syntax

```
module(mname)
module(mname, fname)
```

Description

`module(mname)` loads a dynamic module and creates a corresponding module domain.

`module(mname, fname)` creates a module function environment.

`module(mname)` or, equivalently, `module::new(mname)` uses the function module::load to load a module.

`module(mname, fname)` or, equivalently, `module::new(mname, fname)` uses the function module::func to create a module function environment.

Environment Interactions

If `module(mname)` successfully loads a dynamic module, it creates a corresponding module domain and assigns it to the identifier `name`.

Parameters

mname

Module name: character string or identifier

fname

Function name: character string or identifier

Return Values

Either a module domain of type DOM_DOMAIN or a function environment of type DOM_FUNC_ENV.

Algorithms

Module online documentation can be displayed with the library function module::help.

References

Dynamic Modules - User's Manual and Programming Guide for MuPAD 1.4, Andreas Sorgatz, Oct 1998, Springer Verlag, Heidelberg, with CD-ROM, ISBN 3-540-65043-1.

module::stat

Purpose

Status of the module manager

Note Dynamic modules for MuPAD will be removed in a future release.

Syntax

```
module::stat()
```

Description

`module::stat()` displays information about the current status of the module manager, e.g. the path of the MuPAD module directory, the current and the maximum number of modules which may reside simultaneously in the main memory, the status of module aging as well as the list of the currently loaded modules.

A large part of the information is only interesting for administration and is not needed by normal users.

Return Values

Void object of type DOM_NULL.

Algorithms

`module::stat` uses the module function `stdmod::stat` to collect the status information of the module manager.

The maximum number of seconds that the machine code of an inactive dynamic module resides in the main memory can be limited with the function module::age (see above `Aging:...`).

The maximum number modules which may reside simultaneoulsy in the main memory can be limited with the function module::max (see above `Module:... max = 16`).

The entry `M-Path` specifies the MuPAD module directory which contains dynamic modules including their online documentation.

The entry `LRU = stdmod` specifies that this dynamic module will be displaced next using the least-recently-used strategy.

module::which

Purpose

Installation path of a module

Note Dynamic modules for MuPAD will be removed in a future release.

Syntax

```
module::which(mname)
```

Description

`module::which(mname)` uses the module function `stdmod::which` to determine the module installation path.

Parameters

mname

Module name: character string, identifier or module domain

Return Values

Character string of type DOM_STRING or the value FAIL, if the module cannot be found.

19

numeric – Numerical Algorithms

numeric::spectralradius
numeric::spectralRadius

numeric::butcher

Purpose

Butcher parameters of Runge-Kutta schemes

Syntax

```
numeric::butcher(EULER1 | RKF43 | xRKF43 | RK4 | RKF34 |
xRKF34 | RKF54a | xRKF54a | RKF54b | xRKF54b | DOPRI54
| xDOPRI54 | CK54 | xCK54 | RKF45a | xRKF45a | RKF45b |
xRKF45b | DOPRI45 | xDOPRI45 | CK45 | xCK45 | DOPRI65
| xDOPRI65 | DOPRI56 | xDOPRI56 | BUTCHER6 | RKF87 |
xRKF87 | RKF78 | xRKF78 | DOPRI87 | xDOPRI87 | DOPRI78 |
xDOPRI78 | GAUSS(s) | GAUSS = s, <digits>)
```

Description

`numeric::butcher(method)` returns the Butcher parameters of the Runge-Kutta scheme named `method`.

An s-stage Runge-Kutta method for the numerical integration of a dynamical system dy/dt=f(t, y)$\frac{dy}{dt} = f(t, y)$ with step size h is a map

(t, y) -> fenced(t+h, y+h*b[1]*k[1]+ Symbol::cdots+h*b[s]*k[s])

$$(t, y) \to (t + h,\ y + h\, b_1\, k_1 + \cdots + h\, b_s\, k_s)$$

The "intermediate stages" k_1, …, k_s are defined as the solutions of the algebraic equations

k[i]=f(t+c[i]*h, y+h*a[(i1)]* k[1]+Symbol::cdots+h*a[(is)]*k[(s)]), 1<=i<=s

$$k_i = f(t + c_i\, h,\ y + h\, a_{i1}\, k_1 + \cdots + h\, a_{is}\, k_s),\ 1 \le i \le s$$

If the s s "Butcher matrix" a_{ij} is strictly lower triangular, the method is called "explicit". In this case, the intermediate stages are computed recursively as:

eqsys(k[1]=f(t, y), k[2]=f(t+c[2]*h, y+h*a[(21)]*k[1]), Symbol::hellip, k[s]=f(t+c[s]*h, y+h*a[(s1)]*k[1]+Symbol::hellip+ h*a[(s, s-1)]*k[(s-1)]))

$k_1 = f(t, y)$

$k_2 = f(t + c_2\, h,\ y + h\, a_{21}\, k_1)$

.

.

$k_s = f(t + c_s\, h,\ y + h\, a_{s,1}\, k_1 + \cdots + h\, a_{s,s-1}\, k_{s-1})$

Various numerical schemes arise from different choices of the Butcher parameters: the s s-matrix a_{ij}, the weights $b = [b_1, \ldots, b_s]$ and the abscissae $c = [c_1, c_2, \ldots, c_s]$.

Embedded pairs of Runge-Kutta methods consist of two methods that share the matrix a_{ij} and the abscissae c_i, but use different weights b_i.

The returned list `[s, c, a, b1, b2, order1, order2]` contains the Butcher data of the method: `s` is the number of stages, `c` is the list of abscissae, `a` is the Butcher matrix, `b1` and `b2` are lists of weights. The integers `order1` and `order2` are the orders of the scheme when using the weights `b1` or `b2`, respectively, in conjunction with the matrix `a` and the abscissae `c`.

The methods `EULER1` (order 1), `RK4` (order 4) and `BUTCHER6` (order 6) are single methods with `b1 = b2` and `order1 = order2`. All other methods are embedded pairs of Runge-Kutta-Fehlberg (`RKFxx`), Dormand-Prince (`DOPRIxx`) or Cash-Karp (`CKxx`) type. The names indicate the orders of the subprocesses, e.g., `CK45` is the Cash-Karp pair of orders 4 and 5. `CK54` is the same pair with reversed ordering of the subprocesses. The second subprocess is used to produce a time step of the Runge-Kutta method, the first subprocess is used for estimating the error of the time step.

The methods `GAUSS(s)` or, equivalently, `GAUSS = s` are the implicit Gauss methods with `s` stages of order $2s$.

The data of all explicit methods are returned as exact rational numbers. The data of the Gauss methods are returned as floating-point numbers.

The Butcher data are called by the routines numeric::odesolve, numeric::odesolve2, and numeric::odesolveGeometric.

Environment Interactions

When computing the data for `GAUSS(s)`, the function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

The Butcher data of the classical 4 stage, 4th order Runge-Kutta scheme are:
numeric::butcher(RK4)[4, array(1..4, [0, 1/2, 1/2, 1]), array(1..4, 1..4, [[0, 0, 0, 0], [1/2, 0, 0, 0], [0, 1/2, 0, 0], [0, 0, 1, 0]]), array(1..4, [1/6, 1/3, 1/3, 1/6]), array(1..4, [1/6, 1/3, 1/3, 1/6]), 4, 4]

$$\left[4, \left(0\ \frac{1}{2}\ \frac{1}{2}\ 1\right), \begin{pmatrix} 0 & 0 & 0 & 0 \\ \frac{1}{2} & 0 & 0 & 0 \\ 0 & \frac{1}{2} & 0 & 0 \\ 0 & 0 & 1 & 0 \end{pmatrix}, \left(\frac{1}{6}\ \frac{1}{3}\ \frac{1}{3}\ \frac{1}{6}\right), \left(\frac{1}{6}\ \frac{1}{3}\ \frac{1}{3}\ \frac{1}{6}\right), 4, 4\right]$$

Note that the weights b_1 and b_2 coincide: this classical method does not provide an embedded pair.

The Butcher data of the (implicit) 3 stage Gauss method:
DIGITS := 5: numeric::butcher(GAUSS(3)); delete DIGITS:[3, array(1..3, [0.1127, 0.5, 0.8873]), array(1..3, 1..3, [[0.13889, -0.035977, 0.0097894], [0.30026, 0.22222, -0.022485], [0.26799, 0.48042, 0.13889]]), array(1..3, [0.27778, 0.44444, 0.27778]), array(1..3, [0.27778, 0.44444, 0.27778]), 6, 6]

$$\left[3, \left(0.1127\ 0.5\ 0.8873\right), \begin{pmatrix} 0.13889 & -0.035977 & 0.0097894 \\ 0.30026 & 0.22222 & -0.022485 \\ 0.26799 & 0.48042 & 0.13889 \end{pmatrix}, \left(0.27778\ 0.44444\ 0.27778\right), \left(0.2\right.$$

Example 2

The Butcher data of the embedded Runge-Kutta-Fehlberg pair `RKF34` of orders 3 and 4 are:
[s, c, a, b1, b2, order1, order2] := numeric::butcher(RKF34):

The number of stages s of the 4th order subprocess is 5, the abscissae c and the matrix a are given by:
s, c, a5, array(1..5, [0, 1/4, 4/9, 6/7, 1]), array(1..5, 1..5, [[0, 0, 0, 0, 0], [1/4, 0, 0, 0, 0], [4/81, 32/81, 0, 0, 0], [57/98, -432/343, 1053/686, 0, 0], [1/6, 0, 27/52, 49/156, 0]])

$$5,\ \left(0,\ \frac{1}{4},\ \frac{4}{9},\ \frac{6}{7},\ 1\right),\ \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ \frac{1}{4} & 0 & 0 & 0 & 0 \\ \frac{4}{81} & \frac{32}{81} & 0 & 0 & 0 \\ \frac{57}{98} & -\frac{432}{343} & \frac{1053}{686} & 0 & 0 \\ \frac{1}{6} & 0 & \frac{27}{52} & \frac{49}{156} & 0 \end{pmatrix}$$

Using these parameters with the weights
b1, b2array(1..5, [1/6, 0, 27/52, 49/156, 0]), array(1..5, [43/288, 0, 243/416, 343/1872, 1/12])

$$\left(\frac{1}{6}\ 0\ \frac{27}{52}\ \frac{49}{156}\ 0\right),\ \left(\frac{43}{288}\ 0\ \frac{243}{416}\ \frac{343}{1872}\ \frac{1}{12}\right)$$

yields a numerical scheme of order 3 or 4, respectively:
order1, order23, 4

$$3,\ 4$$

delete s, c, a, b1, b2, order1, order2:

Example 3

We plot the stability regions of the two sub-methods of DOPRI78. The stability function of a Runge-Kutta scheme with Butcher parameters (c, a, b) is given by

p(z)=1+z*linalg::scalarProduct(b, fenced(1-z*a)^(-1) * e)

$$p(z) = 1 + z\left(\left\langle b,\ \frac{e}{(1 - z\,a)}\right\rangle\right)$$

where e is the column vector $(1, 1, \ldots, 1)^T$. For an explicit s-stage scheme (the matrix a is strictly lower triangular), this stability function reduces to the polynomial

p(z)=1+sum(z^i*linalg::scalarProduct(b, a^(i-1) * e), i=1..s)

$$p(z) = 1 + \left(\sum_{i=1}^{s} z^i \left(\left\langle b, a^{i-1} e \right\rangle \right) \right)$$

We compute the coefficients of the stability polynomials associated with the Butcher matrix `a` and the weights b_1 and b_2 of the sub-methods of `DOPRI78`:

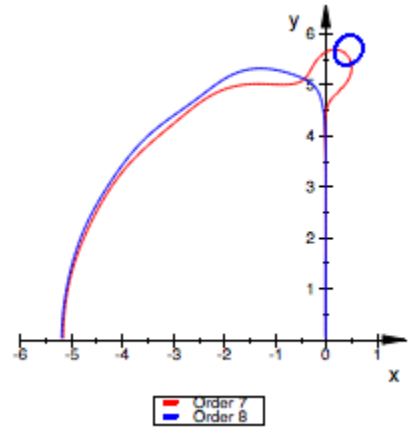
```
[s, c, a, b1, b2, order1, order2] := numeric::butcher(DOPRI78):
e := matrix([1 $ s]): a := float(matrix(a)): b1
:= linalg::transpose(float(matrix(b1))): b2 :=
linalg::transpose(float(matrix(b2))): for i from 1 to s do c1[i] :=
(b1*a^(i-1)*e)[1, 1]; c2[i] := (b2*a^(i-1)*e)[1, 1]; end_for:
```

We define the stability polynomials:

```
z := x + I*y: p1 := 1 + _plus(c1[i]*z^i $ i = 1..s): p2 := 1 + _plus(c2[i]*z^i
$ i = 1..s):
```

The boundary of the stability region SubSet(z, C_, abs(p(z)) < 1)$\{z \in \mathbb{C} \mid |p(z)| < 1\}$ is the curve defined by $|p(z)| = 1$. We plot these implicit curves associated with the stability polynomials $p_1(z)$ and $p_2(z)$ defined above:

```
plot(plot::Implicit2d(abs(p1) = 1, x = -6..1, y = 0..6, Color = RGB::Red,
Legend = "Order 7"), plot::Implicit2d(abs(p2) = 1, x = -6..1, y = 0..6,
Color = RGB::Blue, Legend = "Order 8"), Scaling = Constrained):
```



delete s, c, a, b1, b2, order1, order2, e, c1, c2, z, p1, p2:

Parameters

s

The number of stages of the Gauss method: a positive integer

digits

The number of significant digits with which the Butcher data of the methods `GAUSS(s)` are computed. The default value for `digits` is the current value of the environment variable DIGITS. This argument is only relevant for the Gauss methods.

Return Values

A list `[s, c, a, b1, b2, order1, order2]` is returned.

Algorithms

The Butcher parameters provided in this original paper consist of rational *approximations* of solutions of the order equations of Runge-Kutta systems. The parameters provided by `numeric::butcher` are *exact* rational solutions of the order equations. The approximations given by Prince and Dormand coincide with the MuPAD exact values through 16 decimal digits.

numeric::odesolvenumeric::odesolve2numeric::odesolveGeometric

numeric::complexRound

Purpose

Round a complex number towards the real or imaginary axis

Syntax

```
numeric::complexRound(z, <eps>)
```

Description

`numeric::complexRound(z)` discards small real or imaginary parts of complex floating-point numbers `z`.

If the real part of z satisfies $\Re(z) < eps\,|z|$, then it is replaced by zero and $\Im(z)$i is returned.

If the imaginary part of z satisfies $\Im(z) < eps\,|z|$, then it is replaced by zero and $\Re(z)$ is returned.

With the default of `eps=10^-DIGITS`, this rounding changes a complex floating-point number by less than the relative standard precision.

Only precisions `eps >= 10^-DIGITS` are accepted.

Numerical expressions such as `eps` = PI*sqrt(2)*10^-10 $\pi\sqrt{2}\,10^{-10}$ etc. are accepted as `eps`.

This function removes small real or imaginary parts of complex floating-points numbers generated by numerical roundoff. It is used to simplify the floating-point output of numeric::fsolve, numeric::polyroots, numeric::polysysroots and numeric::sum.

Environment Interactions

The function is sensitive to the environment variable DIGITS.

Examples

Example 1

Exact numbers are not changed:
numeric::complexRound(2 + I/10^20)2 + (1/10000000000000000000)*I

$$2 + \frac{i}{10000000000000000000}$$

Also the following number has an exact imaginary part and is not rounded:

numeric::complexRound(2.0 + sqrt(2)*I/10^20)2.0 + (sqrt(2)*I)/10000000000000000000

$$2.0 + \frac{\sqrt{2}\,i}{10000000000000000000}$$

Rounding occurs for complex floats, if this does not change its value significantly:
numeric::complexRound(1.0 + 2.0*I/10^10), numeric::complexRound(1.0 + 2.0*I/10^11)1.0 + 0.0000000002*I, 1.0

$$1.0 + 0.0000000002\,i,\ 1.0$$

Note that rounding is based on relative precision, i.e., only the ratio of real and imaginary parts is relevant:
numeric::complexRound((1.0 + 2.0*I)/10^100)1.0e-100 + 2.0e-100*I

$$1.0\ 10^{-100} + 2.0\ 10^{-100}\,i$$

numeric::complexRound((1.0 + 1.0/10^11*I)/10^100)1.0e-100

$$1.0\ 10^{-100}$$

The relative precision for rounding may be reduced by the optional parameter `eps`:
numeric::complexRound(2.0/10^10 + I), numeric::complexRound(2.0/10^10 + I, PI/10^5)0.0000000002 + 1.0*I, 1.0*I

$$0.0000000002 + 1.0\,i,\ 1.0\,i$$

Parameters

z

An arbitrary MuPAD object

eps

A real number no less than 10^-DIGITS $\frac{1}{10^{DIGITS}}$

Return Values If z is a complex floating-point number, then a real or complex floating-point number is returned. For all other types, z is returned unchanged.

See Also ceilfloorfracroundtrunc

numeric::cubicSpline

Purpose

Interpolation by cubic splines

Syntax

```
numeric::cubicSpline([x0, y0], [x1, y1],  ,
<BoundaryCondition>, <Symbolic>, <NoWarning>)
numeric::cubicSpline([x0, x1,  ], [y0, y1,  ],
<BoundaryCondition>, <Symbolic>, <NoWarning>)
numeric::cubicSpline([[x0, x1,  ], [y0, y1,  ]],
<BoundaryCondition>, <Symbolic>, <NoWarning>)
```

Description

`numeric::cubicSpline([x0, y0], [x1, y1],  )` returns the cubic spline function interpolating a sequence of coordinate pairs $[x_i, y_i]$.

The call `S := numeric::cubicSpline([x0, y0],  , [xn, yn])` yields the cubic spline function S interpolating the data $[x_0, y_0]$, ..., $[x_n, y_n]$, i.e., $S(x_i) = y_i$ for $i = 0, ..., n$. The spline function is a piecewise polynomial of degree ≤ 3 on the intervals Interval(-infinity, [x_1]), Interval([x_1], [x_2]), Symbol::hellip, Interval([x[n-1]], infinity)$(-\infty, x_1], [x_1, x_2], ..., [x_{n-1}, \infty)$. S and its first two derivatives S', S"S', S'' are continuous at the points $x_1, ..., x_{n-1}$. Note that S extends the polynomial representation on Interval([x[0], x[1]])$[x_0, x_1]$, Interval([x[(n-1)], x[n]])$[x_{n-1}, x_n]$ to Interval(-infinity, [x_0])$(-\infty, x_0]$ and Interval([x[n-1]], infinity)$[x_{n-1}, \infty)$, respectively.

By default, `NotAKnot` boundary conditions are assumed, i.e., the third derivative S"'S''' is continuous at the points x_1 and x_{n-1}. With this boundary condition, S is a cubic polynomial on the intervals Interval(-infinity, [x_2])$(-\infty, x_2]$ and Interval([x[n-2]], infinity)$[x_{n-2}, \infty)$.

By default, all input data are converted to floating-point numbers. This conversion may be suppressed by the option `Symbolic`.

Without the option `Symbolic`, the abscissae x_i must be numerical real values in ascending order. If these data are not ordered, then `numeric::cubicSpline` reorders the abscissae internally, issuing a warning. The warning may be switched off by the option `NoWarning`.

The function S returned by `numeric::cubicSpline` may be called with one, two or three arguments:

- The call `S(z)` returns an explicit expression or a number, if `z` is a real number. Otherwise, the symbolic call `S(z)` is returned.
- The call `S(z, [k])` with a nonnegative integer `k` returns the k-th derivative of S. Cf. "Example 4" on page 19-17. For $k > 3$, zero is returned for any z.
- The call `S(z, i)` is meant for symbolic arguments z. The argument i must be an integer. Internally, z is assumed to satisfy $x_i \le z < x_{i+1}$, and `S(z, i)` returns the polynomial expression in z representing the spline function on this interval.
- The call `S(z, i, [k])` with an integer i and a nonnegative integer k returns the polynomial representation of the k-th derivative of the spline function on the interval $x_i \le z < x_{i+1}$.

If `S` is generated with symbolic abscissae x_i (necessarily using the option `Symbolic`), then the call `S(z)` with numerical `z` leads to an error. The call `S(z, i)` must be used for symbolic abscissae!

Note Note that the interpolation of 2 points (x_0, y_0), (x_1, y_1) must be specified by `numeric::cubicSpline( [x0, y0] , [x1, y1] )`, not by `numeric::cubicSpline( [x0, x1] , [y0, y1] )`!

Examples

Example 1

We demonstrate some calls with numerical input data:

```
data := [i, sin(i*PI/20)] $ i= 0..40: S1 := numeric::cubicSpline(data): S2 := numeric::cubicSpline(data, Natural): S3 := numeric::cubicSpline(data, Periodic): S4 := numeric::cubicSpline(data, Complete = [3, PI]):
```

At the abscissae, the corresponding input data are reproduced:

```
float(data[6][2]), S1(5), S2(5), S3(5), S4(5)0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812
```

0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812
0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812

0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812

Interpolation between the abscissae depends on the boundary condition: S1(4.5), S2(4.5), S3(4.5), S4(4.5)0.6494470263, 0.6494470123, 0.6494470123, 0.6517696766

0.6494470263, 0.6494470123, 0.6494470123, 0.6517696766

These are the cubic polynomials in z defining the spline on the interval $x_0 = 0 \le z < x_1 = 1$:
expand(S1(z, 0)); expand(S2(z, 0)); expand(S3(z, 0)); expand(S4(z, 0))-0.000632116114*z^3 - 0.00002961951081*z^2 + 0.1570962007*z

$-0.000632116114\,z^3 - 0.00002961951081\,z^2 + 0.1570962007\,z$
0.1570790998*z - 0.0006446347923*z^3

$$0.1570790998\,z - 0.0006446347923\,z^3$$

- 0.0006446347923*z^3 + 1.270549421e-21*z^2 + 0.1570790998*z

$$-0.0006446347923\,z^3 + 1.270549421\,10^{-21}\,z^2 + 0.1570790998\,z$$

2.080517906*z^3 - 4.924083441*z^2 + 3.0*z

$$2.080517906\,z^3 - 4.924083441\,z^2 + 3.0\,z$$

delete data, S1, S2, S3, S4:

Example 2

We demonstrate some calls with symbolic data:

S := numeric::cubicSpline([i, y.i] $ i = 0..3):S(1/2)0.3125*y0 + 0.9375*y1 - 0.3125*y2 + 0.0625*y3

$$0.3125\,y0 + 0.9375\,y1 - 0.3125\,y2 + 0.0625\,y3$$

This is the cubic polynomial in z defining the spline on the interval $x_0 = 0 \le z < x_1 = 1$:

S(z, 0)y0 - z*(1.833333333*y0 - 3.0*y1 + 1.5*y2 - 0.3333333333*y3 + z*(2.5*y1 - 1.0*y0 - 2.0*y2 + 0.5*y3 + z*(0.1666666667*y0 - 0.5*y1 + 0.5*y2 - 0.1666666667*y3)))

$$y0 - z\,(1.833333333\,y0 - 3.0\,y1 + 1.5\,y2 - 0.3333333333\,y3 + z\,(2.5\,y1 - 1.0\,y0 - 2.0\,y2 + 0.5\,y3 + z\,(0.1666666667\,y0 - 0.5\,y1 + 0.5\,y2 - 0.1666666667\,y3)))$$

With the option `Symbolic`, exact arithmetic is used:

S := numeric::cubicSpline([i, y.i] $ i = 0..3, Symbolic):S(1/2)(5*y0)/16 + (15*y1)/16 - (5*y2)/16 + y3/16

$$\frac{5\,y0}{16} + \frac{15\,y1}{16} - \frac{5\,y2}{16} + \frac{y3}{16}$$

Also symbolic boundary data are accepted:

S := numeric::cubicSpline([i, exp(i)] $ i = 0..10, Complete = [a, b]):S(0.1)0.08341154273*a + 0.00000005947817812*b + 1.020064753

$$0.08341154273\,a + 0.00000005947817812\,b + 1.020064753$$

S := numeric::cubicSpline([0, y0], [1, y1], [2, y2], Symbolic, Complete = [a, 5]):collect(S(z, 0), z)((3*a)/4 + (5*y0)/4 - 2*y1 + (3*y2)/4 - 5/4)*z^3 + (3*y1 - (9*y0)/4 - (7*a)/4 - (3*y2)/4 + 5/4)*z^2 + a*z + y0

$$\left(\frac{3\,a}{4} + \frac{5\,y0}{4} - 2\,y1 + \frac{3\,y2}{4} - \frac{5}{4}\right) z^3 + \left(3\,y1 - \frac{9\,y0}{4} - \frac{7\,a}{4} - \frac{3\,y2}{4} + \frac{5}{4}\right) z^2 + a\,z + y0$$

((3*a)/4 + (5*y0)/4 - 2*y1 + (3*y2)/4 - 5/4)*z^3 + (3*y1 - (9*y0)/4 - (7*a)/4 - (3*y2)/4 + 5/4)*z^2 + a*z + y0

$$\left(\frac{3\,a}{4} + \frac{5\,y0}{4} - 2\,y1 + \frac{3\,y2}{4} - \frac{5}{4}\right) z^3 + \left(3\,y1 - \frac{9\,y0}{4} - \frac{7\,a}{4} - \frac{3\,y2}{4} + \frac{5}{4}\right) z^2 + a\,z + y0$$

delete S:

Example 3

We demonstrate the use of symbolic abscissae. Here the option `Symbolic` is mandatory.

S := numeric::cubicSpline([x.i, y.i] $ i = 0..2, Symbolic):

The spline function `S` can only be called with 2 arguments. This is the cubic polynomial in `z` defining the spline on the interval $x_0 \le z < x_1$:

S(z, 0)y0 + (x0 - z)*((x0 - z)*((y0 - y1)/((x0 - x1)*(x0 - x2)) - (y1 - y2)/((x0 - x2)*(x1 - x2))) + ((y0 - y1)*(x1 - 2*x0 + x2))/((x0 - x1)*(x0 - x2)) + ((x0 - x1)*(y1 - y2))/((x0 - x2)*(x1 - x2)))

$$y0 + (x0 - z)\left((x0 - z)\left(\frac{y0 - y1}{(x0 - x1)(x0 - x2)} - \frac{y1 - y2}{(x0 - x2)(x1 - x2)}\right) + \frac{(y0 - y1)(x1 - 2\,x0 + x2)}{(x0 - x1)(x0 - x2)} + \frac{(x0 - x$$

y0 + (x0 - z)*((x0 - z)*((y0 - y1)/((x0 - x1)*(x0 - x2)) - (y1 - y2)/((x0 - x2)*(x1 - x2))) + ((y0 - y1)*(x1 - 2*x0 + x2))/((x0 - x1)*(x0 - x2)) + ((x0 - x1)*(y1 - y2))/((x0 - x2)*(x1 - x2)))

$$y0 + (x0 - z)\left((x0 - z)\left(\frac{y0 - y1}{(x0 - x1)(x0 - x2)} - \frac{y1 - y2}{(x0 - x2)(x1 - x2)}\right) + \frac{(y0 - y1)(x1 - 2\,x0 + x2)}{(x0 - x1)(x0 - x2)} + \frac{(x}{(x}$$

delete S:

Example 4

We plot a spline function together with its first three derivatives. The spline approximates the function *sin*(*x*):

```
n := 10: x := array(0..n, [i/n*2*PI $ i = 0..n]): S :=
numeric::cubicSpline([x[i], sin(x[i])] $ i = 0..n, Natural):
delete x: plot( plot::Function2d(S(x), x = 0..2*PI, Color = RGB::Black),

delete n, S:

Example 5

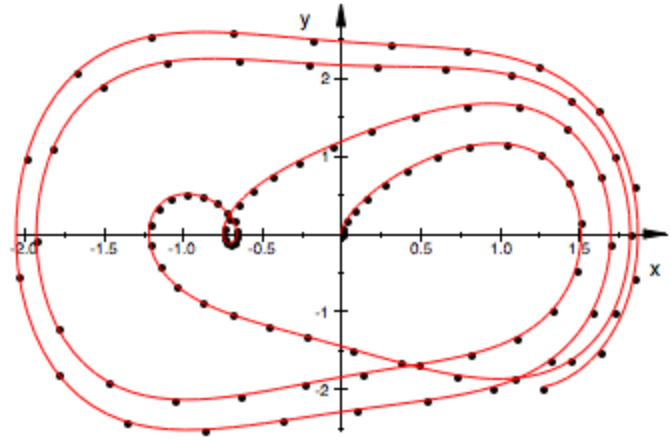
We demonstrate how to generate a phase plot of the differential equation x"(t)+x(t)^3=sin(t)$x''(t) + x(t)^3 = \sin(t)$, with initial conditions x(0)=x'(0)=0$x(0) = x'(0) = 0$. First, we use numeric::odesolve to

compute a numerical mesh of solution points [x[i], y[i]]=[x(t[i]), x'(t[i])]$[x_i, y_i] = [x(t_i), x'(t_i)]$ with $n + 1$ equidistant time nodes $t_0, \ldots, t_n$ in the interval [0, 20]:
DIGITS := 4: n := 100: for i from 0 to n do t[i] := 20/n*i: end_for: f := (t, x) -> [x[2], sin(t) - x[1]^3]: x[0] := 0: y[0] := 0: for i from 1 to n do [x[i], y[i]] := numeric::odesolve(t[i-1]..t[i], f, [x[i-1], y[i-1]]): end_for:

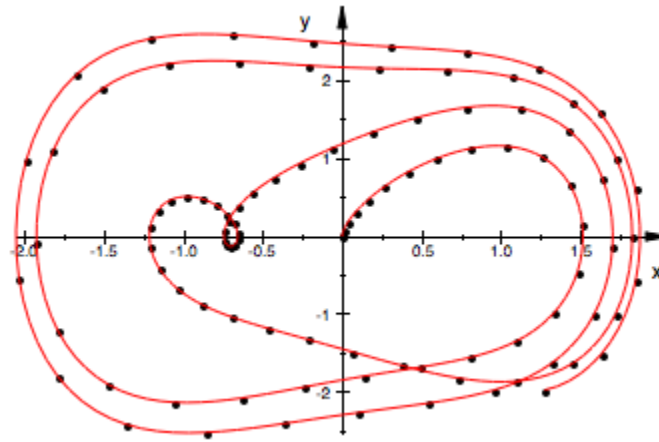
The mesh of the fenced(x(t), x'(t))$(x(t), x'(t))$ phase plot consists of the following points:
Plotpoints := [[x[i], y[i]] $ i = 0..n]:

We wish to connect these points by a spline curve. We define a spline interpoland $Sx(t)$ approximating the solution $x(t)$ by interpolating the data $[t_0, x_0], \ldots, [t_n, x_n]$. A spline interpoland $Sy(t)$ approximating x'(t)$x'(t)$ is obtained by interpolating the data $[t_0, y_0], \ldots, [t_n, y_n]$:
Sx := numeric::cubicSpline([t[i], x[i]] $ i = 0..n): Sy := numeric::cubicSpline([t[i], y[i]] $ i = 0..n):

Finally, we plot the mesh points together with the interpolating spline curve:
plot(plot::PointList2d(Plotpoints, PointColor = RGB::Black), plot::Curve2d([Sx(z), Sy(z)], z = 0..20, Mesh = 5*(n - 1) + 1, LineColor = RGB::Red))



The functions plot::Ode2d and plot::Ode3d serve for displaying numerical solutions of ODEs. In fact, they are implemented as indicated by the previous commands. The following call produces the same plot: plot(plot::Ode2d([t[i] $ i = 0..n], f, [x[0], y[0]], [(t, x) -> [x[1], x[2]], Style = Points, Color = RGB::Black], [(t, x) -> [x[1], x[2]], Style = Splines, Color = RGB::Red])):



delete DIGITS, n, i, t, f, x, y, Plotpoints, Sx, Sy:

Parameters

x_0, x_1, ...

Numerical real values in ascending order

y_0, y_1, ...

Arbitrary expressions

BoundaryCondition

The type of the boundary condition: either `NotAKnot`, `Natural`, `Periodic`, or `Complete = [a, b]` with arbitrary arithmetical expressions `a, b`.

Options

Symbolic

With this option, no conversion of the input data to floating point numbers occurs.

Symbolic abscissae x_i are accepted.

The ordering $x_0 < x_1 < \ldots < x_n$ is assumed by `numeric::cubicSpline`. This ordering is not checked, even if the abscissae are numerical!

NoWarning

The x-values of the interpolation points must be in ascending order. If the input data violate this condition, the routine issues a warning and reorders the data automatically. With this option, the warning is switched off.

NotAKnot

With the default boundary condition `NotAKnot`, the third derivative S'''S''' of the spline function is continuous at the points x_1 and x_{n-1}. With this boundary condition, S is a polynomial on the intervals Interval(-infinity, [x_2])$(-\infty, x_2]$ and Interval([x[n-2]], infinity)$[x_{n-2}, \infty)$.

Natural

The boundary condition `Natural` produces a spline function S satisfying S''(x[0])=S''(x[n])=0$S''(x_0) = S''(x_n) = 0$.

Periodic

The boundary condition `Periodic` produces a spline function S satisfying $S(x_0) = S(x_n)$, S'(x[0])=S'(x[n])$S'(x_0) = S'(x_n)$, S''(x[0])=S''(x[n])$S''(x_0) = S''(x_n)$. With this option, the input data y_0, y_n must coincide, otherwise an error is raised.

Complete

Option, specified as `Complete = [a, b]`

The boundary condition `Complete = [a, b]` produces a spline function S satisfying S'(x[0])=a$S'(x_0) = a$, S'(x[n])=b$S'(x_n) = b$. Symbolic data `a, b` are accepted.

Return Values

Spline interpoland: a MuPAD procedure.

interpolatenumeric::cubicSpline2d

numeric::cubicSpline2d

Purpose

Interpolation by 2-dimensional bi-cubic splines

Syntax

```
numeric::cubicSpline2d([x0, x1,  , xn], [y0, y1,  ,
ym], z, <[xBC, yBC]>, <Symbolic>)
```

Description

`numeric::cubicSpline2d([ x0, x1, ...], [ y0, y1, ...], z)` returns the bi-cubic spline function interpolating data $z_{i,j}$ over a rectangular mesh (x_i, y_j).

The call `S := numeric::cubicSpline2d([x0,  , xn], [y0,  , yn], z, Option)` yields the cubic spline function S interpolating the data $(x_i, y_j, z_{i,j})$, i.e, $S(x_i, y_j) = z_{i,j}$ for $i = 0, \ldots, n$, $j = 0, \ldots, m$. The spline function is a piecewise bi-cubic polynomial: on the 'patch'

p[i, j]=ImageSet(fenced(x, y), x[i] <= x < x[i+1], y[j] <= y < y[j+1])

$$p_{i,j} = \{(x, y) \mid x_i \le x < x_{i+1},\ y_j \le y < y_{j+1}\}$$

it has the representation

S(x, y)=sum(sum(a[i,j]^fenced(u, v)*(x-x[i])^u* (y-y[j])^v, v=0..3), u=0..3)

$$S(x, y) = \sum_{u=0}^{3} \left(\sum_{v=0}^{3} a_{i,j}^{(u,v)} (x - x_i)^u (y - y_j)^v \right)$$

with suitable coefficients $a_{i,j}^{(u,v)}$ depending on the patch. The spline S and its partial derivatives S_x, S_y, S_{xx}, S_{xy}, S_{yy}, S_{xxy}, S_{xyy}, S_{xxyy} are continous functions over the entire x, y plane. In the x-direction, `S` extends the polynomial representation on the boundary patches Interval([x[0], x[1]])$[x_0, x_1]$ and Interval([x[n-1], x[n]])$[x_{n-1}, x_n]$ to Interval(-infinity, [x[1]])$(-\infty, x_1]$ and Interval([x[n-1]], infinity)$[x_{n-1}, \infty)$, respectively. The same holds with respect to the y-direction.

By default, `NotAKnot` boundary conditions are assumed, i.e., the partial derivatives S_{xxx}, S_{yyy}, ..., S_{xxxyyy}, are continuous at the points with x-coordinates x_1 and x_{n-1} or y-coordinates y_1 and y_{m-1}.

By default, all input data are converted to floating-point numbers. This conversion may be suppressed by the option `Symbolic`.

Without the option `Symbolic`, the abscissae x_i, y_j must be numerical real values in ascending order. If these data are not ordered, then `numeric::cubicSpline2d` reorders the abscissae internally, issuing a warning.

The function `S` returned by `numeric::cubicSpline2d` may be called with two, three, four, or five arguments, respectively:

- The call `S(x, y)` returns an arithmetical expression if x and y are numerical expressions. A float is returned if either x or y is a float and all parameters involved can be converted to floats.

  If either x or y contains symbolic objects, the symbolic call `S(x, y)` is returned.

- The call `S(x, y, [u, v])` with nonnegative integers `u`, `v` returns the partial derivative diff(S, xu, yv) $\frac{\partial^{v}}{\partial y^{v}} \frac{\partial^{u}}{\partial x^{u}} S$ of the spline. If either x or y contain symbolic objects, the symbolic call `S(x, y, [u, v])` is returned. The result is 0 if either $u > 3$ or $v > 3$. The calls `S(x, y, [0, 0])` and `S(x, y)` are equivalent.

- The call `S(x, y, i, j)` with nonnegative integers `i`, `j` returns the polynomial representation of the spline on the patch $p_{i,j}$. Here, x and y may be arbitrary numerical or symbolic arithmetical expressions. Internally, (x, y) are assumed to lie in the patch $p_{i,j}$.

- The call `S(x, y, i, j, [u, v])` with nonnegative integers `i`, `j`, `u`, `v` returns the polynomial representation of the partial derivatives of the spline function. In this call, x and y may be arbitrary numerical or symbolic arithmetical expressions which are assumed to lie in the patch $p_{i,j}$. The result is 0 if either $u > 3$ or $v > 3$. The calls `S(x, y, i, j, [0, 0])` and `S(x, y, i, j)` are equivalent.

If `S` is generated with symbolic abscissae x_i, y_j (necessarily using the option `Symbolic`), the call `S(x, y, [ u , v ])` is returned

symbolically. The call `S(x, y, i, j, [ u , v ])` must be used for symbolic abscissae!

Examples

Example 1

We demonstrate some calls with numerical input data. The function $f(x, y) = sin(2\pi(x + y))$ with $0 \le x \le 1$, $0 \le y \le 1$ is to be interpolated by $n + 1 = 11$ equidistant points in the x-direction and $m + 1 = 13$ equidistant points in the y-direction:

```
f := (x, y) -> sin((x + y)*2*PI): n := 10: x := [i/n $ i = 0..n]: m := 12: y
:= [j/m $ j = 0..m]: z := array(0..n, 0..m, [[f(i/n, j/m) $ j = 0..m] $ i =
0..n]): S1 := numeric::cubicSpline2d(x, y, z, [NotAKnot, NotAKnot]):
S2 := numeric::cubicSpline2d(x, y, z, [Natural, Natural]): S3 :=
numeric::cubicSpline2d(x, y, z, [NotAKnot, Periodic]):
```

We consider `Complete` boundary conditions in the y-direction. They consist of the values $f_y(x_i, y_0) = f_y(x_i, 0) = 2\pi cos(2\pi x_i)$ and $f_y(x_i, y_m) = f_y(x_i, 1) = 2\pi cos(2\pi x_i)$:

```
ybc:= [[2*PI*cos(2*PI*i/n) $ i = 0..n], [2*PI*cos(2*PI*i/n) $ i = 0..n]]: S4
:= numeric::cubicSpline2d(x, y, z, [Periodic, Complete = ybc]):
```

At the mesh points (x_i, y_j), the input data $z_{i,j}$ are reproduced:

```
x := 4/n: y := 8/m: float(f(x, y)), S1(x, y), S2(x, y), S3(x, y), S4(x,
y)0.4067366431, 0.4067366431, 0.4067366431, 0.4067366431,
0.4067366431
```

```
0.4067366431, 0.4067366431, 0.4067366431, 0.4067366431, 0.4067366431
```

Interpolation between the mesh points depends on the boundary condition:

```
x := 0.92: y:= 0.55: S1(x, y), S2(x, y), S3(x, y), S4(x, y)0.1879484554,
0.1897776244, 0.1879457306, 0.1873726747
```

```
0.1879484554, 0.1897776244, 0.1879457306, 0.1873726747
```

The approximation of the function value $f(0.92, 0.55)$ is good for the `NotAKnot`, `Periodic`, and `Complete` boundary conditions. The `Natural` boundary conditions are less appropriate because the second

partial derivatives of the function *f* do not vanish at the boundaries. Consequently, the approximation error of `S2` is larger than the other approximation errors:

```
z := float(f(x, y)): S1(x, y) - z, S2(x, y) - z, S3(x, y) - z, S4(x,
y) - z
```

0.0005671407743, 0.002396309797, 0.0005644160155, -0.00000863986878

This is the bi-cubic polynomial in `X`, `Y` defining the spline `S1` on the patch x[0]=0<=X<x[1]=(1)/(n) $x_0 = 0 \le X < x_1 = \frac{1}{n}$, y[3]=(3)/(m)<=Y<=y[4]=(4)/(m) $y_3 = \frac{3}{m} \le Y \le y_4 = \frac{4}{m}$:

```
expand(S1(X, Y, 0, 3))
```

(X*Y^3*z33)/9 + (X^2*Y*z34)/24 + (X^3*Y*z33)/9 - (X*Y^3*z34)/72 -
(X^3*Y*z34)/72

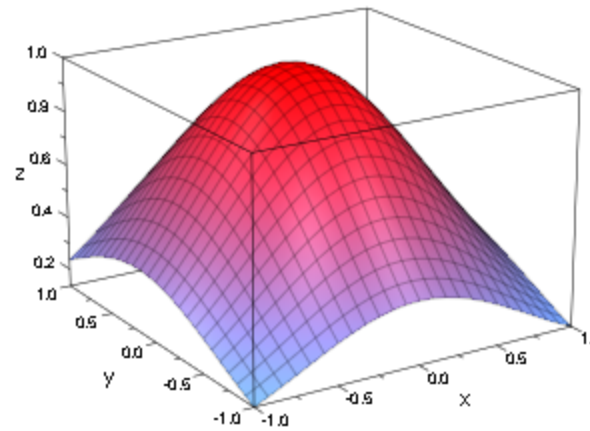
Example 3

We consider a spline interpolation of the function f(x, y)=e^(-x^2-y^2) $f(x, y) = \frac{1}{e^{x^2+y^2}}$ with - 1 ≤ *x* ≤ 1, - 1 ≤ *y* ≤ 1:

```
n := 10: xmesh := [-1 + 2*i/n $ i = 0..n]: m := 12: ymesh := [-1 + 2*j/n $ j = 0..m]: f := (x, y) -> exp(-x^2 - y^2): z := array(0..n, 0..m, [[f(-1 + 2*i/n, -1 + 2*j/m) $ j=0..m] $ i = 0..n]): S := numeric::cubicSpline2d(xmesh, ymesh, z):
```

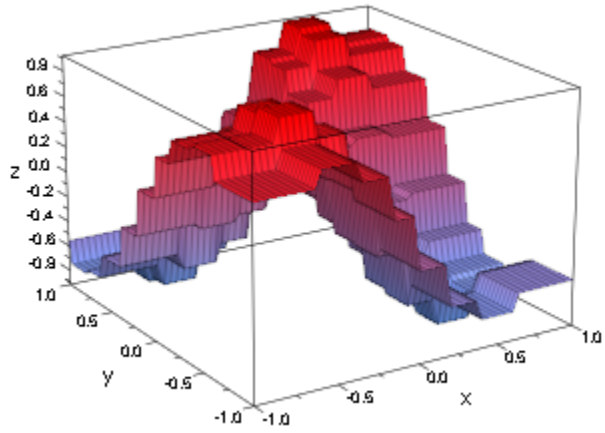
We plot the spline function *S*(*x*, *y*):

```
plotfunc3d(S(x, y), x = -1 .. 1, y = -1 .. 1):
```



We plot the partial derivative $S_{xxxyyy}(x, y)$. It is constant on each patch with jumps at the boundaries of the patches. The renderer uses [5*n* + 1, 5*m* + 1] mesh points: in each direction, 4 extra points between adjacent mesh points of the spline are used for the graphical representation:

```
plotfunc3d(S(x, y, [3, 3])/10, x = -1 .. 1, y = -1 .. 1, Mesh = [5*n + 1, 5*m+ 1])
```



delete n, xmesh, m, ymesh, f, z, S:

Example 4

We demonstrate the spline interpretation of a surface. We consider a sphere parametrized by spherical coordinates u, v with $0 \le u \le 2\pi$, $0 \le v \le \pi$:

x=cos(u)*sin(v), y=sin(u)*sin(v), z=cos(v)

$$x = \cos(u)\sin(v),\ y = \sin(u)\sin(v),\ z = \cos(v)$$

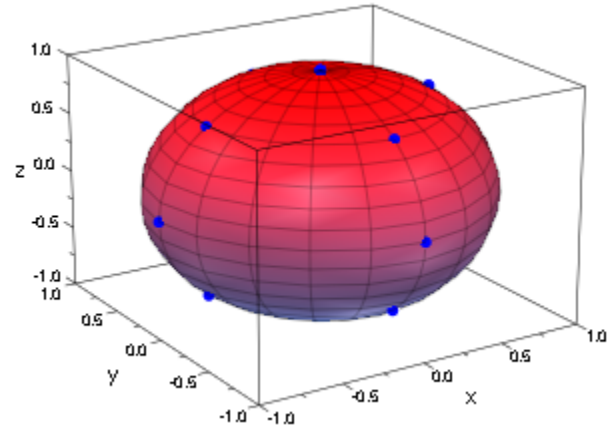
We interpolate the functions x, y, z over a rectangular mesh in the u-v-plane. Since x, y and (trivally) z are 2π-periodic in u, we choose `Periodic` boundary conditions for u. For v, we choose `Complete` boundary conditions with boundary values of the first partial v-derivative fitting the parametrization:

```
x:= (u, v) -> cos(u)*sin(v): x_v := diff(x(u, v), v): y:= (u, v) -> sin(u)*sin(v):
y_v := diff(y(u, v), v): z:= (u, v) -> cos(v): z_v := diff(z(u, v), v): n
:= 4: umesh := [i*2*PI/n $ i = 0..n]: m := 4: vmesh := [j*PI/m $ j =
0..m]: vBC := Complete = [ [subs(x_v, u = umesh[i], v = vmesh[1])
$ i = 1 .. n+1], [subs(x_v, u = umesh[i], v = vmesh[n + 1]) $ i = 1
.. n+1]]: X := numeric::cubicSpline2d(umesh, vmesh, array(0..n,
0..m, [[x(i*2*PI/n, j*PI/m) $ j=0..m] $ i=0..n]), [Periodic, vBC]):
```

```
vBC := Complete = [ [subs(y_v, u = umesh[i], v = vmesh[1]) $ i
= 1 .. n+1], [subs(y_v, u = umesh[i], v = vmesh[n + 1]) $ i = 1 ..
n+1]]: Y := numeric::cubicSpline2d(umesh, vmesh, array(0..n, 0..m,
[[y(i*2*PI/n, j*PI/m) $ j=0..m] $ i=0..n]), [Periodic, vBC]): vBC :=
Complete = [ [subs(z_v, u = umesh[i], v = vmesh[1]) $ i = 1 .. n+1],
[subs(z_v, u = umesh[i], v = vmesh[n + 1]) $ i = 1 .. n+1]]: Z :=
numeric::cubicSpline2d(umesh, vmesh, array(0..n, 0..m, [[z(i*2*PI/n,
j*PI/m) $ j=0..m] $ i=0..n]), [Periodic, vBC]):
```

With only $(n + 1)$ $(m + 1) = 5$ 5 mesh points, the spline surface yields a respectable approximation of a sphere. The interpolation nodes are added to the plot as blue points:

```
plot( plot::Surface([X(u, v), Y(u, v), Z(u, v)], u = 0..2*PI, v = 0..PI, Mesh
= [5*n + 1, 5*m + 1], Color = RGB::Red), plot::Point3d(x(umesh[i],
vmesh[j]), y(umesh[i], vmesh[j]), z(umesh[i], vmesh[j]), PointSize =
2*unit::mm, Color = RGB::Blue ) $ i = 1..n+1 $ j = 1..m+1 ):
```



```
delete x, x_v, y, y_v, z, z_v, n, m, umesh, vmesh, vBC, X, Y, Z:
```

Parameters

x_0, x_1, ...

x_n

The x-coordinates of the nodes: distinct numerical real values in ascending order

y_0, y_1, ...

y_m

The y-coordinates of the nodes: distinct numerical real values in ascending order

z

The function values: an array of the form `array(0..n, 0..m, [...])` with numerical or symbolic arithmetical expressions.

xBC

yBC

The type of the boundary condition: the boundary condition in the x- or y-direction may be one of the flags `NotAKnot`, `Natural`, `Periodic` or `Complete = [...]`.

`Complete` boundary conditions consist of prescribed values for the derivatives S_x or S_y, respectively, along the mesh boundaries in the x- or y-direction, respectively. In the x-direction, these value may be passed in the form `Complete = [[`a_0`, , `a_m`], [`b_0`, , `b_m`]]` with arbitrary numerical or symbolic arithmetical expressions `a0, , bm`.

In the y-direction, these value may be passed in the form `Complete = [[`a_0`, , `a_n`], [`b_0`, , `b_n`]]` with arbitrary numerical or symbolic arithmetical expressions `a0, , bn`.

Options

Symbolic

With this option, no conversion of the input data to floating point numbers occurs.

Symbolic abscissae x_i, y_j are accepted.

The ordering $x_0 < x_1 < \ldots < x_n$, $y_0 < y_1 < \ldots < y_m$ is assumed. This ordering is not checked even if the node coordinates are numerical!

NotAKnot

With the default boundary condition `xBC = yBC = NotAKnot`, all partial derivatives of the spline function are continuous at the nodes with x-coordinates x_1 and x_{n-1} or y-coordinates y_1 and y_{m-1}, respectively. With this boundary condition, `S` is a polynomial on the union of the patches $p_{0,j}$, $p_{1,j}$ and $p_{n-2,j}$, $p_{n-1,j}$ or $p_{i,0}$, $p_{i,1}$ and $p_{i,m-2}$, $p_{i,m-1}$, respectively.

This boundary condition is recommended if no information on the behaviour of the data near the mesh boundaries is available.

Natural

The boundary condition `Natural` produces a spline function `S` with vanishing second partial derivatives at the boundary of the mesh.

This boundary condition is recommended if it is known that the data correspond to a surface with vanishing curvature near the mesh boundaries.

Periodic

The boundary condition `Periodic` produces a spline function `S` satisfying

S(x[0], y)=S(x[n], y), S'(x[0], y)=S'(x[n], y), S"(x[0], y)=S"(x[n], y)

$$S(x_0, y) = S(x_n, y),\ S'(x_0, y) = S'(x_n, y),\ S''(x_0, y) = S''(x_n, y)$$

Or

S(x, y[0])=S(x, y[m]), S'(x, y[0])=S'(x, y[m]), S"(x, y[0])=S"(x, y[m])

$$S(x, y_0) = S(x, y_m),\ S'(x, y_0) = S'(x, y_m),\ S''(x, y_0) = S''(x, y_m)$$

Respectively. With this option, the input data $z_{0,j}$, $z_{n,j}$, respectively $z_{i,0}$, $z_{i,m}$, must coincide. Otherwise, an error is raised.

This boundary condition is recommended if the interpolation is to represent a periodic function.

Complete

Option, specified as `Complete = [...]`

The `xBC` boundary condition `Complete = [[a0, , am], [b0, , bm]]` produces a spline function S satisfying $S_x(x_0, y_j) = a_j$, $S_x(x_n, y_j) = b_j$, $j = 0, \ldots, m$.

The `yBC` boundary condition `Complete = [[a0, , an], [b0, , bn]]` produces a spline function S satisfying $S_y(x_i, y_0) = a_i$, $S_y(x_i, y_m) = b_i$, $i = 0, \ldots, n$.

Symbolic data a_k, b_k are accepted.

This boundary condition is recommended if the data $z_{i,j}$ correpond to a function with known values of the first partial derivatives at the mesh boundaries.

Return Values

Spline function: a MuPAD procedure.

See Also

interpolatenumeric::cubicSpline

numeric::det

Purpose

Determinant of a matrix

Syntax

```
numeric::det(A, <mode>, <MinorExpansion>, <NoWarning>)
```

Description

`numeric::det(A)` returns the determinant of the matrix *A*.

Without the option `Symbolic`, all entries of `A` must be numerical. Numerical expressions such as exp(PI)e^{π}, sqrt(2)$\sqrt{2}$ etc. are accepted and converted to floats. If symbolic entries are found in the matrix, `numeric::det` automatically switches to `Symbolic` issuing a warning.

The option `Symbolic` should be used if the matrix contains symbolic objects that cannot be converted to floating point numbers.

Note Matrices `A` of a matrix domain such as `Dom::Matrix(...)` or `Dom::SquareMatrix(...)` are internally converted to arrays over expressions via `expr(A)`. Note that linalg::det must be used, when the determinant is to be computed over the component domain. See "Example 2" on page 19-36. Note that the option `Symbolic` should be used if the entries cannot be converted to numerical expressions.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

Numerical matrices can be processed with or without the option `Symbolic`:

```
A := array(1..3, 1..3,[[1, 1, I], [1, exp(1), I], [1, 2, 2]]): numeric::det(A), numeric::det(A, Symbolic)3.436563657 + (- 1.718281828*I), exp(1)*(2 - I) - 2 + I
```

$$3.436563657 - 1.718281828\,i,\ e\,(2 - i) - 2 + i$$

The option `Symbolic` must be used when the matrix has non-numerical entries:
A := array(1..2, 1..2, [[1/(x + 1), 1], [1/(x + 2), PI]]): numeric::det(A, Symbolic)(2*PI - x + PI*x - 1)/((x + 1)*(x + 2))

$$\frac{2\,\pi - x + \pi\,x - 1}{(x+1)\,(x+2)}$$

If the option `MinorExpansion` is used, symbolic entries are accepted, even if the option `Symbolic` is not specified:
detN := numeric::det(A, MinorExpansion); detS := numeric::det(A, Symbolic, MinorExpansion)(0.0000000008*(2676990817.0*x + 6603981634.0))/((x + 1.0)*(x + 2.0))

$$0.0000000008\,(2676990817.0\,x + 6603981634.0)$$

(2*PI - x + PI*x - 1)/((x + 1)*(x + 2))

$$\frac{2\,\pi - x + \pi\,x - 1}{(x+1)\,(x+2)}$$

Simplify these results using Simplify:
Simplify(detN), Simplify(detS)3.141592654/(x + 1.0) - 1.0/(x + 2.0), PI/(x + 1) - 1/(x + 2)

$$3.141592654 - \frac{1.0}{x+2.0},\quad \frac{\pi}{x+1} - \frac{1}{x+2}$$

delete A:

Example 2

The following matrix has domain components:
A := Dom::Matrix(Dom::IntegerMod(7))([[6, -1], [1, 6]])Dom::Matrix(Dom::IntegerMod(7))([[-1, -1], [1, -1]])

$$\begin{pmatrix} 6 \bmod 7 & 6 \bmod 7 \\ 1 \bmod 7 & 6 \bmod 7 \end{pmatrix}$$

Note that `numeric::det` computes the determinant of the following matrix:
expr(A), numeric::det(A)array(1..2, 1..2, [[6, 6], [1, 6]]), 30.0

$$\begin{pmatrix} 6 & 6 \\ 1 & 6 \end{pmatrix}, \ 30.0$$

The routine linalg::det must be used, if the determinant is to be computed over the component domain Dom::IntegerMod(7):
linalg::det(A)2 mod 7

$$2 \bmod 7$$

delete A:

Example 3

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned: the computation of the determinant is subject to severe cancellation effects. The following results, both with `HardwareFloats` as well as with `SoftwareFloats`, are marred by numerical roundoff:
A := linalg::hilbert(15): float(numeric::det(A, Symbolic)), numeric::det(A, HardwareFloats), numeric::det(A, SoftwareFloats)1.058542743e-124, -3.822215463e-121, 3.277553006e-123

$$1.058542743\ 10^{-124}, \ -3.822215463\ 10^{-121}, \ 3.277553006\ 10^{-123}$$

delete A:

Parameters

A

A square matrix of domain type DOM_ARRAY, or DOM_HFARRAY, or of category Cat::Matrix

mode

One of the flags `Hard`, `HardwareFloats`, `Soft`, `SoftwareFloats`, or `Symbolic`

Options

Hard

HardwareFloats

Soft

SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix `A` is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 3” on page 19-37.

Symbolic

This option prevents conversion of the input data to floats. With this option, symbolic entries are accepted. It overrides the option `HardwareFloats`.

Note This option should not be used for floating-point matrices! The `Symbolic` algorithm does not implement safeguards against numerical instabilities in floating-point operations.

MinorExpansion

With this option, recursive minor expansion along the columns is used. This option may be useful for small matrices with symbolic entries.

This option implies `SoftwareFloats`.

With this option, symbolic entries are accepted even if the option `Symbolic` is not used.

NoWarning

Suppresses warnings

Return Values

By default, the determinant is returned as a floating-point number. With the option `Symbolic`, an expression is returned.

Algorithms

Without the option `Symbolic`, *QR*-factorization of *A* via Householder transformations is used.

With `Symbolic`, *LU*-factorization of *A* is used.

numeric::eigenvalues

Purpose

Numerical eigenvalues of a matrix

Syntax

```
numeric::eigenvalues(A, options)
```

Description

`numeric::eigenvalues(A)` returns numerical eigenvalues of the matrix `A`.

All entries of `A` must be numerical. Numerical expressions such as exp(PI), sqrt(2)e^{π}, $\sqrt{2}$ etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

Note Matrices `A` of a matrix domain such as `Dom::Matrix(...)` or `Dom::SquareMatrix(..)` are internally converted to arrays over expressions via `expr(A)`. Note that linalg::eigenvalues must be used, when the eigenvalues are to be computed over the component domain. Cf. "Example 2" on page 19-42.

The eigenvalues are sorted by numeric::sort.

Note Eigenvalues are approximated with an *absolute* precision of r/10^DIGITS$\sqrt[DIGITS]{\ }$, where r is the spectral radius of `A` (i.e., r is the maximum of the absolute values of the eigenvalues). Consequently, large eigenvalues should be computed correctly to DIGITS decimal places. The numerical approximations of the small eigenvalues are less accurate.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We compute the eigenvalues of the 3 3 Hilbert matrix:
numeric::eigenvalues(linalg::hilbert(3))[1.408318927, 0.1223270659, 0.002687340356]

[1.408318927, 0.1223270659, 0.002687340356]

The following matrix is ill-conditioned. It has very large as well as very small eigenvalues:
A := array(1..3, 1..3, [[I , PI , exp(1)], [2 , 10^100 , 1], [10^(-100), 10^(-100), 10^(-100)]]):

Precision goal and working precision are set by DIGITS. With the standard setting of *DIGITS* = 10, the following result is computed with `HardwareFloats`:
numeric::eigenvalues(A)[1.0e100, 5.0e-101, 1.0*I]

$$\left[1.0\,10^{100},\ 5.0\,10^{-101},\ 1.0\,i\right]$$

[1.0e100, 5.0e-101, 1.0*I]

$$\left[1.0\,10^{100},\ 5.0\,10^{-101},\ 1.0\,i\right]$$

Note that small eigenvalues may be influenced by roundoff. We increase the working precision by increasing DIGITS. The smallest of the eigenvalues is computed more accurately:
DIGITS := 200: eigenvals := numeric::eigenvalues(A): DIGITS := 5: eigenvals;[1.0e100 + 6.2832e-200*I, 1.0e-100 + 2.7183e-100*I, -6.2832e-100 + 1.0*I]

$$\left[1.0\,10^{100} + 6.2832\,10^{-200}\,i,\ 1.0\,10^{-100} + 2.7183\,10^{-100}\,i,\ -6.2832\,10^{-100} + 1.0\,i\right]$$

delete A, eigenvals, DIGITS:

Example 2

The following matrix has domain components:

A := Dom::Matrix(Dom::IntegerMod(7))([[6, -1, 4], [0, 3, 3], [0, 0, 3]])Dom::Matrix(Dom::IntegerMod(7))([[-1, -1, -3], [0, 3, 3], [0, 0, 3]])

$$\begin{pmatrix} 6 \bmod 7 & 6 \bmod 7 & 4 \bmod 7 \\ 0 \bmod 7 & 3 \bmod 7 & 3 \bmod 7 \\ 0 \bmod 7 & 0 \bmod 7 & 3 \bmod 7 \end{pmatrix}$$

Note that `numeric::eigenvalues` computes the eigenvalues of the following matrix:
expr(A), numeric::eigenvalues(A)array(1..3, 1..3, [[6, 6, 4], [0, 3, 3], [0, 0, 3]]), [6.0, 3.0, 3.0]

$$\begin{pmatrix} 6 & 6 & 4 \\ 0 & 3 & 3 \\ 0 & 0 & 3 \end{pmatrix}, [6.0, 3.0, 3.0]$$

If the eigenvalues are to be computed over the component domain `Dom::IntegerMod(7)`, linalg::eigenvalues should be used:
linalg::eigenvalues(A, Multiple)[[3 mod 7, 2], [6 mod 7, 1]]

$$[[3 \bmod 7, 2], [6 \bmod 7, 1]]$$

delete A:

Example 3

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned: the computation of small eigenvalues is subject to severe roundoff effects. In the following results, both with `HardwareFloats` as well as with `SoftwareFloats`, the small eigenvalues are marred by numerical roundoff:
A := linalg::hilbert(15): numeric::eigenvalues(A, HardwareFloats), numeric::eigenvalues(A, SoftwareFloats)[1.845927746, 0.426627957, 0.05721209253, 0.005639834756, 0.0004364765944, 0.00002710853923, 0.000001361582242, 0.00000005528988436, 0.000000001802959014, 4.657779255e-11, 9.3159051e-13, 1.411852363e-14, 4.695027628e-16, 8.619013323e-17, 2.268836709e-17], [1.845927746, 0.426627957, 0.05721209253, 0.005639834756, 0.0004364765944, 0.00002710853923, 0.000001361582242, 0.00000005528988482, 0.000000001802959751,

numeric::eigenvectors

Purpose

Numerical eigenvalues and eigenvectors of a matrix

Syntax

```
numeric::eigenvectors(A, options)
```

Description

`numeric::eigenvectors(A)` returns numerical eigenvalues and eigenvectors of the matrix `A`.

All entries of the matrix must be numerical. Numerical expressions such as exp(PI), sqrt(2)e^{π}, $\sqrt{2}$ etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

The eigenvalues are sorted by numeric::sort.

The matrix `X` provides the eigenvectors: the i-th column of `X` is a numerical eigenvector corresponding to the eigenvalue `d[i]`. Each column is either zero or normalized to the Euclidean length 1.0.

For matrices with multiple eigenvalues and an insufficient number of eigenvectors, some of the eigenvectors may coincide or may be zero, i.e., `X` is not necessarily invertible.

The list of residues $res = [res_1, res_2, \ldots]$ provides some control over the quality of the numerical spectral data. The residues are given by

res[i]=norm(A*x[i]-d[i]*x[i], 2)

$$res_i = \|A\,x_i - d_i\,x_i\|_2$$

where x_i is the normalized eigenvector (the i-th column of `X`) associated with the numerical eigenvalue d_i. For Hermitean matrices, res_i provides an upper bound for the absolute error of d_i.

With the option `NoResidues`, the computation of the residues is suppressed, the returned value is `NIL`.

If no return type is specified via the option `ReturnType = t`, the domain type of the eigenvector matrix `X` depends on the type of the input matrix `A`:

- The eigenvectors of an array are returned as an array.
- The eigenvectors of an hfarray are returned as an hfarray.
- The eigenvectors of a dense matrix of type `Dom::DenseMatrix()` are returned as a dense matrix of type `Dom::DenseMatrix()` over the ring of expressions.
- For all other matrices of category Cat::Matrix, the eigenvectors are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

Note Matrices `A` of a matrix domain such as `Dom::Matrix(...)` or `Dom::SquareMatrix(...)` are internally converted to arrays over expressions via `expr(A)`. Note that linalg::eigenvectors must be used, when the eigenvalues/vectors are to be computed over the component domain. Cf. "Example 3" on page 19-50.

Note Eigenvalues are approximated with an *absolute* precision of r/10^DIGITS, where r is the spectral radius of `A` (i.e., r is the maximal singular value of `A`). Consequently, large eigenvalues should be computed correctly to DIGITS decimal places. The numerical approximations of the small eigenvalues are less accurate.

Note For a numerical algorithm, it is not possible to distinguish between badly separated distinct eigenvalues and multiple eigenvalues. For this reason, `numeric::eigenvectors` and linalg::eigenvectors use different return formats: the latter can provide information on the multiplicity of eigenvalues due to its internal exact arithmetic.

Use numeric::eigenvalues if only eigenvalues are to be computed.

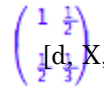
Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We compute the spectral data of the 2 2 Hilbert matrix:
A := linalg::hilbert(2)matrix([[1, 1/2], [1/2, 1/3]])



[d, X, res] := numeric::eigenvectors(A):

The eigenvalues:
d[1.267591879, 0.06574145409]

The eigenvectors:
Xmatrix([[0.8816745988, -0.4718579255], [0.4718579255, 0.8816745988]])

Hilbert matrices are Hermitean, i.e., computing the spectral data is a numerically stable process. This is confirmed by the small residues:
res[2.355138688e-16, 1.388645872e-16]

The routine linalg::hilbert provides the input as a matrix of type `Dom::Matrix()`. Consequently, the eigenvectors also consist of such a

matrix. For further processing, we convert the list of eigenvalues to a diagonal matrix:
d := matrix(2, 2, d, Diagonal):

We reconstruct the matrix from its spectral data:
X*d*X^(-1)matrix([[1.0, 0.5], [0.5, 0.3333333333]])

$$\begin{pmatrix} 1.0 & 0.5 \\ 0.5 & 0.3333333333 \end{pmatrix}$$

We extract an eigenvector from the matrix `X` and doublecheck its numerical quality:
eigenvector1 := X::dom::col(X, 1); norm(A*eigenvector1 - d[1, 1]*eigenvector1)matrix([[0.8816745988], [0.4718579255]])

$$\begin{pmatrix} 0.8816745988 \\ 0.4718579255 \end{pmatrix}$$

1.769417945e-16

$$1.769417945\ 10^{-16}$$

delete A, d, X, res, eigenvector1:

Example 2

We demonstrate a numerically ill-conditioned case. The following matrix has only one eigenvector and cannot be diagonalized. Numerically, the zero vector is returned as the second column of the eigenvector matrix:
A := array(1..2, 1..2, [[5, -1], [4, 1]]): DIGITS := 6:
numeric::eigenvectors(A)[[3.0, 3.0], array(1..2, 1..2, [[0.447214, 0], [0.894427, 0]]), [1.66533e-16, 0.0]]

$$\left[[3.0, 3.0], \begin{pmatrix} 0.447214 & 0 \\ 0.894427 & 0 \end{pmatrix}, \left[1.66533\ 10^{-16}, 0.0\right]\right]$$

delete A, DIGITS:

Example 3

The following matrix has domain components:

```
A := Dom::Matrix(Dom::IntegerMod(7))([[6, -1], [0,
3]])Dom::Matrix(Dom::IntegerMod(7))([[-1, -1], [0, 3]])
```

$$\begin{pmatrix} 6 \bmod 7 & 6 \bmod 7 \\ 0 \bmod 7 & 3 \bmod 7 \end{pmatrix}$$

Note that `numeric::eigenvectors` computes the spectral data of the following matrix:

```
expr(A)array(1..2, 1..2, [[6, 6], [0, 3]])
```

$$\begin{pmatrix} 6 & 6 \\ 0 & 3 \end{pmatrix}$$

```
numeric::eigenvectors(A, NoResidues)[[6.0, 3.0], matrix([[1.0,
0.894427191], [0, -0.4472135955]]), NIL]
```

$$\left[[6.0,\ 3.0],\ \begin{pmatrix} 1.0 & 0.894427191 \\ 0 & -0.4472135955 \end{pmatrix},\ \mathrm{NIL}\right]$$

The routine linalg::eigenvectors should be used if the spectral data are to be computed over the component domain `Dom::IntegerMod(7)`:

```
linalg::eigenvectors(A)[[Dom::IntegerMod(7)(3), 1,
[Dom::Matrix(Dom::IntegerMod(7))([[-2], [1]])]], [Dom::IntegerMod(7)(6),
1, [Dom::Matrix(Dom::IntegerMod(7))([[1], [0]])]]]
```

$$\left[\left[3 \bmod 7,\ 1,\ \left[\begin{pmatrix} 5 \bmod 7 \\ 1 \bmod 7 \end{pmatrix}\right]\right],\ \left[6 \bmod 7,\ 1,\ \left[\begin{pmatrix} 1 \bmod 7 \\ 0 \bmod 7 \end{pmatrix}\right]\right]\right]$$

delete A:

Example 4

We demonstrate the use of hardware floats. The following matrix is degenerate: it has rank 1. For the double eigenvalue 0, different base vectors of the corresponding eigenspace are returned with `HardwareFloats` and `SoftwareFloats`, respectively:

```
A := array(1..3, 1..3, [[1, 2, 3], [2, 4, 6], [3*10^12, 6*10^12, 9*10^12]]):
[d1, X1, res1] := numeric::eigenvectors(A, HardwareFloats): d1,
X1[9.0e12, 0.0, -4.543838814e-16], array(1..3, 1..3, [[3.333333333e-13,
```

0.9486832981, 0.9621023987], [6.666666667e-13, -2.108185107e-13, -0.1012739367], [1.0, -0.316227766, -0.2531848418]])

$$\left[9.0\,10^{12},\ 0.0,\ -4.543838814\,10^{-16}\right],\ \begin{pmatrix} 3.333333333\,10^{-13} & 0.9486832981 & 0.9621023987 \\ 6.666666667\,10^{-13} & -2.108185107\,10^{-13} & -0.1012739367 \\ 1.0 & -0.316227766 & -0.2531848418 \end{pmatrix}$$

[d2, X2, res2] := numeric::eigenvectors(A, SoftwareFloats): d2, X2[9.0e12, 5.421010862e-20, 0.0], array(1..3, 1..3, [[0, 0.9592641938, 0.9486832981], [0, -0.06851887098, 0], [1.0, -0.2740754839, -0.316227766]])

$$\left[9.0\,10^{12},\ 5.421010862\,10^{-20},\ 0.0\right],\ \begin{pmatrix} 0 & 0.9592641938 & 0.9486832981 \\ 0 & -0.06851887098 & 0 \\ 1.0 & -0.2740754839 & -0.316227766 \end{pmatrix}$$

delete A, d1, X1, res1, d2, X2, res2:

Parameters

A

A numerical matrix of domain type DOM_ARRAY, or DOM_HFARRAY, or of category Cat::Matrix.

Options

Hard

HardwareFloats

Soft

SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix `A` is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See "Example 4" on page 19-51.

NoResidues

Suppresses the computation of error estimates

If no error estimates are required, this option may be used to suppress the computation of the residues `res`. The return values for these data are `NIL`.

The alternative option name `NoErrors` used in previous MuPAD versions is still available.

ReturnType

Option, specified as `ReturnType = t`

Return the eigenvectors as a matrix of domain type `t`. The following return types *t* are available: DOM_ARRAY, DOM_HFARRAY, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

NoWarning

Suppresses warnings

Return Values

List `[d, X, res]`. The list `d = [d1, d2, ]` contains the numerical eigenvalue. The *i*-th column of the matrix `X` is the eigenvector associated with the eigenvalue d_i. The list of residues `res = [res1, res2, ]` provides error estimates for the numerical eigenvalues.

Algorithms

The routine implements standard numerical algorithms from the Handbook of Automatic Computation by Wilkinson and Reinsch.

numeric::expMatrix

Purpose

Exponential of a matrix

Syntax

```
numeric::expMatrix(A, <mode>, <method>, options)
numeric::expMatrix(A, x, <mode>, <method>, options)
numeric::expMatrix(A, X, <mode>, <method>, options)
```

Description

`numeric::expMatrix(A)` returns the exponential exp(A)e^A of a square matrix A.

`numeric::expMatrix(A, x)` with a vector x returns the vector exp(A)*x$e^A\,x$.

`numeric::expMatrix(A, X)` with a matrix X returns the matrix exp(A)*X$e^A\,X$.

If no return type is specified via the option `ReturnType = d`, the domain type of the result depends on the type of the input matrix `A`:

- For an array A, the result is returned as an array.
- For an hfarray A, the result is returned as an hfarray.
- For a dense matrix$A$ of type `Dom::DenseMatrix(Ring)`, the result is again a matrix of type `Dom::DenseMatrix()` over the ring of expressions.
- For all other matrices A of category Cat::Matrix, the result is returned as a matrix of type `Dom::Matrix()` over the ring of expressions. This includes input matrices `A` of type `Dom::Matrix(Ring)`, `Dom::SquareMatrix(Ring)`, `Dom::MatrixGroup(Ring)` etc.

The components of A must not contain symbolic objects which cannot be converted to numerical values via float. Numerical symbolic expressions such as π, sqrt(2)$\sqrt{2}$, exp(-1)e^{-1} etc. are accepted. They are converted to floats.

The specification of a method such as `TaylorExpansion` etc. implies `SoftwareFloats`, i.e., the result is computed via the software arithmetic of the MuPAD kernel.

The methods `Diagonalization` and `Interpolation` do not work for all matrices (see below).

With `SoftwareFloats`, special algorithms are implemented for traceless 2 2 matrices and skew symmetric 3 3 matrices. Specification of a particular method does not have any effect for such matrices.

If exp(A)*xe^{A} *x* or exp(A)*Xe^{A} *X* is required, one should not compute exp(A)e^{A} first and then multiply the resulting matrix with the vector/matrix *x*/*X*. In general, the call `numeric::expMatrix(A, x)` or `numeric::expMatrix(A, X)`, respectively, is faster.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We consider a lower triangular matrix given by an array:
A := array(1..2, 1..2, [[1, 0] , [1, PI]]): expA := numeric::expMatrix(A)array(1..2, 1..2, [[2.718281828, 0], [9.536085572, 23.14069263]])

$$\begin{pmatrix} 2.718281828 & 0 \\ 9.536085572 & 23.14069263 \end{pmatrix}$$

We consider a vector given by a list `x1` and by an equivalent 1-dimensional array `x2`, respectively:
x1 := [1, 1]: x2 := array(1..2, [1, 1]):

Futher, an equivalent input vector *X* of type Dom::Matrix`()` is used:
X := matrix(x1):

The following three calls all yield a vector represented by an 2 1 array corresponding to the type of the input matrix *A*:
numeric::expMatrix(A, x1), numeric::expMatrix(A, x2, Krylov), numeric::expMatrix(A, X, Diagonalization)array(1..2, 1..1, [[2.718281828], [32.6767782]]), array(1..2, 1..1, [[2.718281828], [32.6767782]]), array(1..2, 1..1, [[2.718281828], [32.6767782]])

$$\begin{pmatrix} 2.718281828 \\ 32.6767782 \end{pmatrix}, \begin{pmatrix} 2.718281828 \\ 32.6767782 \end{pmatrix}, \begin{pmatrix} 2.718281828 \\ 32.6767782 \end{pmatrix}$$

For further processing, the array `expA` is converted to an element of the matrix domain `Dom::Matrix()`:
expA := matrix(expA):

Now, the overloaded arithmetical operators `+`, `*`, `^` etc. can be used for further computations:
expA*Xmatrix([[2.718281828], [32.6767782]])

$$\begin{pmatrix} 2.718281828 \\ 32.6767782 \end{pmatrix}$$

delete A, expA, x1, x2, X:

Example 2

We demonstrate the different precision goals of the methods. Note that software arithmetic is used when a method is specified:
A := array(1..3, 1..3, [[1000, 1, 0], [0, 1, 1], [1/10^100, 0, -1000]]):

The default method `TaylorExpansion` computes *each component* of exp(A)e^A correctly:
numeric::expMatrix(A, SoftwareFloats)array(1..3, 1..3,
[[1.970071114e434, 1.972043157e431, 9.860215786e427],
[9.860215786e327, 9.870085871e324, 4.935042936e321],
[9.85035557e330, 9.860215786e327, 4.930107893e324]])

$$\begin{pmatrix} 1.970071114\ 10^{434} & 1.972043157\ 10^{431} & 9.860215786\ 10^{427} \\ 9.860215786\ 10^{327} & 9.870085871\ 10^{324} & 4.935042936\ 10^{321} \\ 9.85035557\ 10^{330} & 9.860215786\ 10^{327} & 4.930107893\ 10^{324} \end{pmatrix}$$

The method `Diagonalization` produces a result which is accurate in the sense that norm(error) <= norm(exp(A))*10^-DIGITS $\|error\|_\infty \le \|e^A\|_\infty \frac{1}{10^{DIGITS}}$ holds. Indeed, the largest components of exp(A)e^A are correct. However,

`Diagonalization` does not even get the right order of magnitude of the smaller components:
numeric::expMatrix(A, Diagonalization)array(1..3, 1..3, [[1.970071114e434, 1.972043157e431, 0], [0, 2.718281828, 0], [0, 0, 5.075958898e-435]])

$$\begin{pmatrix} 1.970071114\,10^{434} & 1.972043157\,10^{431} & 0 \\ 0 & 2.718281828 & 0 \\ 0 & 0 & 5.075958898\,10^{-435} \end{pmatrix}$$

Note that exp(A)e^A is very sensitive to small changes in *A*. After elimination of the small lower triangular element, both methods yield the same result with correct digits for all entries:
B := array(1..3, 1..3, [[1000, 1, 0], [0 , 1, 1], [0 , 0, -1000]]): numeric::expMatrix(B, SoftwareFloats)array(1..3, 1..3, [[1.970071114e434, 1.972043157e431, 9.860215786e427], [0, 2.718281828, 0.002715566262], [0, 0, 5.075958897e-435]])

$$\begin{pmatrix} 1.970071114\,10^{434} & 1.972043157\,10^{431} & 9.860215786\,10^{427} \\ 0 & 2.718281828 & 0.002715566262 \\ 0 & 0 & 5.075958897\,10^{-435} \end{pmatrix}$$

numeric::expMatrix(B, Diagonalization)array(1..3, 1..3, [[1.970071114e434, 1.972043157e431, 9.860215786e427], [0, 2.718281828, 0.002715566262], [0, 0, 5.075958898e-435]])

$$\begin{pmatrix} 1.970071114\,10^{434} & 1.972043157\,10^{431} & 9.860215786\,10^{427} \\ 0 & 2.718281828 & 0.002715566262 \\ 0 & 0 & 5.075958898\,10^{-435} \end{pmatrix}$$

delete A, B:

Example 3

Hilbert matrices H[(ij)]=(i+j-1)^(-1)$H_{ij} = \frac{1}{i+j-1}$ have real positive eigenvalues. For large dimension, most of these eigenvalues are small

and may be regarded as a single cluster. Consequently, the option `Krylov` is useful:
numeric::expMatrix(linalg::hilbert(100), [1 $ 100], Krylov) [25.47080919, 18.59337041, Symbol::hellip, 2.863083064, 2.848538965]

```
[25.47080919, 18.59337041, ..., 2.863083064, 2.848538965]
```

Parameters

A

A square n n matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

x

A vector represented by a list `[`x_1`, , `x_n`]` or a 1-dimensional array `array(1..n, [`x_1`, , `x_n`] )`, or a 1-dimensional hfarray `hfarray(1..n, [`x_1`, , `x_n`] )`

X

An n m matrix of domain type DOM_ARRAY, DOM_HFARRAY, Dom::Matrix`(Ring)` or Dom::DenseMatrix(Ring) with a suitable coefficient ring `Ring`

mode

One of the flags `Hard`, `HardwareFloats`, `Soft`, or `SoftwareFloats`

method

One of the flags `Diagonalization`, `Interpolation`, `Krylov`, or `TaylorExpansion`

Options

Hard

HardwareFloats

Soft

SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix `A` is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.

- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Diagonalization

Interpolation

Krylov

TaylorExpansion

The specification of a method implies `SoftwareFloats`, i.e., the result is always computed via the software arithmetic of the MuPAD kernel.

The method `TaylorExpansion` is the default algorithm. It produces fast results for matrices with small norms.

The default method `TaylorExpansion` computes *each individual component* of exp(A)e^A, exp(A)*xe^A x, exp(A)*Xe^A X to a relative precision of about `10^(-DIGITS)`, unless numerical roundoff prevents reaching this precision goal. Roughly speaking: all digits of all components of the result are reliable up to roundoff effects.

Note The methods `Diagonalization`, `Interpolation`, and `Krylov` compute the result to a relative precision w.r.t. the

norm: norm(error) <= norm(result)/10^DIGITS $\|\text{error}\|_\infty \le \frac{\|\text{result}\|_\infty}{10^{\text{DIGITS}}}$. Consequently, if the result has components of different orders of magnitude, then the smaller components have larger relative errors than the large components. Not all digits of the small components are reliable! Cf. "Example 2" on page 19-58.

Note The method `Diagonalization` only works for diagonalizable matrices. For matrices without a basis of eigenvectors, `numeric::expMatrix` may either produce an error or the returned result is dominated by roundoff effects. For symmetric/Hermitean or skew/skew-Hermitean matrices, this method produces reliable results.

Note The method `Interpolation` may become numerically unstable for certain matrices. The algorithm tries to detect such instabilities and stops with an error message.

The method `Krylov` is only available for computing exp(A)*xe^A x with a vector x. Also vectors represented by n 1 matrices are accepted.

This method is fast when x is spanned by few eigenvectors of A. Further, if A has only few clusters of similar eigenvalues, then this method can be much faster than the other methods. Cf. "Example 3" on page 19-59.

NoWarning

Suppresses warnings

ReturnType

Option, specified as `ReturnType = d`

Return the result matrix or vector as a matrix of domain type `d`. The following return types are available: DOM_ARRAY, DOM_HFARRAY, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Return Values

All results are float matrices/vectors. For an n n matrix A:

- `numeric::expMatrix(A, method)` returns exp(A)e^A as an n n matrix,
- `numeric::expMatrix(A, x, method)` returns exp(A)*x$e^A x$ as an n 1 matrix,
- `numeric::expMatrix(A, X, method)` returns exp(A)*X$e^A X$ as an n m matrix.

The domain type of the result depends on the domain type of the input matrix A unless a return type is requested explicitly via `ReturnType = d`.

Algorithms

The method `TaylorExpansion` sums the usual Taylor series

exp(A)=1+A+A^2/2+Symbol::cdots

$$e^A = 1 + A + \frac{A^2}{2} + \cdots$$

in a suitable numerically stable way.

The method `Diagonalization` computes exp(A)=T*diag(exp(Symbol::lambda[1]), exp(Symbol::lambda[2]), Symbol::hellip)*invMatrix(T)$e^A = T\,\mathrm{diag}\left(e^{\lambda_1}, e^{\lambda_2}, \ldots\right) T^{-1}$ by a diagonalization $A = T diag(\lambda_1, \lambda_2, \ldots) T^{-1}$.

The method `Interpolation` computes a polynomial P interpolating the function *exp* at the eigenvalues of A. Evaluation of the matrix polynomial yields exp(A)=P(A)$e^A = P(A)$.

The method `Krylov` reduces A to a Hessenberg matrix H and computes an approximation of exp(A)*x$e^A x$ from exp(H)e^H. Depending on A and x, the dimension of H may be smaller than the dimension of A.

`numeric::expMatrix` uses polynomial arithmetic to multiply matrices and vectors. Thus, sparse matrices are handled efficiently based on the MuPAD internal sparse representation of polynomials.

exp

numeric::factorCholesky

Purpose

Cholesky factorization of a matrix

Syntax

```
numeric::factorCholesky(A, options)
```

Description

`numeric::factorCholesky(A)` returns the factor L of the Cholesky factorization $A = LL^H$ of a positive definite Hermitean matrix A.

`numeric::factorCholesky(A, Symmetric)` returns the factor L of a Cholesky type factorization $A = LL^T$ of a symmetric matrix A.

The Cholesky factorization of a square Hermitean matrix is $A = LL^H$, where L is a regular complex lower triangular matrix and L^H is the Hermitean transpose of L (i.e., the complex conjugate of the transpose of L). Such a factorization only exists if A is positive definite.

By default, a numerical factorization is computed. If the option `Symbolic` is not used, all components of the matrix are converted to floating-point numbers. In this case, the matrix must not contain symbolic objects that cannot be converted to floats. Numerical symbolic expressions such as π, sqrt(2)$\sqrt{2}$, exp(-1)e^{-1} etc. are accepted.

If no return type is specified via the option `ReturnType = d`, the domain type of the Cholesky factor L depends on the type of the input matrix `A`:

- The factor of an array is returned as an array.
- The factor of an hfarray is returned as an hfarray.
- The factor of a dense matrix of type `Dom::DenseMatrix()` is a dense matrix of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category Cat::Matrix, the factor L is returned as a matrix of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

The Cholesky factor returned by `numeric::factorCholesky` is normalized such that its diagonal elements are real and positive.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We consider the matrix
A := array(1..2, 1..2, [[1, I] , [-I, PI]]):

We compute a numerical factorization
numeric::factorCholesky(A)array(1..2, 1..2, [[1.0, 0], [-1.0*I, 1.46341814]])

$$\begin{pmatrix} 1.0 & 0 \\ -1.0\,i & 1.46341814 \end{pmatrix}$$

and a symbolic factorization:
L := numeric::factorCholesky(A, Symbolic, NoCheck)array(1..2, 1..2, [[1, 0], [-I, sqrt(PI - 1)]])

$$\begin{pmatrix} 1 & 0 \\ -i & \sqrt{\pi - 1} \end{pmatrix}$$

For further processing, the Cholesky factor (of domain type DOM_ARRAY) is converted to an element of the matrix domain Dom::Matrix():
L := matrix(L):

Now, the overloaded arithmetical operators +, *, ^ etc. can be used for further computations:
L*linalg::transpose(conjugate(L))matrix([[1, I], [-I, PI]])

$$\begin{pmatrix} 1 & i \\ -i & \pi \end{pmatrix}$$

delete A, L:

Example 2

The following matrix is not positive definite:
A := matrix([[-2, sqrt(2)], [sqrt(2), 1]]): numeric::factorCholesky(A)
Error: The matrix is not positive definite within working precision.
[numeric::factorCholesky]

However, a symmetric factorization with a complex Cholesky factor does exist:
numeric::factorCholesky(A, Symmetric)matrix([[1.414213562*I, 0], [-1.0*I, 1.414213562]])

$$\begin{pmatrix} 1.414213562\,i & 0 \\ -1.0\,i & 1.414213562 \end{pmatrix}$$

delete A:

Example 3

The option `NoCheck` should be used when the matrix contains symbolic objects:
assume(x > 0): assume(z > 0): A := array(1..2, 1..2, [[x, conjugate(y)], [y, z]]): numeric::factorCholesky(A, Symbolic, NoCheck)array(1..2, 1..2, [[sqrt(x), 0], [y/sqrt(x), sqrt(z - abs(y)^2/x)]])

$$\begin{pmatrix} \sqrt{x} & 0 \\ \frac{y}{\sqrt{x}} & \sqrt{z - \frac{|y|^2}{x}} \end{pmatrix}$$

Note that with `NoCheck`, it is assumed that the matrix is Hermitean and positive definite! All upper triangular entries are ignored. The following result implicitly assumes `u = conjugate(y)`:
A := array(1..2, 1..2, [[x, u], [y, z]]): numeric::factorCholesky(A, Symbolic, NoCheck)array(1..2, 1..2, [[sqrt(x), 0], [y/sqrt(x), sqrt(z - abs(y)^2/x)]])

$$\begin{pmatrix} \sqrt{x} & 0 \\ \frac{x}{\sqrt{x}} & \sqrt{z - \frac{x^2}{x}} \end{pmatrix}$$

delete A:

Example 4

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned and difficult to factor with low values of DIGITS. The following results, both with `HardwareFloats` as well as with `SoftwareFloats`, are marred by numerical roundoff. Consequently, the factorization with and without hardware floats, respectively, differ significantly:
A := linalg::hilbert(13): L1 := numeric::factorCholesky(A, HardwareFloats): L2 := numeric::factorCholesky(A, SoftwareFloats): L1[13, 13] <> L2[13, 13]0.0000001052365221 <> 0.00000007585706698

$$0.0000001052365221 \neq 0.00000007585706698$$

All Hilbert matrices are positive definite. However, in the following call, numerical roundoff makes the hardware floating-point tool think that the matrix is not definite:
numeric::factorCholesky(linalg::hilbert(14), HardwareFloats):
Error: The matrix is not positive definite within working precision. [numeric::factorCholesky]

A factorization is computed successfully with `SoftwareFloats`:
L := numeric::factorCholesky(linalg::hilbert(14), SoftwareFloats):
norm(linalg::hilbert(14) - L*linalg::transpose(L))8.67361738e-19

$$8.67361738\ 10^{-19}$$

delete A, L1, L2, L:

Parameters

A

A square matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

Options

Hard

HardwareFloats

Soft

SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix `A` is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD

computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 4” on page 19-69.

Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

The usual arithmetic for MuPAD expressions is used. With this option, the matrix A may contain symbolic objects. Note that the

option `NoCheck` must be used for the Hermitean factorization when non-numerical symbolic objects are present.

Symmetric

Makes `numeric::factorCholesky` compute a symmetric factorization $A = LL^T$ rather than a Hermitean factorization $A = LL^H$

The symmetric Cholesky factorization of a square symmetric matrix is $A = LL^T$, where L is a regular complex lower triangular matrix and L^T is the transpose of L. The matrix A does not have to be positive definite. Consequently, with the option `Symmetric` no internal check is performed whether A is positive definite. Note that the symmetric factorization with regular L does not exist for all matrices.

For real symmetric positive definite matrices A the Cholesky factor L is real and the Hermitean factorization $A = LL^H$ coincides with the symmetric factorization $A = LL^T$.

NoCheck

Prevents `numeric::factorCholesky` from checking that the matrix is Hermitean and positive definite

Without the option `Symmetric`, `numeric::factorCholesky` checks that the matrix A is Hermitean and positive definite. The option `NoCheck` may be used to suppress these checks. It must be used when the matrix contains symbolic objects. Elements in the upper triangular part of the matrix will never be touched by the algorithm!

Note With this option, `numeric::factorCholesky` returns a result for matrices that are not Hermitean or not positive definite (i.e., no Cholesky factorization exists)! When using this option, it is the user's responsibility to make sure that the input matrix is appropriate.

This option has no effect when the option `Symmetric` is used.

NoWarning

Suppresses warnings

If symbolic coefficients are found, `numeric::factorCholesky` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed; the routine still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

ReturnType

Option, specified as `ReturnType = d`

Return the Cholesky factor as a matrix of domain type `d`. The following return types are available: DOM_ARRAY, DOM_HFARRAY, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Return Values

Depending on the type of the input matrix `A`, the lower triangular Cholesky factor L is returned as a matrix of domain type DOM_ARRAY, DOM_HFARRAY, `Dom::Matrix()`, or `Dom::DenseMatrix()`. Its components are real or complex floats, unless the option `Symbolic` is used. Without the option `NoCheck`, an error is raised if the matrix is not Hermitean or not positive definite.

Related Examples

- "Compute Factorizations Numerically"

numeric::factorLU

Purpose

LU factorization of a matrix

Syntax

```
numeric::factorLU(A, options)
```

Description

`numeric::factorLU(A)` returns a *LU* factorization of the matrix *A*.

The *LU* factorization of a real or complex *m n* matrix `A` is *PA* = *LU*. The *m m* matrix *L* is lower triangular, normalized to 1 along the diagonal. The *m n* matrix *U* is upper triangular, i.e., $U_{ij} = 0$ for $j < i$. The list `p = [p1, , pm]` returned by `numeric::factorLU` is a permutation of the numbers 1, …, *m* corresponding to row exchanges of *A*. It represents the following *m m* permutation matrix *P* (we assume that the matrix indices range from 1 to *m*):

P[(ij)]=Symbol::delta[p[i], j]= piecewise([j=p[i], 1], [j<>p[i], 0])

$$P_{ij} = \delta_{p_i,j} = \begin{cases} 1 & \text{if } j = p_i \\ 0 & \text{if } j \neq p_i \end{cases}$$

Left multiplication of matrices and vectors with *P* is realized easily using the permutation list `p`: $Y_{i,j} := X_{p_i,j}$ defines the row permutation *Y* = *PX* of a matrix *X*, $y_i := x_{p_i}$ defines the row permutation *y* = *Px* of a vector *x*.

By default, a numerical factorization with partial pivoting is computed. If the option `Symbolic` is not used, all components of the matrix are converted to floating-point numbers. In this case, the matrix must not contain symbolic objects that cannot be converted to floats. Numerical symbolic expressions such as π, sqrt(2)$\sqrt{2}$, exp(-1)e^{-1} etc. are accepted.

The factorization depends on the pivoting strategy. The results obtained with/without the option `Symbolic` may differ. See “Example 2” on page 19-76. For numerical factorizations, the results obtained with `HardwareFloats` and `SoftwareFloats`, respectively, may differ. See “Example 3” on page 19-77.

If no return type is specified via the option `ReturnType = d`, the domain type of the factors L and U depends on the type of the input matrix `A`:

- The factors of an array are returned as arrays.
- The factors of an hfarray are returned as hfarrays.
- The factors of a dense matrix of type `Dom::DenseMatrix()` are again dense matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category Cat::Matrix, the factors are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

Environment Interactions

Without the optional argument `Symbolic`, the function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We factor a matrix specified by an array:
A := array(1..3, 1..3, [[1, 2, 3], [2, 4, 6], [4, 8, 9]]): [L, U, p] := numeric::factorLU(A)[array(1..3, 1..3, [[1.0, 0, 0], [0.5, 1.0, 0], [0.25, 0, 1.0]]), array(1..3, 1..3, [[4.0, 8.0, 9.0], [0, 0, 1.5], [0, 0, 0.75]]), [3, 2, 1]]

$$\left[\begin{pmatrix} 1.0 & 0 & 0 \\ 0.5 & 1.0 & 0 \\ 0.25 & 0 & 1.0 \end{pmatrix}, \begin{pmatrix} 4.0 & 8.0 & 9.0 \\ 0 & 0 & 1.5 \\ 0 & 0 & 0.75 \end{pmatrix}, [3, 2, 1]\right]$$

The factors (of domain type DOM_ARRAY) are converted to elements of the matrix domain Dom::Matrix(). After the conversion, the overloaded arithmetical operators +, *, ^ etc. can be used for further processing:
L := matrix(L): U := matrix(U): L*Umatrix([[4.0, 8.0, 9.0], [2.0, 4.0, 6.0], [1.0, 2.0, 3.0]])

$$\begin{pmatrix} 4.0 & 8.0 & 9.0 \\ 2.0 & 4.0 & 6.0 \\ 1.0 & 2.0 & 3.0 \end{pmatrix}$$

The product *LU* coincides with *A* after exchanging the rows according to the permutation stored in the list `p`:
PA := array(1..3, 1..3, [[A[p[i], j] $ j=1..3] $ i=1..3])array(1..3, 1..3, [[4, 8, 9], [2, 4, 6], [1, 2, 3]])

$$\begin{pmatrix} 4 & 8 & 9 \\ 2 & 4 & 6 \\ 1 & 2 & 3 \end{pmatrix}$$

delete A, L, U, p, PA:

Example 2

We consider a non-square matrix of dimension 3 2:
A := matrix([[3*I, 10], [I, 1], [I, 1]]): [L1, U1, p1] := numeric::factorLU(A)[matrix([[1.0, 0, 0], [3.0, 1.0, 0], [1.0, 0, 1.0]]), matrix([[1.0*I, 1.0], [0, 7.0], [0, 0]]), [2, 1, 3]]

$$\left[\begin{pmatrix} 1.0 & 0 & 0 \\ 3.0 & 1.0 & 0 \\ 1.0 & 0 & 1.0 \end{pmatrix}, \begin{pmatrix} 1.0\,i & 1.0 \\ 0 & 7.0 \\ 0 & 0 \end{pmatrix}, [2, 1, 3]\right]$$

Note that the symbolic factorization is different, because a different pivoting strategy is used:
[L2, U2, p2] := numeric::factorLU(A, Symbolic)[matrix([[1, 0, 0], [1/3, 1, 0], [1/3, 1, 1]]), matrix([[3*I, 10], [0, -7/3], [0, 0]]), [1, 2, 3]]

$$\left[\begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{3} & 1 & 0 \\ \frac{1}{3} & 1 & 1 \end{pmatrix}, \begin{pmatrix} 3\,i & 10 \\ 0 & -\frac{7}{3} \\ 0 & 0 \end{pmatrix}, [1, 2, 3]\right]$$

Here, the matrix factors are of type `Dom::Matrix()`, because the input matrix *A* was of this type. We can use the overloaded arithmetic directly. We convert the permutation lists `p1`, `p2` to matrices and verify the relation *PA* = *LU* for the factorization:

P1 := matrix(3, 3): P2 := matrix(3, 3): for i from 1 to 3 do P1[i, p1[i]] := 1; P2[i, p2[i]] := 1; end_for: P1*A - L1*U1, P2*A - L2*U2matrix([[0, 0], [0, 0], [0, 0]]), matrix([[0, 0], [0, 0], [0, 0]])

$$\begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix}$$

delete A, L1, U1, p1, L2, U2, p2:

Example 3

We demonstrate the use of hardware floats. The internal rounding of `HardwareFloats` and `SoftwareFloats` differs. Consequently, the following results do not coincide:
n := 14: A := linalg::hilbert(n): [L1, U1, p1] := numeric::factorLU(A, HardwareFloats): [L2, U2, p2] := numeric::factorLU(A, SoftwareFloats): p1, p2[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 13], [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14]

$$[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 13], [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14]$$

However, both factorizations satisfy $PA = LU$ numerically:
P1A := matrix([[A[p1[i], j] $ j = 1..n] $ i = 1..n]): P2A := matrix([[A[p2[i], j] $ j = 1..n] $ i = 1..n]): norm(P1A - L1*U1), norm(P2A - L2*U2)8.131516294e-17, 5.421010862e-19

$$8.131516294\ 10^{-17},\ 5.421010862\ 10^{-19}$$

delete n, A, L1, U1, p1, L2, U2, p2, P1A, P2A:

Parameters

A

An m n matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

Options

Hard

HardwareFloats

Soft

SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix `A` is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See "Example 3" on page 19-77.

Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

The usual arithmetic for MuPAD expressions is used. With this option, the matrix A may contain symbolic objects.

With this option, no row exchanges are performed in the internal Gaussian elimination unless necessary.

NoWarning

Suppresses warnings

If symbolic coefficients are found, `numeric::factorLU` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed; the routine still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

ReturnType

Option, specified as `ReturnType = d`

Return the factors as matrices of domain type `d`. The following return types are available: DOM_ARRAY, DOM_HFARRAY, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Return Values

List `[L, U, p]` is returned. The domain type of the m m matrix `L` and the m n matrix `U` depends on the type of the input matrix `A`; `p` is a list with m elements consisting of a permutation of the integers 1, …, m. It represents row exchanges in pivoting steps. The components of `L` and `U` are real or complex floats, unless the option `Symbolic` is used.

linalg::factorLUnumeric::factorCholeskynumeric::factorQR

Related Examples

- “Compute Factorizations Numerically”

numeric::factorQR

Purpose

QR factorization of a matrix

Syntax

```
numeric::factorQR(A, options)
```

Description

`numeric::factorQR(A)` returns a QR factorization $A = QR$ of the matrix A.

The QR factorization of a real/complex m n matrix is $A = QR$, where the m m matrix Q is orthogonal/unitary and the m n matrix R is upper triangular (i.e., $R_{ij} = 0$ for $j < i$).

By default, a numerical factorization is computed. The matrix must not contain symbolic objects that cannot be converted to floats. Numerical symbolic expressions such as π, sqrt(2)$\sqrt{2}$, exp(-1)e^{-1} etc. are accepted. They will be converted to floats, unless the option `Symbolic` is used.

The R factor is normalized such that its diagonal elements R_{ii} with $i = 1, \ldots, min(m, n)$ are real and nonnegative.

If no return type is specified via the option `ReturnType = d`, the domain type of the factors Q and R depends on the type of the input matrix `A`:

- The factors of an array are returned as arrays.
- The factors of an hfarray are returned as hfarrays.
- The factors of a dense matrix of type `Dom::DenseMatrix()` are dense matrices of type `Dom::DenseMatrix()` over the ring of expressions.
- For all other matrices of categoryCat::Matrix, the factors are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)`, etc.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We consider a quadratic matrix:
A := array(1..2, 1..2, [[1, 0] , [1, PI]]):

First, we compute a numerical factorization:
[Q1, R1] := numeric::factorQR(A)[array(1..2, 1..2, [[0.7071067812, -0.7071067812], [0.7071067812, 0.7071067812]]), array(1..2, 1..2, [[1.414213562, 2.221441469], [0, 2.221441469]])]

$$\left[\begin{pmatrix} 0.7071067812 & -0.7071067812 \\ 0.7071067812 & 0.7071067812 \end{pmatrix}, \begin{pmatrix} 1.414213562 & 2.221441469 \\ 0 & 2.221441469 \end{pmatrix}\right]$$

Next, the symbolic factorization is computed:
[Q2, R2] := numeric::factorQR(A, Symbolic)[array(1..2, 1..2, [[sqrt(2)/2, -sqrt(2)/2], [sqrt(2)/2, sqrt(2)/2]]), array(1..2, 1..2, [[sqrt(2), (PI*sqrt(2))/2], [0, (PI*sqrt(2))/2]])]

$$\left[\begin{pmatrix} \frac{\sqrt{2}}{2} & -\frac{\sqrt{2}}{2} \\ \frac{\sqrt{2}}{2} & \frac{\sqrt{2}}{2} \end{pmatrix}, \begin{pmatrix} \sqrt{2} & \frac{\pi\sqrt{2}}{2} \\ 0 & \frac{\pi\sqrt{2}}{2} \end{pmatrix}\right]$$

For further processing, the factors (of domain type DOM_ARRAY) are converted to elements of the matrix domain Dom::Matrix():
Q1 := matrix(Q1): R1 := matrix(R1): Q2 := matrix(Q2): R2 := matrix(R2):

Now, the overloaded arithmetical operators +, *, ^ etc. can be used for further computations:
Q1*R1, Q2*R2matrix([[1.0, -4.926614672e-16], [1.0, 3.141592654]]), matrix([[1, 0], [1, PI]])

$$\begin{pmatrix} 1.0 & -4.926614672\,10^{-16} \\ 1.0 & 3.141592654 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 1 & \pi \end{pmatrix}$$

We finally verify the othogonality of the factors `Q1` and `Q2`:
Q1 * linalg::transpose(Q1), Q2 * linalg::transpose(Q2)matrix([[1.0, -1.569924746e-16], [-1.569924746e-16, 1.0]]), matrix([[1, 0], [0, 1]])

$$\begin{pmatrix} 1.0 & -1.569924746\,10^{-16} \\ -1.569924746\,10^{-16} & 1.0 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

delete A, Q1, R1, Q2, R2:

Example 2

We consider a non-square matrix of rank 1:
A := array(1..3, 1..2, [[0, 0], [I, 1], [I, 1]]): numeric::factorQR(A, Symbolic)[array(1..3, 1..3, [[0, 1, 0], [(sqrt(2)*I)/2, 0, sqrt(2)/2], [(sqrt(2)*I)/2, 0, -sqrt(2)/2]]), array(1..3, 1..2, [[sqrt(2), -sqrt(2)*I], [0, 0], [0, 0]])]

$$\left[\begin{pmatrix} 0 & 1 & 0 \\ \frac{\sqrt{2}\,i}{2} & 0 & \frac{\sqrt{2}}{2} \\ \frac{\sqrt{2}\,i}{2} & 0 & -\frac{\sqrt{2}}{2} \end{pmatrix}, \begin{pmatrix} \sqrt{2} & -\sqrt{2}\,i \\ 0 & 0 \\ 0 & 0 \end{pmatrix}\right]$$

In this case, the *QR* factorization is not unique. Note that the numerical factorization yields different factors:
numeric::factorQR(A)[array(1..3, 1..3, [[0, 0.7071067812*I, 0.7071067812*I], [0.7071067812*I, 0.5, -0.5], [0.7071067812*I, -0.5, 0.5]]), array(1..3, 1..2, [[1.414213562, -1.414213562*I], [0, 0], [0, 0]])]

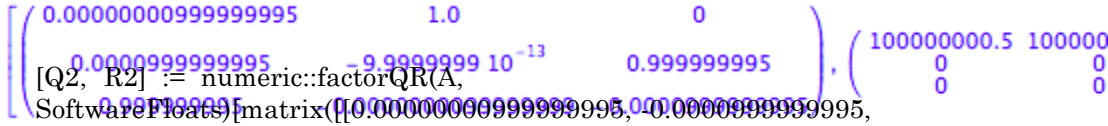
$$\left[\begin{pmatrix} 0 & 0.7071067812\,i & 0.7071067812\,i \\ 0.7071067812\,i & 0.5 & -0.5 \\ 0.7071067812\,i & -0.5 & 0.5 \end{pmatrix}, \begin{pmatrix} 1.414213562 & -1.414213562\,i \\ 0 & 0 \\ 0 & 0 \end{pmatrix}\right]$$

delete A:

Example 3

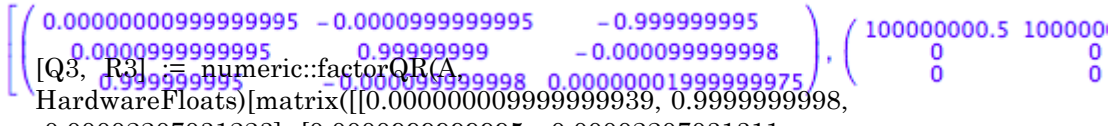
We demonstrate the difference between hardware floats and software floats. For rank deficient matrices, the *QR* factorization is not unique. Depending on the options, different results are returned for the following matrix of rank 1:
A := matrix([[1, 1], [10^4, 10^4], [10^8, 10^8]]): [Q1, R1] := float(numeric::factorQR(A, Symbolic))[matrix([[0.00000000999999995,

1.0, 0], [0.0000999999995, -9.9999999e-13, 0.999999995], [0.999999995, -0.0000000099999999, -0.0000999999995]]), matrix([[100000000.5, 100000000.5], [0, 0], [0, 0]])]



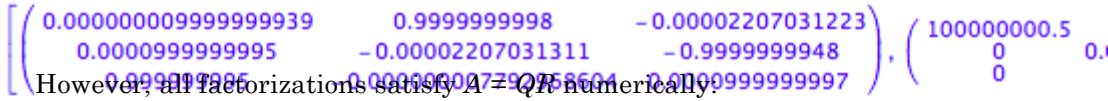
```
[Q2, R2] := numeric::factorQR(A, SoftwareFloats)
```

matrix([[0.000000099999999995, -0.000099999999995, -0.999999995], [0.0000999999995, 0.99999999, -0.000099999998], [0.999999995, -0.000099999998, 0.00000001999999975]]), matrix([[100000000.5, 100000000.5], [0, 0], [0, 0]])]



```
[Q3, R3] := numeric::factorQR(A, HardwareFloats)
```

matrix([[0.000000099999999939, 0.9999999998, -0.00002207031223], [0.0000999999995, -0.00002207031311, -0.9999999948], [0.999999995, -0.000000007792968604, 0.0000999999997]]), matrix([[100000000.5, 100000000.5], [0, 0.0000000149011613], [0, 0]])]



However, all factorizations satisfy $A = QR$ numerically:

```
norm(A - Q1*R1), norm(A - Q2*R2), norm(A - Q3*R3)
```

3.469446952e-18, 7.327374818e-11, 0.00000001583248377

delete A, Q1, R1, Q2, R2, Q3, R3:

Parameters

A

An m n matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

Options

Hard

HardwareFloats

Soft

SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix `A` is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 3” on page 19-83.

Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

The usual arithmetic for MuPAD expressions is used. With this option, the matrix A may contain symbolic objects.

NoWarning

Suppresses warnings

If symbolic coefficients are found, `numeric::factorQR` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed; the routine still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

ReturnType

Option, specified as `ReturnType = d`

Return the Cholesky factor as a matrix of domain type `d`. The following return types are available: DOM_ARRAY, DOM_HFARRAY, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Return Values

List `[Q, R]` with matrices `Q` and `R` is returned. The domain type of the orthogonal/unitary m m matrix `Q` and the upper triangular m n matrix `R` depends on the type of the input matrix `A`. The components of `Q` and `R` are real or complex floats, unless the option `Symbolic` is used.

Algorithms

Householder transformations are used to compute the numerical factorization. With the option `Symbolic`, Gram-Schmidt orthonormalization of the columns of A is used.

For an invertible square matrix A, the QR factorization is unique up to scaling factors of modulus 1. The normalization of R to real positive diagonal elements determines the factorization uniquely. Consequently, the results obtained with/without the option `Symbolic` coincide for invertible square matrices.

For singular or non-square matrices, the factorization is not unique and the results obtained with/without the option `Symbolic` may differ. Cf. “Example 2” on page 19-83.

numeric::fft

Purpose

Fast Fourier Transform

Syntax

```
numeric::fft(L, <mode>, <ReturnType = t>, <Clean>)
numeric::fft(M, <mode>, <ReturnType = t>, <Clean>)
numeric::fft(A, <mode>, <ReturnType = t>, <Clean>)
```

Description

`numeric::fft(data)` returns the discrete Fourier transform of the `data`.

The 1-dimensional discrete Fourier transform $F = fft(L)$ of N data elements L_j stored in the list $L = [L_1, \ldots, L_N]$ is the list $F = [F_1, \ldots, F_N]$ given by

F[k]=sum(L[j]*exp(-I*2*PI*(j-1)*(k-1)/N), j=1..N), k=1,Symbol::hellip,N

$$F_k = \sum_{j=1}^{N} L_j \, e^{-\frac{i\,2\,\pi\,(j-1)\,(k-1)}{N}}, \quad k = 1, \ldots, N$$

`fft` transforms the data by a Fast Fourier Transform (FFT) algorithm.

The d-dimensional discrete Fourier transform $F = fft(A)$ of $N = n_1 \cdots n_d$ data elements $(A_{j_1, \ldots, j_d})$ stored in the array A is the array $F = (F_{k_1, \ldots, k_d})$ given by

F[k[1], Symbol::hellip, k[d]]= _outputSequence(sum(“, j[1]=1..n[1]), Symbol::hellip, sum(A[j[1], Symbol::hellip, j[d]] *exp(-I*2*PI* ((j[1]-1)*(k[1]-1)/n[1] + Symbol::hellip + (j[d]-1)*(k[d]-1)/n[d])), j[d]=1..n[d]))

$$F_{k_1, \ldots, k_d} = \sum_{j_1=1}^{n_1} \cdots \sum_{j_d=1}^{n_d} A_{j_1, \ldots, j_d} \, e^{-i\,2\,\pi \left(\frac{(j_1-1)\,(k_1-1)}{n_1} + \ldots + \frac{(j_d-1)\,(k_d-1)}{n_d} \right)}$$

with $k_1 = 1, \ldots, n_1, \ldots, k_d = 1, \ldots, n_d$.

Data provided by lists or 1-dimensional arrays or hfarrays are transformed according to the 1-dimensional transform. Data provided

by matrices are transformed according to the 2-dimensional transform. Data provided by multidimensional arrays or hfarrays are transformed according to the multi-dimensional transform matching the format of the input array.

If the data size factorizes ($N = pq$, say), the discrete Fourier transform can be computed by p different Fourier transforms of subsets of the data, each subset having the data size q. The corresponding 'divide and conquer' algorithm is known as FFT ('Fast Fourier Transform'). The `fft` routine employs the FFT algorithm. It is most efficient, when the data size N is an integer power of 2 ('radix 2 FFT'). In this case, the algorithm needs O(N*log(2, N)) $O(N \log_2(N))$ elementary operations.

Note More generally, FFT is efficient, if the data size is the product of many small factors!

Following Bluestein, the Fourier transform is written as a convolution if the data size N is a prime. The data are zero-padded to a data length that is an integer power of 2. The convolution is then computed via radix 2 FFTs. Thus, the algorithm needs O(N*log(2, N)) $O(N \log_2(N))$ elementary operations even if N is a prime.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We give a demonstration of 1-dimensional transformations using lists. By default, numerical expressions are converted to floats:

```
L := [1, 2^(1/2), 3*I, PI]: F := numeric::fft(L)[5.555806216 + 3.0*I, 1.0 +
(- 1.272620909*I), - 3.555806216 + 3.0*I, 1.0 + (- 4.727379091*I)]
```

$$[5.555806216 + 3.0\,i,\ 1.0 - 1.272620909\,i,\ -3.555806216 + 3.0\,i,\ 1.0 - 4.727379091\,i]$$

numeric::invfft(F)[1.0, 1.414213562 + 2.512840965e-17*I, 3.0*I, 3.141592654 + (- 2.512840965e-17*I)]

$$\left[1.0,\ 1.414213562 + 2.512840965\ 10^{-17}\ i,\ 3.0\ i,\ 3.141592654 - 2.512840965\ 10^{-17}\ i\right]$$

numeric::invfft(F, Clean)[1.0, 1.414213562, 3.0*I, 3.141592654]

$$[1.0,\ 1.414213562,\ 3.0\ i,\ 3.141592654]$$

Exact arithmetic is used with the option `Symbolic`:
F := numeric::fft(L, Symbolic)[PI + sqrt(2) + 1 + 3*I, PI*I - sqrt(2)*I + 1 + (- 3*I), 1 - sqrt(2) - PI + 3*I, 1 + sqrt(2)*I - PI*I + (- 3*I)]

$$[\pi + \sqrt{2} + 1 + 3\ i,\ \pi\ i - \sqrt{2}\ i + 1 - 3\ i,\ 1 - \sqrt{2} - \pi + 3\ i,\ 1 + \sqrt{2}\ i - \pi\ i - 3\ i]$$

numeric::invfft(F, Symbolic)[1, sqrt(2), 3*I, PI]

$$[1,\ \sqrt{2},\ 3\ i,\ \pi]$$

Symbolic expressions are accepted. Internally, however, the default method `HardwareFloats` (with `DIGITS < 16`) fails because of the symbolic parameter `x`. The following results are computed with the software arithmetic provided by the MuPAD kernel:
L := [x, 2, 3, x]: numeric::fft(L)[2*x + 5.0, x*(1.0 + 1.0*I) - 3.0 + (- 2.0*I), 1.0, x*(1.0 + (- 1.0*I)) - 3.0 + 2.0*I]

$$[2\ x + 5.0,\ x\ (1.0 + 1.0\ i) - 3.0 - 2.0\ i,\ 1.0,\ x\ (1.0 - 1.0\ i) - 3.0 + 2.0\ i]$$

numeric::fft(L, Symbolic)[2*x + 5, x*(1 + I) - 3 + (- 2*I), 1, x*(1 - I) - 3 + 2*I]

$$[2\ x + 5,\ x\ (1 + i) - 3 - 2\ i,\ 1,\ x\ (1 - i) - 3 + 2\ i]$$

delete L, F:

Example 2

We give a demonstration of multi-dimensional transformations. First, a 2-dimensional transformation is computed by using an array with 2 indices:

A := array(1..2, 1..4, [[1, 2, 3, 4], [a, b, c, d]]): numeric::fft(A, Symbolic)array(1..2, 1..4, [[a + b + c + d + 10, a - b*I - c + d*I - 2 + 2*I, a - b + c - d - 2, a + b*I - c - d*I - 2 + (- 2*I)], [10 - b - c - d - a, c + b*I - a - d*I - 2 + 2*I, b - a - c + d - 2, c - b*I - a + d*I - 2 + (- 2*I)]])

$$\begin{pmatrix} a+b+c+d+10 & a-bi-c+di-2+2i & a-b+c-d-2 & a+bi-c-di-2-2i \\ 10-b-c-d-a & c+bi-a-di-2+2i & b-a-c+d-2 & c-bi-a+di-2-2i \end{pmatrix}$$

numeric::invfft(%, Symbolic)array(1..2, 1..4, [[1, 2, 3, 4], [a, b, c, d]])

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ a & b & c & d \end{pmatrix}$$

The next example is 3-dimensional as indicated by the format of the array:

A := array(1..2, 1..4, 1..2, [[[sin(j1*PI/2)*cos(j2*3*PI/4)*sin(j3*PI/2) $ j3 = 1..2] $ j2 = 1..4] $ j1 = 1..2]): numeric::fft(A) array(1..2, 1..4, 1..2, (1, 1, 1) = -1.0, (1, 1, 2) = -1.0, (1, 2, 1) = - 1.414213562 - 1.0 I, (1, 2, 2) = - 1.414213562 - 1.0 I, (1, 3, 1) = 1.0, (1, 3, 2) = 1.0, (1, 4, 1) = - 1.414213562 + 1.0 I, (1, 4, 2) = - 1.414213562 + 1.0 I, (2, 1, 1) = -1.0, (2, 1, 2) = -1.0, (2, 2, 1) = - 1.414213562 - 1.0 I, (2, 2, 2) = - 1.414213562 - 1.0 I, (2, 3, 1) = 1.0, (2, 3, 2) = 1.0, (2, 4, 1) = - 1.414213562 + 1.0 I, (2, 4, 2) = - 1.414213562 + 1.0 I) delete A:

Example 3

Data of arbitrary length can be transformed:

L := [1, 2 + I, PI/3]: numeric::fft(L)[4.047197551 + 1.0*I, 0.3424266282 + (- 1.325151125*I), - 1.389624179 + 0.3251511255*I]

$$[4.047197551 + 1.0\,i,\ 0.3424266282 - 1.325151125\,i,\ -1.389624179 + 0.3251511255\,i]$$

delete L:

Parameters

L

A list or a 1-dimensional array(`1 .. N, [Symbol::hellip]`) or a 1-dimensional hfarray(`1 .. N, [Symbol::hellip]`) of arithmetical expressions.

M

A matrix of category Cat::Matrix of arithmetical expressions.

A

A *d*-dimensional `array( 1..n_1,Symbol::hellip,1..n_d, [Symbol::hellip] )` or a *d*-dimensional `hfarray( 1..n_1,Symbol::hellip,1..n_d, [Symbol::hellip] )` of arithmetical expressions.

mode

One of the flags `Hard`, `HardwareFloats`, `Soft`, `SoftwareFloats`, or `Symbolic`

Options

Hard

HardwareFloats

Soft

SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix `A` is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

With `Soft` and `SoftwareFloats`, symbolic objects are accepted even if they cannot be converted to floating-point numbers. The result consists of arithmetical expressions involving both floating-point numbers as well as symbolic objects. See. “Example 1” on page 19-90.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Symbolic

Without this option, the floating-point converter float is applied to all input data. Use this option if no such conversion is desired. Exact arithmetic is used to compute the Fourier transformation.

This option prevents conversion of the input data to floats.

ReturnType

Option, specified as `ReturnType = t`

Return the result in a container of domain type `t`. The following return types `t` are available: DOM_LIST, or DOM_ARRAY, or DOM_HFARRAY, or matrix, or densematrix.

This option determines the domain type `t` of the result.

If no return type is specified by this option, the result if of the same type and format as the input data.

If the return type DOM_LIST is specified, the result is always a plain list of floating-point numbers. If the input data are given by a matrix or a multi-dimensional array, the returned list represents the operands of the multi-dimensional Fourier data. E.g., if an $n_1\ n_2$ matrix is entered, the return value is a list with $n_1 n_2$ values representing the entries of a $n_1\ n_2$ matrix. The first n_2 entries of the list represent the first row of the result, the next n_2 entries represent the second row, etc.

With `ReturnType` = matrix or `ReturnType` = densematrix, only the results of 1 and 2 dimensional Fourier transformations can be represented.

Clean

Reduce roundoff garbage in the result. All entries of the result with absolute values smaller than `10^(-DIGITS)` times the maximal absolute value of all operands of the result are set to `0.0`. Further, the routine numeric::complexRound is applied to all entries of the result.

Note The postprocessing of the result is done on the software float level. When using hardware floats, this option may increase the runtime significantly!

This option is ignored when used in conjunction with the option `Symbolic`.

Return Values

List/array/hfarray/matrix of the same length and format as the first input parameter `L/A/M`. The type of the return value can be changed with the option `ReturnType`.

numeric::invfft(A, <mode>, <ReturnType = t>, <Clean>)
```

Description

`numeric::invfft(data)` returns the inverse discrete Fourier transform.

The inverse discrete Fourier transform $L = invfft(F)$ of N data elements F_k stored in the list $F = [F_1, \ldots, F_N]$ is the list $L = [L_1, \ldots, L_N]$ given by

L[j]= _divide(1,N)* _outputSequence(sum(F[k]*exp(I*2*PI*(j-1)*(k-1)/N), k=1..N), “), j = 1,Symbol::hellip, N

$$L_j = \frac{1}{N} \sum_{k=1}^{N} F_k \, e^{\frac{i\,2\,\pi\,(j-1)\,(k-1)}{N}}, \quad j = 1, \ldots, N$$

`invfft` transforms the data by a Fast Fourier Transform (FFT) algorithm.

The d-dimensional inverse discrete Fourier transform $A = invfft(F)$ is given by

A[j[1], Symbol::hellip, j[d]]= _mult_intern(_divide(1,N), _outputSequence(sum(“, k[1]=1..n[1]), Symbol::hellip, sum(F[k[1], Symbol::hellip, k[d]] *exp(I*2*PI* ((j[1]-1)*(k[1]-1)/n[1] + Symbol::hellip + (j[d]-1)*(k[d]-1)/n[d])), j[d]=1..n[d])))

$$A_{j_1, \ldots, j_d} = \frac{1}{N} \sum_{k_1=1}^{n_1} \cdots \sum_{k_d=1}^{n_d} F_{k_1, \ldots, k_d} \, e^{i\,2\,\pi \left(\frac{(j_1-1)\,(k_1-1)}{n_1} + \ldots + \frac{(j_d-1)\,(k_d-1)}{n_d} \right)}$$

with $j_1 = 1, \ldots, j_d = n_1, \ldots, j_d = 1, \ldots, n_d$.

Data provided by lists or 1-dimensional arrays or hfarrays are transformed according to the 1-dimensional transform. Data provided by matrices are transformed according to the 2-dimensional transform. Data provided by multidimensional arrays or hfarrays are transformed according to the multidimensional transform matching the format of the input array.

If the data size factorizes ($N = pq$, say), the inverse discrete Fourier transform can be computed by p different inverse Fourier transforms of subsets of the data, each subset having the data size q. The corresponding 'divide and conquer' algorithm is known as FFT ('Fast Fourier Transform'). The `invfft` routine employs the FFT algorithm. It is most efficient, when the data size N is an integer power of 2 ('radix 2 FFT'). In this case, the algorithm needs O(N*log(2, N))$O(N \log_2(N))$ elementary operations.

Note More generally, FFT is efficient, if the data size is the product of many small factors!

Following Bluestein, the inverse Fourier transform is written as a convolution if the data size N is a prime. The data are zero-padded to a data length that is an integer power of 2. The convolution is then computed via radix 2 FFTs. Thus, the algorithm needs O(N*log(2, N))$O(N \log_2(N))$ elementary operations even if N is a prime.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We give a demonstration of 1-dimensional transformations using lists. By default, numerical expressions are converted to floats:

```
L := [1, 2^(1/2), 3*I, PI]: F := numeric::fft(L)[5.555806216 + 3.0*I, 1.0 + (- 1.272620909*I), - 3.555806216 + 3.0*I, 1.0 + (- 4.727379091*I)]
```

$[5.555806216 + 3.0\,i,\ 1.0 - 1.272620909\,i,\ -3.555806216 + 3.0\,i,\ 1.0 - 4.727379091\,i]$

numeric::invfft(F)[1.0, 1.414213562 + 2.512840965e-17*I, 3.0*I, 3.141592654 + (- 2.512840965e-17*I)]

$[1.0,\ 1.414213562 + 2.512840965\ 10^{-17}\,i,\ 3.0\,i,\ 3.141592654 - 2.512840965\ 10^{-17}\,i]$

numeric::invfft(F, Clean)[1.0, 1.414213562, 3.0*I, 3.141592654]

$[1.0,\ 1.414213562,\ 3.0\,i,\ 3.141592654]$

Exact arithmetic is used with the option `Symbolic`:

F := numeric::fft(L, Symbolic)[PI + sqrt(2) + 1 + 3*I, PI*I - sqrt(2)*I + 1 + (- 3*I), 1 - sqrt(2) - PI + 3*I, 1 + sqrt(2)*I - PI*I + (- 3*I)]

$[\pi + \sqrt{2} + 1 + 3\,i,\ \pi\,i - \sqrt{2}\,i + 1 - 3\,i,\ 1 - \sqrt{2} - \pi + 3\,i,\ 1 + \sqrt{2}\,i - \pi\,i - 3\,i]$

numeric::invfft(F, Symbolic)[1, sqrt(2), 3*I, PI]

$[1,\ \sqrt{2},\ 3\,i,\ \pi]$

Symbolic expressions are accepted. Internally, however, the default method `HardwareFloats` (with `DIGITS < 16`) fails because of the symbolic parameter `x`. The following results are computed with the software arithmetic provided by the MuPAD kernel:

L := [x, 2, 3, x]: numeric::fft(L)[2*x + 5.0, x*(1.0 + 1.0*I) - 3.0 + (- 2.0*I), 1.0, x*(1.0 + (- 1.0*I)) - 3.0 + 2.0*I]

$[2\,x + 5.0,\ x\,(1.0 + 1.0\,i) - 3.0 - 2.0\,i,\ 1.0,\ x\,(1.0 - 1.0\,i) - 3.0 + 2.0\,i]$

numeric::fft(L, Symbolic)[2*x + 5, x*(1 + I) - 3 + (- 2*I), 1, x*(1 - I) - 3 + 2*I]

$[2\,x + 5,\ x\,(1 + i) - 3 - 2\,i,\ 1,\ x\,(1 - i) - 3 + 2\,i]$

delete L, F:

Example 2

We give a demonstration of multi-dimensional transformations. First, a 2-dimensional transformation is computed by using an array with 2 indices:

A := array(1..2, 1..4, [[1, 2, 3, 4], [a, b, c, d]]): numeric::fft(A, Symbolic)array(1..2, 1..4, [[a + b + c + d + 10, a - b*I - c + d*I - 2 + 2*I, a - b + c - d - 2, a + b*I - c - d*I - 2 + (- 2*I)], [10 - b - c - d - a, c + b*I - a - d*I - 2 + 2*I, b - a - c + d - 2, c - b*I - a + d*I - 2 + (- 2*I)]])

$$\begin{pmatrix} a+b+c+d+10 & a-bi-c+di-2+2i & a-b+c-d-2 & a+bi-c-di-2-2i \\ 10-b-c-d-a & c+bi-a-di-2+2i & b-a-c+d-2 & c-bi-a+di-2-2i \end{pmatrix}$$

numeric::invfft(%, Symbolic)array(1..2, 1..4, [[1, 2, 3, 4], [a, b, c, d]])

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ a & b & c & d \end{pmatrix}$$

The next example is 3-dimensional as indicated by the format of the array:

A := array(1..2, 1..4, 1..2, [[[sin(j1*PI/2)*cos(j2*3*PI/4)*sin(j3*PI/2) $ j3 = 1..2] $ j2 = 1..4] $ j1 = 1..2]): numeric::fft(A) array(1..2, 1..4, 1..2, (1, 1, 1) = -1.0, (1, 1, 2) = -1.0, (1, 2, 1) = - 1.414213562 - 1.0 I, (1, 2, 2) = - 1.414213562 - 1.0 I, (1, 3, 1) = 1.0, (1, 3, 2) = 1.0, (1, 4, 1) = - 1.414213562 + 1.0 I, (1, 4, 2) = - 1.414213562 + 1.0 I, (2, 1, 1) = -1.0, (2, 1, 2) = -1.0, (2, 2, 1) = - 1.414213562 - 1.0 I, (2, 2, 2) = - 1.414213562 - 1.0 I, (2, 3, 1) = 1.0, (2, 3, 2) = 1.0, (2, 4, 1) = - 1.414213562 + 1.0 I, (2, 4, 2) = - 1.414213562 + 1.0 I) delete A:

Example 3

Data of arbitrary length can be transformed:

L := [1, 2 + I, PI/3]: numeric::fft(L)[4.047197551 + 1.0*I, 0.3424266282 + (- 1.325151125*I), - 1.389624179 + 0.3251511255*I]

$$[4.047197551 + 1.0\,i,\ 0.3424266282 - 1.325151125\,i,\ -1.389624179 + 0.3251511255\,i]$$

delete L:

Parameters

L

A list or a 1-dimensional array(`1 .. N, [Symbol::hellip]`) or a 1-dimensional hfarray(`1 .. N, [Symbol::hellip]`) of arithmetical expressions.

M

A matrix of category Cat::Matrix of arithmetical expressions.

A

A *d*-dimensional `array( 1..n_1,Symbol::hellip,1..n_d, [Symbol::hellip] )` or a *d*-dimensional `hfarray( 1..n_1,Symbol::hellip,1..n_d, [Symbol::hellip] )` of arithmetical expressions.

mode

One of the flags `Hard`, `HardwareFloats`, `Soft`, `SoftwareFloats`, or `Symbolic`

Options

Hard

HardwareFloats

Soft

SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix `A` is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

With `Soft` and `SoftwareFloats`, symbolic objects are accepted even if they cannot be converted to floating-point numbers. The result consists of arithmetical expressions involving both floating-point numbers as well as symbolic objects. See. “Example 1” on page 19-98.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Symbolic

Without this option, the floating-point converter float is applied to all input data. Use this option if no such conversion is desired. Exact arithmetic is used to compute the Fourier transformation.

This option prevents conversion of the input data to floats.

ReturnType

Option, specified as `ReturnType = t`

Return the result in a container of domain type `t`. The following return types `t` are available: DOM_LIST, or DOM_ARRAY, or DOM_HFARRAY, or matrix, or densematrix.

This option determines the domain type `t` of the result.

If no return type is specified by this option, the result if of the same type and format as the input data.

If the return type DOM_LIST is specified, the result is always a plain list of floating-point numbers. If the input data are given by a matrix or a multi-dimensional array, the returned list represents the operands of the multi-dimensional Fourier data. E.g., if an $n_1\ n_2$ matrix is entered, the return value is a list with $n_1 n_2$ values representing the entries of a $n_1\ n_2$ matrix. The first n_2 entries of the list represent the first row of the result, the next n_2 entries represent the second row, etc.

With `ReturnType` = matrix or `ReturnType` = densematrix, only the results of 1 and 2 dimensional Fourier transformations can be represented.

Clean

Reduce roundoff garbage in the result. All entries of the result with absolute values smaller than `10^(-DIGITS)` times the maximal absolute value of all operands of the result are set to `0.0`. Further, the routine numeric::complexRound is applied to all entries of the result.

Note The postprocessing of the result is done on the software float level. When using hardware floats, this option may increase the runtime significantly!

This option is ignored when used in conjunction with the option `Symbolic`.

Return Values

List/array/hfarray/matrix of the same length and format as the first input parameter `L/A/M`. The type of the return value can be changed with the option `ReturnType`.

Concepts

- "Discrete Fourier Transforms"

numeric::fMatrix

Purpose

Functional calculus for numerical square matrices

Syntax

```
numeric::fMatrix(f, A, p1, p2,  , options)
```

Description

`numeric::fMatrix(f, A)` computes the matrix $f(A)$ with a function f and a square matrix A.

If no return type is specified via the option `ReturnType = d`, the domain type of the result depends on the type of the input matrix `A`:

- For an array A, the result is returned as an array.
- For an hfarray A, the result is returned as an array.
- For a dense matrix A of type `Dom::DenseMatrix()` the result is a dense matrix of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices A of category Cat::Matrix, the result is returned as a matrix of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

The components of A must not contain symbolic objects which cannot be converted to numerical values via float. Numerical symbolic expressions such as PI, sqrt(2) $\sqrt{2}$, exp(-1) e^{-1} etc. are accepted. They are converted to floats.

Note The matrix A must be diagonalizable; `numeric::fMatrix` aborts with an error message if it detects numerically that A is not diagonalizable. For most non-diagonalizable matrices, however, the numerical algorithm fails to detect this fact and the returned matrix is dominated by round-off effects. It is the user's responsibility to make sure that the diagonalization is feasible and well conditioned.

Symmetric/Hermitean and skew/skew Hermitean matrices can always be diagonalized in a numerically stable way; `numeric::fMatrix` produces reliable numerical results for such matrices.

The procedure *f* must accept complex floating-point numbers as first argument. It may return arbitrary MuPAD expressions, provided these can be multiplied with floating-point numbers.

The parameters p_1, p_2, may be numerical or symbolic objects. They must be accepted by `f` as 2nd argument, 3rd argument etc.

In contrast to the components of *A*, numerical symbolic objects such as π, sqrt(2)$\sqrt{2}$ etc. passed as parameters p_1, p_2, are not converted to floats.

Inversion or exponentiation of a matrix may be realized with the functions a -> 1/a$a \to \frac{1}{a}$ and exp, respectively. However, it is recommended to use the specialized algorithms numeric::inverse and numeric::expMatrix instead. Also matrix evaluation of low degree polynomials should be done with standard matrix arithmetic rather than with `numeric::fMatrix`.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We compute the matrix power A^{100}:

```
A := array(1..2, 1..2, [[2, PI], [exp(-10), 0]]): numeric::fMatrix(x
-> x^100, A)array(1..2, 1..2, [[1.272133133e30, 1.998190806e30],
[2.887634784e25, 4.535724387e25]])
```

$$\begin{pmatrix} 1.272133133\,10^{30} & 1.998190806\,10^{30} \\ 2.887634784\,10^{25} & 4.535724387\,10^{25} \end{pmatrix}$$

Alternatively, you may use the function _power which takes the exponent as a second parameter:

numeric::fMatrix(_power, A, 100) array(1..2, 1..2, [[1.272133133e30, 1.998190806e30], [2.887634784e25, 4.535724387e25]])

$$\begin{pmatrix} 1.272133133\,10^{30} & 1.998190806\,10^{30} \\ 2.887634784\,10^{25} & 4.535724387\,10^{25} \end{pmatrix}$$

delete A:

Example 2

We compute the square root of a matrix:
A := matrix([[0, 1], [-1, 1]]): B := numeric::fMatrix(sqrt, A)matrix([[0.5773502692, 0.5773502692 + 1.110223025e-16*I], [- 0.5773502692 + 2.775557562e-17*I, 1.154700538 + (- 8.326672685e-17*I)]])

$$\begin{pmatrix} 0.5773502692 & 0.5773502692 + 1.110223025\,10^{-16}\,i \\ -0.5773502692 + 2.775557562\,10^{-17}\,i & 1.154700538 - 8.326672685\,10^{-17}\,i \end{pmatrix}$$

The small imaginary parts are caused by numerical round-off. We eliminate them by extracting the real parts of the components:
B := map(B, Re)matrix([[0.5773502692, 0.5773502692], [-0.5773502692, 1.154700538]])

$$\begin{pmatrix} 0.5773502692 & 0.5773502692 \\ -0.5773502692 & 1.154700538 \end{pmatrix}$$

We verify that `B^2` is `A`. Since A was passed as a matrix of type `Dom::Matrix()`, the matrix B is also of this type. We may compute the square by the overloaded standard arithmetic using the operator `^`:
B^2matrix([[-1.283695372e-16, 1.0], [-1.0, 1.0]])

$$\begin{pmatrix} -1.283695372\,10^{-16} & 1.0 \\ -1.0 & 1.0 \end{pmatrix}$$

delete A, B:

Example 3

We compute exp(t*PI*A)$e^{t \pi A}$ with a symbolic parameter *t*:
A := array(1..2, 1..2, [[0, 1], [-1, 0]]): numeric::fMatrix(exp@_mult, A, t*PI)array(1..2, 1..2, [[0.5*exp(1.0*PI*t*I) + 0.5*exp(-1.0*PI*t*I), (-0.5*exp(1.0*PI*t*I)*I) + 0.5*exp(-1.0*PI*t*I)*I], [0.5*exp(1.0*PI*t*I)*I + (- 0.5*exp(-1.0*PI*t*I)*I), 0.5*exp(1.0*PI*t*I) + 0.5*exp(-1.0*PI*t*I)]])

$$\begin{pmatrix} 0.5\,e^{1.0\,\pi\,t\,i} + 0.5\,e^{-1.0\,\pi\,t\,i} & -0.5\,e^{1.0\,\pi\,t\,i}\,i + 0.5\,e^{-1.0\,\pi\,t\,i}\,i \\ 0.5\,e^{1.0\,\pi\,t\,i}\,i - 0.5\,e^{-1.0\,\pi\,t\,i}\,i & 0.5\,e^{1.0\,\pi\,t\,i} + 0.5\,e^{-1.0\,\pi\,t\,i} \end{pmatrix}$$

delete A:

Example 4

We demonstrate the difference between `HardwareFloats` and `SoftwareFloats`. The diagonalization of the following matrix is ill-conditioned. The result is dominated by round-off effects:
A := array(1..3, 1..3, [[10, 1, 1], [0, 1, 1], [1, 0, 10^(-14)]]): numeric::fMatrix(ln, A, SoftwareFloats)array(1..3, 1..3, [[2.284572396, 0.2635466905, 0.2635466905], [-4.117444729, 4.03009691, 41.43799398], [4.380991419, -4.117444729, -41.5253418]])

$$\begin{pmatrix} 2.284572396 & 0.2635466905 & 0.2635466905 \\ -4.117444729 & 4.03009691 & 41.43799398 \\ 4.380991419 & -4.117444729 & -41.5253418 \end{pmatrix}$$

numeric::fMatrix(ln, A, HardwareFloats)array(1..3, 1..3, [[2.284572396, 0.2635466905, 0.2635466905], [-3.532353481, 3.445005663, 35.5870815], [3.795900172, -3.532353481, -35.67442932]])

$$\begin{pmatrix} 2.284572396 & 0.2635466905 & 0.2635466905 \\ -3.532353481 & 3.445005663 & 35.5870815 \\ 3.795900172 & -3.532353481 & -35.67442932 \end{pmatrix}$$

In the following case, the round-off effects of `HardwareFloats` makes the algorithm think that the matrix cannot be diagonalized. Consequently, FAIL is returned. With `SoftwareFloats`, however, a result is computed:

```
A := array(1..3, 1..3, [[ 1 , 1 , 1 ], [ 0 , 1 , 1 ], [ 10^(-30), 0 , 10^(-30)]]):
numeric::fMatrix(ln, A, SoftwareFloats)FAIL
```

```
FAIL
numeric::fMatrix(ln, A, HardwareFloats)array(1..3, 1..3,
[[-5.469808086e-17, 1.000000477, 0.9999345993], [9.98400946e-31,
-5.632422161e-17, 69.07755279], [0, 0, -69.07755279]])
```

$$\begin{pmatrix} -5.469808086\,10^{-17} & 1.000000477 & 0.9999345993 \\ 9.98400946\,10^{-31} & -5.632422161\,10^{-17} & 69.07755279 \\ 0 & 0 & -69.07755279 \end{pmatrix}$$

delete A:

Parameters

f

A procedure representing a scalar function funcDecl(f, C_, C_)f: $\mathbb{C} \to \mathbb{C}$ or funcDecl(f, C_ times P times Symbol::cdots times P, C_)f: $\mathbb{C} \times P \times \cdots \times P \to \mathbb{C}$, where P is a set of parameters

A

A square matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

P_1, P_2, ...

Arbitrary MuPAD objects accepted by *f* as additional input parameters

Options

Hard

HardwareFloats

Soft

SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix `A` is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.

- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note For ill-conditioned matrices, the result is subject to round-off errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ! See "Example 4" on page 19-108.

NoWarning

Suppresses warnings

ReturnType

Option, specified as `ReturnType = d`

Return the result as a matrix of domain type `d`. The following return types are available: DOM_ARRAY, DOM_HFARRAY, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Return Values

Depending on the type of the input matrix `A`, the matrix $f(A)$ is returned as a matrix of type DOM_ARRAY, DOM_HFARRAY, `Dom::Matrix()` or `Dom::DenseMatrix()`. If the algorithm thinks that `A` is not diagonalizable, then FAIL is returned.

Algorithms

A numerical diagonalization $A = Xdiag(\lambda_1, \lambda_2, \ldots)X^{-1}$ is computed. The columns of X are the (right) eigenvectors of A, the diagonal entries λ_1, λ_2, ... are the corresponding eigenvalues. The function f is mapped to the eigenvalues, the matrix result is computed by

f(A, p[1], p[2], Symbol::hellip)=X*diag(f(Symbol::lambda[1], p[1], p[2], Symbol::hellip), f(Symbol::lambda[2], p[1], p[2], Symbol::hellip), Symbol::hellip)*invMatrix(X)

$$f(A, p_1, p_2, \ldots) = X\,\mathrm{diag}(f(\lambda_1, p_1, p_2, \ldots), f(\lambda_2, p_1, p_2, \ldots), \ldots)\,X^{-1}$$

The eigenvector matrix X may be obtained via `numeric::eigenvectors(A)[2]`.

The condition number norm(X)*norm(X^(-1)) $\|X\|_\infty \left\|\frac{1}{X}\right\|_\infty$ of the eigenvector matrix is a measure indicating how well conditioned the diagonalization of the matrix A is. If this number is larger than 10^{DIGITS}, then not a single digit of the diagonalization data is trustworthy.

The call `numeric::fMatrix(exp, A)` corresponds to `numeric::expMatrix(A, Diagonalization)`.

numeric::fsolve

Purpose

Search for a numerical root of a system of equations

Syntax

```
numeric::fsolve(eq, x, options)
numeric::fsolve(eq, x = a, options)
numeric::fsolve(eq, x = a .. b, options)
numeric::fsolve(eqs, [x_1, x_2,  ], options)
numeric::fsolve(eqs, {x_1, x_2,  }, options)
numeric::fsolve(eqs, [x_1 = a_1, x_2 = a_2,  ], options)
numeric::fsolve(eqs, {x_1 = a_1, x_2 = a_2,  }, options)
numeric::fsolve(eqs, [x_1 = a_1 .. b_1, x_2 = a_2 ..
b_2,  ], options)
numeric::fsolve(eqs, {x_1 = a_1 .. b_1, x_2 = a_2 ..
b_2,  }, options)
```

Description

`numeric::fsolve(eqs, ...)` returns a numerical approximation of a solution of the system of equations `eqs`.

This is the MuPAD numerical solver for non-linear systems of equations.

Note By default, this routine returns only *one* numerical solution!

The equations must not contain symbolic objects other than the unknowns that cannot be converted to numerical values via float. Symbolic objects such as PI or sqrt(2)$\sqrt{2}$ etc. are accepted. The same holds true for starting values and search ranges. Search ranges may contain _outputSequence(Symbol::pm,Symbol::infin)$\pm\infty$. Cf. “Example 2” on page 19-117.

`numeric::fsolve` implements a purely numerical Newton type root search with a working precision set by the environment variable DIGITS. Well separated simple roots should be exact within this precision. However, multiple roots or badly separated roots may be computed with a restricted precision. Cf. “Example 3” on page 19-118.

Note For systems of equations, the expressions defining the equations must have a symbolic derivative!

Overdetermined systems (i.e., more equations than indeterminates) are not accepted. However, there may be more indeterminates than equations. Cf. "Example 4" on page 19-118.

Specifying indeterminates `[x1, x2, ]` without starting values or search ranges is equivalent to the search ranges `[x_1 = -infinity .. infinity, x_2 = -infinity .. infinity, dots]`. Note, however, that the user should assist `numeric::fsolve` by providing specific search ranges whenever possible! If a complex starting point or a search range involving a complex number is specified for at least one of the unknowns, the search is extended to the entire complex plane for all variables for which no explicit search interval is given.

For real equations and real starting points or search ranges, the internal Newton iteration will usually produce real values, i.e., `numeric::fsolve` searches for real roots only (unless square roots, logarithms etc. happen to produce complex values from real input). Use complex starting points or search ranges to search for complex roots of real equations. Cf. "Example 5" on page 19-118.

Starting values and search ranges can be mixed. Cf. "Example 6" on page 19-119.

Search ranges should only be provided if a solution is known to exist inside the search range. Otherwise, the search may take some time before `numeric::fsolve` gives up.

Specification of a search range primarily means that starting points from this range are used for the internal Newton search. For sufficiently small search ranges enclosing a solution the search will usually pick out this solution. However, it may also happen that the Newton iteration drifts towards other solutions.

With the default search strategy `RestrictedSearch`, only solutions from the search range are accepted, even if solutions outside the search

range are found internally. More specifically, if a search range such as `x = a .. b` is specified for the variable `x`, then solutions satisfying `min( (a), (b)) (x) max( (a), (b))` and `min( (a), (b)) (x) max( (a), (b))` are searched for. Thus, the values `a, b` specify the bottom left and top right corner of a rectangular search area in the complex plane when the `RestrictedSearch` strategy is used.

With the search strategy `UnrestrictedSearch`, any solution inside or outside the search range is accepted and returned. Cf. "Example 7" on page 19-119.

If starting values for all indeterminates are provided, then a *single* Newton iteration with these initial data is launched. It either leads to a solution or `numeric::fsolve` gives up and returns FAIL. The same holds true if search ranges `x = a .. a` or `[x_1 = a_1 .. a_1, x_2 = a_2 .. a_2, dots]` of zero length are specified.

Note The risk of failure is high when providing bad starting values! Starting values are appropriate only if a sufficiently good approximation of the solution is known! On the other hand, providing good starting values is the fastest way to a solution. Cf. "Example 8" on page 19-120.

If at least one of the indeterminates has a non-trivial search range, then `numeric::fsolve` uses *several* Newton iterations with different starting values from the search range. Cf. "Example 9" on page 19-121. Search ranges in conjunction with the option `UnrestrictedSearch` provide a higher chance of detecting roots than (bad) starting values!

Note User defined assumptions such as `assume(x > 0)` are not taken into account in the numerical search! Provide search ranges instead! Cf. "Example 2" on page 19-117.

Note Convergence may be slow for multiple roots! Furthermore, `numeric::fsolve` may fail to detect such roots!

`setuserinfo(numeric::fsolve, 3)` provides detailed information on the internal search.

Use linsolve or numeric::linsolve for systems of *linear* equations.

Use numeric::realroots, if *all real roots* of a single non-polynomial real equation in a finite range are desired.

Use polylib::realroots, if *all real roots* of a real univariate polynomial are desired.

Use numeric::polyroots, if *all real and complex roots* of a univariate polynomial are desired.

Use numeric::solve, if *all roots* of a multivariate polynomial system are desired.

The routine numeric::solve provides a common interface to all these numerical solvers.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We compute roots of the sine function:
numeric::fsolve(sin(x) = 0, x)[x = 0.0]

$$[x = 0.0]$$

With the option `Random`, several calls may result in different roots:
numeric::fsolve(sin(x), x, Random)[x = -226.1946711]

$$[x = -226.1946711]$$

numeric::fsolve(sin(x), x, Random)[x = 97.38937226]

$[x = 97.38937226]$

Particular solutions can be chosen by an appropriate starting point close to the wanted solution, or by a search interval:
numeric::fsolve(sin(x), x = 3), numeric::fsolve(sin(x), x = -4 .. -3)[x = 3.141592653], [x = -3.141592654]

$[x = 3.141592653], [x = -3.141592654]$

The solutions found by `numeric::fsolve` can be used in subs and assign to substitute or assign the indeterminates:
eqs := [x^2 = sin(y), y^2 = cos(x)]: solution := numeric::fsolve(eqs, [x, y])[x = -0.8517004887, y = 0.8116062151]

$[x = -0.8517004887, y = 0.8116062151]$

eval(subs(eqs, solution))[0.7253937224 = 0.7253937224, 0.6587046485 = 0.6587046485]

$[0.7253937224 = 0.7253937224, 0.6587046485 = 0.6587046485]$

assign(solution): x, y-0.8517004887, 0.8116062151

$-0.8517004887, 0.8116062151$

delete eqs, solution, x, y:

Example 2

We demonstrate the use of search ranges. The following system has solutions with positive and negative x. The solution with $x \geq 0$ is obtained with the search interval `x = 0 .. infinity`:
numeric::fsolve([x^2 = exp(x*y), x^2 = y^2], [x = 0 .. infinity, y])[x = 0.753089165, y = -0.753089165]

$[x = 0.753089165, y = -0.753089165]$

We search for a solution with $x \le 0$:
numeric::fsolve([x^2 = exp(x*y), x^2 = y^2], [x = -infinity .. 0, y])[x = -0.753089165, y = 0.753089165]

$$[x = -0.753089165,\ y = 0.753089165]$$

Example 3

Multiple roots can only be computed with a restricted precision:
numeric::fsolve(expand((x - 1/3)^5), x = 0.3)[x = 0.3333672906]

$$[x = 0.3333672906]$$

Example 4

The following system of equations is degenerate and has a 1-parameter family of solutions. Each call to `numeric::fsolve` picks out one random solution:
numeric::fsolve([x^2 - y^2, x^2 - y^2], [x, y], Random) $ i = 1 .. 3[x = 34.70258251, y = 34.70258251], [x = -29.16650501, y = 29.16650501], [x = 5.933941324, y = -5.933941324]

$$[x = 34.70258251,\ y = 34.70258251],\ [x = -29.16650501,\ y = 29.16650501],\ [x = 5.933941324,\ y = -$$

The equation may also be specified as an underdetermined system:
numeric::fsolve([x^2 - y^2], [x, y])[x = 0.0, y = 0.0]

$$[x = 0.0,\ y = 0.0]$$

Example 5

The following equation has no real solution. Consequently, the numerical search with real starting values fails:
numeric::fsolve(sin(x) + cos(x)^2 = 3, x)FAIL

FAIL

With a complex starting value, a solution is found:
numeric::fsolve(sin(x) + cos(x)^2 = 3, x = I)[x = 0.2972513613 + 1.128383965*I]

$[x = 0.2972513613 + 1.128383965\,i]$

Also complex search ranges may be specified. In the following, the internal starting point is a random value on the line from `2 + I` to `3 + 2*I`. Solutions are accepted if they lie in the complex rectangle with the bottom left corner `2 + I` and the top right corner `3 + 2*I`:
numeric::fsolve(sin(x) + cos(x)^2 = 3, x = 2 + I .. 3 + 2*I)[x = 2.844341292 + 1.128383965*I]

$[x = 2.844341292 + 1.128383965\,i]$

Example 6

Starting values and search intervals can be mixed:
numeric::fsolve([x^2 + y^2 = 1, y^2 + z^2 = 1, x^2 + z^2 = 1], [x = 1, y = 0 .. 10, z])[x = 0.7071067812, y = 0.7071067812, z = 0.7071067812]

$[x = 0.7071067812,\ y = 0.7071067812,\ z = 0.7071067812]$

Example 7

With `UnrestrictedSearch`, search intervals are only used for choosing starting values for the internal Newton search. The numerical iteration may drift towards a solution outside the search range:
eqs := [x*sin(10*x) = y^3, y^2 = exp(-2*x/3)]: numeric::fsolve(eqs, [x = 0 .. 1, y = -1 .. 0], UnrestrictedSearch)[x = 1.232766201, y = -0.6630386021]

$[x = 1.232766201,\ y = -0.6630386021]$

With the default strategy `RestrictedSearch`, only solutions inside the search range are accepted:
numeric::fsolve(eqs, [x = 0 .. 1, y = -1 .. 0])[x = 0.9816416007, y = -0.7209295436]

$[x = 0.9816416007, y = -0.7209295436]$

In the last search, also the previous solution outside the search range was found. With the option `MultiSolutions`, `numeric::fsolve` returns a sequence of all solutions that were found in the internal search:
numeric::fsolve(eqs, [x = 0 .. 1, y = -1 .. 0], MultiSolutions)[x = 0.9816416007, y = -0.7209295436], [x = 1.232766201, y = -0.6630386021]

$[x = 0.9816416007, y = -0.7209295436], [x = 1.232766201, y = -0.6630386021]$

delete eqs:

Example 8

Usually, most of the time is spent internally searching for some (crude) approximations of the root. If high precision roots are required, it is recommended to compute first approximations with moderate values of DIGITS and use them as starting values for a refined search:
eq := exp(-x) = x: DIGITS := 10: firstApprox := numeric::fsolve(eq, x)[x = 0.5671432904]

$[x = 0.5671432904]$

This output is suitable as input defining a starting value for x:
DIGITS := 1000: numeric::fsolve(eq, firstApprox)[x = _outputSequence(0.56714329040978387299996866221035554975381578718651250813513107922304579

$[x = 0.56714329040978387299996866221035554975381578718651250813513107922304579...]$

[x =
0.56714329040978387299996866221035554975381578718651250813513107922304579

delete eq, firstApprox, DIGITS:

Example 9

Specifying starting values for the indeterminates launches a *single* Newton iteration. This may fail, if the starting values are not sufficiently close to the solution:

```
eq := [x*y = x + y - 4, x/y = x - y + 4]: numeric::fsolve(eq, [x = 1, y = 1])FAIL
```

If a search range is specified for at least one of the unknowns, then *several* Newton iterations with random starting values in the search range are used, until a solution is found or until `numeric::fsolve` gives up:

```
numeric::fsolve(eq, [x = 1, y = 0 .. 10])[x = 4.02644145e-14, y = 4.0]
```

$$\left[x = 4.02644145\ 10^{-14},\ y = 4.0\right]$$

delete eq:

Parameters

eq

An arithmetical expression or an equation in one indeterminate `x`. An expression `eq` is interpreted as the equation `eq = 0`.

eqs

A list, set, array, or matrix (Cat::Matrix) of expressions or equations in several indeterminates `x1, x2, ...`. Expressions are interpreted as homogeneous equations.

x

x_1, x_2, ...

Identifiers or indexed identifiers to be solved for.

a

a_1, a_2, ...

Real or complex numerical starting values for the internal search. Typically, crude approximations of solution.

a .. b

a_1 .. b_1, a_2 .. b_2, ...

Ranges of numerical values defining search intervals for the numerical root.

Options

RestrictedSearch

Makes `numeric::fsolve` return only numerical roots in the user-defined search range `x = a .. b` and `[x_1 = a_1 .. b_1, x_2 = a_2 .. b_2, Symbol::hellip]`, respectively. This is the default search strategy, if a search range is specified for at least one of the unknowns.

Once a root with components (r_1, r_2, ...) is found, it is checked whether $min(\Re(a_i), \Re(b_i)) \le \Re(r_i) \le max(\Re(a_i), \Re(b_i))$ and $min(\Im(a_i), \Im(b_i)) \le \Im(r_i) \le max(\Im(a_i), \Im(b_i))$ is satisfied. If the root is not inside the search range, the search is continued. Note that solutions outside the search range may be found internally. These may

be accessed with the option `MultiSolutions`. See “Example 7” on page 19-119.

UnrestrictedSearch

Allows `numeric::fsolve` to find and return solutions outside the specified search range. With this option, the search range is only used to choose random starting points for the internal numerical search.

This option switches off the search strategy `RestrictedSearch`. With `UnrestrictedSearch`, `numeric::fsolve` stops its internal search whenever a root is found, even if the root is not inside the specified search range. Starting points for the internal Newton search are taken from the search range.

MultiSolutions

Makes `numeric::fsolve` return all solutions found in the internal search

This option only has an effect when used with the default search strategy `RestrictedSearch`. A sequence of all roots found in the internal search is returned. Cf. “Example 7” on page 19-119.

Random

With this option, several calls to `numeric::fsolve` with the same input parameters may produce different roots.

With this option, random starting values are chosen for the internal search. Consequently, calling `numeric::fsolve` several times with the same parameters may lead to different solutions. This may be useful when several roots of one and the same equation or set of equations are desired.

Return Values

Single numerical root is returned as a list of equations `[x = value]` or $[x_1 = value_1, x_2 = value_2, \ldots]$, respectively. FAIL is returned if no solution is found. With the option `MultiSolutions`, sequences of solutions may be returned.

Algorithms

Internally the set of equations $f(x) = 0$ is solved by a modified Newton iteration (x) -> x-t*invMatrix(f'(x))*f(x)$x \to x - t\,f'(x)^{-1}\,f(x)$ with some adaptively chosen step size t. For degenerate or ill-conditioned Jacobians f' f a minimization strategy for linalg::scalarProduct(f, f)$\langle f, f \rangle$ is implemented. For scalar real equations, numeric::realroot is used, if a real finite search range is specified.

Concepts

- "Solve Equations Numerically"

numeric::gaussAGM

Purpose

Gauss' arithmetic geometric mean

Syntax

```
numeric::gaussAGM(a, b)
```

Description

`numeric::gaussAGM(a, b)` computes the arithmetic geometric mean of the numbers a and b.

The iteration

a[(n+1)]=(a[n]+b[n])/2, b[n+1] = (a[n]+b[n])*sqrt(a[n]*b[n]/(a[n]+b[n])^2)

$$a_{n+1} = \frac{a_n + b_n}{2},\quad b_{n+1} = (a_n + b_n)\sqrt{\frac{a_n\, b_n}{(a_n + b_n)^2}}$$

with the starting values $a_0 = a$, $b_0 = b$ converges quadratically to some value limit(a[n], n=infinity) = limit(b[n], n=infinity)$\lim_{n\to\infty} a_n = \lim_{n\to\infty} b_n$. This limit is called Gauss' arithmetic geometric mean of the starting values a, b.

If both arguments a and b can be converted to real or complex floating-point numbers, then a floating point value is computed and returned. Otherwise, the symbolic call `numeric::gaussAGM(a, b)` is returned.

If $a = 0$ or $b = 0$ or $a + b = 0$, then 0.0 is returned, even if a or b are symbolic objects.

The following relation to elliptic integrals holds for all complex values a and b:

numeric::gaussAGM(a, b) = (PI/4)*((a+b)/ellipticK(sqrt(((a-b)/(a+b))^2)))

$$\text{numeric::gaussAGM}(a,\ b) = \frac{\pi}{4}\,\frac{a+b}{K\left(\sqrt{\left(\frac{a-b}{a+b}\right)^2}\right)}$$

Environment Interactions

The function is sensitive to the environment variable DIGITS.

Examples

Example 1

A floating-point number is returned if the arguments can be converted to floating-point numbers:
numeric::gaussAGM(0, 5)0.0

0.0
numeric::gaussAGM(sqrt(2), PI)2.192033978

2.192033978
numeric::gaussAGM(-10, PI)- 2.377943461 + (- 2.966350545*I)

$-2.377943461 - 2.966350545\,i$
numeric::gaussAGM(1 + I, 1 + 2*I)1.020054126 + 1.471349363*I

$1.020054126 + 1.471349363\,i$

A symbolic call is returned if one of the arguments cannot be converted to a float:
numeric::gaussAGM(1, b)numeric::gaussAGM(1, b)

numeric::gaussAGM(1, *b*)

For the special cases $a = 0$, $b = 0$ and $a + b = 0$, the result 0.0 is returned even for symbolic arguments:
numeric::gaussAGM(a, 0)0.0

0.0
numeric::gaussAGM(a, -a)0.0

```
0.0
```

Parameters

a

b

arithmetical expressions

Return Values

Floating point number or a symbolic call `numeric::gaussAGM(a, b)`.

ellipticK

numeric::gldata

Purpose

Weights and abscissae of Gauss-Legendre quadrature

Syntax

```
numeric::gldata(n, digits)
```

Description

`numeric::gldata(n, digits)` returns the weights and the abscissae of the Gauss-Legendre quadrature rule with n nodes with a precision of `digits` decimal digits.

The Gauss-Legendre quadrature rule sum(b[i]*f(c[i]), i=1..n)$\sum_{i=1}^{n} b_i f(c_i)$ produces the exact integral int(f(x), x=0..1) $\int_0^1 f(x)\,dx$ for all polynomial integrands $f(x)$ through degree $2n$ - 1. The weights b_i and abscissae c_i are related to the roots of the n-th Legendre polynomial.

The weights and abscissae are computed by a straightforward numerical algorithm with a working precision set by the argument `digits`. The resulting floating-point numbers are correct to `digits` leading decimal places.

Typically, the argument `digits` is chosen as the current value of the environment variable DIGITS.

The data for `n = 20, 40, 80, 160` with `digits <= 200` are stored internally. They are returned immediately without any computational costs.

Due to the internal remember mechanism, only the first call to `numeric::gldata` leads to computational costs. For any further call with the same arguments, the data are returned immediately.

For odd n, the abscissa c[(n+1)/2]=1/2$c_{\frac{n+1}{2}} = \frac{1}{2}$ and the corresponding weight b[(n+1)/2]$b_{\frac{n+1}{2}}$ are rational numbers.

Environment Interactions

`numeric::gldata` is *not* sensitive to changes of the environment variable DIGITS, because the numerical working precision is specified by the second argument `digits`.

The function uses option remember.

Examples

Example 1

The following call computes the Gauss-Legendre data with a precision given by the current value of the environment variable DIGITS (the default value is `DIGITS = 10`):

```
[b, c] := numeric::gldata(4, DIGITS)[[0.1739274226, 0.3260725774,
0.3260725774, 0.1739274226], [0.0694318442, 0.3300094782,
0.6699905218, 0.9305681558]]
```

```
[[0.1739274226, 0.3260725774, 0.3260725774, 0.1739274226], [0.0694318442, 0.3300094782
```

The Gauss-Legendre data with 4 nodes provide exact numerical quadrature results for polynomials through degree 7:

```
f := x -> x^7: int(f(x), x= 0..1) = _plus(b[i]*f(c[i]) $ i=1..4)1/8 = 0.125
```

$\frac{1}{8} = 0.125$

delete b, c, f:

Example 2

For odd n, exact rational data for c[(n+1)/2] $c_{\frac{n+1}{2}}$ and b[(n+1)/2] $b_{\frac{n+1}{2}}$ are returned. The other data are computed as floating-point approximations:

```
DIGITS := 4: numeric::gldata(5, DIGITS)[[0.1185, 0.2393, 64/225,
0.2393, 0.1185], [0.04691, 0.2308, 1/2, 0.7692, 0.9531]]
```

$$\left[\left[0.1185, 0.2393, \frac{64}{225}, 0.2393, 0.1185\right], \left[0.04691, 0.2308, \frac{1}{2}, 0.7692, 0.9531\right]\right]$$

delete DIGITS:

Parameters

n

The number of nodes: a positive integer

digits

The number of decimal digits: a positive integer

Return Values List `[b, c]` is returned. The lists `b = [`b_1`, , `b_n`]` and `c = [`c_1`, , `c_n`]` are numerical approximations of the weights and abscissae with `digits` significant digits.

Algorithms The numerical integrator numeric::quadrature calls `numeric::gldata` to provide the data for Gaussian quadrature.

See Also numeric::gtdatanumeric::ncdatanumeric::intnumeric::quadrature

numeric::gtdata

Purpose

Weights and abscissae of Gauss-Tschebyscheff quadrature

Syntax

```
numeric::gtdata(n)
```

Description

`numeric::gtdata(n)` returns the weights and the abscissae of the Gauss-Tschebyscheff quadrature rule with n nodes.

The Gauss-Tschebyscheff quadrature rule sum(b[i]*f(c[i]), i=1..n)$\sum_{i=1}^{n} b_i f(c_i)$ produces the exact integral int(f(x), x=0..1) $\int_0^1 f(x)\,dx$

for all integrands of the form f(x)=p(x)/sqrt(x*(1-x))$f(x) = \frac{p(x)}{\sqrt{x(1-x)}}$ with polynomials $p(x)$ through degree $2n$ - 1.

The exact weights $b = [b_1, \ldots, b_n]$ and abscissae $c = [c_1, \ldots, c_n]$ are given by

b[i]=(PI)/(2*n)*sin(((2*i-1)*PI)/(2*n)), c[i]=1/2*(1+cos((2*i-1)*PI/(2*n)))

$$b_i = \frac{\pi}{2n} \sin\left(\frac{(2i-1)\pi}{2n}\right), \quad c_i = \frac{1 + \cos\left(\frac{(2i-1)\pi}{2n}\right)}{2}$$

Environment Interactions

`numeric::gtdata` is not sensitive to the environment variable DIGITS.

The function uses option remember.

Examples

Example 1

The following call produces exact data for the quadrature rule with two nodes:
numeric::gtdata(2)[[(PI*sqrt(2))/8, (PI*sqrt(2))/8], [sqrt(2)/4 + 1/2, 1/2 - sqrt(2)/4]]

$$\left[\left[\frac{\pi\sqrt{2}}{8}, \frac{\pi\sqrt{2}}{8}\right], \left[\frac{\sqrt{2}}{4} + \frac{1}{2}, \frac{1}{2} - \frac{\sqrt{2}}{4}\right]\right]$$

Parameters

n

The number of nodes: a positive integer

Return Values

List `[b,c]` is returned. The lists `b = [`b_1`, , `b_n`]` and `c = [`c_1`, , `c_n`]` are the exact weights and abscissae of the Gauss-Tschebyscheff quadrature rule, respectively.

Algorithms

The numerical integrator numeric::quadrature calls `numeric::gtdata` to provide the data for Gauss-Tschebyscheff quadrature.

numeric::gldatanumeric::ncdatanumeric::intnumeric::quadrature

numeric::indets

Purpose

Search for indeterminates

Syntax

```
numeric::indets(object)
```

Description

`numeric::indets(object)` returns a set of the indeterminates contained in the `object`.

This is an auxiliary routine used by numeric::polyroots, numeric::quadrature, numeric::realroots, numeric::solve etc. to find indeterminates.

It recursively searches the operands of `object` for indeterminates. In particular, the search is applied to the elements of lists, sets, arrays, tables, etc.

Following objects are regarded as indeterminates: identifiers, indexed identifiers and the indeterminates of DOM_POLY objects. Also coefficients of such polynomials are searched for indeterminates.

The following objects are *not* regarded as indeterminates: the numerical constants PI, EULER, and CATALAN (cf. Type::ConstantIdents) and zero operands of expressions and subexpressions (i.e., the function names in unevaluated function calls such as `f(2)`, `sin(PI/13)` etc.). Also integration variables in unevaluated calls of int, numeric::int and numeric::quadrature and summation indices in unevaluated calls of sum and numeric::sum are not considered.

Examples

Example 1

Identifiers and indexed identifiers are regarded as indeterminates:
numeric::indets([{a + b*PI}, sin(c + sqrt(2) + EULER), table(1 = d - cos(e), 2 = f + 0.1*I), array(1..2, [g, h]), F(i[2], i[2]), D([1], G)(j[1]), k[3 + L[4]]]){a, b, c, d, e, f, g, h, i[2], j[1], k[L[4] + 3]}

Both indeterminates as well as symbolic coefficients are considered in polynomials of domain type DOM_POLY:
numeric::indets(poly(a[1]*x^2 + a[2]*x +a, [x, y])){a, x, y, a[1], a[2]}

$\{a, x, y, a_1, a_2\}$

Example 2

The zero operands of unevaluated function calls such as `f( )` or `sin( )` are not regarded as indeterminates:
numeric::indets(f(a + sin(b) + PI + EULER)){a, b}

$\{a, b\}$

Integration variables and summation indices are not regarded as indeterminates:
numeric::indets({int(f(x), x = a..b), sum(f(i), i = c..infinity)}){a, b, c}

$\{a, b, c\}$

Parameters

object

An arbitrary MuPAD object

Return Values

Set of indeterminates is returned, if the argument is an object of some basic data type of the kernel. The empty set is returned, if the object is from some library domain.

indetsfreeIndets

numeric::int

Purpose

Numerical integration (the Float attribute of Int)

Syntax

```
numeric::int(f(x), x = a .. b, options)
float(holdint(f(x), x = a .. b, options))
float(freezeint(f(x), x = a .. b, options))
```

Description

`numeric::int(f(x), x = a..b)` computes a numerical approximation of int(f(x), x=a..b) $\int_a^b f(x)\,dx$.

The calls `numeric::int(...)`, `float ( freeze(int)(...))`, and `float ( hold(int)(...))` are equivalent.

The calls `numeric::int(...)` and `numeric::quadrature(...)` are almost equivalent: `numeric::int` calls `numeric::quadrature`. A numerical result produced by `numeric::quadrature` is returned as is. Otherwise, `hold(numeric::int)(...)` is returned.

See the help page of numeric::quadrature for details.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We demonstrate some equivalent calls for numerical integration: numeric::int(exp(x^2), x = -1..1), float(hold(int)(exp(x^2), x = -1..1)), float(freeze(int)(exp(x^2), x = -1..1)), numeric::quadrature(exp(x^2), x = -1..1)2.925303492, 2.925303492, 2.925303492, 2.925303492

```
2.925303492, 2.925303492, 2.925303492, 2.925303492
```

numeric::int(max(1/10, cos(PI*x)), x = -2..0.0123), float(hold(int)(max(1/10, cos(PI*x)), x = -2..0.0123)), float(freeze(int)(max(1/10, cos(PI*x)), x = -2..0.0123)), numeric::quadrature(max(1/10, cos(PI*x)), x = -2..0.0123)0.752102471, 0.752102471, 0.752102471, 0.752102471

0.752102471, 0.752102471, 0.752102471, 0.752102471
numeric::int(exp(-x^2), x = -2..infinity), float(hold(int)(exp(-x^2), x = -2..infinity)), float(freeze(int)(exp(-x^2), x = -2..infinity)), numeric::quadrature(exp(-x^2), x = -2..infinity)1.768308316, 1.768308316, 1.768308316, 1.768308316

1.768308316, 1.768308316, 1.768308316, 1.768308316
numeric::int(sin(x)/x, x = -1..10, GaussLegendre = 5), float(hold(int)(sin(x)/x, x = -1..10, GaussLegendre = 5)), float(freeze(int)(sin(x)/x, x = -1..10, GaussLegendre = 5)), numeric::quadrature(sin(x)/x, x = -1..10, GaussLegendre = 5)2.604430665, 2.604430665, 2.604430665, 2.604430665

2.604430665, 2.604430665, 2.604430665, 2.604430665

The calls `numeric::int(...)`, `float(hold(int)(...))`, and `numeric::quadrature(...)` are equivalent in multiple numerical integrations, too:
numeric::int(numeric::int(x*y, x = 0..y), y = 0..1), numeric::int(numeric::quadrature(x*y, x = 0..y), y = 0..1), float(freeze(int)(numeric::int(x*y, x = 0..y), y = 0..1)), float(hold(int)(numeric::quadrature(x*y, x = 0..y), y = 0..1)), numeric::quadrature(numeric::int(x*y, x = 0..y), y = 0..1), numeric::quadrature(numeric::quadrature(x*y, x = 0..y), y = 0..1)0.125, 0.125, 0.125, 0.125, 0.125, 0.125

0.125, 0.125, 0.125, 0.125, 0.125, 0.125

Example 2

The following integral do not exist. Consequently, numerical integration runs into problems:
numeric::quadrature(1/x, x = 0..infinity) Warning: Precision goal is not achieved after 10000 function calls. Increase 'MaxCalls' and try again for a more accurate result. [numeric::quadrature] 172.711431

```
172.711431
```

Note that `numeric::int` handles errors produced by numeric::quadrature and returns a symbolic call to `numeric::int`: numeric::int(1/x, x = 0..infinity)numeric::int(1/x, x = 0..infinity)

$$\text{numeric::int}\left(\frac{1}{x},\ x = 0..\infty\right)$$

Parameters

f(x)

An arithmetical expression in *x*

x

An identifier or an indexed identifier

a

b

arithmetical expressions

Options

All options of numeric::quadrature can be used.

Return Values

Floating point number or a symbolic call `numeric::int(f(x), x = a..b)` if the integral cannot be evaluated numerically.

intnumeric::quadrature

Concepts

- “Integration”

numeric::inverse

Purpose

Inverse of a matrix

Syntax

```
numeric::inverse(A, options)
```

Description

`numeric::inverse(A)` returns the inverse of the matrix `A`.

If no return type is specified via the option `ReturnType = t`, the domain type of the inverse depends on the type of the input matrix `A`:

- The inverse of an array is returned as an array.
- The inverse of an hfarray is returned as an hfarray.
- The inverse of a dense matrix of type `Dom::DenseMatrix()` is a dense matrix of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category Cat::Matrix, the inverse is returned as a matrix of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

The option `Symbolic` should be used if the matrix contains symbolic objects that cannot be converted to floating point numbers.

Without the option `Symbolic`, all entries of `A` must be numerical. Floating point arithmetic is used, the working precision is set by the environment variable DIGITS. Exact numerical expressions such as PI + sqrt(2)$\pi + \sqrt{2}$, `sin(3)` etc. are accepted and converted to floats. If symbolic entries are found in the matrix, `numeric::inverse` automatically switches to `Symbolic`, issuing a warning. This warning may be suppressed via the option `NoWarning`.

Note Invertibility of the matrix can only be safely detected with exact arithmetic, i.e., using the option `Symbolic`. See "Example 2" on page 19-140.

Note Matrices `A` of a matrix domain such as Dom::Matrix`(..)` or Dom::SquareMatrix`(..)` are internally converted to arrays over expressions via `expr(A)`. Note that `Symbolic` should be used if the entries cannot be converted to numerical expressions.

Note that `1/A` must be used, when the inverse is to be computed over the component domain. See "Example 3" on page 19-142.

We recommend to use numeric::linsolve or numeric::matlinsolve if a sparse system of linear equations is to be solved. In particular, these routines are more efficient than `numeric::inverse` for large sparse systems.

numeric::linsolve uses sparse input and output via symbolic equations and features internal sparse arithmetic.

Alternatively, sparse matrices of domain type `Dom::Matrix()` may be used with numeric::matlinsolve.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

Numerical matrices can be processed with or without the option `Symbolic`. In the following, the inverses are returned as arrays because the input matrix is an array:

```
A := array(1..2, 1..2, [[1, 2], [3, PI]]):numeric::inverse(A),
numeric::inverse(A, Symbolic)array(1..2, 1..2, [[-1.099071012,
```

0.6996903372], [1.049535506, -0.3498451686]]), array(1..2, 1..2, [[PI/(PI - 6), -2/(PI - 6)], [-3/(PI - 6), 1/(PI - 6)]])

$$\begin{pmatrix} -1.099071012 & 0.6996903372 \\ 1.049535506 & -0.3498451686 \end{pmatrix}, \begin{pmatrix} \frac{\pi}{\pi-6} & -\frac{2}{\pi-6} \\ -\frac{3}{\pi-6} & \frac{1}{\pi-6} \end{pmatrix}$$

Matrices of category Cat::Matrix are accepted. The inverse is returned as a corresponding matrix:
A := Dom::Matrix()([[2, PI], [0, 1]]): numeric::inverse(A);
domtype(%)matrix([[0.5, -1.570796327], [0, 1.0]])

$$\begin{pmatrix} 0.5 & -1.570796327 \\ 0 & 1.0 \end{pmatrix}$$

Dom::Matrix()

Dom::Matrix()
delete A:

Example 2

The following matrix is not invertible:
A := linalg::hilbert(6): A[6,6] := 5773/63504: Amatrix([[1, 1/2, 1/3, 1/4, 1/5, 1/6], [1/2, 1/3, 1/4, 1/5, 1/6, 1/7], [1/3, 1/4, 1/5, 1/6, 1/7, 1/8], [1/4, 1/5, 1/6, 1/7, 1/8, 1/9], [1/5, 1/6, 1/7, 1/8, 1/9, 1/10], [1/6, 1/7, 1/8, 1/9, 1/10, 5773/63504]])

$$\begin{pmatrix} 1 & \frac{1}{2} & \frac{1}{3} & \frac{1}{4} & \frac{1}{5} & \frac{1}{6} \\ \frac{1}{2} & \frac{1}{3} & \frac{1}{4} & \frac{1}{5} & \frac{1}{6} & \frac{1}{7} \\ \frac{1}{3} & \frac{1}{4} & \frac{1}{5} & \frac{1}{6} & \frac{1}{7} & \frac{1}{8} \\ \frac{1}{4} & \frac{1}{5} & \frac{1}{6} & \frac{1}{7} & \frac{1}{8} & \frac{1}{9} \\ \frac{1}{5} & \frac{1}{6} & \frac{1}{7} & \frac{1}{8} & \frac{1}{9} & \frac{1}{10} \\ \frac{1}{6} & \frac{1}{7} & \frac{1}{8} & \frac{1}{9} & \frac{1}{10} & \frac{5773}{63504} \end{pmatrix}$$

With exact arithmetic, `numeric::inverse` detects this fact:
numeric::det(A, Symbolic), numeric::inverse(A, Symbolic)0, FAIL

0, FAIL

Due to internal round-off, the matrix is regarded as invertible if float arithmetic is used:
numeric::det(A, HardwareFloats), numeric::inverse(A, HardwareFloats);-3.239912837e-28, matrix([[-1.339975706e11, 4.019927119e12, -2.813948983e13, 7.503863956e13, -8.441846951e13, 3.37673878e13], [4.019927119e12, -1.205978136e14, 8.441846951e14, -2.251159187e15, 2.532554085e15, -1.013021634e15], [-2.813948983e13, 8.441846951e14, -5.909292865e15, 1.575811431e16, -1.77278786e16, 7.091151439e15], [7.503863956e13, -2.251159187e15, 1.575811431e16, -4.202163815e16, 4.727434292e16, -1.890973717e16], [-8.441846951e13, 2.532554085e15, -1.77278786e16, 4.727434292e16, -5.318363579e16, 2.127345432e16], [3.37673878e13, -1.013021634e15, 7.091151439e15, -1.890973717e16, 2.127345432e16, -8.509381726e15]])

With `SoftwareFloats`, the internal rounding is slightly different and the kernel of the matrix is detected:
numeric::det(A, SoftwareFloats), numeric::inverse(A, SoftwareFloats)-3.731550906e-30, FAIL

$$-3.239912837\,10^{-28}$$

$-3.731550906\ 10^{-30}$, FAIL
delete A:

Example 3

The following matrix has domain components:
A := Dom::Matrix(Dom::IntegerMod(7))([[6, -1], [1, 6]])Dom::Matrix(Dom::IntegerMod(7))([[-1, -1], [1, -1]])

$$\begin{pmatrix} 6 \bmod 7 & 6 \bmod 7 \\ 1 \bmod 7 & 6 \bmod 7 \end{pmatrix}$$

Note that `numeric::inverse` computes the inverse of the following matrix:
expr(A), numeric::inverse(A)array(1..2, 1..2, [[6, 6], [1, 6]]), matrix([[0.2, -0.2], [-0.03333333333, 0.2]])

$$\begin{pmatrix} 6 & 6 \\ 1 & 6 \end{pmatrix}, \begin{pmatrix} 0.2 & -0.2 \\ -0.03333333333 & 0.2 \end{pmatrix}$$

The overloaded arithmetic should be used if the inverse is to be computed over the component domain Dom::IntegerMod(7):
1/ADom::Matrix(Dom::IntegerMod(7))([[3, -3], [3, 3]])

$$\begin{pmatrix} 3 \bmod 7 & 4 \bmod 7 \\ 3 \bmod 7 & 3 \bmod 7 \end{pmatrix}$$

delete A:

Example 4

The option `Symbolic` should not be used for float matrices because no internal pivoting is used to stabilize the numerical algorithm:
A := matrix([[1.0/10^20, 1.0], [1.0, 1.0]]): bad = numeric::inverse(A, Symbolic), good = numeric::inverse(A)bad = matrix([[0, 1.0], [1.0, -1.0e-20]]), good = matrix([[-1.0, 1.0], [1.0, -1.0e-20]])

$$\text{bad} = \begin{pmatrix} 0 & 1.0 \\ 1.0 & -1.0\,10^{-20} \end{pmatrix},\ \text{good} = \begin{pmatrix} -1.0 & 1.0 \\ 1.0 & -1.0\,10^{-20} \end{pmatrix}$$

delete A:

Example 5

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned and difficult to invert with low values of DIGITS. The following results, both with `HardwareFloats` as well as with `SoftwareFloats`, are marred by numerical round-off. Consequently, the inverses with and without hardware floats, respectively, differ significantly:
A := linalg::hilbert(10): DIGITS := 10: B1 := numeric::inverse(A, HardwareFloats): B2 := numeric::inverse(A, SoftwareFloats): B1[8, 8] <> B2[8, 8]3.267405722e12 <> 3.26785917e12

$$3.267405722\,10^{12} \neq 3.26785917\,10^{12}$$

norm(B1 - B2)1681640193.0

$$1681640193.0$$

delete A, B1, B2:

Parameters

A

A square matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

Options

Hard

HardwareFloats

Soft

SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard`

and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix `A` is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill-conditioned matrices, the result is subject to round-off errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ! See "Example 2" on page 19-140 and "Example 5" on page 19-143.

Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

This option prevents conversion of the input data to floats. With this option, symbolic entries are accepted.

Note This option should not be used for floating-point matrices! No internal pivoting is used, unless necessary. Consequently, numerical instabilities may occur in floating-point operations. See "Example 4" on page 19-142.

NoWarning

Without the option `Symbolic`, `numeric::inverse` automatically switches to the `Symbolic` mode with a warning if symbolic coefficients are found. With the option `NoWarning`, this warning is suppressed. Note, however, that `numeric::inverse` still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

ReturnType

Option, specified as `ReturnType = t`

Return the inverse as a matrix of domain type `t`. The following return types are available: DOM_ARRAY, DOM_HFARRAY, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Return Values

Depending on the type of the input matrix `A`, the inverse is returned as a matrix of domain type DOM_ARRAY, DOM_HFARRAY, `Dom::Matrix()`, or `Dom::DenseMatrix()`. FAIL is returned if the inverse cannot be computed.

Algorithms

Gaussian elimination with partial pivoting is used. Partial pivoting is switched off by the option `Symbolic`.

numeric::leastSquares

Purpose

Least squares solution of linear equations

Syntax

```
numeric::leastSquares(A, B, <mode>, <method>, options)
```

Description

`numeric::leastSquares(A, B)` computes a matrix X that solves the linear matrix equation $AX = B$ in the least squares sense: the columns X_j of `X` minimize norm(A*X[j] - B[j],2) $\|A\,X_j - B_j\|_2$ where the B_j are the columns of `B`.

For a given vector B, a vector X minimizes norm(A*X-B,2) $\|A\,X - B\|_2$ if and only if X is a solution of the "normal equations" $A^H AX = A^H B$, where A^H is the Hermitean transpose of the m n matrix A. The solution is unique if $rank(A) = n$.

`numeric::leastSquares` allows to solve several least squares problems simultaneously by combining several 'right hand sides' B_j columnwise to a matrix `B`.

If no return type is specified via the option `ReturnType = d`, the domain type of the return data depends on the type of the input matrix `A`:

- The special solution X as well as the kernel of an array A are returned as arrays.
- The special solution and the kernel of an hfarray of domain type DOM_HFARRAY are returned as hfarrays.
- For a dense matrix A of type `Dom::DenseMatrix()`, both the special solution X as well as the kernel are returned as matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category Cat::Matrix, both the special solution X as well as the kernel are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

Without `Symbolic`, the input data are converted to floating-point numbers. The matrix A must not contain non-convertible parameters, unless `Symbolic` is used. If such objects are found, `numeric::leastSquares` automatically switches to its symbolic mode, issuing a warning. This warning may be suppressed via `NoWarning`.

Symbolic parameters in B are accepted without warning. However, `HardwareFloats` cannot be used if there are any symbolic parameters in A or B.

If $A^H A$ has a non-trivial kernel, the least squares solution X is not unique. The return value `X` is a *special* solution of the equation $A^H AX = A^H B$. With the `SVD` method, `X` is the special solution with columns of minimal Euclidean length.

Note The result computed with `HardwareFloats` may differ from the solution computed with `SoftwareFloats` or `Symbolic`! In particular, this is the case for systems with a non-trivial kernel. Further, the The results computed with `QRD` and `SVD` may differ.

The kernel is computed only in the symbolic mode (option `Symbolic`). All floating-point methods return the value `NIL` for the kernel.

With `Symbolic`, the n d matrix `KernelBasis` is the most general solution of $A^H AX = 0$. Its columns span the d-dimensional kernel of $A^H A$.

If the kernel is 0-dimensional, the return value of `KernelBasis` is the integer 0. If `KernelBasis` is returned as an array, the dimension d of the kernel is `d = op(KernelBasis, [0, 3, 2])`. If `KernelBasis` is returned as a matrix of type `Dom::Matrix()` or `Dom::DenseMatrix()`, the dimension d of the kernel is `d = KernelBasis::dom::matdim(KernelBasis)[2]`.

Note Without the option `Symbolic`, the implemented algorithms take care of numerical stabilization.

With `Symbolic`, exact data are assumed. The least squares solutions is computed via `numeric::matlinsolve( A^H A, A^H B , Symbolic)`. The symbolic strategy tries do maximize speed and does not take care of numerical stabilization! Do not use `Symbolic` for systems involving floating-point entries! In particluar, due to round-off, it may happen that no solution of $A^H AX = A^H B$ is found. In such a case, `[FAIL, NIL, NIL]` is returned. Cf. "Example 4" on page 19-152.

All entries of `A` and `B` must be arithmetical expressions.

Note Apart from matrices of type `Dom::Matrix(...)`, Cat::Matrix objects `A` from matrix domains such as Dom::DenseMatrix`(...)` or Dom::SquareMatrix`(...)` are internally converted to arrays over expressions via `expr(A)`. Note that the option `Symbolic` should be used if the entries cannot be converted to numerical expressions.

The same holds true for matrices `B` passed as `Cat::Matrix` objects.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We consider a matrix A of rank 1:
A := array(1..3, 1..2, [[1, 2], [1, 2], [1, 2]]): B := [3, 4, 5]:

The normal equations have a 1-parameter set of of solutions:
[X, KernelBasis, Res] := numeric::leastSquares(A, B, Symbolic)[array(1..2, 1..1, [[4], [0]]), array(1..2, 1..1, [[-2], [1]]), [sqrt(2)]]

$$\left[\begin{pmatrix}4\\0\end{pmatrix}, \begin{pmatrix}-2\\1\end{pmatrix}, [\sqrt{2}]\right]$$

The numerical method `QRD` produces a special solution:
[X, KernelBasis, Res] := numeric::leastSquares(A, B, QRD)[array(1..2, 1..1, [[4.0], [0]]), NIL, [1.414213562]]

$$\left[\begin{pmatrix}4.0\\0\end{pmatrix}, \text{NIL}, [1.414213562]\right]$$

The numerical method `SVD` produces a solution X of minimal norm:
[X, KernelBasis, Res] := numeric::leastSquares(A, B, SVD)[array(1..2, 1..1, [[0.8], [1.6]]), NIL, [1.414213562]]

$$\left[\begin{pmatrix}0.8\\1.6\end{pmatrix}, \text{NIL}, [1.414213562]\right]$$

delete A, B, X, KernelBasis, Res:

Example 2

We consider an ill-conditioned least squares problem. By construction, the following overdetermined system has an exact solution $X = [1, 2, \ldots, n]$:
m := 10: n := 8: A := array(1..m, 1..n, [[1/(i + j + 100) $ j=1..n] $ i=1..m]): B := array(1..m, [_plus(A[i,j]*j $ j=1..n) $ i=1..m]):
numeric::leastSquares(A, B, Symbolic)[array(1..8, 1..1, [[1], [2], [3], [4], [5], [6], [7], [8]]), 0, [0]]

$$\left[\begin{pmatrix}1\\2\\3\\4\\5\\6\\7\\8\end{pmatrix}, 0, [0]\right]$$

The coefficient matrix A is rather ill-conditioned:
singvals := numeric::singularvalues(A): conditionOfA := max(op(singvals))/min(op(singvals))6.31539107e16

$6.31539107\ 10^{16}$

Consequently, round-off has a drastic effect in a numerical approximation. The methods yield results of different quality:
numeric::leastSquares(A, B, QRD)[array(1..8, 1..1, [[205.7634088], [-506.7540812], [336.9881724], [0], [0], [0], [0], [0]]), NIL, [0.000000007174860922]]

$$\begin{pmatrix} 205.7634088 \\ -506.7540812 \\ 336.9881724 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

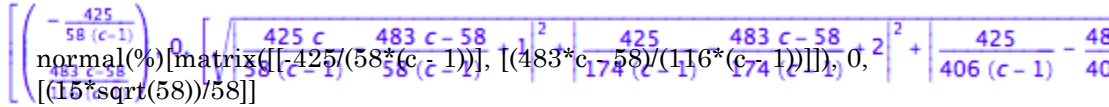
numeric::leastSquares(A, B, SVD)[array(1..8, 1..1, [[44440.34961], [-36432.38255], [-44826.69677], [-14839.48585], [23895.8882], [45730.9635], [28571.67227], [-46506.25357]]), NIL, [0.0000007416898216]]

$$\begin{pmatrix} 44440.34961 \\ -36432.38255 \\ -44826.69677 \\ -14839.48585 \\ 23895.8882 \\ 45730.9635 \\ 28571.67227 \\ -46506.25357 \end{pmatrix}$$

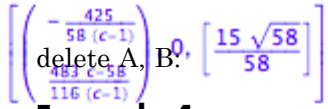
delete m, n, A, B, singvals, conditionOfA:

Example 3

This example involves a symbolic parameter `c` in the matrix *A*. The option `Symbolic` must be used:
A:= matrix([[c, 2], [1/3, 2/3], [1/7, 2/7]]): B:= [1, 2, 3]:
numeric::leastSquares(A, B, Symbolic)[matrix([[-425/(58*(c - 1))], [(483*c - 58)/(116*(c - 1))]]), 0, [sqrt(abs((425*c)/(58*(c - 1)) - (483*c - 58)/(58*(c - 1)) + 1)^2 + abs(425/(174*(c - 1)) - (483*c - 58)/(174*(c - 1)) + 2)^2 + abs(425/(406*(c - 1)) - (483*c - 58)/(406*(c - 1)) + 3)^2)]]



normal(%)[matrix([[-425/(58*(c - 1))], [(483*c - 58)/(116*(c - 1))]]), 0, [(15*sqrt(58))/58]]



delete A, B:

Example 4

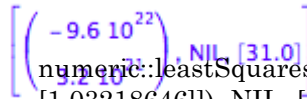
Floating point entries may cause problems in conjunction with the option `Symbolic`, because the computation is not stabilized numerically in the symbolic node. The following matrix A has rank 2:
A := matrix([[1, 30], [10.0^(-15), 31*10.0^(-15)]]):

However, due to round-off, the 'normal matrix' $A^H A$ has rank 1. No solution is found with `Symbolic`:
A::dom::transpose(A) * Amatrix([[1.0, 30.0], [30.0, 900.0]])

numeric::leastSquares(A, [31, 32*10^5], Symbolic)[FAIL, NIL, NIL]

[FAIL, NIL, NIL]

No such problem arises in the numerical schemes. Note, however, that the numerical methods yield different results in this extremely ill-conditioned problem:
numeric::leastSquares(A, [31, 32*10^5], QRD)[matrix([[-9.6e22], [3.2e21]]), NIL, [31.0]]



numeric::leastSquares(A, [31, 32*10^5], SVD)[matrix([[0.03440621532], [1.03218646]]), NIL, [3200000.0]]

delete A:

Parameters

A

An m n matrix of domain type DOM_ARRAY or of category Cat::Matrix

B

An m p matrix of domain type DOM_ARRAY or of category Cat::Matrix. Column vectors `B` may also be represented by a 1-dimensional `array(1..m, [B1, B2, ])` or by a list `[B1, B2, ]`.

mode

One of the flags `Hard`, `HardwareFloats`, `Soft`, `SoftwareFloats`, or `Symbolic`

method

One of the flags `QRD`, `SVD`

Options

Hard

HardwareFloats

Soft

SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard`

and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix `A` is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

This option *must* be used, if the matrix A contains symbolic parameters that cannot be converted to floating-point numbers.

The normal equations $A^H AX = A^H B$ are passed to numeric::matlinsolve with the option `Symbolic`.

If the least squares problem does not have a unique solution, a special solution X is returned together with the kernel of $A^H A$. Cf. "Example 1" on page 19-149.

Note This option should not be used for systems with floating-point coefficients! Numerical instabilities may occur in floating-point operations. Further, if the rank of A is not maximal, then `numeric::leastSquares` may fail to find a solution due to numerical round-off. In such a case, `[FAIL, NIL, NIL]` is returned. Cf. "Example 4" on page 19-152.

QRD

Use a QR decomposition. All entries of A must be convertible to floating-point values.

This is the default method.

The matrix A must not contain symbolic parameters that cannot be converted to floating point numbers. If such objects are found, then `numeric::leastSquares` automatically switches to its `Symbolic` mode, issuing a warning. The computation proceeds with exact arithmetic, using the input data without floating-point conversions.

The warning may be suppressed by the option `NoWarning`.

Symbolic parameters in B are accepted without warning. They are processed by the floating-point algorithm.

Numerical expressions such as exp(PI), sqrt(2)e^{π}, $\sqrt{2}$ etc. are accepted and converted to floats.

If the least squares problem does not have a unique solution, only a special solution is returned. The kernel is not computed: it is returned as `NIL`.

The method `QRD` provides a numerically stable way of solving the normal equations $A^H AX = A^H B$ by a QR decomposition. In extremely ill-conditioned situations, it may be worthwhile to consider the slower, yet more stable method `SVD`.

The conditioning is given by the ratio of the largest singular value of A divided by the smallest singular value of A. If this value is large, the problem is ill-conditioned.

Cf. “Example 2” on page 19-150.

SVD

Use a singular value decomposition. All entries of A must be convertible to floating-point values.

The matrix A must not contain symbolic parameters that cannot be converted to floating point numbers. If such objects are found, then `numeric::leastSquares` automatically switches to its

symbolic mode, issuing a warning. The computation proceeds with exact arithmetic, using the input data without floating point conversions.

The warning may be suppressed by the option `NoWarning`.

Symbolic parameters in B are accepted without warning. They are processed by the floating-point algorithm.

Numerical expressions such as exp(PI), sqrt(2)e^{π}, $\sqrt{2}$ etc. are accepted and converted to floats.

If the least squares problem does not have a unique solution, the columns X_j of the solution X have a minimal Euclidean length norm(X[j], 2)$\|X_j\|_2$.

The kernel is not computed: it is returned as `NIL`.

A singular value decomposition $A = UDV^H$ is used to solve the normal equations in the form $D^2V^HX = DU^HB$. For small or zero singular values d_j in $D = diag(d_1, d_2, \ldots)$, the corresponding components of V^Hx are set to zero.

Usually, the numerical method `SVD` is slower than the default method `QRD`. However, in ill-conditioned situations, it is numerically more stable.

The conditioning is given by the ratio of the largest singular value of A divided by the smallest singular value of A. If this value is large, the problem is ill-conditioned.

NoWarning

Suppresses warnings

If symbolic coefficients are found in A, `numeric::leastSquares` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed.

ReturnType

Option, specified as `ReturnType = d`

Return the (special) solution and the kernel as matrices of domain type `d`. The following return types *d* are available: DOM_ARRAY, or DOM_HFARRAY, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Return Values

A list `[X, KernelBasis, Residues]` is returned.

The (special) least squares solution `X` is an *n p* matrix.

With `Symbolic`, `KernelBasis` is an *n d* matrix (*d* is the dimension of the kernel of $A^H A$). Its columns span the kernel of $A^H A$. If the kernel is trivial, `KernelBasis` is the integer 0.

Without `Symbolic`, the kernel is not computed. The value `NIL` is returned for the `KernelBasis`.

The list of arithmetical expressions `Residues` consists of the minimized least squares deviations norm(A*X[j]-B[j], 2)$\|A\,X_j - B_j\|_2$ corresponding to the columns of `X` and `B`.

numeric::linsolve

Purpose

Solve a system of linear equations

Syntax

```
numeric::linsolve(eqs, <vars>, options)
```

Description

`numeric::linsolve(eqs, vars)` solves a system of linear equations `eqs` for the unknowns `vars`.

`numeric::linsolve` is a fast numerical linear solver. It is also a recommended solver for linear systems with exact or symbolic coefficients (using `Symbolic`).

Expressions are interpreted as homogeneous equations. E.g., the input `[x = y - 1, x - y]` is interpreted as the system of equations `[x = y - 1, x - y = 0]`.

Note Without the option `Symbolic`, the input data are converted to floating-point numbers. The coefficient matrix A of the system $Ax = b$ represented by `eqs` must not contain non-convertible parameters, unless the option `Symbolic` is used! If such objects are found, then `numeric::linsolve` automatically switches to its symbolic mode, issuing a warning. This warning may be suppressed via `NoWarning`. Symbolic parameters in the "right hand side" b are accepted without warning.

The numerical working precision is set by the environment variable DIGITS.

The solutions are returned as a list of solved equations of the form

[x[1]=value[1], x[2]=value[2], Symbol::hellip]

$$[x_1 = \text{value}_1,\ x_2 = \text{value}_2,\ \ldots]$$

where x_1, x_2, … are the unknowns. These simplified equations should be regarded as constraints on the unknowns. E.g., if an unknown x_1,

say, does not turn up in the form [x_1 = ..., ...] in the solution, then there is no constraint on this unknown; it is an arbitrary parameter. Generally, all unknowns that do not turn up on the left hand side of the solved equations are arbitrary parameters spanning the solution space. Cf. “Example 9” on page 19-177.

In particular, if the empty list is returned as the solution, there are no constraints whatsoever on the unknowns, i.e., the system is trivial.

The ordering of the solved equations corresponds to the ordering of the unknowns `vars`. It is recommended that the user specifies `vars` by a *a list* of unknowns. This guarantees that the solved equations are returned in the expected order. If `vars` are specified by a set, or if no `vars` are specified at all, then an internal ordering is used.

If no unknowns are specified by `vars`, `numeric::linsolve` solves for all symbolic objects in `eqs`. The unknowns are determined internally by `indets(eqs, PolyExpr)`.

`numeric::linsolve` returns the general solution of the system `eqs`. It is valid for arbitrary complex values of the symbolic parameters which may be present in `eqs`. If no such solution exists, FAIL is returned. Solutions that are valid only for special values of the symbolic parameters may be obtained with the option `ShowAssumptions`. See “Example 2” on page 19-162, “Example 3” on page 19-163, “Example 4” on page 19-164, and “Example 11” on page 19-179.

The solved equations representing the solution are suitable as input for assign and subs. See “Example 8” on page 19-176.

`numeric::linsolve` is suitable for solving large sparse systems. See “Example 6” on page 19-165.

If `eqs` represents a system with a banded coefficient matrix, then this is detected and used by `numeric::linsolve`. Note that in this case, it is important to specify both the equations as well as the unknowns by lists to guarantee the desired form of the coefficient matrix. When using sets, the data may be reordered internally leading to a loss of band structure and, consequently, of efficiency. See “Example 6” on page 19-165.

Note `numeric::linsolve` is tuned for speed. For this reason, it does not check systematically that the equations `eqs` are indeed linear in the unknowns! For non-linear equations, strange things may happen; `numeric::linsolve` might even return wrong results! See "Example 5" on page 19-164.

Note `numeric::linsolve` does not react to any properties of the unknowns or of symbolic parameters that are set via assume.

Note Gaussian elimination with partial pivoting is used. Without the option `Symbolic`, floating-point arithmetic is used and the pivoting strategy takes care of numerical stabilization. With `Symbolic`, exact data are assumed and the pivoting strategy tries do maximize speed, not taking care of numerical stabilization! See "Example 7" on page 19-176.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

Equations and variables may be entered as sets or lists:
numeric::linsolve({x = y - 1, x + y = z}, {x, y}); numeric::linsolve([x = y - 1, x + y = z], {x, y}); numeric::linsolve({x = y - 1, x + y = z}, [x, y]); numeric::linsolve([x = y - 1, x + y = z], [x, y])[x = 0.5*z - 0.5, y = 0.5*z + 0.5]

$$[x = 0.5\,z - 0.5,\ y = 0.5\,z + 0.5]$$

[x = 0.5*z - 0.5, y = 0.5*z + 0.5]

$[x = 0.5\,z - 0.5,\ y = 0.5\,z + 0.5]$

[x = 0.5*z - 0.5, y = 0.5*z + 0.5]

$[x = 0.5\,z - 0.5,\ y = 0.5\,z + 0.5]$

[x = 0.5*z - 0.5, y = 0.5*z + 0.5]

$[x = 0.5\,z - 0.5,\ y = 0.5\,z + 0.5]$

With the option `Symbolic`, exact arithmetic is used. The following system has a 1-parameter set of solution; the unknown x_3 is arbitrary:
numeric::linsolve([x[1] + x[2] = 2, x[1] - x[2] = 2*x[3]], [x[1], x[2], x[3]], Symbolic)[x[1] = x[3] + 1, x[2] = 1 - x[3]]

$[x_1 = x_3 + 1,\ x_2 = 1 - x_3]$

The unknowns may be expressions:
numeric::linsolve([f(0) - sin(x + 1) = 2, f(0) = 1 - sin(x + 1)], [f(0), sin(x + 1)])[f(0) = 1.5, sin(x + 1) = -0.5]

$[f(0) = 1.5,\ \sin(x + 1) = -0.5]$

The following system does not have a solution:
numeric::linsolve([x + y = 1, x + y = 2], [x, y])FAIL

FAIL

Example 2

We demonstrate some examples with symbolic coefficients. Note that the option `Symbolic` has to be used:
eqs := [x + a*y = b, x + A*y = b]: numeric::linsolve(eqs, [x, y], Symbolic)[x = b, y = 0]

$[x = b,\ y = 0]$

Note that for $a = A$, this is not the general solution. Using the option `ShowAssumptions`, it turns out that the above result is the general solution subject to the assumption $a \neq A$:
numeric::linsolve(eqs, [x, y], Symbolic, ShowAssumptions)[[x = b, y = 0], [], [A - a <> 0]]

$$[[x = b,\ y = 0],\ [],\ [A - a \neq 0]]$$

delete eqs:

Example 3

We give a further demonstration of the option `ShowAssumptions`. The following system does not have a solution for all values of the parameter `a`:
numeric::linsolve([x + y = 1, x + y = a], [x, y], Symbolic)FAIL

FAIL

With `ShowAssumptions`, `numeric::linsolve` investigates under which conditions (on the parameter `a`) there is a solution:
numeric::linsolve([x + y = 1, x + y = a], [x, y], Symbolic, ShowAssumptions)[[x = 1 - y], [a - 1 = 0], []]

$$[[x = 1 - y],\ [a - 1 = 0],\ []]$$

We conclude that there is a 1-parameter set of solutions for $a = 1$. The constraint in `a` is a linear equation, since the parameter `a` enters the equations linearly. If `a` is regarded as an unknown rather than as a parameter, the constraint becomes part of the solution:
numeric::linsolve([x + y = 1, x + y = a], [x, y, a], Symbolic, ShowAssumptions)[[x = 1 - y, a = 1], [], []]

$$[[x = 1 - y,\ a = 1],\ [],\ []]$$

Example 4

With exact arithmetic, PI is regarded as a symbolic parameter. The following system has a solution subject to the constraint `PI = 1`:
numeric::linsolve([x = x - y + 1, y = PI], [x, y], Symbolic, ShowAssumptions)[[y = PI], [1 - PI = 0], []]

$$[[y = \pi], [1 - \pi = 0], []]$$

With floating-point arithmetic, PI is converted to `3.1415...`. The system has no solution:
numeric::linsolve([x = x - y + 1, y = PI], [x, y], ShowAssumptions)[FAIL, [], []]

[FAIL, [], []]

Example 5

Since `numeric::linsolve` does not do a systematic internal check for non-linearities, the user should make sure that the equations to be solved are indeed linear in the unknowns. Otherwise, strange things may happen. Garbage is produced for the following non-linear systems:
a := sin(x): numeric::linsolve([y = 1 - a, x = y], [x, y], Symbolic)[x = 1 - sin(x17^3), y = 1 - sin(x17^3)]

$$[x = 1 - \sin(x17^3), y = 1 - \sin(x17^3)]$$

numeric::linsolve([a*x + y = 1, x = y], [x, y], Symbolic)[x = 1/(sin(x18^3) + 1), y = 1/(sin(x18^3) + 1)]

$$\left[x = \frac{1}{\sin(x18^3) + 1}, y = \frac{1}{\sin(x18^3) + 1}\right]$$

Polynomial non-linearities are usually detected. Regarding `x, y, c` as unknowns, the following quadratic system yields an error:
numeric::linsolve([x*c + y = 1, x = y], Symbolic) Error: This system does not seem to be linear. [numeric::linsolve] Error: This system does not seem to be linear. [numeric::linsolve]

This system is linear in `x, y` if `c` is regarded as a parameter:
numeric::linsolve([x*c + y = 1, x = y], [x, y], Symbolic)[x = 1/(c + 1), y = 1/(c + 1)]

$$\left[x = \frac{1}{c+1},\ y = \frac{1}{c+1}\right]$$

delete a:

Example 6

We solve a large sparse system. The coefficient matrix has only 3 diagonal bands. Note that both the equations as well as the variables are passed as lists. This guarantees that the band structure is not lost internally:
n := 500: x[0] := 0: x[n + 1] := 0: eqs := [x[i-1] - 2*x[i] + x[i+1] = 1 $ i = 1..n]: vars := [x[i] $ i = 1..n]: numeric::linsolve(eqs, vars) [x[1] = -250.0, x[2] = -499.0, x[3] = -747.0, x[4] = -994.0, dots, x[498] = -747.0, x[499] = -499.0, x[500] = -250.0]

$$[x_1 = -250.0,\ x_2 = -499.0,\ x_3 = -747.0,\ x_4 = -994.0,\ \ldots,\ x_{498} = -747.0,\ x_{499} = -499.0,\ x_{500} = -25$$

delete n, x, eqs, vars:

Example 7

The option `Symbolic` should not be used for equations with floating-point coefficients, because the symbolic pivoting strategy favors efficiency instead of numerical stability.
eqs := [x + 10^20*y = 10^20, x + y = 0]:

The float approximation of the exact solution is:
map(numeric::linsolve(eqs, [x, y], Symbolic), map, float)[x = -1.0, y = 1.0]

$$[x = -1.0,\ y = 1.0]$$

We now convert the exact coefficients to floating-point numbers:
feqs := map(eqs, map, float)[x + 1.0e20*y = 1.0e20, x + y = 0.0]

$$[x + 1.0\ 10^{20}\ y = 1.0\ 10^{20},\ x + y = 0.0]$$

The default pivoting strategy stabilizes floating-point operations. Consequently, one gets a correct result:
numeric::linsolve(feqs, [x, y])[x = -1.0, y = 1.0]

$$[x = -1.0,\ y = 1.0]$$

With `Symbolic`, the pivoting strategy optimizes speed, assuming exact arithmetic. Numerical instabilities may occur if floating-point coefficients are involved. The following incorrect result is caused by internal round-off effects (“cancellation”):
numeric::linsolve(feqs, [x, y], Symbolic)[x = 0.0, y = 1.0]

$$[x = 0.0,\ y = 1.0]$$

delete eqs, feqs:

Example 8

We demonstrate that the simplified equations representing the solution can be used for further processing with subs:

```
eqs := [x + y = 1, x + y = a]: [Solution, Constraints, Pivots] :=
numeric::linsolve(eqs, [x, y], ShowAssumptions)[[x = 1.0 - 1.0*y], [1.0*a
- 1.0 = 0], []]
```

$$[[x = 1.0 - 1.0\,y], [1.0\,a - 1.0 = 0], []]$$

```
subs(eqs, Solution)[1.0 = 1, 1.0 = a]
```

$$[1.0 = 1, 1.0 = a]$$

The solution can be assigned to the unknowns via assign:

```
assign(Solution): x, y, eqs1.0 - 1.0*y, y, [1.0 = 1, 1.0 = a]
```

$$1.0 - 1.0\,y,\ y,\ [1.0 = 1, 1.0 = a]$$

```
delete eqs, Solution, Constraints, Pivots, x:
```

Example 9

If the solution of the linear system is not unique, then some of the unknowns are used as “free parameters” spanning the solution space. In the following example, the unknowns `z, w` are such parameters. They do not turn up on the left hand side of the solved equations:

```
eqs := [x + y = z, x + 2*y = 0, 2*x - z = -3*y, y + z = 0]: vars := [x, y, z, w]:
Solution := numeric::linsolve(eqs, vars, Symbolic)[x = 2*z, y = -z]
```

$$[x = 2\,z,\ y = -z]$$

You may define a function such as the following `NewSolutionList` to rename your free parameters to “myName1”, “myName2” etc. and fill up your list of solved equations accordingly:

```
NewSolutionList := proc(Solution : DOM_LIST, vars : DOM_LIST,
myName : DOM_STRING) local i, solvedVars, newEquation;
begin solvedVars := map(Solution, op, 1); for i from 1 to nops(vars)
do if not has(solvedVars, vars[i]) then newEquation := vars[i] =
genident(myName); Solution := listlib::insertAt( subs(Solution,
newEquation), newEquation, i) end_if end_for: Solution
end_proc:NewSolutionList(Solution, vars, "FreeParameter")[x =
```

2*FreeParameter1, y = -FreeParameter1, z = FreeParameter1, w = FreeParameter2]

delete eqs, vars, Solution, NewSolutionList:

Example 10

We demonstrate the difference between hardware and software arithmetic. The following problem is very ill-conditioned. The results, both with `HardwareFloats` as well as with `SoftwareFloats`, are marred by numerical round-off:

```
n:= 10: eqs:= [(_plus(x[j]/(i + j -1) $ j = 1..n) = 1) $ i = 1..n]: vars:=
[x[i] $ i = 1..n]: numeric::linsolve(eqs, vars, SoftwareFloats);
numeric::linsolve(eqs, vars, HardwareFloats)[x[1] = -9.999986342,
x[2] = 989.9988244, x[3] = -23759.97502, x[4] = 240239.7733, x[5]
= -1261258.92, x[6] = 3783777.035, x[7] = -6726715.139, x[8] =
7001275.306, x[9] = -3938217.537, x[10] = 923779.4586]
```

[x[1] = -9.997364824, x[2] = 989.7718609, x[3] = -23755.13378, x[4] = 240195.7143, x[5] = -1261048.597, x[6] = 3783198.501, x[7] = -6725765.49, x[8] = 7000357.238, x[9] = -3937735.418, x[10] = 923673.4085]

This is the exact solution:

```
numeric::linsolve(eqs, vars, Symbolic);[x[1] = -10, x[2] = 990, x[3] =
-23760, x[4] = 240240, x[5] = -1261260, x[6] = 3783780, x[7] = -6726720,
x[8] = 7001280, x[9] = -3938220, x[10] = 923780]
```

$[x_1 = -10, x_2 = 990, x_3 = -23760, x_4 = 240240, x_5 = -1261260, x_6 = 3783780, x_7 = -6726720, x_8$
delete eqs, vars:

Example 11

We demonstrate how a complete solution of the following linear system in x, y with symbolic parameters a, b, c, d may be found:
eqs := [x + y = d, a*x + b*y = 1, x + c*y = 1]: numeric::linsolve(eqs, [x, y], Symbolic, ShowAssumptions)[[x = -(b*d - 1)/(a - b), y = (a*d - 1)/(a - b)], [a - b + c + b*d - a*c*d - 1 = 0], [b - a <> 0]]

$$\left[\left[x = -\frac{b\,d-1}{a-b},\ y = \frac{a\,d-1}{a-b}\right],\ [a-b+c+b\,d-a\,c\,d-1=0],\ [b-a\neq 0]\right]$$

This is the general solution, assuming $a \neq b$. We now set $b = a$ to investigate further solution branches:
eqs := subs(eqs, b = a): numeric::linsolve(eqs, [x, y], Symbolic, ShowAssumptions)[[x = (c*d - 1)/(c - 1), y = -(d - 1)/(c - 1)], [1 - a*d = 0], [c - 1 <> 0]]

$$\left[\left[x = \frac{c\,d-1}{c-1},\ y = -\frac{d-1}{c-1}\right],\ [1-a\,d=0],\ [c-1\neq 0]\right]$$

This is the general solution for $a = b$, assuming $c \neq 1$. We finally set $c = 1$ to obtain the last solution branch:
eqs := subs(eqs, c = 1): numeric::linsolve(eqs, [x, y], Symbolic, ShowAssumptions)[[x = d - y], [1 - a*d = 0, 1 - d = 0], []]

$$[[x = d-y],\ [1-a\,d=0,\ 1-d=0],\ []]$$

From the constraints on the symbolic parameters a and d, we conclude that there is a special 1-parameter solution $x = 1 - y$ for $a = b = c = d = 1$.
delete eqs:

Parameters

eqs

A list, set, array, or matrix (Cat::Matrix) of linear equations or arithmetical expressions

vars

A list or set of unknowns to solve for. Unknowns may be identifiers or indexed identifiers or arithmetical expressions.

Options

Hard

HardwareFloats

Soft

SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix `A` is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill-conditioned systems, the result is subject to round-off errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See“Example 10” on page 19-178.

Symbolic

Prevents conversion of input data to floating-point numbers. This option overrides `HardwareFloats` and `SoftwareFloats`.

This option *must* be used if the coefficients of the equations contain symbolic parameters that cannot be converted to floating-point numbers.

Note This option should not be used for equations with floating-point coefficients! Numerical instabilities may occur in floating-point operations. See "Example 7" on page 19-176.

ShowAssumptions

Returns information on internal assumptions on symbolic parameters in `eqs`.

This option is only useful if the equations contain symbolic parameters. Consequently, it should only be used in conjunction with the option `Symbolic`.

Note The format of the return value is changed to `[Solution, Constraints, Pivots]`.

`Solution` is a set of simplified equations representing the general solution subject to `Constraints` and `Pivots`.

`Constraints` is a list of equations for symbolic parameters in `eqs`, which are necessary and sufficient to make the system solvable.

Such constraints arise if Gaussian elimination of the original equations leads to equations of the form $0 = c$, where c is some expression involving symbolic parameters in the "right hand side" of the system. All such equations are collected in `Constraints`. `numeric::linsolve` assumes that these equations are satisfied and returns a solution.

If no such constraints arise, the return value of `Constraints` is the empty list.

`Pivots` is a list of inequalities involving symbolic parameters in the coefficient matrix A of the linear system $Ax = b$ represented by `eqs`. Internally, division by pivot elements occurs in the Gaussian elimination. The expressions collected in `Pivots` are the numerators of the pivot elements that contain symbolic parameters. If only numerical pivot elements were used, the return value of `Pivots` is the empty list.

Note The option `ShowAssumptions` changes the return strategy for "unsolvable" systems. Without the option `Symbolic`, FAIL is returned whenever Gaussian elimination produces an equation $0 = c$ with non-zero c. With `ShowAssumptions`, such equations are returned via `Constraints`, provided c involves symbolic parameters.

If c is a purely numerical value, then `[FAIL, [], []]` is returned.

See "Example 2" on page 19-162, "Example 3" on page 19-163, "Example 4" on page 19-164, and "Example 11" on page 19-179.

NoWarning

Suppresses warnings

If symbolic coefficients are found, `numeric::linsolve` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed; `numeric::linsolve` still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

Return Values

Without the option `ShowAssumptions`, a list of simplified equations is returned. It represents the general solution of the system `eqs`. FAIL is returned if the system is not solvable.

With `ShowAssumptions`, a list `[Solution, Constraints, Pivots]` is returned. `Solution` is a list of simplified equations representing the general solution of `eqs`. The lists `Constraints` and `Pivots` contain equations and inequalities involving symbolic parameters in `eqs`. Internally, these were assumed to hold true when solving the system.

`[FAIL, [], []]` is returned if the system is not solvable.

numeric::matlinsolve

Purpose

Solve a linear matrix equation

Syntax

```
numeric::matlinsolve(A, B, options)
```

Description

`numeric::matlinsolve(A, B)` returns the matrix solution X of the matrix equation $AX = B$ together with the kernel of the matrix A.

`numeric::matlinsolve` is a fast numerical linear solver for both sparse and dense systems. It is also a recommended solver for linear systems with exact or symbolic coefficients (use option `Symbolic`).

If no return type is specified via the option `ReturnType = d`, the domain type of the return data depends on the type of the input matrix `A`:

- The special solution X as well as the kernel of an array A are returned as arrays.
- The special solution X as well as the kernel of an hfarray A are returned as hfarrays.
- For a dense matrix$A$ of type `Dom::DenseMatrix()`, both the special solution X as well as the kernel of A are returned as matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category Cat::Matrix, both the special solution X as well as the kernel of A are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

Without `Symbolic`, exact numerical input data such as `PI + sqrt(2)`, `sin(3)` etc. are converted to floating-point numbers. Floating point arithmetic is used. Its precision is given the environment variable DIGITS. If symbolic data are found that cannot be converted to floating-point numbers, `numeric::matlinsolve` automatically switches to its symbolic mode, issuing a warning. This warning may be suppressed via `NoWarning`.

With `Symbolic`, symbolic parameters in the coefficient matrix `A` as well as in the right hand side `B` are accepted and processed without a warning.

With `SofwareFloats`, the right hand side `B` may contain symbolic parameters that cannot be converted to floating-point numbers. All entries of the coefficient matrix `A`, however, must be convertible to floating-point numbers.

With `HardwareFloats`, neither A nor B must contain symbolic parameters that cannot be converted to floating-point numbers.

`X` is a *special* solution of the equation $AX = B$. If A has a non-trivial kernel, the solution X is not unique.

Note The result computed with `HardwareFloats` may differ from the solution computed with `SoftwareFloats` or `Symbolic`! In particular, this is the case for systems with a non-trivial kernel.

Cf. "Example 9" on page 19-194.

The n d matrix `KernelBasis` is the most general solution of $AX = 0$. Its columns span the d-dimensional kernel of A.

Thus, the kernel of A may be computed via `numeric::matlinsolve(A, [0, ..., 0])[2]`.

If the kernel is 0-dimensional, the return value of `KernelBasis` is the integer 0. If `KernelBasis` is returned as an array, the dimension d of the kernel is `d = op(KernelBasis, [0, 3, 2]])`. If `KernelBasis` is returned as a matrix of type `Dom::Matrix()` or `Dom::DenseMatrix()`, the dimension d of the kernel is `d = KernelBasis::dom::matdim(KernelBasis)[2]`.

Note Due to round-off errors, some or all basis vectors in the kernel of `A` may be missed in the numerical modes.

The special solution `X` in conjunction with `KernelBasis` provides the general solution of $AX = B$. Solutions generated without the option `ShowAssumptions` are valid for arbitrary complex values of the symbolic parameters which may be present in `A` and `B`. If no such solution exists, then `[FAIL,NIL]` is returned. Solutions that are valid only for special values of the symbolic parameters may be obtained with `ShowAssumptions`. See "Example 3" on page 19-189, "Example 4" on page 19-190, and "Example 7" on page 19-193.

`numeric::matlinsolve` internally uses a sparse representation of the matrices. It is suitable for solving large sparse systems. See "Example 5" on page 19-191.

Note `numeric::matlinsolve` does not react to any assumptions on symbolic parameters in `A,B` that are set via assume.

Note Gaussian elimination with partial pivoting is used. Without the option `Symbolic`, the pivoting strategy takes care of numerical stabilization. With `Symbolic`, exact data are assumed. The symbolic pivoting strategy tries do maximize speed and does not take care of numerical stabilization! Do not use `Symbolic` for linear systems involving floating-point entries! See "Example 6" on page 19-192.

Note Apart from matrices of type `Dom::Matrix(...)`, Cat::Matrix objects `A` from matrix domains such as Dom::DenseMatrix`(...)` or Dom::SquareMatrix`(...)` are internally converted to arrays over expressions via `expr(A)`. Note that the option `Symbolic` should be used if the entries cannot be converted to numerical expressions.

Note that linalg::matlinsolve must be used, when the solution is to be computed over the component domain. See . “Example 8” on page 19-194.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We use equivalent input formats `(B1, B2)` to represent a vector with components [*a*, π]. First, this vector is defined as a 2-dimensional array: A := array(1..2, 1..3, [[1, 2, 3],[1, 1, 2]]): B1 := array(1..2, 1..1, [[a], [PI]]): numeric::matlinsolve(A, B1)[array(1..3, 1..1, [[6.283185307 - 1.0*a], [1.0*a - 3.141592654], [0]]), array(1..3, 1..1, [[-1.0], [-1.0], [1.0]])]

$$\left[\begin{pmatrix} 6.283185307 - 1.0\,a \\ 1.0\,a - 3.141592654 \\ 0 \end{pmatrix}, \begin{pmatrix} -1.0 \\ -1.0 \\ 1.0 \end{pmatrix}\right]$$

Next, we use a 1-dimensional array and compute an exact solution: B2 := array(1..2, [a, PI]): numeric::matlinsolve(A, B2, Symbolic)[array(1..3, 1..1, [[2*PI - a], [a - PI], [0]]), array(1..3, 1..1, [[-1], [-1], [1]])]

$$\left[\begin{pmatrix} 2\,\pi - a \\ a - \pi \\ 0 \end{pmatrix}, \begin{pmatrix} -1 \\ -1 \\ 1 \end{pmatrix}\right]$$

Now, a list is used to specify the vector. No internal assumptions were used by `numeric::matlinsolve` to obtain the solution:
B3 := [a, PI]: numeric::matlinsolve(A, B3, ShowAssumptions)[array(1..3, 1..1, [[6.283185307 - 1.0*a], [1.0*a - 3.141592654], [0]]), array(1..3, 1..1, [[-1.0], [-1.0], [1.0]]), [], []]

$$\left[\begin{pmatrix} 6.283185307 - 1.0\,a \\ 1.0\,a - 3.141592654 \\ 0 \end{pmatrix}, \begin{pmatrix} -1.0 \\ -1.0 \\ 1.0 \end{pmatrix}, [\,], [\,]\right]$$

Finally, we use Dom::Matrix objects to specify the system. Note that the results are returned as corresponding matrix objects:
A := matrix([[1, 2, 3],[1, 1, 2]]): B4 := matrix([a, PI]): numeric::matlinsolve(A, B4)[matrix([[6.283185307 - 1.0*a], [1.0*a - 3.141592654], [0]]), matrix([[-1.0], [-1.0], [1.0]])]

$$\left[\begin{pmatrix} 6.283185307 - 1.0\,a \\ 1.0\,a - 3.141592654 \\ 0 \end{pmatrix}, \begin{pmatrix} -1.0 \\ -1.0 \\ 1.0 \end{pmatrix}\right]$$

delete A, B1, B2, B3, B4:

Example 2

We invert a matrix by solving $AX = 1$:
A := hfarray(1..3, 1..3, [[1, 1, 0], [0, 1, 1], [0, 0, 1]]): B := matrix::identity(3, 3): InverseOfA := numeric::matlinsolve(A, B, Symbolic)[1]hfarray(1..3, 1..3, [1.0, -1.0, 1.0, 0.0, 1.0, -1.0, 0.0, 0.0, 1.0])

$$\begin{pmatrix} 1.0 & -1.0 & 1.0 \\ 0.0 & 1.0 & -1.0 \\ 0.0 & 0.0 & 1.0 \end{pmatrix}$$

delete A, B, InverseOfA:

Example 3

We solve an equation with a symbolic parameter x:

```
A := matrix([[2, 2, 3], [1, 1, 2], [3, 3, 5]]): B := matrix([sin(x)^2, cos(x)^2,
0]): [X, Kernel, Constraints, Pivots] := numeric::matlinsolve(A, B,
Symbolic, ShowAssumptions)[matrix([[5*sin(x)^2], [0], [-3*sin(x)^2]]),
matrix([[-1], [1], [0]]), [cos(x)^2 + sin(x)^2 = 0], []]
```

$$\left[\begin{pmatrix} 5\sin(x)^2 \\ 0 \\ -3\sin(x)^2 \end{pmatrix}, \begin{pmatrix} -1 \\ 1 \\ 0 \end{pmatrix}, [\cos(x)^2 + \sin(x)^2 = 0], []\right]$$

This solution holds subject to the constraint $sin(x)^2 + cos(x)^2 = 0$ on the parameter x. `numeric::matlinsolve` does not investigate the `Constraints` and does not realize that they cannot be satisfied. We check the consistency of the "result" by inserting the solution into the original system. Since the input matrix A was of type `Dom::Matrix()`, the results `X` and `Kernel` were returned as corresponding matrices. The overloaded operators `*` and `-` for matrix multiplication and subtraction can be used:

```
A*X - B, A*Kernelmatrix([[0], [- cos(x)^2 - sin(x)^2], [0]]), matrix([[0],
[0], [0]])
```

$$\begin{pmatrix} 0 \\ -\cos(x)^2 - \sin(x)^2 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

delete A, B, X, Kernel, Constraints, Pivots:

Example 4

We give a further demonstration of the option `ShowAssumptions`. The following system does not have a solution for all values of the parameter `a`:

```
A := array(1..2, 1..2, [[1, 1], [1, 1]]): B := array(1..2, 1..1, [[1], [a]]):
numeric::matlinsolve(A, B, Symbolic)[FAIL, NIL]
```

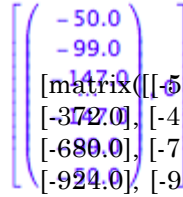
[FAIL, NIL]

With `ShowAssumptions`, `numeric::matlinsolve` investigates under which conditions (on the parameter `a`) there is a solution:
numeric::matlinsolve(A, B, Symbolic, ShowAssumptions)[array(1..2, 1..1, [[1], [0]]), array(1..2, 1..1, [[-1], [1]]), [a - 1 = 0], []]

We conclude that there is a 1-dimensional solution space for $a = 1$.
delete A, B:

Example 5

We solve a sparse system with 3 diagonal bands:
n := 100: A := matrix(n, n, [1, -2, 1], Banded): B := array(1..n, [1 $ n]):
numeric::matlinsolve(A, B) [matrix([[-50.0], [-99.0], [-147.0], [dots], [-147.0], [-99.0], [-50.0]]), 0]



[matrix([[-50.0], [-99.0], [-147.0], [-194.0], [-240.0], [-285.0], [-329.0], [-372.0], [-414.0], [-455.0], [-495.0], [-534.0], [-572.0], [-609.0], [-645.0], [-680.0], [-714.0], [-747.0], [-779.0], [-810.0], [-840.0], [-869.0], [-897.0], [-924.0], [-950.0], [-975.0], [-999.0], [-1022.0], [-1044.0], [-1065.0], [-1085.0], [-1104.0], [-1122.0], [-1139.0], [-1155.0], [-1170.0], [-1184.0], [-1197.0], [-1209.0], [-1220.0], [-1230.0], [-1239.0], [-1247.0], [-1254.0], [-1260.0], [-1265.0], [-1269.0], [-1272.0], [-1274.0], [-1275.0], [-1275.0], [-1274.0], [-1272.0], [-1269.0], [-1265.0], [-1260.0], [-1254.0], [-1247.0], [-1239.0], [-1230.0], [-1220.0], [-1209.0], [-1197.0], [-1184.0], [-1170.0], [-1155.0], [-1139.0], [-1122.0], [-1104.0], [-1085.0], [-1065.0], [-1044.0], [-1022.0], [-999.0], [-975.0], [-950.0], [-924.0], [-897.0], [-869.0], [-840.0], [-810.0], [-779.0], [-747.0], [-714.0], [-680.0], [-645.0], [-609.0], [-572.0],

[-534.0], [-495.0], [-455.0], [-414.0], [-372.0], [-329.0], [-285.0], [-240.0], [-194.0], [-147.0], [-99.0], [-50.0]]), 0]delete n, A, B:

Example 6

The option `Symbolic` should not be used for equations with floating-point coefficients, because the symbolic pivoting strategy favors efficiency instead of numerical stability.
A := array(1..2, 1..2, [[1, 10^20], [1, 1]]): B := array(1..2, 1..1, [[10^20], [0]]):

The float approximation of the exact solution is:
map(numeric::matlinsolve(A, B, Symbolic)[1], float)array(1..2, 1..1, [[-1.0], [1.0]])

$$\begin{pmatrix} -1.0 \\ 1.0 \end{pmatrix}$$

We now convert the exact input data to floating-point approximations:
A := map(A, float): B := map(B, float):

The default pivoting strategy of the floating-point algorithm stabilizes floating-point operations. Consequently, one gets a correct result:
numeric::matlinsolve(A, B)[1]array(1..2, 1..1, [[-1.0], [1.0]])

$$\begin{pmatrix} -1.0 \\ 1.0 \end{pmatrix}$$

With the option `Symbolic`, however, the pivoting strategy optimizes speed, assuming exact arithmetic. Numerical instabilities may occur if floating-point coefficients are involved. The following result is caused by internal round-off effects (“cancellation”):
numeric::matlinsolve(A, B, Symbolic)[1]array(1..2, 1..1, [[0], [1.0]])

$$\begin{pmatrix} 0 \\ 1.0 \end{pmatrix}$$

We need to increase `DIGITS` to obtain a better result:

```
DIGITS := 20: numeric::matlinsolve(A, B, Symbolic)[1]array(1..2, 1..1,
[[-1.00000001490116119381], [1.0]])
```

$$\begin{pmatrix} -1.00000001490116119381 \\ 1.0 \end{pmatrix}$$

delete A, B, DIGITS:

Example 7

We demonstrate how a complete solution of the following linear system with symbolic parameters may be found:

```
A := array(1..3, 1..2, [[1, 1], [a, b], [1, c]]): B := array(1..3,
1..1, [[1], [1], [1]]): numeric::matlinsolve(A, B, Symbolic,
ShowAssumptions)[array(1..2, 1..1, [[-(b - 1)/(a - b)], [(a - 1)/(a - b)]]), 0,
[-(a - 1)*(c - 1) = 0], [b - a <> 0]]
```

$$\left[\begin{pmatrix} -\frac{b-1}{a-b} \\ \frac{a-1}{a-b} \end{pmatrix}, 0, [-(a-1)\,(c-1) = 0], [b-a \neq 0]\right]$$

This is the general solution assuming $a \neq b$. We now set $b = a$ to investigate further solution branches:

```
A := subs(A, b = a): numeric::matlinsolve(A, B, Symbolic,
ShowAssumptions)[array(1..2, 1..1, [[1], [0]]), 0, [1 - a = 0], [c - 1 <> 0]]
```

$$\left[\begin{pmatrix} 1 \\ 0 \end{pmatrix}, 0, [1-a = 0], [c-1 \neq 0]\right]$$

This is the general solution for $a = b$, assuming $c \neq 1$. We finally set $c = 1$ to obtain the last solution branch:

```
A := subs(A, c = 1): numeric::matlinsolve(A, B, Symbolic,
ShowAssumptions)[array(1..2, 1..1, [[1], [0]]), array(1..2, 1..1, [[-1],
[1]]), [1 - a = 0], []]
```

$$\left[\begin{pmatrix} 1 \\ 0 \end{pmatrix}, \begin{pmatrix} -1 \\ 1 \end{pmatrix}, [1-a = 0], []\right]$$

From the constraint on `a`, we conclude that there is a 1-dimensional solution space for the special values $a = b = c = 1$ of the symbolic parameters.
delete A, B:

Example 8

Matrices from a domain such as Dom::Matrix`(...)` are converted to arrays with numbers or expressions. Hence, `numeric::matlinsolve` finds no solution for the following system:
M := Dom::Matrix(Dom::IntegerMod(7)): A := M([[1, 4], [6, 3], [3, 2]]): B := M([[9], [5], [0]]): numeric::matlinsolve(A, B)[FAIL, NIL]

[FAIL, NIL]

Use linalg::matlinsolve to solve the system over the coefficient field of the matrices. A solution does exist over the field Dom::IntegerMod`(7)`:
linalg::matlinsolve(A, B)Dom::Matrix(Dom::IntegerMod(7))([[1], [2]])

$$\begin{pmatrix} 1 \bmod 7 \\ 2 \bmod 7 \end{pmatrix}$$

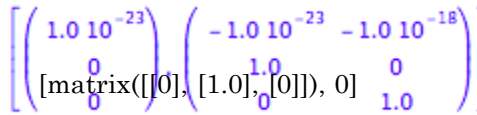
delete M, A, B:

Example 9

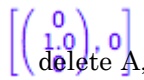
We demonstrate the difference between `Symbolic`, `HardwareFloats`, and `SoftwareFloats`. The following matrix A has a 1-dimensional kernel. Due to round-off, a further spurious kernel vector appears with `SoftwareFloats`. No kernel vector is detected with `HardwareFloats`:
A := matrix([[2*10^14 + 2, 2*10^(-9), 2*10^(-4)], [3*10^15 + 3, 3*10^(-8), 3*10^(-3)], [4*10^16 + 4, 4*10^(-7), 4*10^(-2)]]): b := matrix([2*10^(-9), 3*10^(-8), 4*10^(-7)]): float(numeric::matlinsolve(A, b, Symbolic)); numeric::matlinsolve(A, b, SoftwareFloats); numeric::matlinsolve(A, b, HardwareFloats)[matrix([[0], [1.0], [0]]), matrix([[0], [-100000.0], [1.0]])]

$$\left[\begin{pmatrix} 0 \\ 1.0 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ -100000.0 \\ 1.0 \end{pmatrix}\right]$$

[matrix([[1.0e-23], [0], [0]]), matrix([[-1.0e-23, -1.0e-18], [1.0, 0], [0, 1.0]])]



[matrix([[0], [1.0], [0]]), 0]



delete A, b:

Parameters

A

An *m* *n* matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

B

An *m* *p* matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix. Column vectors `B` may also be represented by a 1-dimensional `array(1..m, [B1, B2, ] )`, a 1-dimensional `hfarray(1..m, [B1, B2, ] )`, or by a list `[B1, B2, ]`.

Options

Hard

HardwareFloats

Soft

SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled

C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix `A` is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill-conditioned matrices, the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See "Example 9" on page 19-194.

Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

This option *must* be used if the matrix *A* contains symbolic parameters that cannot be converted to floating-point numbers.

Note This option should not be used for matrices with floating-point entries! Numerical instabilities may occur in floating-point operations. Cf. "Example 6" on page 19-192.

ShowAssumptions

Returns information on internal assumptions on symbolic parameters in `A` and `B`. With this option, either exact arithmetic or `SoftwareFloats` are used.

This option is only useful if the matrices contain symbolic parameters. Consequently, it should only be used in conjunction with the option `Symbolic`.

Note This option changes the format of the return value to `[X, KernelBasis, Constraints, Pivots]`.

`X` and `KernelBasis` represent the general solution subject to `Constraints` and `Pivots`.

`Constraints` is a list of equations for symbolic parameters in B which are necessary and sufficient for $AX = B$ to be solvable.

Such constraints arise if Gaussian elimination leads to equations of the form $0 = c$, where c is some expression involving symbolic parameters contained in B. All such equations are collected in `Constraints`; `numeric::matlinsolve` assumes that these equations are satisfied and returns a special solution `X`.

If no such constraints arise, the return value of `Constraints` is the empty list.

`Pivots` is a list of inequalities involving symbolic parameters in A. Internally, division by pivot elements occurs in the Gaussian elimination. The expressions collected in `Pivots` are the numerators of those pivot elements that involve symbolic parameters contained in A. If only numerical pivot elements are used, then the return value of `Pivots` is the empty list.

Note `Constraints` usually is a list of *non-linear* equations for the symbolic parameters. It is not investigated by `numeric::matlinsolve`, i.e., solutions may be returned, even if the `Constraints` cannot be satisfied. See "Example 3" on page 19-189.

Note This option changes the return strategy for "unsolvable" systems. Without the option `ShowAssumptions`, the result `[FAIL,NIL]` is returned, whenever Gaussian elimination produces an equation $0 = c$ with non-zero c. With `ShowAssumptions`, such equations are returned via `Constraints`, provided c involves symbolic parameters. If c is a purely numerical value, then `[FAIL, NIL, [], []]` is returned.

See "Example 3" on page 19-189, "Example 4" on page 19-190, and "Example 7" on page 19-193.

NoWarning

Suppresses warnings

If symbolic coefficients are found, `numeric::matlinsolve` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed; `numeric::matlinsolve` still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

ReturnType

Option, specified as `ReturnType = d`

Return the (special) solution and the kernel as matrices of domain type `d`. The following return types d are available: DOM_ARRAY, DOM_HFARRAY, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Sparse

Use a sparse internal representation for matrices.

This option only has an effect when used in conjunction with `HardwareFloats`. With the `Sparse` option, the linear solver uses a sparse representation of the matrices to save memory and increase efficiency. However, if the coefficient matrix is not sparse, this option will cost some additional memory and runtime.

Return Values

Without the option `ShowAssumptions`, a list `[X, KernelBasis]` is returned. The (special) solution `X` is an $n\ p$ matrix. `KernelBasis` is an $n\ d$ matrix (d is the dimension of the kernel of A). Its columns span the kernel of A. If the kernel is trivial, `KernelBasis` is the integer 0.

`[FAIL, NIL]` is returned if the system is not solvable.

With `ShowAssumptions`, a list `[X, KernelBasis, Constraints, Pivots]` is returned. The lists `Constraints` and `Pivots` contain equations and inequalities involving symbolic parameters in `A` and `B`. Internally these were assumed to hold true when solving the system. `[FAIL, NIL, [], []]` is returned if the system is not solvable.

numeric::ncdata

Purpose

Weights and abscissae of Newton-Cotes quadrature

Syntax

```
numeric::ncdata(n)
```

Description

`numeric::ncdata(n)` returns the weights and the abscissae of the Newton-Cotes quadrature rule with n equidistant nodes.

The Newton-Cotes quadrature rule sum(b[i]*f(c[i]), i=1..n) $\sum_{i=1}^{n} b_i f(c_i)$ produces the exact integral int(f(x), x=0..1) $\int_0^1 f(x)\,dx$ for all polynomials f through degree n - 1. If n is odd, then the quadrature rule is exact through degree n.

The equidistant abscissae $c = [c_1, \ldots, c_n]$ are given by c[i]=(i-1)/(n-1) $c_i = \frac{i-1}{n-1}$.

Environment Interactions

`numeric::ncdata` is not sensitive to the environment variable DIGITS.

The function uses option remember.

Examples

Example 1

The following call produces exact data for the quadrature rule with four nodes:
numeric::ncdata(4)[[1/8, 3/8, 3/8, 1/8], [0, 1/3, 2/3, 1]]

$$\left[\left[\frac{1}{8}, \frac{3}{8}, \frac{3}{8}, \frac{1}{8}\right], \left[0, \frac{1}{3}, \frac{2}{3}, 1\right]\right]$$

Parameters

n

The number of nodes: a positive integer

Return Values

List `[b,c]` is returned. The lists `b = [b1, , bn]` and `c = [c1, , cn]` are the rational weights and abscissae of the Newton-Cotes quadrature rule, respectively.

Algorithms

The numerical integrator numeric::quadrature calls `numeric::ncdata` to provide the data for Newton-Cotes quadrature.

numeric::odesolve

Purpose

Numerical solution of an ordinary differential equation

Syntax

```
numeric::odesolve(f, t0 .. t, Y0, <method>, <RelativeError = rtol>, <AbsoluteError = atol>, <Stepsize = h>, <MaxStepsize = hmax>, <Alldata = n>, <Symbolic>)
numeric::odesolve(t0 .. t, f, Y0, <method>, <RelativeError = rtol>, <AbsoluteError = atol>, <Stepsize = h>, <MaxStepsize = hmax>, <Alldata = n>, <Symbolic>)
```

Description

`numeric::odesolve(f, t0..t, Y0)` returns a numerical approximation of the solution $Y(t)$ of the first order differential equation (dynamical system) dY/dt = f(t, Y) $\frac{dY}{dt} = f(t, Y)$, $Y(t_0) = Y_0$ with t, t_0 in R_$t, t_0 \in \mathbb{R}$ and Y(t), Y_0 in C_^n $Y(t), Y_0 \in \mathbb{C}^n$.

`numeric::odesolve` is a general purpose solver able to deal with initial value problems of various kinds of ordinary differential equations. Equations y^(fenced(p))=f(t, y, y', Symbol::hellip, y^(fenced(p-1))) $y^{(p)} = f\left(t, y, y', \ldots, y^{(p-1)}\right)$ of order p can be solved by `numeric::odesolve` after reformulation to dynamical system form. This can always be achieved by writing the equation as a first order system

_outputSequence('d '/dt, matrix([[Y[1]], [dots], [Y[(p-1)]], [Y[p]]])) = matrix([[Y[2]], [dots], [Y[p]], [f(t, Y[1], dots, Y[p])]])

$$\frac{d}{dt}\begin{pmatrix} Y_1 \\ \ldots \\ Y_{p-1} \end{pmatrix} = \begin{pmatrix} Y_2 \\ \ldots \\ f(t, Y_1, \ldots, Y_p) \end{pmatrix}$$

for the vector Y=[Y[1], Symbol::hellip, Y[p]]=[y, y', Symbol::hellip, y^(fenced(p-1))] $Y = [Y_1, \ldots, Y_p] = \left[y, y', \ldots, y^{(p-1)}\right]$. See "Example 4" on page 19-208.

Presently the following single step Runge-Kutta type methods are implemented:

`EULER1` (order 1),	`RKF43` (order 3),	`xRKF43` (order 3),
`RKF34` (order 4),	`xRKF34` (order 4),	`RK4` (order 4),
`RKF54a` (order 4),	`RKF54b` (order 4),	`DOPRI54` (order 4),
`xDOPRI54`(order 4),	`CK54` (order 4),	`xRKF54a` (order 4),
`xRKF54b` (order 4),	`xCK54` (order 4),	`RKF45a` (order 5),
`RKF45b` (order 5),	`DOPRI45` (order 5),	`CK45` (order 5),
`xRKF45a` (order 5),	`xRKF45b` (order 5),	`xDOPRI45`(order 5),
`xCK45` (order 5),	`DOPRI65` (order 5),	`xDOPRI65` (order 5),
`DOPRI56` (order 6),	`xDOPRI56` (order 6),	`BUTCHER6` (order 6),
`RKF87` (order 7),	`xRKF87` (order 7),	`DOPRI87`(order 7),
`xDOPRI87` (order 7),	`RKF78` (order 8),	`xRKF78` (order 8),
`DOPRI78` (order 8),	`xDOPRI78` (order 8),	`GAUSS(s)` (order 2*s*),
`GAUSS = s`.		

For the Gauss methods, `GAUSS(s)` is equivalent to `GAUSS = s`. The positive integer `s` indicates the number of stages. The order of the `s` stage Gauss method is 2*s*.

The utility function numeric::ode2vectorfield may be used to produce the input parameters *f*, t_0, Y_0 from a set of differential expressions representing the ODE. See “Example 1” on page 19-206.

The input data t_0, t and Y_0 must not contain symbolic objects which cannot be converted to floating point values via float. Numerical expressions such as exp(PI)e^{π}, sqrt(2)$\sqrt{2}$ etc. are accepted.

The vector field *f* defining the dynamical system Y'=f(t, Y)$Y' = f(t, Y)$ must be represented by a procedure with two input parameters: the scalar time *t* and the vector *Y*. `numeric::odesolve` internally calls this function with real floating-point values *t* and a list *Y* of floating-point values. It has to return the vector *f*(*t*, *Y*) either as a list or as a 1-dimensional array. The output of *f* may contain numerical expressions

such as π, exp(2)e^2 etc. However, all values must be convertible to real or complex floating point numbers by float.

Autonomous systems, where $f(t, Y)$ does not depend on t, must also be represented by a procedure with 2 arguments `t` and `Y`.

Scalar functions `Y` also must be represented by a list or an array with one element. For instance, the input data for the scalar initial value problem y'=t*sin(y), y(0)=1 $y' = t\sin(y),\ y(0) = 1$ may be of the form

```
f := proc(t,Y)                    /* Y is a 1-dimensional vector */
local y;                          /* represented by a list with */
begin                             /* one element: Y = [y]. */
   y := Y[1];
   [t*sin(y)]                     /* the output is a list with 1
                                     element */
end_proc:
Y0 := [1]:                        /* the initial value */
```

The numerical precision is controlled by the global variable DIGITS: an adaptive control of the step size keeps local relative discretization errors below `rtol=10^-DIGITS`, unless a different tolerance is specified via the option `RelativeError = rtol`. For small values of the solution vector Y, the absolute discretization error can be bounded by the threshold `atol` specified via the option `AbsoluteError = atol`.

If `AbsoluteError` is not specified, only relative discretization errors are controlled and kept below `rtol`.

The error control may be switched off by specifying a fixed `Stepsize = h`.

Note Only local errors are controlled by the adaptive mechanism. No control of the global error is provided!

With `Y := t -> numeric::odesolve(f, t_0..t, Y_0)`, the numerical solution can be repesented by a MuPAD function: the call `Y(t)` will start the numerical integration from t_0 to `t`. A more sophisticated form of this function may be generated via `Y := numeric::odesolve2(f, t_0, Y_0)`.

This equips `Y` with a remember mechanism that uses previously computed values to speed up the computation. See “Example 2” on page 19-207.

For systems of the special form Y'=f(t, Y)*Y$y' = f(t, Y)\,y$ with a matrix valued function $f(t, Y)$, there is a special solver numeric::odesolveGeometric which preserves geometric features of the system more faithfully than `numeric::odesolve`.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We compute the numerical solution $y(10)$ of the initial value problem y'=t*sin(y)$y' = t\sin(y)$, $y(0) = 2$:
f := proc(t, Y) begin [t*sin(Y[1])] end_proc: numeric::odesolve(f, 0..10, [2])[3.141592654]

```
[3.141592654]
```

Alternatively, the utility function numeric::ode2vectorfield can be used to generate the input parameters in a more intuitive way:
[f, t0, Y0] := [numeric::ode2vectorfield({y'(t) = t*sin(y(t)), y(0) = 2}, [y(t)])]['proc f(t, Y) ... end', 0, [2]]

```
[proc f(t, Y) ... end, 0, [2]]
```

numeric::odesolve(f, t0..10, Y0)[3.141592654]

```
[3.141592654]
```

delete f, t0, Y0:

Example 2

We consider y'=y$y' = y$, $y(0) = 1$. The numerical solution may be represented by the function
Y := t -> numeric::odesolve((t,Y) -> Y, 0..t, [1]):

Calling `Y(t)` starts the numerical integration:
Y(-5), Y(0), Y(1), Y(PI)[0.006737946999], [1.0], [2.718281828], [23.14069263]

[0.006737946999], [1.0], [2.718281828], [23.14069263]

delete Y:

Example 3

We compute the numerical solution $Y(\pi) = [x(\pi), y(\pi)]$ of the system

x'=x+y, y'=x-y, x(0)=1, y(0)= sqrt(-1)

$x' = x + y,\ y' = x - y,\ x(0) = 1,\ y(0) = \sqrt{-1}$

f := (t, Y) -> [Y[1] + Y[2], Y[1] - Y[2]]: Y0 := [1, I]: numeric::odesolve(f, 0..PI, Y0)[72.57057163 + 30.05484302*I, 30.05484302 + 12.46088558*I]

[72.57057163 + 30.05484302 i, 30.05484302 + 12.46088558 i]

The solution of a linear dynamical system Y'=A*Y$Y' = A\,Y$ with a constant matrix A is Y(t)=exp(t*A)*Y[0]$Y(t) = e^{t\,A}\,Y_0$. The solution of the system above can also be computed by:
t := PI: tA := array(1..2, 1..2, [[t, t], [t, -t]]): numeric::expMatrix(tA, Y0)array(1..2, 1..1, [[72.57057163 + 30.05484303*I], [30.05484303 + 12.46088558*I]])

$$\begin{pmatrix} 72.57057163 + 30.05484303\,i \\ 30.05484303 + 12.46088558\,i \end{pmatrix}$$

delete f, Y0, t, tA:

Example 4

We compute the numerical solution $y(1)$ of the differential equation y"=y^2$y'' = y^2$ with initial conditions $y(0) = 0$, y'(0)=1$y'(0) = 1$. The second order equation is converted to a first order system for the vector Y=[y, y']=[y, z]$Y = [y, y'] = [y, z]$:

y'=z, z'=y^2, y(0)=0, z(0)=1

$y' = z,\ z' = y^2,\ y(0) = 0,\ z(0) = 1$

```
f := proc(t, Y) begin [Y[2], Y[1]^2] end_proc: Y0 := [0, 1]:
numeric::odesolve(f, 0..1, Y0)[1.087473533, 1.362851121]
```

[1.087473533, 1.362851121]

```
delete f, Y0:
```

Example 5

We demonstrate how numerical data can be obtained on a user defined time mesh `t[i]`. The initial value problem is y'=sin(t)-y$y' = \sin(t) - y$, $y(0) = 1$, the sample points are $t_0 = 0.0$, $t_1 = 0.1$, …, $t_{100} = 10.0$. First, we define the differential equation and the initial condition:

```
f := (t, Y) -> [sin(t) - Y[1]]: Y[0] := [1]:
```

We define the time mesh:

```
for i from 0 to 100 do t[i] := i/10 end_for:
```

The equation is integrated iteratively from `t[i-1]` to `t[i]` with a working precision of 4 significant decimal places:

```
DIGITS := 4: for i from 1 to 100 do Y[i] := numeric::odesolve(f, t[i-1]..t[i],
Y[i-1]) end_for:
```

The following mesh data are produced:

```
[t[i], Y[i]] $ i = 0..100[[0, [1]], [1/10, [0.9097]], [1/5, [0.8374]], [3/10,
[0.7813]], [2/5, [0.7397]], dots, [99/10, [0.2159]], [10, [0.1476]]]
```

$\left[[0, [1]], \left[\frac{1}{10}, [0.9097]\right], \left[\frac{1}{5}, [0.8374]\right], \left[\frac{3}{10}, [0.7813]\right], \left[\frac{2}{5}, [0.7397]\right], \ldots, \left[\frac{99}{10}, [0.2159]\right], [10, [0.147\right.$

[0, [1]], [1/10, [0.9097]], [1/5, [0.8374]], [3/10, [0.7813]], [2/5, [0.7397]], [1/2, [0.7107]], [3/5, [0.6929]], [7/10, [0.6846]], [4/5, [0.6843]], [9/10, [0.6907]], [1, [0.7024]], [11/10, [0.7181]], [6/5, [0.7366]], [13/10, [0.7568]], [7/5, [0.7776]], [3/2, [0.7981]], [8/5, [0.8172]], [17/10, [0.8343]], [9/5, [0.8485]], [19/10, [0.8591]], [2, [0.8657]], [21/10, [0.8677]], [11/5, [0.8647]], [23/10, [0.8564]], [12/5, [0.8425]], [5/2, [0.8229]], [13/5, [0.7976]], [27/10, [0.7665]], [14/5, [0.7298]], [29/10, [0.6876]], [3, [0.6402]], [31/10, [0.5879]], [16/5, [0.5311]], [33/10, [0.4702]], [17/5, [0.4057]], [7/2, [0.3381]], [18/5, [0.2681]], [37/10, [0.1962]], [19/5, [0.1231]], [39/10, [0.04945]], [4, [-0.02411]], [41/10, [-0.09687]], [21/5, [-0.1682]], [43/10, [-0.2373]], [22/5, [-0.3037]], [9/2, [-0.3667]], [23/5, [-0.4257]], [47/10, [-0.4801]], [24/5, [-0.5295]], [49/10, [-0.5733]], [5, [-0.6112]], [51/10, [-0.6428]], [26/5, [-0.6677]], [53/10, [-0.6858]], [27/5, [-0.697]], [11/2, [-0.701]], [28/5, [-0.6979]], [57/10, [-0.6877]], [29/5, [-0.6705]], [59/10, [-0.6466]], [6, [-0.6161]], [61/10, [-0.5794]], [31/5, [-0.5368]], [63/10, [-0.4888]], [32/5, [-0.4358]], [13/2, [-0.3785]], [33/5, [-0.3173]], [67/10, [-0.2529]], [34/5, [-0.186]], [69/10, [-0.1171]], [7, [-0.04709]], [71/10, [0.02345]], [36/5, [0.09378]], [73/10, [0.1632]], [37/5, [0.231]], [15/2, [0.2965]], [38/5, [0.3591]], [77/10, [0.4181]], [39/5, [0.4729]], [79/10, [0.523]], [8, [0.5679]], [81/10, [0.6072]], [41/5, [0.6404]], [83/10, [0.6671]], [42/5, [0.6873]], [17/2, [0.7006]], [43/5, [0.7068]], [87/10, [0.7061]], [44/5, [0.6982]], [89/10, [0.6834]], [9, [0.6618]], [91/10, [0.6336]], [46/5, [0.599]], [93/10, [0.5585]], [47/5, [0.5124]], [19/2, [0.4611]], [48/5, [0.4053]], [97/10, [0.3454]], [49/5, [0.2821]], [99/10, [0.2159]], [10, [0.1476]]

These data can be displayed by a list plot:

```
plotpoints := [[t[i], op(Y[i])] $ i = 0..100]:
plot(plot::PointList2d(plotpoints, PointColor = RGB::Black)):
```

$$[0, [1]], \left[\frac{1}{10}, [0.9097]\right], \left[\frac{1}{5}, [0.8374]\right], \left[\frac{3}{10}, [0.7813]\right], \left[\frac{2}{5}, [0.7397]\right], \left[\frac{1}{2}, [0.7107]\right], \left[\frac{3}{5}, [0.6929]\right], [$$

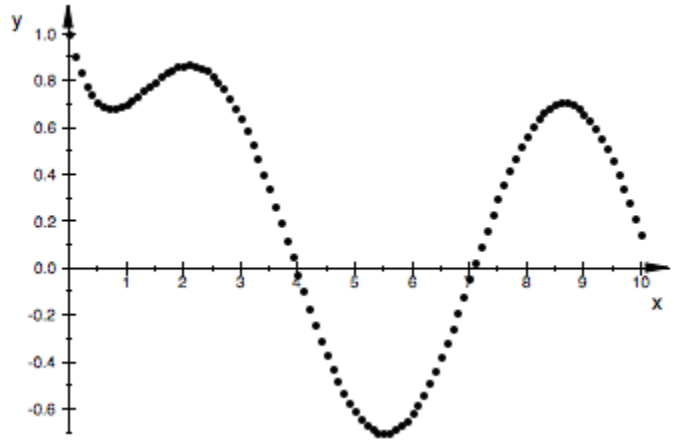
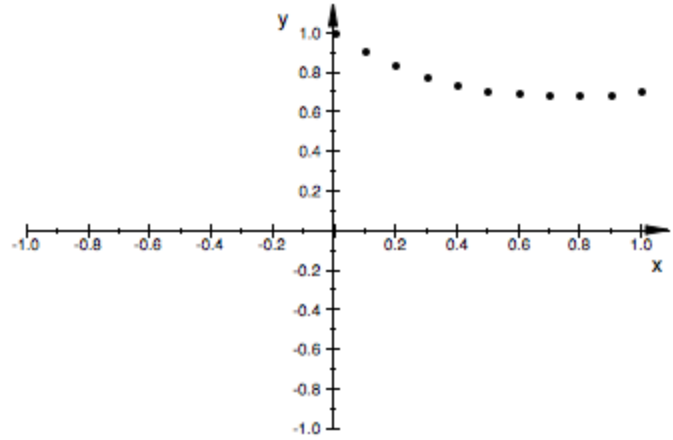
$$\left[\frac{43}{10}, [-0.2373]\right], \left[\frac{22}{5}, [-0.3037]\right], \left[\frac{9}{2}, [-0.3667]\right], \left[\frac{23}{5}, [-0.4257]\right], \left[\frac{47}{10}, [-0.4801]\right], \left[\frac{24}{5}, [-0.5\right.$$

$$\left[\frac{51}{\ }, [\ \ \ ]\right], \left[\frac{26}{\ }, [\ \ \ ]\right], \left[\frac{53}{\ }, [\ \ \ ]\right], \left[\frac{27}{\ }, [\ \ \ ]\right], \left[\frac{11}{\ }, [\ \ \ ]\right], \left[\frac{28}{\ }, [\ \ \ ]\right.$$



The same plot can be obtained directly via plot::Ode2d:
plot(plot::Ode2d([t[i] $ i = 0..100], f, Y[0], [(t, Y) -> [t, Y[1]], Style = Points, Color = RGB::Black]))



delete f, t, DIGITS, Y, plotpoints:

Example 6

We compute the numerical solution $y(1)$ of y'=y, y(0)=1$y' = y,\ y(0) = 1$ by the classical 4-th order Runge-Kutta method `RK4`. By internal local extrapolation, its effective order is 5:
f := (t, Y) -> Y: DIGITS := 13: numeric::odesolve(f, 0..1, [1], RK4)[2.718281828459]

[2.718281828459]

Next, we use local extrapolation `xRKF78` of the 8-th order submethod of the Runge-Kutta-Fehlberg pair `RKF78`. This scheme has effective order 9:
numeric::odesolve(f, 0..1, [1], xRKF78)[2.718281828459]

[2.718281828459]

Both methods yield the same result because of the internal adaptive error control. However, due to its higher order, the method `xRKF78` is faster.
delete f, DIGITS:

Example 7

We consider the stiff ODE y'=10^4 * (cos(t)-y), y(0)=1$y' = 10^4\ (\cos(t) - y),\ y(0) = 1$. The default method `DOPRI78` is explicit and not very efficient in solving very stiff problems:
f := (t, Y) -> [10^4*(cos(t) - Y[1])]: t0 := time(): numeric::odesolve(f, 0..1, [1]), (time() - t0)*msec [0.5403864476], 16065.004*msec

[0.5403864476], 16065.004 msec

We use the implicit A-stable method `GAUSS(6)`. For this stiff problem, it is more efficient than the default method `DOPRI78`:
t0 := time(): numeric::odesolve(f, 0..1, [1], GAUSS(6)), (time() - t0)*msec [0.5403864476], 796.05*msec

[0.5403864476], 796.05 msec
delete t0:

Example 8

We consider the initial value problem y'=-10^(20)*y*(1-cos(y)) $y' = -10^{20}\, y\,(1-\cos(y))$, $y(0) = 1$. We note that the numerical evaluation of the right hand side of the equation suffers from cancellation effects, when $|y|$ is small.
f := (t, Y) -> [-10^20*Y[1]*(1 - cos(Y[1]))]: Y0 := [1]:

We first attempt to compute $y(1)$ with a working precision of 6 digits using the default setting `RelativeError = 10^-DIGITS=10^(-6)`:
DIGITS := 6: numeric::odesolve(f, 0..1, Y0)[3.29271e-10]

[0.000000000329271]

Due to numerical round-off in the internal steps, no digit of this result is correct. Next, we use a working precision of 20 significant decimal places to eliminate roundoff effects:
DIGITS := 20: numeric::odesolve(f, 0..1, Y0, RelativeError = 10^(-6))[0.00000000010000000007495004558]

[0.00000000010000000007495004558]

Since relative local discretization errors are of the magnitude 10^{-6}, not all displayed digits are trustworthy. We finally use a working precision of 20 digits and constrain the local relative discretization errors by the tolerance 10^{-10}:
numeric::odesolve(f, 0..1, Y0, RelativeError = 10^(-10))[0.00000000010000000000003105061]

[0.00000000010000000000003105061]
delete f, Y0, DIGITS:

Example 9

We compute the numerical solution $y(1)$ of y'=y$y' = y$, $y(0) = 1$ with various methods and various constant step sizes. We compare the result with the exact solution y(1)=exp(1)=_outputSequence(2.718281828, dots)$y(1) = e = 2.718281828...$.
f := (t, Y) -> Y: Y0 := [1]:

We first use the Euler method of order 1 with two different step sizes:
Y := numeric::odesolve(f, 0..1, Y0, EULER1, Stepsize = 0.1):
Y, globalerror = float(exp(1)) - Y[1][2.59374246], globalerror = 0.1245393684

[2.59374246], globalerror = 0.1245393684

Decreasing the step size by a factor of 10 should reduce the global error by a factor of 10. Indeed:
Y := numeric::odesolve(f, 0..1, Y0, EULER1, Stepsize = 0.01):
Y, globalerror = float(exp(1)) - Y[1][2.704813829], globalerror = 0.01346799904

[2.704813829], globalerror = 0.01346799904

Next, we use the classical Runge-Kutta method of order 4 with two different step sizes:
Y := numeric::odesolve(f, 0..1, Y0, RK4, Stepsize = 0.1): Y, globalerror = float(exp(1)) - Y[1][2.718279744], globalerror = 0.00000208432388

[2.718279744], globalerror = 0.00000208432388

Decreasing the step size by a factor of 10 in a 4-th order scheme should reduce the global error by a factor of 10^4. Indeed:
Y := numeric::odesolve(f, 0..1, Y0, RK4, Stepsize = 0.01): Y, globalerror = float(exp(1)) - Y[1][2.718281828], globalerror = 0.0000000002246438591

[2.718281828], globalerror = 0.0000000002246438591
delete f, Y0, Y:

Example 10

We integrate y'=y^2$y' = y^2$, $y(0) = 1$ over the interval $t \in [0, 0.99]$ with a working precision of 4 digits. The exact solution is y(t)=1/(1-t)$y(t) = \frac{1}{1-t}$. Note the singularity at $t = 1$.

```
DIGITS := 4: f := (t, Y) -> [Y[1]^2]: Y0 := [1]:
```

The option `Alldata`, equivalent to `Alldata = 1`, yields all mesh data generated during the internal adaptive process:

```
numeric::odesolve(f, 0..0.99, Y0, Alldata)[[0.0, [1.0]], [0.4933, [1.974]],
[0.74, [3.846]], [0.8633, [7.314]], [0.9249, [13.32]], [0.9558, [22.61]],
[0.9712, [34.71]], [0.9866, [74.68]], [0.99, [99.97]]]
```

```
[[0.0, [1.0]], [0.4933, [1.974]], [0.74, [3.846]], [0.8633, [7.314]], [0.9249, [13.32]], [0.9558, [22.6
[0.99, [99.97]]]
```

With `Alldata = 2`, only each second point is returned:

```
numeric::odesolve(f, 0..0.99, Y0, Alldata = 2)[[0.0, [1.0]], [0.74, [3.846]],
[0.9249, [13.32]], [0.9712, [34.71]], [0.99, [99.97]]]
```

```
[[0.0, [1.0]], [0.74, [3.846]], [0.9249, [13.32]], [0.9712, [34.71]], [0.99, [99.97]]]
```

One can control the time mesh using the option `Stepsize = h`:

```
numeric::odesolve(f, 0..0.99, Y0, Stepsize=0.1, Alldata = 1)[[0.0, [1.0]],
[0.1, [1.111]], [0.2, [1.25]], [0.3, [1.429]], [0.4, [1.667]], [0.5, [2.0]], [0.6,
[2.5]], [0.7, [3.333]], [0.8, [5.0]], [0.9, [10.0]], [0.99, [94.3]]]
```

```
[[0.0, [1.0]], [0.1, [1.111]], [0.2, [1.25]], [0.3, [1.429]], [0.4, [1.667]], [0.5, [2.0]], [0.6, [2.5]], [0.7,
[0.99, [94.3]]]
```

However, with the option `Stepsize = h`, no automatic error control is provided by `numeric::odesolve`. Note the poor approximation $y(t) = 94.3$ for $t = 0.99$ (the exact value is $y(0.99) = 100.0$). The next computation with smaller step size yields better results:

numeric::odesolve(f, 0..0.99, Y0, Stepsize = 0.01, Alldata = 10)[[0.0, [1.0]], [0.1, [1.111]], [0.2, [1.25]], [0.3, [1.429]], [0.4, [1.667]], [0.5, [2.0]], [0.6, [2.5]], [0.7, [3.333]], [0.8, [5.0]], [0.9, [10.0]], [0.99, [100.0]]]

[[0.0, [1.0]], [0.1, [1.111]], [0.2, [1.25]], [0.3, [1.429]], [0.4, [1.667]], [0.5, [2.0]], [0.6, [2.5]], [0.7, [3.3
[0.99, [100.0]]]

"Example 5" on page 19-208 demonstrates how accurate numerical data on a user defined time mesh can be generated using the automatic error control of `numeric::odesolve`.
delete DIGITS, f, Y0:

Example 11

The second order equation y"+sin(y)=0$y'' + \sin(y) = 0$ is written as the dynamical system y'=z$y' = z$, z'=-sin(y)$z' = -\sin(y)$ for the vector $Y = [y, z]$. A single symbolic step

[y(t[0]), z(t[0])] --> [y(t[0]+h), z(t[0]+h)]

$[y(t_0), z(t_0)] \to [y(t_0 + h), z(t_0 + h)]$

of the Euler method is computed:
f := proc(t, Y) begin [Y[2], -sin(Y[1])] end_proc: numeric::odesolve(f, t0..t0+h, [y0, z0], EULER1, Symbolic)[y0 + h*z0, z0 - h*sin(y0)]

[y0 + h z0, z0 – h sin(y0)]

delete f:

Parameters

Name of the Runge-Kutta scheme. See "Example 6" on page 19-212. For details on these schemes, see the Algorithms section.

GAUSS

Name of the Runge-Kutta scheme specified as `GAUSS(s)` or `GAUSS = s`.

The methods `GAUSS(s)` or, equivalently, `GAUSS = s` are the implicit Gauss methods with `s` stages of order 2*s*.

These methods are implicit A-stable schemes. The time steps are rather costly to compute. The Gauss methods are useful for integrating stiff ODEs. For non-stiff ODEs, there is usually no

need to change the default method `DOPRI78`. This method is an embedded Runge-Kutta pair of orders 7 and 8.

Further, the Gauss methods are symplectic methods. When used with constant step size (`Stepsize = h`), numerical integration of Hamiltonian systems benefits from this property.

See "Example 7" on page 19-212.

RelativeError

AbsoluteError

Option specified as `RelativeError = rtol` forces internal numerical Runge-Kutta steps to use step sizes with relative local discretization errors below `rtol`. This tolerance must be a positive numerical real value not smaller than 10^(-DIGITS) $10^{-\frac{1}{DIGITS}}$. The default tolerance is `RelativeError = 10^(-DIGITS)`.

Option specified as `AbsoluteError = atol` forces internal numerical Runge-Kutta steps to use step sizes with absolute local discretization errors below `atol`. This tolerance must be a nonnegative numerical real value. The default tolerance is `AbsoluteError = 10^(-10*DIGITS)`.

The internal control mechanism estimates the local discretization error of a Runge-Kutta step and adjusts the step size adaptively to keep this error below the specified tolerances `rtol` or `atol`, respectively. The code uses the criterion

norm('discretization error') = max(norm(Y)*rtol, atol)

$$\|\text{discretization error}\|_\infty = \max(\|Y\|_\infty \, \text{rtol}, \text{atol})$$

For accepting a solution vector *Y*. Roughly speaking, the relative error is controlled when the solution *Y* is sufficiently large. For very small solution values *Y*, absolute discretization errors are kept below the threshold `atol`.

Specify `AbsoluteError` = 0 if only control of the relative discretization errors is desired.

The error control may be switched off by specifying a fixed `Stepsize = h`.

The default setting of rtol=10^-DIGITS$_{\text{rtol} = \frac{1}{10^{\text{DIGITS}}}}$, atol=10^(-10*DIGITS)$_{\text{atol} = \frac{1}{10^{10\,\text{DIGITS}}}}$ ensures that the local discretization errors are of the same order of magnitude as numerical roundoff.

Usually there is no need to use these options to change this setting. However, occasionally the numerical evaluation of the Runge-Kutta steps may be ill-conditioned or step sizes are so small that the time parameter cannot be incremented by the step size within working precision. In such a case these options may be used to bound the local discretization errors and use a higher working precision given by DIGITS.

Only positive real numerical values rtol >= 10^-DIGITS$_{\text{rtol} \geq \frac{1}{10^{\text{DIGITS}}}}$ are accepted.

Note The global error of the result returned by `numeric::odesolve` is usually larger than the local errors bounded by `rtol`, `atol`, respectively. Although the result is displayed with DIGITS decimal places one should not expect that all of them are correct. The relative precision of the final result is `rtol` at best!

See “Example 8” on page 19-213.

Stepsize

Option, specified as `Stepsize = h`

Switches off the internal error control and uses a Runge-Kutta iteration with constant step size `h` which must be a positive numerical value.

By default, `numeric::odesolve` uses an adaptive step size control mechanism in the numerical iteration. The option `Stepsize = h` switches off this adaptive mechanism and uses the Runge-Kutta method specified (or the default method `DOPRI78`) with constant step size `h`.

A final step with smaller step size is used to match the end `t` of the integration interval `t_0..t` if (t-t_0)/h$\frac{t-t_0}{h}$ is not an integer.

Note With this option, there is no automatic error control! Depending on the problem and on the order of the method the result may be a poor numerical approximation of the exact solution.

There is usually no need to invoke this option. However, occasionally the built-in adaptive error control mechanism may fail when integrating close to a singularity. In such a case this option may be used to customize a control mechanism for the global error by using different step sizes and investigating the convergence of the corresponding results.

Cf. “Example 9” on page 19-214.

MaxStepsize

Option, specified as `MaxStepsize = hmax`

Restricts adaptive step sizes to values not larger than `h_max`; `h_max` must be a positive numerical value.

By default, `numeric::odesolve` uses an adaptive step size control mechanism in the numerical iteration. The option `MaxStepsize = `h_{max} restricts the adaptive step size to values no larger than h_{max}.

If a larger stepsize `h` is requested explicitly by `Stepsize = h`, the option `MaxStepsize = `h_{max} reduces `h` to h_{max}.

Alldata

Option, specified as `Alldata = n`

Makes `numeric::odesolve` return a list of numerical mesh points generated by the internal Runge-Kutta iteration. The integer `n` controls the size of the output list.

With this option, `numeric::odesolve` returns a list of numerical mesh points $[[t_0, Y_0], [t_1, Y_1], \ldots, [t, Y(t)]]$ generated by the internal Runge-Kutta iteration.

The integer `n` controls the size of the output list. For $n = 1$, all internal mesh points are returned. This case may also be invoked by entering the simplified option `Alldata`, which is equivalent to `Alldata = 1`. For $n > 1$, only each n-th mesh point is stored in the list. The list always contains the initial point $[t_0, Y_0]$ and the final point $[t, Y(t)]$. For $n \leq 0$, only the data $[[t_0, Y_0], [t, Y(t)]]$ are returned.

The output list may be useful to inspect the internal numerical process. Also further graphical processing of the mesh data may be useful.

Cf. "Example 10" on page 19-215.

Symbolic

Makes `numeric::odesolve` return a vector of symbolic expressions representing a single symbolic step of the Runge-Kutta iteration.

The call `numeric::odesolve(f, t0..t, Y0, < method >, Symbolic)` returns a vector (list or array) of expressions representing a single step of the numerical scheme with step size $t - t_0$. In this mode symbolic values for t_0, t and the components of Y_0 are accepted.

This option may be useful if the specified numerical method applied to a given differential equation is to be investigated symbolically.

Cf. "Example 11" on page 19-216.

Return Values

The solution vector $Y(t)$ is returned as a list or as a 1-dimensional array of floating-point values. The type of the result vector coincides with the type of the input vector Y_0.

With the option `Alldata`, a list of mesh data is returned.

Algorithms

All methods presently implemented are adaptive versions of Runge-Kutta type single step schemes.

The methods `RKF43`, `RKF34`, `RKF54a`, `RKF54b`, `RKF45a`, `RKF45b`, `RKF87`, `RKF78`, `DOPRI54`, `DOPRI45`, `DOPRI65`, `DOPRI56`, `DOPRI87`, `DOPRI78`, `CK54`, `CK45` are embedded pairs of Runge-Kutta-Fehlberg, Dormand-Prince and Cash-Karp type, respectively. Estimates of the local discretization error are obtained in the usual way by comparing the results of the two submethods of the pair. The names indicate the orders of the subprocesses. For instance, `RKF34` and `RKF43` denote the same embedded Runge-Kutta-Fehlberg pair with orders 3 and 4. In `RKF34` the result of the fourth order submethod is accepted, whereas `RKF43` advances using the result of the third order submethod. In both cases the discretization error of the lower order subprocess is estimated and controlled.

For the single methods `EULER1` (the first order Euler scheme), `RK4` (the classical fourth order Runge-Kutta scheme) and `BUTCHER6` (a Runge-Kutta scheme of order 6), the relative local error is controlled by comparing steps with different step sizes. The effective order of these methods is increased by one through local extrapolation.

Local extrapolation is also available for the submethods of the embedded pairs. For instance, the method `xRKF78` uses extrapolation of the 8-th order subprocess of `RKF78`, yielding a method of effective order 9. The 7-th order subprocess is ignored. The cheap error estimate based on the embedded pair is not used implying some loss of efficiency when comparing `RKF78` (order 8) and `xRKF78` (effective order 9).

The call `numeric::butcher(method)` returns the Butcher data of the methods used in `numeric::odesolve`. Here `method` is one of `EULER1`, `RKF43`, `RK4`, `RKF34`, `RKF54a`, `RKF54b`, `DOPRI54`, `CK54`, `RKF45a`, `RKF45b`, `DOPRI45`, `CK45`, `DOPRI65`, `DOPRI56`, `BUTCHER6`, `RKF87`, `DOPRI87`, `RKF78`, `DOPRI78`.

Note Only local errors are controlled by the adaptive mechanism. No control of the global error is provided!

Note The run time of the numerical integration with a method of order p grows like O(10^(DIGITS/(p+1)))$O\left(10^{\frac{DIGITS}{p+1}}\right)$, when DIGITS is increased. Computations with high precision goals are very expensive! High order methods such as the default method `DOPRI78` should be used.

Presently, only single step methods of Runge-Kutta type are implemented. Stiff problems cannot be handled efficiently with explicit methods such as the default method `DOPRI78`. For stiff problems, one may use one of the implicit A-stable methods `GAUSS(s)`. See "Example 7" on page 19-212.

For problems of the special type Y'=f(t, Y)*Y$Y' = f(t, Y)\,Y$ with a matrix valued function $f(t, Y)$, there is a specialized ("geometric") integration routine numeric::odesolveGeometric. Generally, `numeric::odesolve` is faster than the geometric integrator. However, `odesolveGeometric` preserves certain invariants of the system more faithfully.

Concepts

- "Solve Equations Numerically"

numeric::odesolve2

Purpose

Numerical solution of an ordinary differential equation

Syntax

```
numeric::odesolve2(f, t0, Y0, <method>, <RememberLast>,
<RelativeError = rtol>, <AbsoluteError = atol>,
<Stepsize = h>, <MaxStepsize = hmax>)
```

Description

`numeric::odesolve2( f, t0, Y0, )` returns a function representing the numerical solution $Y(t)$ of the first order differential equation (dynamical system) dY/dt = f(t, Y)$\frac{dY}{dt} = f(t, Y)$, $Y(t_0) = Y_0$ with t, t_0 in R_$t, t_0 \in \mathbb{R}$ and Y(t), Y_0 in C_^n$Y(t), Y_0 \in \mathbb{C}^n$.

The utility function numeric::ode2vectorfield may be used to produce the input parameters `f, t0, Y0` from a set of differential expressions representing the ODE. Cf. “Example 1” on page 19-226.

The function generated by `Y := numeric::odesolve2(f, t0, Y0)` is essentially

`Y := t -> numeric::odesolve(t_0..t, f, Y_0)`.

Numerical integration is launched, when `Y` is called with a real numerical argument. The call `Y(t)` returns the solution vector in a format corresponding to the type of the initial condition Y_0 with which `Y` was defined: `Y(t)` either yields a list or a 1-dimensional array.

If `t` is not a real numerical value, then `Y(t)` returns a symbolic function call.

See the help page of numeric::odesolve for details on the parameters and the options.

The options `Alldata = n` and `Symbolic` accepted by numeric::odesolve have no effect: `numeric::odesolve2` ignores these options.

Note Without `RememberLast`, the function `Y` remembers all values it has computed. When calling `Y(t)`, it searches its remember table for the time T closest to t and integrates from T to t using the previously computed $Y(T)$ as initial value. This reduces the costs of a call considerably, if `Y` has to be evaluated many times (e.g., when plotting). However, the result $Y(t)$ depends on the history of the MuPAD session! This can lead to unexpected side effects. See "Example 3" on page 19-228. We recommend to call Y only with a monotonically increasing (or decreasing) sequence of values t starting from t_0. Further, the function must be re-initialized whenever `DIGITS` is increased. See "Example 4" on page 19-230.

After the command `setuserinfo(Y,1)`, information on the current integration interval is displayed by each call to `Y`.

Environment Interactions

The function returned by `numeric::odesolve2` is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Without `RememberLast`, the function returned by `numeric::odesolve2` uses option remember.

Examples

Example 1

The numerical solution of the initial value problem y'=t*sin(y)$y' = t\sin(y)$, $y(0) = 2$ is represented by the following function $Y = [y]$:

```
f := (t, Y) -> [t*sin(Y[1])]:
```

Alternatively, the utility function numeric::ode2vectorfield can be used to generate the input parameters in a more intuitive way:

```
[f, t0, Y0] := [numeric::ode2vectorfield({y'(t) = t*sin(y(t)), y(0) = 2},
[y(t)])]['proc f(t, Y) ... end', 0, [2]]
```

```
[proc f(t, Y) ... end, 0, [2]]
```

```
Y := numeric::odesolve2(f, t0, Y0)'proc Y(t) ... end'
```

proc Y(t) ... end

The procedure `Y` starts the numerical integration when called with a numerical argument:
Y(-2), Y(0), Y(0.1), Y(PI + sqrt(2))[2.968232567], [2.0], [2.004541745], [3.141552691]

[2.968232567], [2.0], [2.004541745], [3.141552691]

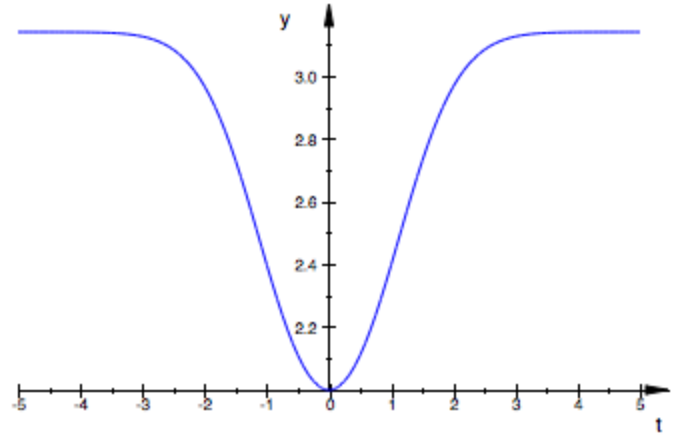
Calling `Y` with a symbolic argument yields a symbolic call:
Y(t), Y(t + 5), Y(t^2 - 4)Y(t), Y(t + 5), Y(t^2 - 4)

$Y(t),\ Y(t+5),\ Y(t^2-4)$

eval(subs(%, t = PI))[3.13235701], [3.141592654], [3.141592611]

[3.13235701], [3.141592654], [3.141592611]

The numerical solution can be plotted. Note that `Y(t)` returns a list, so we plot the list element `Y(t)[1]`:
plotfunc2d(Y(t)[1], t = -5..5):



delete f, t0, Y0, Y:

Example 2

We consider the differential equation y"=y^2 $y'' = y^2$ with initial conditions $y(0) = 0$, y'(0)=1 $y'(0) = 1$. The second order equation is converted to a first order system for Y=[Y_1, Y_2]=[y, y'] $Y = [Y_1, Y_2] = [y, y']$:

Y_1'=Y_2, Y_2'=Y_1^2, Y_1(0)=0, Y_2(0)=1

$Y_1' = Y_2,\ Y_2' = Y_1^2,\ Y_1(0) = 0,\ Y_2(0) = 1$

f := (t, Y) -> [Y[2], Y[1]^2]: t0 := 0: Y0 := [0, 1]: Y := numeric::odesolve2(f, t0, Y0): Y(1), Y(PI)[1.087473533, 1.362851121], [1274.867469, 37166.52262]

[1.087473533, 1.362851121], [1274.867469, 37166.52262]

delete f, t0, Y0, Y:

Example 3

We demonstrate a pitfall with the remember mechanism built into the functions returned by `numeric::odesolve2`. Consider the initial value problem y'=t*sin(y) $y' = t\sin(y)$, $y(0) = 2$:
DIGITS := 5: Y := numeric::odesolve2((t, Y) -> [t*sin(Y[1])], 0, [2]):

The following result is computed and stored in the remember table of `Y`:
setuserinfo(Y, 1): Y(8.0)Info: integrating from t0=0 to t=8.0 using Y(t0)=[2] [3.1416]

[3.1416]

The following value `Y(4.1)` is obtained using the previously computed `Y(8.0)`, integrating backward in time from $t = 8.0$ to $t = 4.1$:
Y(4.1)Info: integrating from t0=8.0 to t=4.1 using Y(t0)=[3.1416] [0.0001802]

[0.0001802]

```
Y := subsop(Y, 5 = NIL):
```

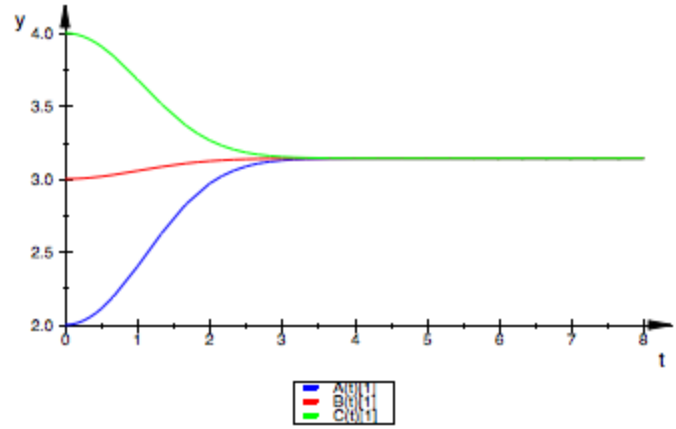
The direct integration from the initial time $t_0 = 0$ to $t = 4.1$ yields a more accurate result than the previous computation:

```
Y(4.1)Info: integrating from t0=0 to t=4.1 using Y(t0)=[2] [3.1413]
```

```
[3.1413]
```

The reason for this phenomenon becomes obvious, when the solution of the ode is computed for various initial values $Y(0) = 2, 3, 4$:

```
A := numeric::odesolve2((t, Y) -> [t*sin(Y[1])], 0, [2]): B
:= numeric::odesolve2((t, Y) -> [t*sin(Y[1])], 0, [3]): C :=
numeric::odesolve2((t, Y) -> [t*sin(Y[1])], 0, [4]): plotfunc2d(A(t)[1],
B(t)[1], C(t)[1], t = 0..8, Mesh = 25):
```



In fact, all solutions with initial values $Y(0)$ in the interval $[0, 2\pi]$ approach the same attracting point $Y(\infty) = \pi$. While numerical integration forward in time is a very stable process, it is virtually impossible to recover the correct solution curve integrating backward in time starting at a point close to the attractor.

```
setuserinfo(Y, 0): delete DIGITS, Y, A, B, C:
```

Example 4

We consider the system

x'=x+y, y'=x-y, x(0)=1, y(0)= sqrt(-1)

$$x' = x + y,\ y' = x - y,\ x(0) = 1,\ y(0) = \sqrt{-1}$$

```
f := (t, Y) -> [Y[1] + Y[2], Y[1] - Y[2]]: Y := numeric::odesolve2(f, 0, [1, I]):
DIGITS := 5: Y(1)[3.5465 + 1.3683*I, 1.3683 + 0.80988*I]
```

```
[3.5465 + 1.3683 i, 1.3683 + 0.80988 i]
```

Increasing DIGITS does not lead to a more accurate result because of the remember mechanism:

```
DIGITS := 15: Y(1)[3.54648112716477 + 1.36829878277279*I,
1.36829878277279 + 0.809883561619181*I]
```

```
[3.54648112716477 + 1.36829878277279 i, 1.36829878277279 + 0.809883561619181 i]
```

This is the previous value computed with 5 digits, printed with 15 digits. Indeed, only 5 digits are correct. For getting a result that is accurate to full precision, one has to erase the remember table via `Y:=subsop(Y,5=NIL)`. Alternatively, one may create a new numerical solution with a fresh (empty) remember table:

```
Y := numeric::odesolve2(f, 0, [1, I]): Y(1)[3.54648242861716 +
1.36829887200859*I, 1.36829887200859 + 0.80988468459998*I]
```

```
[3.54648242861716 + 1.36829887200859 i, 1.36829887200859 + 0.80988468459998 i]
```

delete f, Y, DIGITS:

Example 5

We demonstrate the effect of the option `RememberLast`. We consider the ODE

y'(t)=-y+sin(t), y(0)= 1

$y'(t) = -y + \sin(t),\ y(0) = 1$

f := (t, Y) -> [-Y[1] + sin(t)]: Y := numeric::odesolve2(f, 0, [1]): Z := numeric::odesolve2(f, 0, [1], RememberLast):

After many calls of `Y`, its remember table has grown large. In each call, searching the remember table for input parameters close to the present time value becomes expensive. Created with `RememberLast`, the procedure `Z` does not remember all its previously computed values apart from the last one. Consequently, it becomes faster than `Y`:
time(for i from 1 to 1000 do Y(i/100) end)*msec, time(for i from 1 to 1000 do Z(i/100) end)*msec 11592.724*msec, 4352.272*msec

11592.724 msec, 4352.272 msec

Apart from the efficiency, the values returned by `Y` and `Z` coincide:
Y(10.5), Z(10.5)[-0.2020381113], [-0.2020381113]

[-0.2020381113], [-0.2020381113]

delete f, Y, Z, i:

Parameters

f

A procedure representing the vector field of the dynamical system

t_0

A numerical real value for the initial time

Y_0

A list or 1-dimensional array of numerical values representing the initial value

method

One of the Runge-Kutta schemes listed below.

Option, specified as `GAUSS = s`

Name of the Runge-Kutta scheme. For details, see the documentation of numeric::odesolve.

RememberLast

Modifies the internal remember mechanism: the procedure returned by `numeric::odesolve2` does not remember the results of all previous calls, but only the result of the last call.

Without this option, the procedure returned by `numeric::odesolve2` employs option remember to remember the results of all preceding calls. If the function is called very often (hundreds or thousands of times), the remember table grows large and searching this table for entries close to the current time value may become costly. With `RememberLast`, the procedure returned by `numeric::odesolve2` does not use option remember to remember *all* previous results but implements a very simple and inexpensive mechanism to remember only the result of the very last call.

This option is highly recommended when the numerical procedure returned by `numeric::odesolve2` is to be called often (hundreds of thousands of times) with monotonically increasing or decreasing time values. Cf. “Example 5” on page 19-230.

RelativeError

Option, specified as `RelativeError = rtol`

Forces internal numerical Runge-Kutta steps to use step sizes with relative local discretization errors below `rtol`. This tolerance must be a positive numerical real value not smaller than

10^(-DIGITS)  . The default tolerance is `RelativeError = 10^(-DIGITS)`. See the help page of numeric::odesolve for further details.

AbsoluteError

Option, specified as `AbsoluteError = atol`

Forces internal numerical Runge-Kutta steps to use step sizes with absolute local discretization errors below `atol`. This tolerance must be a non-negative numerical real value. The default tolerance is `AbsoluteError = 10^(-10*DIGITS)`. See the help page of numeric::odesolve for further details.

Stepsize

Option, specified as `Stepsize = h`

Switches off the internal error control and uses a Runge-Kutta iteration with constant step size `h`. `h` must be a positive real value. See the help page of numeric::odesolve for further details.

MaxStepsize

Option, specified as `MaxStepsize = hmax`

Restricts adaptive step sizes to values not larger than h_{max}; h_{max} must be a positive numerical value. See the help page of numeric::odesolve for further details.

Return Values

Procedure.

Concepts

- “Solve Equations Numerically”

numeric::odesolveGeometric

Purpose

Numerical solution of an ordinary differential equation on a homogeneous manifold

Syntax

```
numeric::odesolveGeometric(f, t0 .. t, Y0, <LieGroupAction =
LAMBDA>, <method>, <RelativeError = tol>, <Stepsize
= h>, <Alldata = n>)
numeric::odesolveGeometric(t0 .. t, f, Y0, <LieGroupAction =
LAMBDA>, <method>, <RelativeError = tol>, <Stepsize
= h>, <Alldata = n>)
```

Description

`numeric::odesolveGeometric(f, t_0..t, Y_0 )` approximates the solution of dY(t)/dt=f(t, Y(t))*Y(t)$\frac{dY(t)}{dt} = f(t, Y(t))\ Y(t)$, where $f(t, Y(t))$ returns n n matrices and Y in C_^(n times m)$Y \in \mathbb{C}^{n \times m}$.

`numeric::odesolveGeometric` is a “geometrical integrator” for ordinary differential equations on homogeneous manifolds embedded in the space of n m matrices.

The call `numeric::odesolveGeometric(f, t_0..t, Y_0 )` returns a numerical approximation of the solution $Y(t)$ of the first order differential equation (dynamical system)

dY(t)/dt =f(t, Y(t))*Y(t), Y(t_0)=Y_0

$$\frac{dY(t)}{dt} = f(t, Y(t))\ Y(t),\ Y(t_0) = Y_0$$

with t, t_0 in R_$t, t_0 \in \mathbb{R}$. Here, $Y(t)$ is a curve of n m matrices (or vectors in R_^n$\mathbb{R}^n$ or C_^n$\mathbb{C}^n$). The function f must produce n n matrices as return values.

The following geometrical feature is preserved by the numerical solution: If the matrices produced by f lie in some Lie subalgebra g of the n n matrices, then, within the numerical working precision, the approximation produced by `numeric::odesolveGeometric` stays on the homogeneous manifold ImageSet(m*Y_0, m in G)$\{m\ Y_0 \mid m \in G\}$, where G is the matrix Lie group of g.

As an introductory example, consider the ODE dY/dt=f(t, Y)*Y$\frac{dY}{dt} = f(t, Y)\,Y$, where Y is a vector in R_^n$\mathbb{R}^n$ and `f` produces skew symmetric matrices. The solution lies on the orbit of the orthogonal group $SO(n)$ generated by the skew symmetric matrices through the inital point Y_0 in R_^n$Y_0 \in \mathbb{R}^n$. Here, $SO(n)$ acts on R_^n$\mathbb{R}^n$ by standard matrix multiplication. The homogeneous manifold given by the orbit of $SO(n)$ through Y_0 is the sphere

ImageSet(G*Y_0, G in SO(n))= SubSet(Y, R_^n, linalg::scalarProduct(Y, Y) = linalg::scalarProduct(Y_0, Y_0))

$$\{G\,Y_0 \mid G \in SO(n)\} = \{Y \in \mathbb{R}^n \mid \langle Y, Y\rangle = \langle Y_0, Y_0\rangle\}$$

Using standard numerical schemes, the numerical solution drifts away from this manifold in the course of the integration. The geometrical "Lie group" integrator `numeric::odesolveGeometric`, however, produces a numerical solution that stays on this manifold, preserving the invariants of the group action. In this case, the invariant linalg::scalarProduct(Y, Y)$\langle Y, Y\rangle$ is preserved numerically. See "Example 1" on page 19-240.

With $Y(t) = G(t)Y_0$, the matrix ODE

dG(t)/dt=f(t, G(t)*Y_0)*G(t), G(t_0) = 1[n,n]

$$\frac{dG(t)}{dt} = f(t, G(t)\,Y_0)\,G(t),\ G(t_0) = 1_{n,n}$$

is solved on the space C_^(n times n)$\mathbb{C}^{n\times n}$ of the complex n n matrices ($1_{n,n}$ is the identity matrix). Following Munthe-Kaas [1], the ansatz G(t)=exp(u(t))$G(t) = e^{u(t)}$ reduces a time step for the ode above to the solution of the matrix ODE

du/dt=dexpinv(u, f) =f- 1/2*[u, f]+ 1/12*[u, [u, f]]+Symbol::cdots, u(t_0) = 0

$$\frac{du}{dt} = \mathrm{dexpinv}(u, f) = f - \frac{[u, f]}{2} + \frac{[u, [u, f]]}{12} + \cdots,\ u(t_0) = 0$$

where f=f(t, exp(u(t))*Y_0)$f = f\left(t, e^{u(t)}\, Y_0\right)$ and [u, f] = uf - fu is the commutator on the Lie algebra of n n matrices. In each step, the ODE for u is solved numerically in a classical way by the Runge-Kutta scheme specified by the parameter `method`. Finally, `numeric::odesolveGeometric` performs the time step t_0 --> t_0+h$t_0 \to t_0 + h$ by computing Y(t_0+h)=G(t_0+h)*Y_0=exp(u(h))*Y_0$Y(t_0 + h) = G(t_0 + h)\, Y_0 = e^{u(h)}\, Y_0$.

If the matrices produced by $f(t, Y)$ lie in a Lie subalgebra g of the n n matrices, then the numerical solution u also lies in g. The matrix G=exp(u)$G = e^u$ is an element of the corresponding Lie group, and $Y = GY_0$ lies on the orbit of the Lie group through the initial value Y_0. Thus, the geometrical invariants of the homogeneous manifold are preserved in the course of the numerical integration.

The input data t_0 and t must not contain symbolic objects which cannot be converted to floating point values via float. Numerical expressions such as exp(PI)e^{π}, sqrt(2)$\sqrt{2}$ etc. are accepted.

The initial condition Y_0 defines the space in which the homogeneous manifold containing the solution is embedded.

If Y_0 is a list with n entries or a 1-dimensional array `array(1..n)`, then the solution $Y(t)$ consists of vectors from a submanifold of R_^n$\mathbb{R}^n$ or C_^n$\mathbb{C}^n$, respectively.

If Y_0 is specified as a 2-dimensional `array(1..n, 1..m)` or as a matrix of the corresponding dimension generated by the function matrix, then the solution $Y(t)$ consists of matrices from a submanifold of the space C_^(n times m)$\mathbb{C}^{n \times m}$ of n m matrices.

Internally, 2-dimensional n m arrays are used to represent the points on the manifold where m = 1 for vectors in R_^n$\mathbb{R}^n$ or C_^n$\mathbb{C}^n$. It is recommended to specify Y_0 in the form `array(1..n, 1..m)` in order to avoid the overhead of internal conversions.

The "vector field" `f` defining the dynamical system dY/dt=f(t, Y)*Y$\frac{dY}{dt} = f(t, Y)\, Y$ must be represented by a procedure with two input parameters: the scalar time t and the matrix or vector Y. Internally, f

is called with real floating-point values *t* and matrices/vectors *Y* of the same domain type as the initial condition Y_0.

The procedure `f` has to return an *n* *n* matrix either as an `array(1..n, 1..n)` or as a corresponding matrix object of category Cat::Matrix (generated by the function matrix).

It is recommended that the procedure returns an array of the type `array(1..n, 1..n)`. This avoids the overhead of internal conversions.

The return value of `f` may contain numerical expressions such as PI, sqrt(2)$\sqrt{2}$ etc. However, all values must be convertible to real or complex floating point numbers by float.

Autonomous systems, where *f*(*t*, *Y*) does not depend on *t*, must be represented by a procedure with two arguments `t` and `Y`, too.

The optional arguments `method`, `RelativeError = tol`, and `Stepsize = h` determine how the ODE du/dt=dexpinv(u, f)$\frac{du}{dt} = \mathrm{dexpinv}(u, f)$ is solved. They correspond to the methods of the classical ODE solver numeric::odesolve.

The numerical precision is controlled by the global variable `DIGITS`: an adaptive control of the step size keeps local relative discretization errors below tol=10^-DIGITS$\mathrm{tol} = \frac{1}{10^{\mathrm{DIGITS}}}$, unless a different tolerance is specified via the option `RelativeError = tol`. The error control may be switched off by specifying a fixed `Stepsize = h`.

Note Only local errors are controlled by the adaptive mechanism. No control of the global error is provided!

With `Y := t -> numeric::odesolveGeometric(f, t_0..t, Y_0)`, the numerical solution can be repesented by a MuPAD function: the call `Y(t)` will start the numerical integration from t_0 to *t*.

Classical integration preserves the geometrical invariants up to the relative precision of the solution whereas the geometrical integrator preserves the invariants independent of *tol* up to the working precision

set by DIGITS: departure from the homogeneous manifold is a pure roundoff effect.

`numeric::odesolveGeometric` is useful when a tolerance *tol* much largerthan 10^(-DIGITS) is specified by `RelativeError = tol`. For small tolerances, you may consider to use the classical solver numeric::odesolve instead.

Since classical integration is significantly faster, larger values of DIGITS and smaller tolerances for the discretization error may be used in numeric::odesolve. Depending on the concrete problem, this may lead to better results than produced by `numeric::odesolveGeometric`.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We consider the initial value problem

dY/dt=matrix([[(J_2-J_3)*Y[2]*Y[3]], [(J_3-J_1)*Y[3]*Y[1]], [(J_1-J_2)*Y[1]*Y[2]]]), Y(0) = matrix([1,1,1])

$$\frac{dY}{dt} = \begin{pmatrix} (J_2 - J_3)\, Y_2\, Y_3 \\ (J_3 - J_1)\, Y_3\, Y_1 \\ (J_1 - J_2)\, Y_1\, Y_2 \end{pmatrix}, \quad Y(0) = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}$$

for Y=[Y[1], Y[2], Y[3]] in R_^3 $Y = [Y_1, Y_2, Y_3] \in \mathbb{R}^3$ with fixed parameters J_1=1/2 $J_1 = \frac{1}{2}$, $J_2 = 1$, $J_3 = 2$. Writing this ODE as

dY/dt = matrix([[0, -J_3*Y[3], J_2*Y[2]], [J_3*Y[3], 0, -J_1*Y[1]], [-J_2*Y[2], J_1*Y[1], 0]]) * matrix([Y[1], Y[2], Y[3]]) = f_1(t, Y)*Y

$$\frac{dY}{dt} = \begin{pmatrix} 0 & -J_3\, Y_3 & J_2\, Y_2 \\ J_3\, Y_3 & 0 & -J_1\, Y_1 \\ -J_2\, Y_2 & J_1\, Y_1 & 0 \end{pmatrix} \begin{pmatrix} Y_1 \\ Y_2 \\ Y_3 \end{pmatrix} = f_1(t, Y)\, Y$$

it is clear that the solution is restricted to the orbit of the orthogonal group $SO(3)$ through the initial point (f_1 produces skew symmetric matrices). The invariant of this action is H[1](Y)=linalg::scalarProduct(Y, Y)=Y[1]^2+Y[2]^2+Y[3]^2$H_1(Y) = \langle Y,\ Y\rangle = {Y_1}^2 + {Y_2}^2 + {Y_3}^2$, i.e., the solution is restricted to a sphere. Writing the ODE as

dY/dt= matrix([[0, J_2*Y[3], -J_3*Y[2]], [-J_1*Y[3], 0, J_3*Y[1]], [J_1*Y[2], -J_2*Y[1], 0]]) * matrix([Y[1], Y[2], Y[3]]) = f_2(t, Y)*Y

$$\frac{dY}{dt} = \begin{pmatrix} 0 & J_2\,Y_3 & -J_3\,Y_2 \\ -J_1\,Y_3 & 0 & J_3\,Y_1 \\ J_1\,Y_2 & -J_2\,Y_1 & 0 \end{pmatrix} \begin{pmatrix} Y_1 \\ Y_2 \\ Y_3 \end{pmatrix} = f_2(t,\ Y)\ Y$$

"= matrix([[0, Y[3], -Y[2]], [-Y[3], 0, Y[1]], [Y[2], -Y[1], 0]]) * matrix([[J_1, 0, 0], [0, J_2, 0], [0, 0, J_3]]) * matrix([Y[1], Y[2], Y[3]])

$$= \begin{pmatrix} 0 & Y_3 & -Y_2 \\ -Y_3 & 0 & Y_1 \\ Y_2 & -Y_1 & 0 \end{pmatrix} \begin{pmatrix} J_1 & 0 & 0 \\ 0 & J_2 & 0 \\ 0 & 0 & J_3 \end{pmatrix} \begin{pmatrix} Y_1 \\ Y_2 \\ Y_3 \end{pmatrix}$$

it is clear that the solution is also restricted to the orbit of the "J-orthogonal" group $SO(J, 3)$ through the initial point. This group consists of matrices G satisfying $G^T J G = J$, where $J = diag(J_1, J_2, J_3)$. The invariant of this group action is H[2](Y)=linalg::scalarProduct(Y, J*Y) =J_1*Y[1]^2+J_2*Y[2]^2+J_3*Y[3]^2$H_2(Y) = \langle Y,\ J\,Y\rangle = J_1\,{Y_1}^2 + J_2\,{Y_2}^2 + J_3\,{Y_3}^2$, i.e., the solution is restricted to an ellipsoid.

We consider the first representation and compute a numerical solution that is restricted to a sphere:
f1 := proc(t, Y) begin array(1..3, 1..3, [[0 , -J3*Y[3], J2*Y[2]], [J3*Y[3], 0 , -J1*Y[1]], [-J2*Y[2], J1*Y[1], 0]]) end_proc: J1 := 1/2: J2 := 1: J3 := 2: tol := 10^(-2): Gsolve:= (f, t0_t, Y0) -> numeric::odesolveGeometric(f, t0_t, Y0, RelativeError = tol): Y(0) := [1.0, 1.0, 1.0]; Y(1) := Gsolve(f1, 0..1, Y(0)); Y(2) := Gsolve(f1, 1..2, Y(1)); Y(3) := Gsolve(f1, 2..3, Y(2)); Y(4) := Gsolve(f1, 3..4, Y(3)); Y(5) := Gsolve(f1, 4..5, Y(4))[1.0, 1.0, 1.0]

i = 1..53.045480534e-14, -2.691596945e-14, 4.011374566e-14, 3.491859579e-13, 2.851746617e-13

$3.045480534\ 10^{-14}, -2.691596945\ 10^{-14}, 4.011374566\ 10^{-14}, 3.491859579\ 10^{-13}, 2.851746617\ 10$

The invariant H_2 is only preserved within the relative precision of the solution set by the option `RelativeError = tol`:
H2 := Y -> J1*Y[1]^2 + J2*Y[2]^2 + J3*Y[3]^2: H2(Y(i)) - H2(Y(0)) $
i = 1..5-0.00003216929769, -0.00001480619998, -0.0002478937317, -0.0002651787298, -0.0002541517488

-0.00003216929769, -0.00001480619998, -0.0002478937317, -0.0002651787298, -0.0002541

Now, we solve the ODE using the second representation:
f2 := proc(t, Y) begin array(1..3, 1..3, [[0 , J2*Y[3], -J3*Y[2]], [-J1*Y[3], 0 , J3*Y[1]], [J1*Y[2], -J2*Y[1], 0]]) end_proc: Y(0) := [1.0, 1.0, 1.0]; Y(1) := Gsolve(f2, 0..1, Y(0)); Y(2) := Gsolve(f2, 1..2, Y(1)); Y(3) := Gsolve(f2, 2..3, Y(2)); Y(4) := Gsolve(f2, 3..4, Y(3)); Y(5) := Gsolve(f2, 4..5, Y(4))[1.0, 1.0, 1.0]

[1.0, 1.0, 1.0]
[-0.1234661822, 1.573904531, 0.7124614294]

[-0.1234661822, 1.573904531, 0.7124614294]
[-1.188842584, 0.6165012417, 1.098465492]

[-1.188842584, 0.6165012417, 1.098465492]
[-0.7810696492, -1.258800682, 0.8973254548]

[-0.7810696492, -1.258800682, 0.8973254548]
[0.3534089311, -1.520647212, 0.7500610376]

[1.28178089, -0.1880404787, 1.149599855]

Now, the invariant H_2 is preserved to working precision, whilst H_1 is only preserved to the tolerance specified by `RelativeError = tol`:
H2(Y(i)) - H2(Y(0)) $ i = 1..52.70894418e-14, 5.287437155e-15, 2.071884331e-13, 1.704608676e-13, 2.268046861e-13

$2.70894418\ 10^{-14}$, $5.287437155\ 10^{-15}$, $2.071884331\ 10^{-13}$, $1.704608676\ 10^{-13}$, $2.268046861\ 1$
H1(Y(i)) - H1(Y(0)) $ i = 1..50.0000206606336, 0.00004690748333, -0.0001580733145, -0.0001426238818, -0.0000987012679

0.0000206606336, 0.00004690748333, -0.0001580733145, -0.0001426238818, -0.00009870126

delete J1, J2, J3, Gsolve, f1, f2, Y, H1, H2:

Example 2

We consider the "Toda lattice equations"

da[i]/dt=a[i]*(b[i]-b[(i+1)]), i in {1,dots,n-1}

$$\frac{da_i}{dt} = a_i (b_i - b_{i+1}),\ i \in \{1, \ldots, n-1\}$$

db[i]/dt = 2*(a[i-1]^2 - a[i]^2), i in {1,dots,n}

$$\frac{db_i}{dt} = 2\left(a_{i-1}^{\,2} - a_i^{\,2}\right),\ i \in \{1, \ldots, n\}$$

with $a_0 = a_n = 0$. Introducing the tridiagonal n n matrices

Y=matrix([[b[1], a[1], ", "], [a[1], dots, dots, "], [", dots, dots, a[(n-1)]], [", ", a[(n-1)], b[n]]]), f(Y) = matrix([[0, -a[1], ", "], [a[1], dots, dots, "], [", dots, dots, -a[(n-1)]], [", ", a[(n-1)], 0]])

$$Y = \begin{pmatrix} b_1 & a_1 & & \\ a_1 & \ddots & \ddots & \\ & \ddots & \ddots & a_{n-1} \\ & & a_{n-1} & b_n \end{pmatrix},\ f(Y) = \begin{pmatrix} 0 & -a_1 & & \\ a_1 & \ddots & \ddots & \\ & \ddots & \ddots & -a_{n-1} \\ & & a_{n-1} & 0 \end{pmatrix}$$

these equations can be encoded by the matrix ODE dY/dt=f(Y)*Y-Y*f(Y) $\frac{dY}{dt} = f(Y)\,Y - Y\,f(Y)$. The solution $Y(t)$ is known to be "isospectral", i.e., the eigenvalues of $Y(t)$ do not depend on the time paramter t. As mentioned in the description of the option `LieGroupAction`, the solution of this type of matrix ODE is given by the group action $Y(t) = G(t)Y(0)G(t)^{-1} = G(t)Y(0)G(t)^T$, where $G(t)$ are orthogonal matrices (note that $f(Y)$ is skew symmetric). The eigenvalues of the matrices $Y(t)$ are invariants of the group action.

The exact dynamics also preserves the tridiagonal form of the matrices. The numerical dynamics, however, fills in further elements. The following vector field *f* ignores alle elements outside the central bands:
f := proc(t, Y) local i, r; begin r := array(1..n, 1..n, [[0 $ n] $ n]); for i from 1 to n - 1 do r[i + 1, i] := Y[i, i + 1]; r[i, i + 1] := -Y[i, i + 1]; end_for; return(r) end_proc:

In the following, the initial value *Y*(0) is specified by a matrix generated by the function matrix. Consequently, both arguments *G* and *Y* are passed to the Lie group action `LAMBDA` as corresponding matrices. They can be multiplied by the multiplication operator `*`:
LAMBDA:= proc(G, Y) begin G*Y*(G::dom::transpose(G)) end_proc:

We define the initial value:
n := 3: Y(0) := matrix(n, n, [1, 1, 1], Banded)matrix([[1, 1, 0], [1, 1, 1], [0, 1, 1]])

$$\begin{pmatrix} 1 & 1 & 0 \\ 1 & 1 & 1 \\ 0 & 1 & 1 \end{pmatrix}$$

Now, the dynamics is integrated from $t = 0$ to $t = 1$:
tol := 10^(-4): Y(1) := numeric::odesolveGeometric(f, 0..1, Y(0), LieGroupAction = LAMBDA, RelativeError = tol)matrix([[-0.256354686, 0.4591148565, -1.716329601e-14], [0.4591148565, 1.0, 0.4591148565], [-1.716329601e-14, 0.4591148565, 2.256354686]])

$$\begin{pmatrix} -0.256354686 & 0.4591148565 & -1.716329601\,10^{-14} \\ 0.4591148565 & 1.0 & 0.4591148565 \\ -1.716329601\,10^{-14} & 0.4591148565 & 2.256354686 \end{pmatrix}$$

The invariants of the dynamics are the eigenvalues of the matrices $Y(t)$. They are preserved numerically:
numeric::eigenvalues(Y(0)) = numeric::eigenvalues(Y(1))[2.414213562, 1.0, -0.4142135624] = [2.414213562, 1.0, -0.4142135624]

$$[2.414213562,\ 1.0,\ -0.4142135624] = [2.414213562,\ 1.0,\ -0.4142135624]$$

For comparison, we also solve the Toda lattice equations by classical numerics using numeric::odesolve. The system is encoded by a vector $Y = [b_1, \ldots, b_n, a_1, \ldots, a_{n-1}]$ in R_^(2*n-1)$\mathbb{R}^{2n-1}$:
f := proc(t, Y) local a, b, i; begin b := [Y[i] $ i = 1..n]; a := [Y[n + i] $ i = 1..n-1]; [-2*a[1]^2, // = d/dt b[1] 2*(a[i-1]^2 - a[i]^2) $ i = 2..n-1, // = d/dt b[i] 2*a[n-1]^2, // = d/dt b[n] a[i]*(b[i] - b[i+1]) $ i = 1..n-1 // = d/dt a[i]] end_proc: solution := numeric::odesolve(f, 0..1, [1 $ 2*n - 1], RelativeError = tol);[-0.2563650696, 1.0, 2.25636507, 0.459099923, 0.459099923]

```
[-0.2563650696, 1.0, 2.25636507, 0.459099923, 0.459099923]
```

The invariants are only preserved up to the precision of the solution determined by the tolerance set via `RelativeError = tol`:
Y(1) := array(1..n, 1..n, [[0 $ n] $ n]): for i from 1 to n do Y(1)[i, i] := solution[i]; end_for: for i from 1 to n-1 do Y(1)[i, i + 1] := solution[n + i]; Y(1)[i + 1, i] := solution[n + i]; end_for: Y(1)array(1..3, 1..3, [[-0.2563650696, 0.459099923, 0], [0.459099923, 1.0, 0.459099923], [0, 0.459099923, 2.25636507]])

$$\begin{pmatrix} -0.2563650696 & 0.459099923 & 0 \\ 0.459099923 & 1.0 & 0.459099923 \\ 0 & 0.459099923 & 2.25636507 \end{pmatrix}$$

numeric::eigenvalues(Y(1))[2.414213091, 1.0, -0.4142130909]

```
[2.414213091, 1.0, -0.4142130909]
```

Comparing these data with the previously computed eigenvalues of the initial condition $Y(0)$, one sees that the invariants are not preserved numerically to the working precision determined by DIGITS.
delete f, LAMBDA, n, Y, tol, solution, i:

Parameters

f

A procedure accepting two parameters `(t, Y)`

t_0

A numerical real value for the initial time

t

A numerical real value (the “time”)

Y_0

The initial condition: a list, a 1-dimensional `array(1..n)`, a 2-dimensional `array(1..n, 1..m)`, or an n m matrix of category Cat::Matrix with numerical entries

Options

LieGroupAction

Option, specified as `LieGroupAction = LAMBDA`

The procedure `LAMBDA = proc(G, Y) ... end_proc` defines the action of the group element `G` (an n n matrix) on the point Y on the homogeneous manifold (an n m matrix or an n dimensional vector). This procedure must return a corresponding point (a matrix or a vector).

The default action is the usual matrix multiplication (G, Y) -> G*Y($G, Y \to G\,Y$.

With this option, the default group action `LAMBDA`: (G, Y) -> G*Y($G, Y \to G\,Y$ of the n n matrices G acting on the n m matrices or n dimensional vectors `Y` by left multiplication may be replaced by other group actions.

As a group action, the procedure `LAMBDA` must satisfy $LAMBDA(1_{n,}$ $_{n}$, $Y) = Y$ and

LAMBDA(G_2, LAMBDA(G_1, Y)) = LAMBDA(G_2*G_1, Y)

$\mathrm{LAMBDA}(G_2, \mathrm{LAMBDA}(G_1, Y)) = \mathrm{LAMBDA}(G_2\ G_1, Y)$

`numeric::odesolveGeometric` computes the solution of the matrix ODE

dG(t)/dt=f(t, LAMBDA(G(t),Y_0))*G(t), G(t_0) = 1[n,n]

$\frac{dG(t)}{dt} = f(t, \text{LAMBDA}(G(t), Y_0))\, G(t),\ G(t_0) = 1_{n,n}$

On the space C_^(n times n)$\mathbb{C}^{n\times n}$ of the n n matrices and returns $Y(t) = LAMBDA(G(t), Y_0)$.

For the standard group action $LAMBDA(G, Y) = GY$, this is the solution of the ODE dY/dt=f(t, Y)*Y$\frac{dY}{dt} = f(t, Y)\, Y$.

For homogeneous manifolds embedded in the n n matrices, the group action $LAMBDA(G, Y) = GYG^{-1}$ may be considered. For this action, the curve $Y(t) = LAMBDA(G(t), Y_0)$ returned by `numeric::odesolveGeometric` is the solution of the ODE dY/dt=f(t, Y)*Y-Y*f(t, Y)$\frac{dY}{dt} = f(t, Y)\, Y - Y\, f(t, Y)$. Cf. “Example 2” on page 19-244.

`LAMBDA(G, Y)` is called with n m matrices or n dimensional vectors `Y` of the same domain type as the initial condition Y_0. If Y_0 is a matrix generated by the function matrix, then also the n n matrix G is passed to `LAMBDA` as such a matrix object. In all other cases, G is passed as a 2-dimensional `array(1..n, 1..n)`.

The procedure `LAMBDA` should return a 2-dimensional `array(1..n, 1..m)` or a corresponding matrix of category Cat::Matrix.

If the initial condition Y_0 is specified by a list or a 1-dimensional `array(1..n)`, `LAMBDA` may also return a corresponding list or array.

Internally, the return value of `LAMBDA` is converted to a 2-dimensional `array(1..n, 1..m)` where $m = 1$ if a list or a 1-dimensional array is returned.

It is recommended that `LAMBDA` returns a 2-dimensional `array(1..n, 1..m)` in order to avoid the overhead of internal conversions.

RelativeError

Option, specified as `RelativeError = tol`

Forces internal numerical Runge-Kutta steps to use step sizes with local discretization errors below `tol`. This tolerance must be a numerical real value ">=10^-DIGITS $\geq \frac{1}{10^{DIGITS}}$. The default tolerance is 10^(-DIGITS) $\frac{1}{10^{DIGITS}}$.

The internal control mechanism estimates the local relative discretization error of a Runge-Kutta step and adjusts the step size adaptively to keep this error below `tol`.

The default setting of tol=10^-DIGITS $tol = \frac{1}{10^{DIGITS}}$ ensures that the local discretization errors are of the same order of magnitude as numerical roundoff.

Usually there is no need to use this option to change this setting. However, occasionally the numerical evaluation of the Runge-Kutta steps may be ill-conditioned or step sizes are so small that the time parameter cannot be incremented by the step size within working precision. In such a case, this option may be used to bound the local discretization error by *tol* and use a higher working precision given by DIGITS.

Only real numerical values tol >= 10^-DIGITS $tol \geq \frac{1}{10^{DIGITS}}$ are accepted.

Note Usually, the global error of the numeric approximation returned by `numeric::odesolveGeometric` is larger than the local errors bounded by `tol`. Although the result is displayed with DIGITS decimal places, one should not expect that all of them are correct. The relative precision of the final result is `tol` at best!

Stepsize

Option, specified as `Stepsize = h`

Switches off the internal error control and uses a Runge-Kutta iteration with constant step size `h`. `h` must be a numerical real value.

By default, `numeric::odesolveGeometric` uses an adaptive step size control mechanism in the numerical iteration. The option `Stepsize = h` switches off this adaptive mechanism and uses the Runge-Kutta method specified by `method` (or the default method `DOPRI78`) with constant step size `h`.

A final step with smaller step size is used to match the end t of the integration interval t_0..t$t_0..t$, if (t-t_0)/h$\frac{t-t_0}{h}$ is not an integer.

Note With this option, there is no automatic error control! Depending on the problem and on the order of the method, the result may be a poor numerical approximation of the exact solution.

There is usually no need to invoke this option. However, occasionally the builtin adaptive error control mechanism may fail when integrating close to a singularity. In such a case, this option may be used to customize a control mechanism for the global error by using different step sizes and investigating the convergence of the corresponding results.

Alldata

Option, specified as `Alldata = n`

With this option, `numeric::odesolveGeometric` returns a list of numerical mesh points $[[t_0, Y_0], [t_1, Y_1], \ldots, [t, Y(t)]]$ generated by the internal Runge-Kutta iteration.

The integer n controls the size of the output list. For $n = 1$, all internal mesh points are returned. This case may also be invoked by entering the simplified option `Alldata`, which is equivalent to `Alldata = 1`. For $n > 1$, only each n-th mesh point is stored

in the list. The list always contains the initial point $[t_0, Y_0]$ and the final point $[t, Y(t)]$. For $n \le 0$, only the data $[[t_0, Y_0], [t, Y(t)]]$ are returned.

The output list may be useful to inspect the internal numerical process. Also further graphical processing of the mesh data may be useful.

Return Values

The solution $Y(t)$ is returned as a list or as an array of floating-point values. The type of the result matrix/vector coincides with the type of the input matrix/vector Y_0.

With the option `Alldata`, a list of mesh data is returned.

numeric::ode2vectorfield

Purpose

Convert an ode system to vectorfield notation

Syntax

```
numeric::ode2vectorfield(IVP, fields)
```

Description

`numeric::ode2vectorfield` converts a system of ordinary differential equations of arbitrary order to a vector field representation suitable for the numerical ODE solver numeric::odesolve2.

`numeric::ode2vectorfield` and numeric::odeToVectorField are equivalent.

`numeric::ode2vectorfield` is a utility function to generate input parameters for the numerical ODE solver numeric::odesolve2. This solver requires a procedure representing the vectorfield $f(t, Y)$ of a first order system of differential equations (dynamic system) (dY)/(dt)=f(t, Y)$\frac{dY}{dt} = f(t, Y)$ and initial data $Y_0 = Y(t_0)$. Given an initial value problem `IVP` consisting of (possibly higher order) differential expressions together with initial conditions, `numeric::ode2vectorfield` converts the higher order equations to an equivalent system of first order ODEs and returns the input parameters for numeric::odesolve2.

Higher-order differential equations can always be represented as an equivalent dynamic system (dY)/(dt)=f(t, Y)$\frac{dY}{dt} = f(t, Y)$ with some vector Y. E.g., the n-th order equation

y^(fenced(n))=g(t, y, y', Symbol::hellip, y^(fenced(n-1)))

$$y^{(n)} = g\left(t, y, y', \ldots, y^{(n-1)}\right)$$

may be written as the first order system

(dY)/(dt)=[y', dots,y^fenced(n-1), g(t,y,dots,y^fenced(n-1))]

$$\frac{dY}{dt} = \left[y', \ldots, y^{(n-1)}, g\left(t, y, \ldots, y^{(n-1)}\right)\right]$$

for the vector Y=[y, y', Symbol::hellip, y^(fenced(n-1))] $Y = \left[y, y', \ldots, y^{(n-1)}\right]$.

The input list `fields` correponds to the vector *Y*. It must be a *complete* specification of all functions and their derivatives through but *not including the highest derivates* of the unknown functions. E.g., for the second order differential equation y"(t) = y(t)$y''(t) = y(t)$, the appropriate list of unknown fields is [y(t), y'(t)]$[y(t),\ y'(t)]$. The differential equations y"(t) = z(t), z'(t) = y(t)$y''(t) = z(t),\ z'(t) = y(t)$ are of second order in *y* and of first order in *z*. Hence, the appropriate list of unknown fields is `[y(t), y'(t), z(t)]`.

The ordering of the fields in `list` determines the ordering of the components of the list that the numerical solver produces as the solution vector. Cf. "Example 2" on page 19-254.

The differential equations must be linear in the highest derivatives of the unknown functions involved. E.g., the ODE (y'(t))^2 = y(t)$y'(t)^2 = y(t)$ is not admitted. However, equations such as y_2(t)*y_1'(t) = y_1(t), y_1(t)*y_2'(t) = y_2(t)$y_2(t)\ y_1'(t) = y_1(t),\ y_1(t)\ y_2'(t) = y_2(t)$ are accepted and converted to y_1'(t) = y_1(t)/y_2(t), y_2'(t) = y_2(t)/y_1(t)$y_1'(t) = \frac{y_1(t)}{y_2(t)},\ y_2'(t) = \frac{y_2(t)}{y_1(t)}$.

A *complete* specification of initial conditions must be contained in `IVP`: for each component in `list`, an initial value must be provided. The initial conditions may be specified by linear equations which will be solved for the initial values of the unknown fields automatically. E.g., for `fields = [y(t), y'(t), z(t)]`, initial conditions may be specified explicitly by $y(t_0) = 1$, $y'(t\_0) = 2$, $z(t_0) = 3$, say, or via linear equations such as $y(t\_0) + z(t\_0) = y'(t\_0)$, $y(t_0) = z(t_0)$, $z(t_0) = 2\ y(t_0)$. Cf. "Example 3" on page 19-255.

The differential equations, the initial 'time' t_0, and the initial conditions may involve symbolic parameters. However, such parameters must evaluate to numerical objects, when the sequence returned by `numeric::ode2vectorfield` is passed to the numerical solver.

The vectorfield procedure `f` and the initial values Y_0 returned by `numeric::ode2vectorfield` can also be used by the functions numeric::odesolve, plot::Ode2d, plot::Ode3d. Cf. "Example 3" on page 19-255.

Examples

Example 1

We consider the initial value problem

y'(t)=t*sin(y(t)), y(0) = 1

$$y'(t) = t\sin(y(t)),\ y(0) = 1$$

The solver numeric::odesolve2 requires the procedure `f:`(t, Y) -> t*sin(Y[1])$(t, Y) \to t\sin(Y_1)$ for the 1-dimensional vector $Y = [y(t)]$ specified by `fields`. The utility `numeric::ode2vectorfield` accepts a more convenient representation via arithmetical expressions:
IVP := {y'(t) = t*sin(y(t)), y(t0) = y0}: fields := [y(t)]: IVP := numeric::ode2vectorfield(IVP, fields)‘proc(t, Y) ... end‘, t0, [y0]

```
proc(t, Y) ... end, t0, [y0]
```

This sequence may be passed to the numerical solver which returns a procedure representing the numerical solution:
t0 := 0: y0 := 1: Y := numeric::odesolve2(IVP)‘proc Y(t) ... end‘

```
proc Y(t) ... end
```

Calling the numerical solution `Y` invokes the numerical integration from the intial ‘time’ $t_0 = 0$ to the ‘time’ specified in the call to `Y`:
Y(0), Y(1), Y(2), Y(3)[1.0], [1.466404006], [2.655911348], [3.100928494]

```
[1.0], [1.466404006], [2.655911348], [3.100928494]
```

delete IVP, fields, Y:

Example 2

We consider the second order initial value problem

y''(t)=t*sin(y(t)), y(0) = 1, y'(0) = 0

$$y''(t) = t\sin(y(t)),\ y(0) = 1,\ y'(0) = 0$$

The corresponding vectorfield representation involves the vector Y=[y(t), y'(t)] $Y = [y(t), y'(t)]$ specified by `fields`:
IVP := {y"(t) = t*sin(y(t)), y(0) = 1, y'(0) = 0}: fields := [y(t), y'(t)]: numeric::ode2vectorfield(IVP, fields)‘proc(t, Y) ... end‘, 0, [1, 0]

```
proc(t, Y) ... end, 0, [1, 0]
```

This sequence is accepted by numeric::odesolve2. The numerical solution `Y` returns lists representing the components of the vector specified by `fields`:
Y := numeric::odesolve2(%): Y(5)[1.916536393, -0.8765542819]

```
[1.916536393, -0.8765542819]
```

With a reordering of the unknown fields, the numerical solver returns the solution vector with rearranged components:
fields := [y'(t), y(t)]: Y := numeric::odesolve2(numeric::ode2vectorfield(IVP, fields)): Y(5)[-0.8765542819, 1.916536393]

```
[-0.8765542819, 1.916536393]
```

delete IVP, fields, Y:

Example 3

The following IVP involves the unknown fields $u(t)$, $v(t)$, $w(t)$. Since it is of second order in u, of first order in v and of third order in w, the list of unknowns `[y(t), y'(t), v(t), w(t), w'(t), w''(t)]` is appropriate:
IVP := {u"(t) - u(t)*v'(t) = exp(-t)*v'(t), v'(t) = w"(t), u'(t)*w"'(t) = t + u"(t), u(PI) = 3, u'(PI) = 1, v(PI) = 0, w(PI) = w'(PI), w'(PI) = 2 - w(PI), w"(PI) = 3*w(PI)}: fields := [u(t), u'(t), v(t), w(t), w'(t), w"(t)]: ivp := numeric::ode2vectorfield(IVP, fields)‘proc(t, Y) ... end‘, PI, [3, 1, 0, 1, 1, 3]

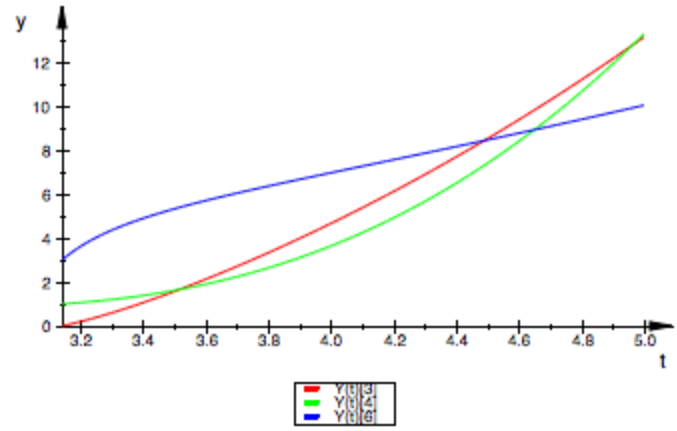
```
proc(t, Y) ... end, π, [3, 1, 0, 1, 1, 3]
```

```
Y := numeric::odesolve2(ivp): Y(5)[195.9501263, 604.3872242,
13.15053015, 13.29454726, 14.15053015, 10.04763196]
```

```
[195.9501263, 604.3872242, 13.15053015, 13.29454726, 14.15053015, 10.04763196]
```

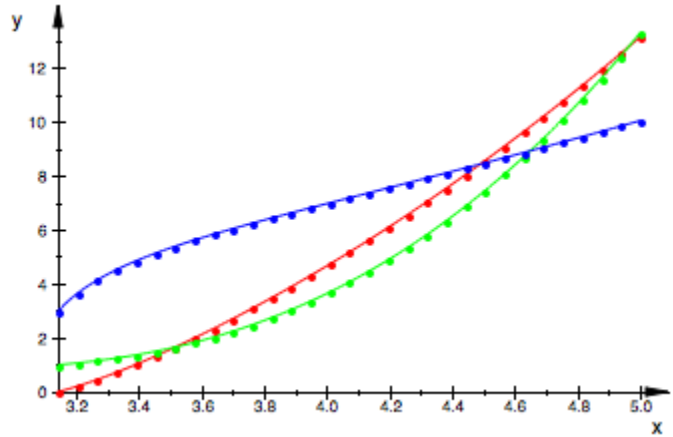
We plot the components v, w, and w"w'' of the solution vector:

```
plotfunc2d(Y(t)[3], Y(t)[4], Y(t)[6], t = PI .. 5, Colors = [RGB::Red,
RGB::Green, RGB::Blue]):
```



Alternatively, we use the vectorfield procedure `ivp[1]` and the initial conditions `ivp[3]` as input parameters for plot::Ode2d:

```
plot(plot::Ode2d([PI + i*(5 - PI)/30 $ i = 0..30], ivp[1], ivp[3], [(t, Y) -> [t,
Y[3]], Color = RGB::Red], [(t, Y) -> [t, Y[4]], Color = RGB::Green], [(t, Y)
-> [t, Y[6]], Color = RGB::Blue])):
```



delete IVP, fields, ivp, Y:

Parameters

IVP

The initial value problem: a list or a set of equations involving univariate function calls $y_1(t)$, $y_2(t)$ etc. and derivates y_1'(t)$y_1'(t)$, y_1''(t)$y_1''(t)$, ..., y_2'(t)$y_2'(t)$, y_2''(t)$y_2''(t)$ etc. The differential equations must be quasi-linear: the highest derivative of each of the dependent functions $y_1(t)$, $y_2(t)$ etc. must enter the equations linearly. `IVP` must also contain corresponding initial conditions specified by linear equations in the expressions $y_1(t_0)$, y_1'(t_0)$y_1'(t_0)$, ..., $y_2(t_0)$, y_2'(t_0)$y_2'(t_0)$ etc. Alternatively, arithmetical expressions may be specified which are interpreted as equations with vanishing right hand side.

fields

The vector of the dynamical system equivalent to `IVP`: a list of symbolic function calls such as `[y_1(t), y_1'(t), dots, y_2(t), y_2'(t), dots]` representing the unknown fields to be solved for.

Return Values

Sequence `f, t0, Y0`. These data represent the dynamical system (dY)/(dt)=f(t, Y) $\frac{dY}{dt} = f(t, Y)$ with the initial condition $Y(t_0) = Y_0$ equivalent to `IVP`. The vectorfield `f:`(t, Y) -> f(t, Y) $(t, Y) \to f(t, Y)$ is a procedure, `t0` is a numerical expression representing the initial 'time', and `Y0` is a list of numerical expressions representing the components of the initial vector Y_0.

numeric::odeToVectorField

Purpose

Convert an ode system to vectorfield notation

Syntax

```
numeric::odeToVectorField(IVP, fields)
```

Description

`numeric::odeToVectorField` converts a system of ordinary differential equations of arbitrary order to a vector field representation suitable for the numerical ODE solver numeric::odesolve2.

`numeric::odeToVectorField` and numeric::ode2vectorfield are equivalent.

`numeric::odeToVectorField` is a utility function to generate input parameters for the numerical ODE solver numeric::odesolve2. This solver requires a procedure representing the vectorfield $f(t, Y)$ of a first order system of differential equations (dynamic system) (dY)/(dt)=f(t, Y)$\frac{dY}{dt} = f(t, Y)$ and initial data $Y_0 = Y(t_0)$. Given an initial value problem `IVP` consisting of (possibly higher order) differential expressions together with initial conditions, `numeric::odeToVectorField` converts the higher order equations to an equivalent system of first order ODEs and returns the input parameters for numeric::odesolve2.

Higher-order differential equations can always be represented as an equivalent dynamic system (dY)/(dt)=f(t, Y)$\frac{dY}{dt} = f(t, Y)$ with some vector Y. E.g., the n-th order equation

y^(fenced(n))=g(t, y, y', Symbol::hellip, y^(fenced(n-1)))

$$y^{(n)} = g\left(t, y, y', \ldots, y^{(n-1)}\right)$$

may be written as the first order system

(dY)/(dt)=[y', dots,y^fenced(n-1), g(t,y,dots,y^fenced(n-1))]

$$\frac{dY}{dt} = \left[y', \ldots, y^{(n-1)}, g\left(t, y, \ldots, y^{(n-1)}\right)\right]$$

for the vector Y=[y, y', Symbol::hellip, y^(fenced(n-1))] $Y = \left[y, y', \ldots, y^{(n-1)}\right]$.

The input list `fields` correponds to the vector *Y*. It must be a *complete* specification of all functions and their derivatives through but *not including the highest derivates* of the unknown functions. E.g., for the second order differential equation y”(t) = y(t) $y''(t) = y(t)$, the appropriate list of unknown fields is [y(t), y’(t)] $[y(t), y'(t)]$. The differential equations y”(t) = z(t), z’(t) = y(t) $y''(t) = z(t),\ z'(t) = y(t)$ are of second order in *y* and of first order in *z*. Hence, the appropriate list of unknown fields is `[y(t), y'(t), z(t)]`.

The ordering of the fields in `list` determines the ordering of the components of the list that the numerical solver produces as the solution vector. Cf. “Example 2” on page 19-261.

The differential equations must be linear in the highest derivatives of the unknown functions involved. E.g., the ODE (y’(t))^2 = y(t) $y'(t)^2 = y(t)$ is not admitted. However, equations such as y_2(t)*y_1’(t) = y_1(t), y_1(t)*y_2’(t) = y_2(t) $y_2(t)\ y_1'(t) = y_1(t),\ y_1(t)\ y_2'(t) = y_2(t)$ are accepted and converted to y_1’(t) = y_1(t)/y_2(t), y_2’(t) = y_2(t)/y_1(t) $y_1'(t) = \frac{y_1(t)}{y_2(t)},\ y_2'(t) = \frac{y_2(t)}{y_1(t)}$.

A *complete* specification of initial conditions must be contained in `IVP`: for each component in `list`, an initial value must be provided. The initial conditions may be specified by linear equations which will be solved for the initial values of the unknown fields automatically. E.g., for `fields = [y(t), y'(t), z(t)]`, initial conditions may be specified explicitly by $y(t_0) = 1$, `y'(t_0) = 2`, $z(t_0) = 3$, say, or via linear equations such as `y(t_0) + z(t_0) = y'(t_0)`, $y(t_0) = z(t_0)$, $z(t_0) = 2\ y(t_0)$. Cf. “Example 3” on page 19-262.

The differential equations, the initial ‘time’ t_0, and the initial conditions may involve symbolic parameters. However, such parameters must evaluate to numerical objects, when the sequence returned by `numeric::odeToVectorField` is passed to the numerical solver.

The vectorfield procedure `f` and the initial values Y_0 returned by `numeric::odeToVectorField` can also be used by the functions numeric::odesolve, plot::Ode2d, plot::Ode3d. Cf. “Example 3” on page 19-262.

Examples

Example 1

We consider the initial value problem

y'(t)=t*sin(y(t)), y(0) = 1

$$y'(t) = t\sin(y(t)),\ y(0) = 1$$

The solver numeric::odesolve2 requires the procedure `f:`(t, Y) -> t*sin(Y[1])$(t, Y) \to t\sin(Y_1)$ for the 1-dimensional vector $Y = [y(t)]$ specified by `fields`. The utility numeric::ode2vectorfield accepts a more convenient representation via arithmetical expressions:
IVP := {y'(t) = t*sin(y(t)), y(t0) = y0}: fields := [y(t)]: IVP := numeric::ode2vectorfield(IVP, fields)‘proc(t, Y) ... end‘, t0, [y0]

```
proc(t, Y) ... end, t0, [y0]
```

This sequence may be passed to the numerical solver which returns a procedure representing the numerical solution:
t0 := 0: y0 := 1: Y := numeric::odesolve2(IVP)‘proc Y(t) ... end‘

```
proc Y(t) ... end
```

Calling the numerical solution `Y` invokes the numerical integration from the intial ‘time’ $t_0 = 0$ to the ‘time’ specified in the call to `Y`:
Y(0), Y(1), Y(2), Y(3)[1.0], [1.466404006], [2.655911348], [3.100928494]

```
[1.0], [1.466404006], [2.655911348], [3.100928494]
```

delete IVP, fields, Y:

Example 2

We consider the second order initial value problem

y''(t)=t*sin(y(t)), y(0) = 1, y'(0) = 0

$$y''(t) = t\sin(y(t)),\ y(0) = 1,\ y'(0) = 0$$

The corresponding vectorfield representation involves the vector Y=[y(t), y'(t)] $Y = [y(t), y'(t)]$ specified by `fields`:
IVP := {y"(t) = t*sin(y(t)), y(0) = 1, y'(0) = 0}: fields := [y(t), y'(t)]: numeric::ode2vectorfield(IVP, fields)`proc(t, Y) ... end`, 0, [1, 0]

```
proc(t, Y) ... end, 0, [1, 0]
```

This sequence is accepted by numeric::odesolve2. The numerical solution `Y` returns lists representing the components of the vector specified by `fields`:
Y := numeric::odesolve2(%): Y(5)[1.916536393, -0.8765542819]

```
[1.916536393, -0.8765542819]
```

With a reordering of the unknown fields, the numerical solver returns the solution vector with rearranged components:
fields := [y'(t), y(t)]: Y := numeric::odesolve2(numeric::ode2vectorfield(IVP, fields)): Y(5)[-0.8765542819, 1.916536393]

```
[-0.8765542819, 1.916536393]
```

delete IVP, fields, Y:

Example 3

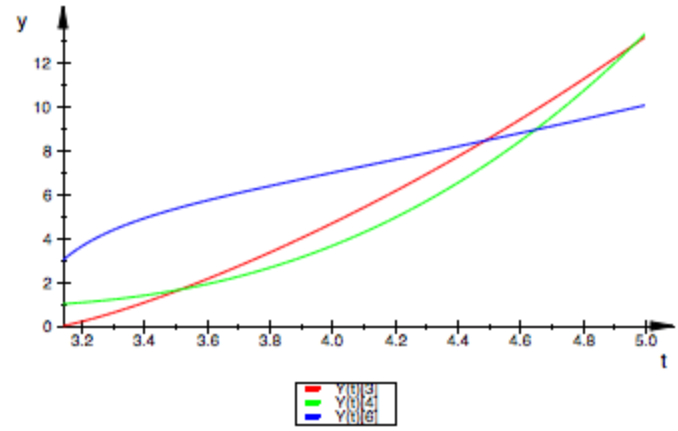
The following IVP involves the unknown fields $u(t)$, $v(t)$, $w(t)$. Since it is of second order in u, of first order in v and of third order in w, the list of unknowns `[y(t), y'(t), v(t), w(t), w'(t), w''(t)]` is appropriate:
IVP := {u"(t) - u(t)*v'(t) = exp(-t)*v'(t), v'(t) = w"(t), u'(t)*w"'(t) = t + u"(t), u(PI) = 3, u'(PI) = 1, v(PI) = 0, w(PI) = w'(PI), w'(PI) = 2 - w(PI), w"(PI) = 3*w(PI)}: fields := [u(t), u'(t), v(t), w(t), w'(t), w"(t)]: ivp := numeric::ode2vectorfield(IVP, fields)`proc(t, Y) ... end`, PI, [3, 1, 0, 1, 1, 3]

```
proc(t, Y) ... end, π, [3, 1, 0, 1, 1, 3]
```

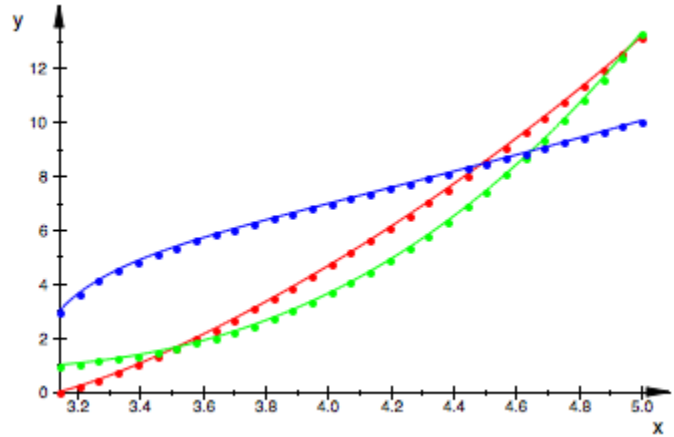
Y := numeric::odesolve2(ivp): Y(5)[195.9501263, 604.3872242, 13.15053015, 13.29454726, 14.15053015, 10.04763196]

[195.9501263, 604.3872242, 13.15053015, 13.29454726, 14.15053015, 10.04763196]

We plot the components v, w, and w"w'' of the solution vector: plotfunc2d(Y(t)[3], Y(t)[4], Y(t)[6], t = PI .. 5, Colors = [RGB::Red, RGB::Green, RGB::Blue]):



Alternatively, we use the vectorfield procedure `ivp[1]` and the initial conditions `ivp[3]` as input parameters for plot::Ode2d: plot(plot::Ode2d([PI + i*(5 - PI)/30 $ i = 0..30], ivp[1], ivp[3], [(t, Y) -> [t, Y[3]], Color = RGB::Red], [(t, Y) -> [t, Y[4]], Color = RGB::Green], [(t, Y) -> [t, Y[6]], Color = RGB::Blue])):



delete IVP, fields, ivp, Y:

Parameters

IVP

The initial value problem: a list or a set of equations involving univariate function calls $y_1(t)$, $y_2(t)$ etc. and derivates y_1'(t)$y_1'(t)$, y_1"(t)$y_1''(t)$, ..., y_2'(t)$y_2'(t)$, y_2"(t)$y_2''(t)$ etc. The differential equations must be quasi-linear: the highest derivative of each of the dependent functions $y_1(t)$, $y_2(t)$ etc. must enter the equations linearly. `IVP` must also contain corresponding initial conditions specified by linear equations in the expressions $y_1(t_0)$, y_1'(t_0)$y_1'(t_0)$, ..., $y_2(t_0)$, y_2'(t_0)$y_2'(t_0)$ etc. Alternatively, arithmetical expressions may be specified which are interpreted as equations with vanishing right hand side.

fields

The vector of the dynamical system equivalent to `IVP`: a list of symbolic function calls such as `[y_1(t), y_1'(t), dots, y_2(t), y_2'(t), dots]` representing the unknown fields to be solved for.

Return Values

Sequence `f, t0, Y0`. These data represent the dynamical system (dY)/(dt)=f(t, Y) $\frac{dY}{dt} = f(t, Y)$ with the initial condition $Y(t_0) = Y_0$ equivalent to `IVP`. The vectorfield `f:`(t, Y) -> f(t, Y) $(t, Y) \to f(t, Y)$ is a procedure, `t0` is a numerical expression representing the initial 'time', and `Y0` is a list of numerical expressions representing the components of the initial vector Y_0.

numeric::polyrootbound

Purpose

Bound for the roots of a univariate polynomial

Syntax

```
numeric::polyrootbound(p)
```

Description

`numeric::polyrootbound(p)` returns a bound b, such that all real and complex roots z of the univariate polynomial p satisfy $|z| \le b$.

The coefficients of `p` may be real or complex numbers. Also exact numerical coefficients such as PI, sqrt(2) $\sqrt{2}$ etc. are accepted if they can be converted to floats.

For non-zero constant polynomials, `numeric::polyrootbound` returns infinity.

For monomials $p(x) = c_n x^n$ with $n > 0$, `numeric::polyrootbound` returns `0.0`.

Consider the polynomial $p(z) = z^n + c_{n-1} z^{n-1} + \cdots + c_0$. If $max(|c_{n-1}|, \ldots, |c_0|) > 0$, the polynomial

z^n-abs(c[(n-1)])*z^(n-1)-Symbol::cdots-abs(c[0])

$$z^n - |c_{n-1}|\, z^{n-1} - \cdots - |c_0|$$

has a single real root $b > 0$ which is an upper bound for the absolute values of all real and complex roots of p. The bound returned by `numeric::polyrootbound(p)` approximates b to about 3 leading decimal digits.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

Both polynomial expressions as well as DOM_POLY objects may be used to specify the polynomial:
p := x^3 + PI*x - sqrt(2): numeric::polyrootbound(p)1.966316026

```
1.966316026
```

```
p := poly(p, [x]): numeric::polyrootbound(p)1.966316026
```

```
1.966316026
```

The absolute values of all real and complex roots of *p* are bounded by this number:
numeric::polyroots(p)[0.4256164232, - 0.2128082116 + 1.810374176*I, - 0.2128082116 + (- 1.810374176*I)]

```
[0.4256164232, -0.2128082116 + 1.810374176 i, -0.2128082116 - 1.810374176 i]
```

```
max(abs(z) $ z in %)1.822838993
```

```
1.822838993
```

```
delete p:
```

Parameters

p

A univariate polynomial expression or a univariate polynomial of domain type DOM_POLY.

Return Values

Nonnegative real floating-point number or infinity.

See Also

RootOfnumeric::fsolvenumeric::polyrootsnumeric::polysysrootsnumeric::realrootnumeric::

numeric::polyroots

Purpose

Numerical roots of a univariate polynomial

Syntax

```
numeric::polyroots(eqs, <FixedPrecision>, <SquareFree>,
<Factor>, <NoWarning>)
```

Description

`numeric::polyroots(eqs)` returns numerical approximations of all real and complex roots of the univariate polynomials `eqs`.

The coefficients may be real or complex numbers. Also symbolic coefficients are accepted if they can be converted to floats.

The trivial polynomial *eqs* = 0 results in an error message. The empty list is returned for constant polynomials *eqs* ≠ 0.

Multiple roots are listed according to their multiplicities, i.e., the length of the root list coincides with the degree of *eqs*.

The root list is sorted by numeric::sort.

Up to roundoff effects, the numerical roots should be accurate to DIGITS significant digits, unless the option `FixedPrecision` is used.

All floating-point entries in `eqs` are internally approximated by rational numbers: `numeric::polyroots(eqs)` computes the roots of `numeric::rationalize(eqs, Minimize)`.

For polynomial expressions in factored form, the numerical search is applied to each factor separately.

With `setuserinfo(numeric::polyroots, 2)`, detailed information on the internal search is provided.

It is recommended to use numeric::realroots or polylib::realroots if `eqs` is a real polynomial and only real roots are of interest.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

Both polynomial expressions as well as DOM_POLY objects may be used to specify the polynomial:
numeric::polyroots(x^3 - 3*x - sqrt(2))[1.931851653, -0.5176380902, -1.414213562]

[1.931851653, −0.5176380902, −1.414213562]

numeric::polyroots(PI*z^4 + I*z + 0.1)[0.5936837297 + (-0.3729248918*I), 0.6455316068*I, 0.1003181767*I, - 0.5936837297 + (- 0.3729248918*I)]

[0.5936837297 − 0.3729248918 i, 0.6455316068 i, 0.1003181767 i, −0.5936837297 − 0.372924

numeric::polyroots(poly(x^5 - x^2, [x]))[1.0, 0.0, 0.0, - 0.5 + 0.8660254038*I, - 0.5 + (- 0.8660254038*I)]

[1.0, 0.0, 0.0, −0.5 + 0.8660254038 i, −0.5 − 0.8660254038 i]

Example 2

The following polynomial has exact coefficients:
p := poly((x - 1)*(x - PI)^3, [x]): numeric::polyroots(p)[3.141592654, 3.141592654, 3.141592654, 1.0]

[3.141592654, 3.141592654, 3.141592654, 1.0]

Note that roundoff errors in the coefficients of `eqs` have a dramatic effect on multiple roots:
p := poly((x - 1.0)*(x - float(PI))^3, [x]):
numeric::polyroots(p)[3.144422386, 3.140177788 + 0.00244957836*I, 3.140177788 + (- 0.00244957836*I), 0.9999999995]

[3.144422386, 3.140177788 + 0.00244957836 i, 3.140177788 − 0.00244957836 i, 0.999999999

These are the roots of the following rationalized polynomial:

numeric::rationalize(p, Minimize)poly(x^4 - (461286*x^3)/44249 + (176627*x^2)/4525 - (2515405*x)/41498 + 1837649/59267, [x])

$$\mathrm{poly}\left(x^4 - \frac{461286\,x^3}{44249} + \frac{176627\,x^2}{4525} - \frac{2515405\,x}{41498} + \frac{1837649}{59267}, [x]\right)$$

delete p:

Example 3

The multiple root I/3 of the following polynomial can only be computed with restricted precision by fixed precision arithmetic:
p := poly((x^2 - 6*x +8)*(x - I/3)^5, [x]): numeric::polyroots(p, FixedPrecision)[4.0, 2.0, 0.005647662458 + 0.330762663*I, 0.004162114315 + 0.3378408591*I, - 0.0007618302219 + 0.3271290976*I, - 0.002938026857 + 0.3387257645*I, - 0.006109919675 + 0.3322082825*I]

[4.0, 2.0, 0.005647662458 + 0.330762663 i, 0.004162114315 + 0.3378408591 i, − 0.0007618302219 − 0.002938026857 + 0.3387257645 i, − 0.006109919675 + 0.3322082825 i]

Without the option `FixedPrecision`, the working precision is increased internally to compute better approximations:

A square free factorization reduces the multiplicity of the root I/3:
numeric::polyroots(p, SquareFree)Info: starting squarefree factorization Info: computing roots of factor poly(x^2 - 6*x + 8, [x]) Info: increasing working precision to DIGITS=20 Info: computing roots of factor poly(- 3*I*x - 1, [x]) [4.0, 2.0, 0.3333333333*I, 0.3333333333*I, 0.3333333333*I, 0.3333333333*I, 0.3333333333*I]

[4.0, 2.0, 0.3333333333 i, 0.3333333333 i, 0.3333333333 i, 0.3333333333 i, 0.3333333333 i]

setuserinfo(numeric::polyroots, 0): delete p:

Example 4

The following polynomial has badly separated roots. `numeric::polyroots` does not manage to separate them properly:

```
p := poly(_mult((x - 1 - i/10^9) $ i=0..5), [x]):
numeric::polyroots(p)
```

[1.000000003, 1.000000003, 1.000000003, 1.000000003, 1.000000003, 0.9999999987]

One can preprocess the polynomial by a symbolic factorization:
numeric::polyroots(p, Factor)[1.000000005, 1.000000004, 1.000000003, 1.000000002, 1.000000001, 1.0]

[1.000000005, 1.000000004, 1.000000003, 1.000000002, 1.000000001, 1.0]

Alternatively, one can increase the working precision to separate the roots:

```
DIGITS := 20: numeric::polyroots(p)[1.000000005, 1.000000004,
1.000000003, 1.000000002, 1.000000001, 1.0]
```

```
[1.000000005, 1.000000004, 1.000000003, 1.000000002, 1.000000001, 1.0]
```

```
delete p, DIGITS:
```

Parameters

eqs

A univariate polynomial expression or a univariate polynomial of domain type DOM_POLY. The function also accepts a list, set, array, or matrix (Cat::Matrix) of polynomial expressions.

Options

FixedPrecision

This option provides the fastest way to obtain approximations of the roots by a numerical search with a fixed internal precision of 2*DIGITS* decimal places.

Note that badly isolated roots or multiple roots will usually not be approximated to DIGITS decimals when using this option. The problem of finding such roots is numerically ill-conditioned, i.e., such roots cannot be found to full precision with fixed precision arithmetic. Typically, a *q*-fold root will be approximated only to about 2*DIGITS/q$\frac{2\ DIGITS}{q}$ decimal places. Cf. “Example 3” on page 19-270.

Without this option, `numeric::polyroots` internally increases the working precision until all roots are found to DIGITS decimal places.

SquareFree

With this option, a symbolic square free factorization is computed via `polylib::sqrfree(eqs)`. The numerical root finding algorithm is then applied to each square free factor.

This option is recommended, when `p` is known to have multiple roots. Such roots force `numeric::polyroots` to increase the working precision internally increasing the costs of the numerical search. A square free factorization reduces the multiplicity of each root to one, speeding up the final numerical search. Cf. "Example 3" on page 19-270.

For polynomials with real rational coefficients, a square free factorization is always used, i.e., this option does not have any effect for such polynomials. For all other types of coefficients, a square free factorization may be costly and must be requested by this option.

Multiple roots of `eqs` can be successfully dealt with by this option. However, for badly separated distinct roots the square free factorization will not improve the performance of the numerical search.

Factor

With this option, a symbolic factorizations of `eqs` via factor are computed. The numerical root finding algorithm is then applied to each factor.

This option is useful, when `eqs` can be successfully factorized (e.g., when each expression from `eqs` has multiple roots). The numerical search on the factors is much more efficient than the search on the original polynomial. On the other hand, symbolic factorization of `eqs` may be costly.

NoWarning

Suppresses warnings

Return Values

List of numerical roots.

Algorithms

The numerical root finding algorithm implemented by `numeric::polyroots` is Laguerre's method: W.H. Press, B.P. Flannery,

S.A. Teukolsky and W.T. Vetterling: *Numerical Recipes in C*, Cambridge University Press, 1988.

numeric::polysysroots

Purpose

Numerical roots of a system of polynomial equations

Syntax

```
numeric::polysysroots(eqs, <NoWarning>)
numeric::polysysroots(eqs, vars, <NoWarning>)
```

Description

`numeric::polysysroots(eqs, ...)` returns numerical approximations of all real and complex roots of the polynomial system of equations `eqs`.

The coefficients of the polynomials may contain symbolic parameters.

If no unknowns are specified by `vars`, then`numeric::indets(eqs)` is used in place of `vars`.

In most cases, the solution is returned as a set of lists of solved equations of the form

[x[1]=value[1], x[2]=value[2], Symbol::hellip]

$[x_1 = \text{value}_1, x_2 = \text{value}_2, \ldots]$

where x_1, x_2, … are the unknowns. These simplified equations should be regarded as constraints on the unknowns. E.g., if an unknown x_1, say, does not turn up in the form x_1 = … in the solution, then there is no constraint on this unknown and it is an arbitrary parameter. This holds true in general for all unknowns that do not turn up on the left hand side of the solved equations. Cf. “Example 2” on page 19-277.

If no explicit solutions can be computed, expressions of the form

matrix([[x[1]], [x[2]], [Symbol::hellip]]) in $S\begin{pmatrix} x_1 \\ x_2 \\ \cdots \end{pmatrix} \in S$ may be returned, where S is the solution set.

The ordering of the unknowns in `vars` determines the ordering of the solved equations. If a *set*`vars` is used, then an internal ordering is used.

Note If the solution set of `eqs` is not finite, then `numeric::polysysroots` may return solutions with some of the unknowns remaining as free parameters. In this case the representation of the solution depends on the ordering of the unknowns! Cf. "Example 3" on page 19-277. Further, if higher degree polynomials are involved, then `numeric::polysysroots` may fail to compute roots. Cf. "Example 5" on page 19-278. The same may happen, when `eqs` contains symbolic parameters.

You may try numeric::fsolve to compute a single numerical root, if `numeric::polysysroots` cannot compute all roots of the system. Note, however, that numeric::fsolve does not accept symbolic parameters in the equations.

We recommend to use numeric::polyroots to compute all roots of a single univariate polynomial with numerical coefficients.

`numeric::polysysroots` is a hybrid routine: it calls the symbolic solver `solve(eqs, vars, BackSubstitution = FALSE)` and processes its symbolic result numerically. Cf. "Example 4" on page 19-278.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

Equations, expressions as well as DOM_POLY objects may be used to specify the polynomials:

```
numeric::polysysroots(x^2 = PI^2, x)
```

{[x = 3.141592654], [x = -3.141592654]}

```
numeric::polysysroots({x^2 + y^2 - 1, x^2 - y^2 = 1/2}, [x, y])
```

{[x = 0.8660254038, y = 0.5], [x = 0.8660254038, y = -0.5], [x = -0.8660254038, y = -0.5], [x = -0.8660254038, y = 0.5]}

$$\{[x = 0.8660254038, y = 0.5], [x = 0.8660254038, y = -0.5], [x = -0.8660254038, y = -0.5], [x =$$

numeric::polysysroots({poly(x^2 + y + 1), y^2 + x = 1}, [x, y]){[x = -0.4533976515, y = -1.20556943], [x = 0.2266988258 + 1.467711509*I, y = 1.102784715 + (- 0.6654569512*I)], [x = 0, y = -1.0], [x = 0.2266988257 + (- 1.467711509*I), y = 1.102784715 + 0.6654569512*I]}

$$\{[x = -0.4533976515, y = -1.20556943], [x = 0.2266988258 + 1.467711509\,i, y = 1.102784715 -$$

Symbolic parameters are accepted:

$$[x = 0.2266988257 - 1.467711509\,i, y = 1.102784715 - 0.6654569512\,i]\}$$

numeric::polysysroots(x^2 + y + exp(z), [x, y]){[x = sqrt(- 1.0*y - 1.0*exp(z))], [x = -1.0*sqrt(- 1.0*y - 1.0*exp(z))]}

$$\left\{\left[x = \sqrt{-1.0\,y - 1.0\,e^z}\right], \left[x = -1.0\sqrt{-1.0\,y - 1.0\,e^z}\right]\right\}$$

Example 2

The returned solutions may contain some of the unknowns remaining as free parameters:

numeric::polysysroots({x^2 + y^2 = z}, [x, y, z]){[x = sqrt(z - 1.0*y^2)], [x = -1.0*sqrt(z - 1.0*y^2)]}

$$\left\{\left[x = \sqrt{z - 1.0\,y^2}\right], \left[x = -1.0\sqrt{z - 1.0\,y^2}\right]\right\}$$

Example 3

The ordering of the unknowns determines the representation of the solution, if the solution set is not finite. First, the following equation is solved for x leaving y as a free parameter:

numeric::polysysroots({x^3 = y^2}, [x, y]){[x = (y^2)^(1/3)], [x = (y^2)^(1/3)*(- 0.5 + 0.8660254038*I)], [x = (y^2)^(1/3)*(- 0.5 + (- 0.8660254038*I))]}

$$\left\{\left[x = (y^2)^{1/3}\right], \left[x = (y^2)^{1/3}\,(-0.5 + 0.8660254038\,i)\right], \left[x = (y^2)^{1/3}\,(-0.5 - 0.8660254038\,i)\right]\right\}$$

Reordering the unknowns leads to a representation with x as a free parameter:
numeric::polysysroots({x^3 = y^2}, [y, x]){[y = sqrt(x^3)], [y = -1.0*sqrt(x^3)]}

$$\left\{\left[y = \sqrt{x^3}\right], \left[y = -1.0\sqrt{x^3}\right]\right\}$$

Example 4

The symbolic solver produces a RootOf solution of the following system:
eqs := {y^2 - y = x, x^3 = y^3 + x}: solve(eqs, BackSubstitution = FALSE)matrix([[x], [y]]) in {matrix([[0], [0]])} union Dom::ImageSet(matrix([[y^2 - y], [z1]]), z1, RootOf(z^5 - 3*z^4 + 3*z^3 - 2*z^2 - z + 1, z))

$$\begin{pmatrix} x \\ y \end{pmatrix} \in \left\{\begin{pmatrix} 0 \\ 0 \end{pmatrix}\right\} \cup \left\{ \begin{pmatrix} y^2 - y \\ z1 \end{pmatrix} \;\middle|\; z1 \in \mathrm{RootOf}\left(z^5 - 3z^4 + 3z^3 - 2z^2 - z + 1, z\right) \right\}$$

Internally, `numeric::polysysroots` calls solve and processes this result numerically:
numeric::polysysroots(eqs, [x, y]){[x = 2.237302267, y = 2.077118343], [x = - 1.445049623 + (- 0.1279930535*I), y = 0.441542078 + 1.094745154*I], [x = 0.8911259621, y = -0.5682349751], [x = -0.2383289841, y = 0.6080324762], [x = - 1.445049623 + 0.1279930535*I, y = 0.441542078 + (- 1.094745154*I)], [x = 0, y = 0]}

delete eqs:

Example 5

The following equation is solved for the first of the specified unknowns:
eqs := y^5 - PI*y = x: solve(eqs, [x, y]){[x = z^5 - PI*z, y = z]}

$$\{[x = z^5 - \pi z,\ y = z]\}$$

`numeric::polysysroots` processes this output numerically:
numeric::polysysroots(eqs, [x, y]){[x = y^5 - 3.141592654*y]}

$$\{[x = y^5 - 3.141592654\ y]\}$$

The equation is solved for `y` when the unknowns are reordered. However, no simple representation of the solution exists, so a RootOf object is returned:
solve(eqs, [y, x])matrix([[y], [x]]) in
solvelib::Union(Dom::ImageSet(matrix([[z1], [z2]]), z1, RootOf(z^5 - PI*z - z2, z)), z2, C_)

$$\begin{pmatrix} y \\ x \end{pmatrix} \in \bigcup_{z2 \in \mathbb{C}} \left\{ \begin{pmatrix} z1 \\ z2 \end{pmatrix} \mid z1 \in \mathrm{RootOf}(z^5 - \pi z - z2,\ z) \right\}$$

The roots represented by the RootOf expression cannot be computed numerically, because the symbolic parameter `x` is involved:
numeric::polysysroots(eqs, [y, x])matrix([[y], [x]]) in
solvelib::Union(Dom::ImageSet(matrix([[z1], [z2]]), z1, RootOf(z^5 - PI*z - z2, z)), z2, C_)

$$\begin{pmatrix} y \\ x \end{pmatrix} \in \bigcup_{z2 \in \mathbb{C}} \left\{ \begin{pmatrix} z1 \\ z2 \end{pmatrix} \mid z1 \in \mathrm{RootOf}(z^5 - \pi z - z2,\ z) \right\}$$

delete eqs:

Parameters

eqs

A polynomial equation or a list, set, array, or matrix (Cat::Matrix) of such equations. Also expressions and polynomials of domain type DOM_POLY are accepted wherever an equation is expected. They are interpreted as homogeneous equations.

vars

An unknown or a list or set of unknowns. Unknowns may be identifiers or indexed identifiers.

Options

NoWarning

By default, the roots are double-checked, automatically. Warnings are issued if a solution seems to be marred by some numerical instability. With this option, this check is suppressed and no warnings will be issued.

Return Values

a set of lists of equations or an expression of the form matrix([[x[1]], [x[2]], [Symbol::hellip]]) in $S\begin{pmatrix} x_1 \\ x_2 \\ \dots \end{pmatrix} \in S$, where x_1, x_2, … are the unknowns and S is the solution set.

The set {[]} containing an empty list is returned, if no solutions can be computed.

numeric::product

Purpose

Numerical approximation of products

Syntax

```
numeric::product(f, i = a .. b)
numeric::product(f, i in RootOf(p, <x>))
numeric::product(f, i = RootOf(p, <x>))
numeric::product(f, i in {x_1, x_2,  })
numeric::product(f, i = {x_1, x_2,  })
```

Description

`numeric::product(f, i = a..b)` computes a numerical approximation of product(f(i), i = a..b)$\prod_{i=a}^{b} f(i)$.

`numeric::product (f, i = RootOf(p,x))` computes a numerical approximation of the product of `f` over the roots of the polynomial `p`.

`numeric::product(f, i in { x_1, x_2,  })` computes a numerical approximation of product(f(i), i in { x[1], x[2], Symbol::dots

})$\prod_{i \in \{x_1, x_2, \ldots\}} f(i)$.

The call `numeric::product(...)` is equivalent to calling the `float` attribute of product via `float ( hold( product )(...))`, `float ( freeze( product )(...))` or `product::float(...)`.

If there are other symbolic parameters in *f*, apart from the variable *i*, a symbolic call to `numeric::product` is returned. Numerical expressions such as exp(PI)e^{π}, sqrt(2)$\sqrt{2}$ etc. are accepted and converted to floating-point numbers.

Note For finite products, `numeric::product` just returns `_mult ( float(f) $ i=a..b)`. Cf. “Example 3” on page 19-283.

The call `numeric::product(f, i = { x_1, x_2,  })` computes numerical approximations of `x[1]`, `x[2]` etc., substitutes these values into *f*(*i*) and multiplies the results.

The calls `numeric::product(f, i in { x1, x2, })` and `numeric::product(f, i = { x1, x2, })` are equivalent.

The call `numeric::product (f, i in RootOf(p, x))` computes numerical approximations of all roots of *p*, substitutes these values into *f*(*i*) and multiplies the results. Cf. “Example 2” on page 19-283.

The calls `numeric::product(f, i in RootOf(p, x))` and `numeric::product(f, i = RootOf(p, x))` are equivalent.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision and influences the maximum number of steps used in the computation.

Examples

Example 1

We demonstrate some equivalent calls for numerical products: numeric::product(1+1/k^2, k = 1..infinity), float(hold(product)(1+1/k^2, k = 1..infinity)), float(freeze(product)(1+1/k^2, k = 1..infinity)), product::float(1+1/k^2, k = 1..infinity);3.67607791, 3.67607791, 3.67607791, 3.67607791

```
3.67607791, 3.67607791, 3.67607791, 3.67607791
```

product fails to find a closed form for the following product: product(1 - 1/4^k, k = 1..infinity);product((2^(2*k) - 1)/2^(2*k), k = 1..infinity)

$$\prod_{k=1}^{\infty} \frac{2^{2k}-1}{2^{2k}}$$

float implicitly uses `numeric::product` to compute a numerical approximation: float(%);0.6885375371

```
0.6885375371
```

The exact value of the following infinite product is exp((1-sqrt(2))*zeta(1/2)):

$$e^{(1-\sqrt{2})\,\zeta\left(\frac{1}{2}\right)}$$

numeric::product(exp((-1)^(k+1)*k^(-1/2)), k = 1..infinity) = float(exp((1-sqrt(2))*zeta(1/2)))1.831066609 = 1.831066609

$$1.831066609 = 1.831066609$$

Example 2

We calculate an approximation of the product over the roots of a polynomial:

numeric::product(sin(r), r = RootOf(x^2 - PI^2/4, x))-1.0

$$-1.0$$

If the polynomial expression contains additional indeterminates, a symbolic call to `numeric::product` is returned:

numeric::product(r+PI, r = RootOf(x^8 + c*x - PI^2/4, x))numeric::product(r + 3.141592654, r = RootOf(x^8 + c*x - 2.4674011, x))

$$\text{numeric::product}\left(r + 3.141592654,\ r = \text{RootOf}\left(x^8 + c\,x - 2.4674011,\ x\right)\right)$$

Example 3

`numeric::product` can also be used to compute finite products:

numeric::product(1-1/k^2, k = 2..10^n) $ n in { 2, 3, 4 }0.505, 0.5005, 0.50005

$$0.505,\ 0.5005,\ 0.50005$$

However, since `numeric::product` uses _mult internally anyway, it is more efficient to call _mult directly:

_mult(float(1-1/k^2) $ k = 2..10^n) $ n in { 2, 3, 4 }0.505, 0.5005, 0.50005

$$0.505,\ 0.5005,\ 0.50005$$

Example 4

The following product is returned symbolically because it contains the additional indeterminate `k`:
numeric::product(1-1/n^k, n = 2..infinity)numeric::product(1.0 - 1.0/n^(1.0*k), n = 2..infinity)

$$\text{numeric::product}\left(1.0 - \frac{1.0}{n^{1.0\,k}},\ n = 2..\infty\right)$$

Parameters

f

An arithmetical expression depending on `i`

i

The product index: an identifier or indexed indentifier

a

b

integers or _outputSequence(Symbol::pm,infinity)$\pm\infty$ satisfying $a \le b$

p

A univariate polynomial expression in `x`

x

Indeterminate

x_1, x_2, ...

numerical expressions

Return Values

floating-point number or a symbolic expression of type `numeric::product`.

Algorithms

Infinite products are calculated by summing the series sum(ln(f), i = a..infinity)$\sum_{i=a}^{\infty} \ln(f)$ via numeric::sum.

`numeric::product` uses numeric::polyroots to calculate numerical approximations to the roots of a polynomials.

See Also

_multproductnumeric::sumnumeric::polyroots

numeric::quadrature

Purpose

Numerical integration (Quadrature)

Syntax

```
numeric::quadrature(f(x), x = a .. b, <GaussLegendre
= n | GaussTschebyscheff = n | NewtonCotes = n>,
<Adaptive = v>, <MaxCalls = m>)
```

Description

`numeric::quadrature(f(x), x = a..b)` computes a numerical approximation of int(f(x), x=a..b) $\int_a^b f(x)\,dx$.

`numeric::quadrature` returns itself symbolically if the integrand `f(x)` contains symbolic objects apart from the integration variable `x` that cannot be converted to numerical values via float. Symbolic objects such as π or sqrt(2) $\sqrt{2}$ etc. are accepted.

The integrand `f(x)` should be integrable in the Riemann sense. In particular, `f(x)` should be bounded on the integration interval `x = a..b`. Certain types of mild singularities are handled, but numerical convergence is not guaranteed and will be slow in most cases. Also discontinuities and singularities of (higher) derivatives of `f(x)` slow down numerical convergence. For integrands with irregular points, it is recommended to split the integration into several parts, using subintervals on which the integrand is smooth. Cf. “Example 4” on page 19-290.

Integrands given by user-defined procedures can be handled. See “Example 4” on page 19-290 and “Example 5” on page 19-291.

`numeric::quadrature` returns itself symbolically if the boundaries `a,b` contain symbolic objects that cannot be converted to numerical values via float. Symbolic objects such as π or sqrt(2) $\sqrt{2}$ etc. as well as infinity and `-infinity` are accepted.

Note For infinite ranges, the user should make sure that the integral exists! If `f(x)` does not decay as fast as O(abs(x)^(-2)) $O\left(\frac{1}{|x|^2}\right)$ at infinity, then convergence may be slow.

Boundaries $a > b$ are accepted, using int(f(x), x=a..b)=-int(f(x), x=b..a) $\int_a^b f(x)\,\mathrm{d}\,x = -\int_b^a f(x)\,\mathrm{d}\,x$.

For complex values of `a,b`, the integration is to be understood as a contour integral along a straight line from `a` to `b`. Complex boundaries must not involve infinity.

Multi-dimensional integration such as

```
numeric::quadrature ( numeric::quadrature(f(x,y), y =
A(x)..B(x)), x = a..b)
```

is possible. See “Example 3” on page 19-289 and “Example 5” on page 19-291.

Internally, an adaptive mechanism based on a fixed quadrature rule specified by `method = n` is used. It tries to keep the relative quadrature error of the result below 10^(-DIGITS) $10^{-\mathrm{DIGITS}}$. The last digit(s) of the result may be incorrect due to roundoff effects.

The routine `numeric::quadrature` is purely numerical: no symbolic check for singularities etc. is carried out.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We demonstrate the standard calls for adaptive numerical integration: numeric::quadrature(exp(x^2), x = -1..1)2.925303492

```
2.925303492
```

numeric::quadrature(max(1/10, cos(PI*x)), x = -2..0.0123)0.752102471

```
0.752102471
```

numeric::quadrature(exp(-x^2), x = -2..infinity)1.768308316

```
1.768308316
```

The precision goal is set by DIGITS:
DIGITS := 50: numeric::quadrature(besselJ(0, x), x = 0..PI)1.34752631467399017123147312796121496422054005227 74

```
1.34752631467399017123147312796121496422054005227 74
```

Note that due to the internal adaptive mechanism, the choice of different methods should not have any significant effect on the quadrature result:
DIGITS := 10: numeric::quadrature(sin(x)/x, x = -1..10, GaussLegendre = 5), numeric::quadrature(sin(x)/x, x = -1..10, GaussLegendre = 160), numeric::quadrature(sin(x)/x, x = -1..10, NewtonCotes = 8)2.604430665, 2.604430665, 2.604430665

```
2.604430665, 2.604430665, 2.604430665
```

Example 2

The user should make sure that the integrand is well defined and sufficiently regular. The following fails, because Newton-Cotes quadrature tries to evaluate the integrand at the boundaries:
numeric::quadrature(sin(x)/x, x = 0..1, NewtonCotes = 8) Error: Division by zero. [_power] Evaluating: Quadsum

One may cure this problem be assigning a value to `f(0)`. The integrand is passed to the integrator as `hold(f)` to prevent premature evaluation of `f(x)` to `sin(x)/x`. Internally, `numeric::quadrature` replaces `x` by numerical values and then evaluates the integrand. Note that one has to define `f(0.0) := 1` rather than `f(0) := 1`:
f := x -> sin(x)/x: f(0.0) := 1: numeric::quadrature(hold(f)(x), x = 0..1, NewtonCotes = 8)0.9460830704

```
0.9460830704
```

The default method (Gauss-Legendre quadrature) does not evaluate the integrand at the end points:

numeric::quadrature(sin(x)/x, x = 0..1)0.9460830704

0.9460830704

Nevertheless, problems may still arise for improper integrals: numeric::quadrature(ln((1 + x^4)^2 - 1), x = 0 .. 1) Warning: Precision goal is not achieved after 10000 function calls. Increase 'MaxCalls' and try again for a more accurate result. [numeric::quadrature] -3.213735532

-3.213735532

In this example, the integrand is evaluated close to 0. The expression $(1 + x^4)^2 - 1$ suffers from severe numerical cancellation and is dominated by round-off. A numerically stable representation is $(1 + x^4)^2 - 1 = x^4(x^4 + 2)$: numeric::quadrature(ln(x^4*(x^4 + 2)), x = 0..1)-3.218234378

-3.218234378

Note that convergence is rather slow, because the integrand is not bounded.
delete f:

Example 3

We demonstrate multi-dimensional quadrature:
Q := numeric::quadrature: Q(Q(exp(x*y), x = 0..y), y = 0..1)0.6589510757

0.6589510757

Also more complex types of nested calls are possible. We use numerically defined functions
b := y -> Q(exp(-t^2-t*y), t = y..infinity):

and
f := y -> cos(y^2) + Q(exp(x*y), x = 0..b(y)):

for the following quadrature:

Q(f(y), y = 0..1)1.261578952

```
1.261578952
```

Multi dimensional quadrature is computationally expensive. Note that a call to `numeric::quadrature` evaluates the integrand at least $3n$ times, where n is the number of nodes of the internal quadrature rule (by default, $n = 20$ for $DIGITS \leq 10$). The following triple quadrature would call the *exp* function no less than $(320)^3 = 216000$ times!
Q(Q(Q(exp(x*y*z), x = 0..y+z), y = 0..z), z = 0..1)

For low precision goals, low order quadrature rules suffice. In the following, we reduce the computational costs by using Gauss-Legendre quadrature with 5 nodes. We use the shorthand notation `GL` to specify the `GaussLegendre` method:
DIGITS := 4: Q(Q(Q(exp(x*y*z), x=0..y+z, GL=5), y=0..z, GL=5), z=0..1, GL=5)0.665

```
0.665
```

delete Q, b, f, DIGITS:

Example 4

We demonstrate how integrands given by user-defined procedures should be handled. The following integrand
f := proc(x) begin if x<1 then sin(x^2) else cos(x^5) end_if end_proc:

cannot be called with a symbolic argument:
f(x) Error: Cannot evaluate to Boolean. [_less] Evaluating: f

Consequently, one must use hold to prevent premature evaluation of `f(x)`:
numeric::quadrature(hold(f)(x), x = -1..PI/2)0.5354101317

```
0.5354101317
```

Note that the above integrand is discontinuous at $x = 1$, causing slow convergence of the numerical quadrature. It is much more efficient to split the integral into two subquadratures with smooth integrands:
numeric::quadrature(sin(x^2), x = -1..1) + numeric::quadrature(cos(x^5), x = 1..PI/2)0.5354101318

0.5354101318

See "Example 5" on page 19-291 for multi-dimensional quadrature of user-defined procedures.
delete f:

Example 5

The following integrand
f := proc(x, y) begin if x<y then x-y else (x-y) + (x-y)^5 end_if end_proc:

can only be called with numerical arguments and must be delayed twice for 2-dimensional quadrature:
Q := numeric::quadrature:Q(Q(hold(hold(f))(x, y), x = 0..1), y = 0..1)0.02380952381

0.02380952381

Note that delaying the integrand via hold will not work for triple or higher-dimensional quadrature! The user can handle this by making sure that the integrand can also be evaluated for symbolic arguments:
f := proc(x, y, z) begin if not testtype([args()], Type::ListOf(Type::Numeric)) then return(procname(args())) end_if; if x^2 + y^2 + z^2 <= 1 then return(1) else return(0) end_if end_proc:

Note that this function is not continuous, implying slow convergence of the numerical quadrature. For this reason, we use a low precision goal of only 2 digits and reduce the costs by using a low order quadrature rule:
DIGITS := 2: Q(Q(Q(f(x, y, z), x=0..1, GL=5), y=0..1, GL=5), z=0..1, GL=5)0.52

```
0.52
```

delete f, Q, DIGITS:

Example 6

The following example uses non-adaptive Gauss-Tschebyscheff quadrature with an increasing number of nodes. The results converge quickly to the exact value:
a := exp(x)/sqrt(1 - x^2), x = -1..1: numeric::quadrature(a, Adaptive = FALSE, GT = n) $ n = 3..73.97732196, 3.977462635, 3.977463259, 3.977463261, 3.977463261

```
3.97732196, 3.977462635, 3.977463259, 3.977463261, 3.977463261
```

delete a:

Example 7

The improper integral int(x^(-9/10), x=0..1)=10 $\int_0^1 \frac{1}{x^{9/10}}\,dx = 10$ exists. Numerical convergence, however, is rather slow because of the singularity at $x = 0$:
numeric::quadrature(x^(-9/10), x = 0..1) Warning: Precision goal is not achieved after 10000 function calls. Increase 'MaxCalls' and try again for a more accurate result. [numeric::quadrature] 9.998221195

```
9.998221195
```

We remove the limit for the number of function calls and let `numeric::quadrature` grind along until a result is found. The time for the computation grows accordingly, the last digit is incorrect due to roundoff effects:
numeric::quadrature(x^(-9/10), x = 0..1, MaxCalls = infinity)9.999999993

```
9.999999993
```

Example 8

The following integral does not exist in the Riemann sense, because the integrand is not bounded:
numeric::quadrature(1/x, x = -1..2) Warning: Precision goal is not achieved after 10000 function calls. Increase 'MaxCalls' and try again for a more accurate result. [numeric::quadrature] 116.9391252

```
116.9391252
```

We increase `MaxCalls`. There is no convergence of the numerical algorithm, because the integral does not exist. Consequently, some internal problem must arise: `numeric::quadrature` reaches its maximal recursive depth:
numeric::quadrature(1/x, x = -1..2, MaxCalls = infinity) Warning: Precision goal is not achieved after 'MAXDEPTH=500' recursive calls. There might be a singularity of '1/x' close to 'x=3.910318545e-148'. Increase 'MAXDEPTH' and try again for a more accurate result. [adaptiveQuad] 3.262987586

```
3.262987586
```

Parameters

f(x)

An arithmetical expression in x

x

An identifier or an indexed identifier

a

b

Real or complex numerical values or _outputSequence(Symbol::pm,infinity) $\pm\infty$

Options

GaussLegendre

GaussTschebyscheff

NewtonCotes

Options, specified as `GaussLegendre = n`, `GaussTschebyscheff = n`, `NewtonCotes = n`

The name of the underlying quadrature scheme. Each quadrature rule can be used with an arbitrary number of nodes specified by the positive integer *n*.

Usually there is no need to use this option to change the default method `GaussLegendre = n` with `n = 20,40,80` or `160`, depending on the precision goal determined by the environment variable DIGITS. Due to the corresponding high quadrature orders 40, 80, 160 or 320, respectively, the default settings are suitable for high precision computations.

With `GaussLegendre = n`, an adaptive version of Gauss-Legendre quadrature with *n* nodes is used.

For *DIGITS* ≤ 200, the weights and abscissae of Gaussian quadrature with *n* = 20, 40, 80, and 160 nodes are available and the integration starts immediately.

For *DIGITS* > 200, the routine numeric::gldata is called to compute the Gaussian data before the actual integration starts. This will be noted by some delay in the first call of `numeric::quadrature`.

For DIGITS much larger than 200, it is recommended not to use the default setting but to use `GaussLegendre = n` with sufficiently high `n` instead. A reasonable choice is $n \approx DIGITS$.

With `GaussTschebyscheff = n`, non-adaptive Gauss-Tschebyscheff quadrature with *n* nodes is used. This method may only be used in conjunction with `Adaptive = FALSE`.

Note With `NewtonCotes = n`, an adaptive version of Newton-Cotes quadrature with n nodes is used. Note that these quadrature rules become numerically unstable for large n (n much larger than 10).

Following alternative names for the methods are accepted:

`GaussLegendre`, `Gauss`, `GL`,

`GaussTschebyscheff`, `GT`, `GaussChebyshev`, `GC`,

`NewtonCotes`, `NC`.

Adaptive

Option, specified as `Adaptive = v`

`v` may be TRUE or FALSE. With `Adaptive = FALSE`, the internal error control is switched off.

The default setting is `Adaptive = TRUE`. An adaptive quadrature scheme with automatic control of the quadrature error is used.

The call `numeric::quadrature(f(x), x = a..b, method = n, Adaptive = FALSE)` returns the quadrature sum (b-a)*sum(B[i]*f(a+C[i]*(b-a)), i=1..n) $(b-a)\left(\sum_{i=1}^{n} B_i f(a + C_i (b-a))\right)$ approximating int(f(x), x=a..b) $\int_a^b f(x)\,dx$ without any control of the quadrature error. The weights B_i and abscissae C_i are determined by the quadrature rule given by `method = n`. For the methods `GaussLegendre`, `GaussTschebyscheff` and `NewtonCotes`, these data are available via numeric::gldata, numeric::gtdata and numeric::ncdata, respectively.

`Adaptive = FALSE` may only be used in conjunction with `method = n`.

Usually there is no need to switch off the internal adaptive quadrature via `Adaptive = FALSE`. This option is meant to give easy access to standard non-adaptive quadrature rules of Gauss-Legendre, Gauss-Tschebyscheff and Newton-Cotes type,

respectively. The user may want to build his own adaptive quadrature based on these non-adaptive rules. Cf. “Example 6” on page 19-292.

MaxCalls

Option, specified as `MaxCalls = m`

`m` must be a (large) positive integer or infinity. It is the maximal number of evaluations of the integrand, before `numeric::quadrature` gives up.

When called interactively, `numeric::quadrature` returns the approximation it has computed so far and issues a warning. See “Example 7” on page 19-292. When called from inside a procedure, `numeric::quadrature` returns FAIL.

The default value is `m = MAXDEPTH*n`. The environment variable MAXDEPTH (default value 500) represents the maximal recursive depth of a function. `n` is the number of nodes of the basic quadrature rule specified by the optional argument `method = n`. If no such method is specified by the user, then Gauss-Legendre quadrature is used with $n = 20$ for $DIGITS \le 10$, $n = 40$ for $10 < DIGITS \le 50$, $n = 80$ for $50 < DIGITS \le 100$, $n = 160$ for $100 < DIGITS$. Thus, for $DIGITS = 10$, the default setting is `MaxCalls = 10000`.

The default value of `m` ensures that the `MaxCalls` limit is reached before `numeric::quadrature` reaches its maximal internal recursive depth. Specifying `MaxCalls = infinity` removes this restriction and `numeric::quadrature` computes until it obtains an approximation with about DIGITS correct digits or until it runs into an internal error. The typical error that may occur is the evaluation of the integrand at a singularity. There also is the danger of `numeric::quadrature` reaching its maximal internal recursive depth. When called interactively, `numeric::quadrature` returns the approximation it has computed so far and issues a warning. See “Example 8” on page 19-293. When called from inside a procedure, `numeric::quadrature` returns FAIL.

Return Values

Floating point number is returned, unless non-numerical symbolic objects in the integrand `f(x)` or in the boundaries `a,b` prevent numerical evaluation. In this case, `numeric::quadrature` returns itself symbolically. If numerical problems occur, then FAIL is returned.

intnumeric::gldatanumeric::gtdatanumeric::intnumeric::ncdata

numeric::rank

Purpose

Numerical estimate of the rank of a matrix

Syntax

```
numeric::rank(A, <eps>, options)
```

Description

`numeric::rank(A)` returns an integer indicating the rank of the matrix *A*.

All entries of the input matrix must be numerical, i.e., they must be floating-point numbers or expressions that can be converted to floating-point numbers.

The rank of a matrix coincides with the number of non-zero singular values.

A numerical estimate of the rank is computed by counting all singular values that are larger than $epss_max$, where s_max is the largest singular value. (All smaller singular values are regarded as round-off artifacts and treated as zero.)

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We consider a quadratic matrix of rank 2:
A := matrix([[1, 1, I], [1, 2, 3], [2, 4, 6]]): numeric::rank(A)2

2

Hilbert matrices have full rank. However, they are extremely ill-conditioned and it is difficult to compute their rank numerically. The 10 10 Hilbert matrix has rank 10. Numerically, however, some of the singular values are so small that they may be regarded as zero resulting in a smaller numerical rank. In particular, with the default value `eps` = 10^(-DIGITS)$\frac{1}{10^{DIGITS}}$, two singular values are smaller than

$epss_max$ where s_max = _outputSequence(1.7519 , dots)1.7519... is the maximal singular value:
A := linalg::hilbert(10): numeric::singularvalues(A)[1.75191967, 0.3429295485, 0.03574181627, 0.002530890769, 0.0001287496143, 0.000004729689293, 0.0000001228967739, 0.00000002147438818, 2.26674678e-11, 1.093197787e-13]

numeric::rank(A)8

$$[1.75191967, 0.3429295485, 0.03574181627, 0.002530890769, 0.0001287496143, 0.0000047\ldots$$
$$0.00000002147438818, 2.26674678\,10^{-11}, 1.093197787\,10^{-13}]$$

8

We specify a second argument eps = 10^{-14} to allow smaller singular values to be regarded as non-zero. Now, the numerical rank is 10:
numeric::rank(A, 10^(-14))10

10

delete A:

Example 2

We consider a non-square matrix of rank 1:
A := matrix([[0, 0], [I, 1], [I, 1]]): numeric::rank(A)1

1

delete A:

Example 3

We demonstrate the difference between hardware floats and software floats:
A := linalg::hilbert(15): numeric::rank(A, 10^(-20), SoftwareFloats), numeric::rank(A, 10^(-20), HardwareFloats)14, 15

```
14, 15
```
delete A:

Parameters

A

An m n matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

eps

Relative tolerance: regard all singular values `s` of `A` as zero if they satisfy $s \leq epss_max$, where s_max is the largest singular value of `A`.

The default value of `eps` is 10^(-DIGITS)$_{10^{-DIGITS}}$.

Options

Hard

HardwareFloats

Soft

SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point

numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix `A` is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

Note For ill-conditioned matrices, the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 3” on page 19-299.

Return Values Positive integer.

See Also linalg::rank

numeric::rationalize

Purpose

Approximate a floating-point number by a rational number

Syntax

```
numeric::rationalize(object, <Exact | Minimize
| Restore>, <digits>)
```

Description

`numeric::rationalize(object)` replaces all floating-point numbers in `object` by rational numbers.

An object of a library domain, characterized by `domtype(extop(object,0))=DOM_DOMAIN` is returned unchanged. For all other objects, `numeric::rationalize` is applied recursively to all operands. Objects of library domains can be rationalized if the domain has an appropriate `map` method. See "Example 5" on page 19-307.

A floating-point number f is approximated by a rational number r satisfying $|f - r| < \varepsilon |f|$.

Note With the options `Exact` and `Minimize`, the guaranteed precision is Symbol::epsiv=10^(-digits)$_{\varepsilon = \frac{1}{10^{digits}}}$. With `Restore`, the guaranteed precision is only Symbol::epsiv=10^(-digits/2)$_{\varepsilon = \frac{1}{10^{\frac{digits}{2}}}}$.

The default precision is `digits = DIGITS`.

The user defined precision must not be larger than the internal floating-point precision set by DIGITS: an error occurs for `digits > DIGITS`.

Environment Interactions

The function is sensitive to the environment variable DIGITS.

Examples

Example 1

`numeric::rationalize` is applied to each operand of a composite object:

numeric::rationalize(0.2*a+b^(0.7*I))a/5 + b^((7/10)*I)

$$\frac{a}{5} + b^{\frac{7\,i}{10}}$$

numeric::rationalize([{poly(0.2*x, [x]), sin(7.2*PI) + 1.0*I}, exp(3 + ln(2.0*x))])[{sin((36*PI)/5) + I, poly(x/5, [x])}, exp(ln(2*x) + 3)]

$$\left[\left\{\sin\left(\frac{36\,\pi}{5}\right) + i,\ \mathrm{poly}\left(\frac{x}{5}, [x]\right)\right\},\ e^{\ln(2\,x)+3}\right]$$

Example 2

We demonstrate the default strategy `Exact`:
numeric::rationalize(12.3 + 0.5*I), numeric::rationalize(0.33333), numeric::rationalize(1/3.0)123/10 + (1/2)*I, 33333/100000, 33333333333/100000000000

$$\frac{123}{10} + \frac{i}{2},\ \frac{33333}{100000},\ \frac{33333333333}{100000000000}$$

numeric::rationalize(10^12/13.0), numeric::rationalize(10^(-12)/13.0)76923076923, 76923076923/10000000000000000000000000

$$76923076923,\ \frac{76923076923}{10000000000000000000000000}$$

We reduce the precision of the approximation to 5 digits:
numeric::rationalize(10^12/13.0, 5), numeric::rationalize(10^(-12)/13.0, 5)76923100000, 769231/10000000000000000000

$$76923100000,\ \frac{769231}{10000000000000000000}$$

Example 3

We demonstrate the strategy `Minimize` for minimizing the complexity of the resulting rational number:

numeric::rationalize(1/13.0, 5), numeric::rationalize(1/13.0, Minimize, 5), numeric::rationalize(0.333331, 5), numeric::rationalize(0.333331, Minimize, 5), numeric::rationalize(14.285, 5), numeric::rationalize(14.2857, Minimize, 5), numeric::rationalize(1234.1/56789.2), numeric::rationalize(1234.1/56789.2, Minimize)769231/10000000, 1/13, 333331/1000000, 1/3, 2857/200, 100/7, 21731244673/1000000000000, 12341/567892

$$\frac{769231}{10000000}, \frac{1}{13}, \frac{333331}{1000000}, \frac{1}{3}, \frac{2857}{200}, \frac{100}{7}, \frac{21731244673}{1000000000000}, \frac{12341}{567892}$$

We compute rational approximations of π with various precisions:
numeric::rationalize(float(PI), Minimize, i) $ i = 1..103, 22/7, 22/7, 355/113, 355/113, 355/113, 355/113, 102573/32650, 104348/33215, 208341/66317

$$3, \frac{22}{7}, \frac{22}{7}, \frac{355}{113}, \frac{355}{113}, \frac{355}{113}, \frac{355}{113}, \frac{102573}{32650}, \frac{104348}{33215}, \frac{208341}{66317}$$

Example 4

We demonstrate the strategy `Restore` for restoring rational numbers after elementary float operations. In many cases, also the `Minimize` strategy restores:
numeric::rationalize(1/7.3, Exact), numeric::rationalize(1/7.3, Minimize), numeric::rationalize(1/7.3, Restore)13698630137/100000000000, 10/73, 10/73

$$\frac{13698630137}{100000000000}, \frac{10}{73}, \frac{10}{73}$$

However, using `Restore` improves the chances of recovering from roundoff effects:
numeric::rationalize(10^9/13.0, Minimize), numeric::rationalize(10^9/13.0, Restore)923076923/12, 1000000000/13

$$\frac{923076923}{12}, \frac{1000000000}{13}$$

DIGITS:= 11: numeric::rationalize(1234.56/12345.67, Minimize), numeric::rationalize(1234.56/12345.67, Restore)88183/881835, 123456/1234567

$$\frac{88183}{881835}, \frac{123456}{1234567}$$

In some cases, `Restore` manages to recover from roundoff error propagation in composite arithmetical operations:
DIGITS:= 10: x:= float(122393/75025): y:= float(121393/75025): z := (x^2 - y^2)/(x + y)0.01332889037

$$0.01332889037$$

numeric::rationalize(z, Restore)40/3001

$$\frac{40}{3001}$$

The result with `Restore` corresponds to exact arithmetic:
rx := numeric::rationalize(x, Restore): ry := numeric::rationalize(y, Restore): rx, ry, (rx^2 - ry^2)/(rx + ry)122393/75025, 121393/75025, 40/3001

$$\frac{122393}{75025}, \frac{121393}{75025}, \frac{40}{3001}$$

Note that an approximation with `Restore` may have a reduced precision of only `digits/2`:
x := 1.0 + 1/10^6: numeric::rationalize(x, Exact), numeric::rationalize(x, Restore)1000001/1000000, 1

$$\frac{1000001}{1000000}, 1$$

delete x, y, z, rx, ry:

Example 5

The floats inside objects of library domains are not rationalized directly. However, for most domains the corresponding `map` method can forward `numeric::rationalize` to the operands:
Dom::Multiset(0.2, 0.2, 1/5, 0.3){[0.2, 2], [1/5, 1], [0.3, 1]}

$$\{[0.2, 2], [\frac{1}{5}, 1], [0.3, 1]\}$$

numeric::rationalize(%), map(%, numeric::rationalize, Restore){[0.2, 2], [1/5, 1], [0.3, 1]}, {[1/5, 3], [3/10, 1]}

$$\{[0.2, 2], [\frac{1}{5}, 1], [0.3, 1]\}, \{[\frac{1}{5}, 3], [\frac{3}{10}, 1]\}$$

Parameters

object

An arbitrary MuPAD object

digits

A positive integer (the number of decimal digits) not bigger than the environment variable DIGITS. It determines the precision of the rational approximation.

Options

Exact

Specifies the strategy for approximating floating-point numbers by rational numbers. This is the default strategy, so there is no real need to pass `Exact` as a parameter to `numeric::rationalize`.

Any real floating-point number $f \neq 0.0$ has a unique representation

f=sign(f) * mantissa * 10^(exponent)

$$f = \text{sign}(f)\ \text{mantissa}\ 10^{\text{exponent}}$$

With integer exponent and $1.0 \le mantissa < 10.0$. With the option `Exact`, the float mantissa is replaced by the rational approximation

round(mantissa * 10^digits)/(10^digits)

$$\frac{\mathrm{round}\left(\mathrm{mantissa}\ 10^{\mathrm{digits}}\right)}{10^{\mathrm{digits}}}$$

This guarantees a relative precision of `digits` significant decimals of the rational approximation.

Minimize

Specifies the strategy for approximating floating-point numbers by rational numbers. This strategy tries to minimize the complexity of the rational approximation, i.e., numerators and denominators are to be small.

The guaranteed precision of the rational approximation is `digits`.

See "Example 3" on page 19-304.

Restore

Specifies the strategy for approximating floating-point numbers by rational numbers. This strategy tries to restore rational numbers obtained after *elementary* arithmetical operations applied to floating-point numbers. E.g., for rational `r`, the float division `f = 1/float(r)` introduces additional roundoff, which the `Restore` algorithm tries to eliminate: `numeric::rationalize(f, Restore) = 1/r`. This strategy, however, is purely heuristic and will not succeed when significant roundoff is caused by arithmetical float operations!

Note The guaranteed precision of the rational approximation is only `digits/2`!

See “Example 4” on page 19-305.

Return Values

If the argument is an object of some kernel domain, then it is returned with all floating-point operands replaced by rational numbers. An object of some library domain is returned unchanged.

Overloaded By

`object`

Algorithms

Continued fraction (CF) expansion is used with the options `Minimize` and `Restore`.

With `Minimize`, the first CF approximation satisfying the precision criterion is returned.

The `Restore` algorithm stops, when large coefficients of the CF expansion are found.

numeric::realroot

Purpose

Numerical search for a real root of a real univariate function

Syntax

```
numeric::realroot(f(x), x = a .. b, <SearchLevel = s>)
```

Description

`numeric::realroot(f(x), x = a..b)` computes a numerical real root of $f(x)$ in the interval $[a, b]$.

The expression `f(x)` must not contain symbolic objects other than the indeterminate `x` that cannot be converted to numerical values via float. Symbolic objects such as PI or sqrt(2)$\sqrt{2}$ etc. are accepted. The same holds true for the boundaries `a, b` of the search interval.

The function must produce real values. If `float(f(x))` does not yield real floating-point numbers for all real floating-point numbers `x` from the interval Interval([a, b])$[a, b]$, internal problems may occur. See "Example 5" on page 19-312.

`numeric::realroot` never tries to evaluate `f(x)` outside the search interval. Consequently, singularities outside the interval do not cause any problems. In many cases also singularities inside the interval do not affect the numerical search. However, `numeric::realroot` is not guaranteed to work in such a case. An error may occur, if the internal search accidentally hits a singularity. See "Example 5" on page 19-312.

Up to roundoff effects numerical roots r with

abs(r)>=10^(-DIGITS)$|r| \geq \frac{1}{10^{DIGITS}}$ are computed to a relative precision of DIGITS significant decimal places. Roots of smaller absolute size are

computed to an absolute precision of 10^(-2*DIGITS)$\frac{1}{10^{2\,DIGITS}}$. These precision goals are not achieved, if significant roundoff occurs in the numerical evaluation of $f(x)$.

If f takes opposite signs at the endpoints a, b of the search interval and does not have zero-crossing singularities, then `numeric::realroot` is bound to find a root in the interval Interval([a,b])$[a, b]$.

User defined functions can be handled. See "Example 2" on page 19-311.

Note `numeric::realroot` approximates a point where `f(x)` changes its sign. This is a root only if the function `f` is continuous. See "Example 3" on page 19-312.

`setuserinfo(numeric::realroot,1)` provides information on the internal search.

Note that numeric::realroots may be used to isolate *all* real roots. However, this function is much slower than `numeric::realroot`, if *f* is not a polynomial.

For univariate polynomials we recommend to use numeric::realroots or polylib::realroots rather than `numeric::realroot`.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

The following functions assume different signs at the boundaries, so the searches are bound to succeed:
numeric::realroot(x^3 - exp(3), x = -PI..10)2.718281828

```
2.718281828
```

numeric::realroot(exp(-x[1]) = x[1], x[1] = 0..1)0.5671432904

```
0.5671432904
```

Example 2

The following function cannot be evaluated for non-numerical `x`. So one has to delay evaluation via hold:
f := proc(x) begin if x<0 then 1 - x else exp(x) - 10*x end_if end_proc:
numeric::realroot(hold(f)(x), x = -10..10)0.1118325592

```
0.1118325592
```

delete f:

Example 3

`numeric::realroot` approximates a point, where $f(x)$ changes its sign. For the following function this happens at the discontinuity $x = 1$:

```
f := proc(x) begin if x<1 then -1 else x end_if end_proc:
numeric::realroot(hold(f)(x), x = 0..3)1.0
```

```
1.0
```

delete f:

Example 4

The following function does not have a real root. Consequently, `numeric::realroot` fails:

```
numeric::realroot(x^2 + 1, x = -2..2)FAIL
```

```
FAIL
```

The following function does not have a real root in the search interval:

```
numeric::realroot(x^2 - 1, x = 2..3)FAIL
```

```
FAIL
```

Example 5

The following function is complex valued for $x^2 < 3.5$. An error occurs, when the internal search hits such a point:

```
numeric::realroot(ln(x^2 - 3.5), x = -2..3) Error: Cannot evaluate to
Boolean. [_less] Evaluating: numeric::BrentFindRoot
```

The singularity at $x = 1$ does not cause any problem in the following call:

```
numeric::realroot((x-2)/(x-1), x = -10..10)2.0
```

```
2.0
```

However, the singularity may be hit accidentally in the internal search: numeric::realroot((x-2)/(x-1), x = 0..3) Error: Division by zero. [_power] Evaluating: f

Example 6

The following function has a root close to 1.0, which is difficult to detect. With the default search level $s = 1$, this root is not found:
f := 2 - exp(-100*(x - 2)^2) - 2*exp(-1000*(x - 1)^2): numeric::realroot(f, x = 0..5)FAIL

```
FAIL
```

The root is detected with an increased search level:
numeric::realroot(f, x = 0..5, SearchLevel = 3)1.0

```
1.0
```

delete f:

Parameters

f(x)

An arithmetical expression in one unknown `x` or a list, set, array, or matrix (Cat::Matrix) of expressions. Alternatively, equations in the form $f_1(x) = f_2(x)$ equivalent to the expressions $f_1(x) - f_2(x)$.

x

An identifier or an indexed identifier

a

b

Finite real numerical values

Options

SearchLevel

Option, specified as `SearchLevel = s`

The nonnegative integer s controls the internal refinement of the search. The default value is $s = 1$. Increasing s increases the chance of finding roots that are difficult to detect numerically. See “Example 6” on page 19-313.

Note that increasing s by 1 may quadruple the time before `FAIL` is returned, if no real root is found. For this reason we recommend to restrict s to small values ($s \leq 5$, say).

Return Values

Single numerical real root of domain type DOM_FLOAT. If no solution is found, then FAIL is returned.

Algorithms

A mixture of bisectioning, secant steps and quadratic interpolation is used by `numeric::realroot`.

Concepts

- “Solve Equations Numerically”

numeric::realroots

Purpose

Isolate intervals containing real roots of a univariate function

Syntax

```
numeric::realroots(f(x), <x = a .. b>, <eps>, <Merge = c>)
```

Description

`numeric::realroots(f(x), x = a..b)` searches for real roots of $f(x)$ in the interval Interval([a, b])$[a, b]$. It returns a list of subintervals in which real roots of $f(x)$ may exist. It is guaranteed that there are no real roots in the interval Interval([a, b])$[a, b]$ lying outside the union of the returned subintervals.

With `Merge = FALSE`, all intervals returned by `numeric::realroots` have length $b_i - a_i < eps$ with a default value $eps = 0.01$. The absolute precision of the root isolation may be redefined using the optional parameter `eps`.

Note The intervals returned by `numeric::realroots` define a subset of Interval([a, b])$[a, b]$ that may contain real roots. For polynomial expressions $f(x)$, each of the subintervals of Interval([a, b])$[a, b]$ returned by `numeric::realroots` is guaranteed to contain exactly one root. For non-polynomial expressions $f(x)$, however, some of the subintervals may contain no root! Cf. "Example 6" on page 19-319.

In any case, the complement Interval([a,b]) minus solvelib::Union(Interval([a[i], b[i]]), i, {1, dots, n})$[a, b] \setminus (\bigcup_{i \in \{1, \ldots, n\}} [a_i, b_i])$ of the subintervals Interval([a[i], b[i]])$[a_i, b_i]$ returned by `numeric::realroots` is guaranteed to contain no real roots. In particular, from the return value [], one may positively conclude that no root exists in the search interval Interval([a, b])$[a, b]$. Cf. "Example 2" on page 19-317.

Symbolic parameters in $f(x)$ are not allowed: `float(f(x))` must evaluate to a floating point number for all x from the interval Interval([a, b])$[a, b]$.

Infinite intervals of the form `x = -infinity..b` are not refined if $b \le -10^5$.

Infinite intervals of the form `x = a..infinity` are not refined if $a \ge 10^5$.

Such intervals are returned directly if `numeric::realroots` thinks that they may contain roots. Cf. “Example 5” on page 19-319.

$f(x)$ may contain complex expressions. Only the search parameter x is assumed to be real. For complex expressions `f(x)`, the intervals are returned where both the real and the imaginary part of the expression vanish simultaneously.

Note The expression `f(x)` must be suitable for interval arithmetic. In particular, MuPAD must be able to evaluate `f(a...b)`. Note that not all MuPAD functions support this kind of arithmetic.

Presently, the following special functions support interval arithmetic: abs, arccos, arccosh, arccoth, arccot, arccsc, arccsch, arcsec, arcsech, arcsin, arcsinh, arctan, arctanh, arg, beta, ceil, cos, cosh, cot, coth, csc, csch, dirac, exp, floor, gamma, Im, ln, Re, round, sec, sech, sin, sinh, sqrt, tan, tanh, trunc. Real roots can be searched for any expression that is built from these functions using the standard arithmetical operations +, -, *, /, ^.

The default value is *eps* = 0.01. User defined precision goals must satisfy eps>= 10^-DIGITS$\mathrm{eps} \ge \frac{1}{10^{\mathrm{DIGITS}}}$.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

The following expression has integer zeros. The solutions in the specified interval are approximated to the default precision 0.01:

numeric::realroots(sin(PI*x), x = -2..sqrt(2))[[-2.0, -1.993331614], [-1.006410506, -0.9997421204], [-0.006152626661, 0.000515759203], [0.9941052529, 1.000773639]]

[[-2.0, -1.993331614], [-1.006410506, -0.9997421204], [-0.006152626661, 0.0005157592

The following equation is solved with an absolute precision of 7 digits:
numeric::realroots(x*sin(x) = exp(-x), x = -1..1, 10^(-7))[[0.7271005511, 0.7271006107]]

[[0.7271005511, 0.7271006107]]

Example 2

The following expression does not have a real root:
numeric::realroots(exp(x) + x^2, x = -100..100)[]

[]

Example 3

We demonstrate the option `Merge`. If interval arithmetic can not isolate roots to the desired precision *eps* (default 0.01), then adjacent intervals are produced, each of length smaller than *eps*. This happens in the following example:
numeric::realroots(ln(x^2 -2*x + 2) = 0, x = -10..10, Merge = FALSE)[[0.869140625, 0.87890625], [0.87890625, 0.888671875], [0.888671875, 0.8984375], dots, [1.123046875, 1.1328125], [1.1328125, 1.142578125]]

[[0.869140625, 0.87890625], [0.87890625, 0.888671875], [0.888671875, 0.8984375], ..., [1.123

[[0.869140625, 0.87890625], [0.87890625, 0.888671875], [0.888671875, 0.8984375], [0.8984375, 0.908203125], [0.908203125, 0.91796875], [0.91796875, 0.927734375], [0.927734375, 0.9375], [0.9375, 0.947265625], [0.947265625, 0.95703125], [0.95703125, 0.966796875],

[0.966796875, 0.9765625], [0.9765625, 0.986328125], [0.986328125, 0.99609375], [0.99609375, 1.005859375], [1.005859375, 1.015625], [1.015625, 1.025390625], [1.025390625, 1.03515625], [1.03515625, 1.044921875], [1.044921875, 1.0546875], [1.0546875, 1.064453125], [1.064453125, 1.07421875], [1.07421875, 1.083984375], [1.083984375, 1.09375], [1.09375, 1.103515625], [1.103515625, 1.11328125], [1.11328125, 1.123046875], [1.123046875, 1.1328125], [1.1328125, 1.142578125]]

With `Merge = TRUE`, these intervals are combined to a single larger interval. Since `Merge = TRUE` is the default setting for non-polynomial functions, it suffices to omit the option `Merge = FALSE`:
numeric::realroots(ln(x^2 -2*x + 2) = 0, x = -10..10)[[0.869140625, 1.142578125]]

```
[[0.869140625, 1.142578125]]
```

Example 4

The following expression has infinitely many solutions x=1/n$x = \frac{1}{n}$ with n = 1, 2, … in the search interval [0, 1]:
numeric::realroots(sin(PI/x), x = 0..1, 0.1, Merge = FALSE)[[0.0, 0.0625], [0.0625, 0.125], [0.125, 0.1875], [0.1875, 0.25], [0.25, 0.3125], [0.3125, 0.375], [0.4375, 0.5], [0.5, 0.5625], [0.9375, 1.0]]

```
[[0.0, 0.0625], [0.0625, 0.125], [0.125, 0.1875], [0.1875, 0.25], [0.25, 0.3125], [0.3125, 0.375], [0.43
```

Omitting `Merge = FALSE`, adjacent intevals are merged to larger intervals. The first of the following intervals contains infinitely many roots:
numeric::realroots(sin(PI/x), x = 0..1, 0.1)[[0.0, 0.375], [0.4375, 0.5625], [0.9375, 1.0]]

```
[[0.0, 0.375], [0.4375, 0.5625], [0.9375, 1.0]]
```

Example 5

If no search interval is specified, the entire real line is considered:
numeric::realroots(x^3 = exp(x))[[1.841783524, 1.871585846], [4.523992538, 4.553794861], [100000.0, infinity]]

[[1.841783524, 1.871585846], [4.523992538, 4.553794861], [100000.0, ∞]]

Apart from two finite intervals, `numeric::realroots` tells us that there may be a root close to infinity (but that there is positively no root close to -infinity). Analytically, it is clear that the subinterval Interval([10000.0, infinity])[10000.0, ∞] cannot contain a root, since exp(x)e^x grows much faster than x^3 as x goes to infinity. If a finite upper limit for the search interval is specified, this fact is detected:
numeric::realroots(x^3 = exp(x), x = -infinity .. 10^100)[[1.842076975, 1.877795331], [4.512024084, 4.556672029]]

[[1.842076975, 1.877795331], [4.512024084, 4.556672029]]

We isolate the two finite roots more closely by specifying a precision goal of 10^(-DIGITS)$10^{-\frac{1}{DIGITS}}$:
numeric::realroots(x^3 = exp(x), x = -infinity .. 10^100, 10^(-DIGITS))[[1.85718386, 1.85718386], [4.536403655, 4.536403655]]

[[1.85718386, 1.85718386], [4.536403655, 4.536403655]]

Example 6

The following equation has no root close to 0. However, interval arithmetic does not produce realistic values of sin(PI*x)/x$\frac{\sin(\pi\,x)}{x}$ for small intervals containing $x = 0$, so an isolating interval around 0 is returned:
numeric::realroots(sin(PI*x)/x = 0, x = -1..1.2)[[-1.0, -0.99140625], [-0.003125, 0.00546875], [0.99375, 1.00234375]]

[[−1.0, −0.99140625], [−0.003125, 0.00546875], [0.99375, 1.00234375]]

A similar phenomenon occurs with x^x=exp(x*ln(x))$x^x = e^{x \ln(x)}$ in a neighbourhood of $x = 0$. An isolating interval around 0 is returned, although no solution exists there:
numeric::realroots(x^x*cos(PI*x) = tan(x), x = 0..1)[[0.0, 0.0078125], [0.328125, 0.3359375]]

```
[[0.0, 0.0078125], [0.328125, 0.3359375]]
```

This cannot be cured by increasing the precision goal:
numeric::realroots(x^x*cos(PI*x) = tan(x), x = 0..1, 10^(-DIGITS))[[0.0, 5.820766091e-11], [0.3334737903, 0.3334737903]]

```
[[0.0, 5.820766091 10^-11], [0.3334737903, 0.3334737903]]
```

Parameters

f(x)

An expression in one indeterminate `x` or a list, set, array, or matrix (Cat::Matrix) of expressions. Alternatively, equations in the form `f1(x) = f2(x)` equivalent to the expressions `f1(x) - f2(x)`.

x

An identifier or an indexed identifier

a

b

Real numbers or numerical expressions satisfying $a < b$. Also `-infinity` and infinity may be used.

eps

A (small) positive real numerical value defining the precision goal. The default value is 0.01.

Options

Merge

Option, specified as `Merge = b`

b can be TRUE or FALSE. With `Merge = FALSE`, `numeric::realroots` returns subintervals of length not larger than `eps`. With `Merge = TRUE`, `numeric::realroots` merges adjacent subintervals to larger intervals, i.e., subintervals of length larger than `eps` may be returned.

The default setting is `Merge = FALSE` for polynomial functions $f(x)$. Otherwise, it is `Merge = TRUE`.

`numeric::realroots` isolates intervals Interval([a[i], b[i]])$[a_i, b_i]$ that may contain roots. Internally, all these intervals satisfy $b_i - a_i < eps$ where eps is the precision goal.

With `Merge = FALSE`, these intervals are returned.

With `Merge = TRUE`, adjacent intervals Interval([a[i], b[i]]), Interval([a[(i+1)], b[(i+1)]])$[a_i, b_i], [a_{i+1}, b_{i+1}]$ with $b_i = a_{i+1}$ are combined to larger intervals Interval([a[i], b[(i+1)]])$[a_i, b_{i+1}]$. See “Example 3” on page 19-317 and “Example 4” on page 19-318.

The default setting is `Merge = FALSE` for polynomial functions. Otherwise, it is `Merge = TRUE`.

Return Values

List $[[a_1, b_1], [a_2, b_2], \ldots]$ of disjoint floating-point intervals Interval([a[i], b[i]]) subset Interval([a,b])$[a_i, b_i] \subset [a, b]$ which may contain roots of $f(x)$. The empty list is returned if no root exists in the search interval $[a, b]$.

Algorithms

Let X be a subset of the real numbers. Interval arithmetic produces a set $F(X)$ such that the set of image values ImageSet(f(x), x in X)$\{f(x) \mid x \in X\}$ is contained in $F(X)$. The MuPAD domain DOM_INTERVAL facilitates this kind of arithmetic. The routine `numeric::realroots` computes F := f(a[i] ... b[i])$F := f([a_i \ldots b_i])$ for various subintervals Interval([a[i], b[i]])$[a_i, b_i]$ of Interval([a, b])$[a, b]$. If F does not contain zero, then this subinterval is eliminated from the search interval. Otherwise, the subinterval is returned as a candidate for containing zeros of $f(x)$. However, one cannot conclude that F does indeed contain at least one zero, since F is usually larger than the true image set ImageSet(f(x), x in Interval([a_i,b_i]))$\{f(x) \mid x \in [a_i, b_i]\}$ (‘overestimation’).

For polynomials $f(x)$, the routine polylib::realroots is called. Its results are intersected with the search interval Interval([a, b])$[a, b]$. No interval arithmetic is used for polynomial expressions. For polynomial equations, each isolating interval returned by `numeric::realroots` is guaranteed to contain at least one root if `Merge = TRUE` is specified. With the default setting of `Merge = FALSE` for polynomials, each isolating interval is guaranteed to contain exactly one root.

Concepts

- "Solve Equations Numerically"

numeric::rotationMatrix

Purpose

Orthogonal matrix of the rotation about an axis

Syntax

```
numeric::rotationMatrix(angle, axis, <Symbolic>,
<ReturnType = t>)
```

Description

`numeric::rotationMatrix(angle, axis)` returns an orthogonal matrix corresponding to the rotation about the given axis by the given angle.

The rotation by the angle *alpha* about the axis given by the vector [*x*, *y*, *z*] of Euclidean length 1 is given by the rotation matrix

exp(alpha * matrix([[0,-z, y], [z, 0,-x], [-y, x, 0]])) = matrix([[t*x^2 + c, t*x*y - s*z, t*x*z + s*y], [t*x*y + s*z, t*y^2 + c, t*y*z - s*x], [t*x*z - s*y, t*y*z + s*x, t*z^2 + c]])

$$e^{\mathrm{alpha}\begin{pmatrix} 0 & -z & y \\ z & 0 & -x \\ -y & x & 0 \end{pmatrix}} = \begin{pmatrix} t x^2 + c & t x y - s z & t x z + s y \\ t x y + s z & t y^2 + c & t y z - s x \\ t x z - s y & t y z + s x & t z^2 + c \end{pmatrix}$$

with $c = cos(alpha)$, $s = sin(alpha)$, and $t = 1 - c = 2*\sin(\mathrm{alpha}/2)^2$.

The rotation is implemented following the “right hand rule”: Stretch the thumb of your right hand and bend the fingers. When the thumb points into the direction of the rotation axis, your finger tips indicate the direction of the rotation.

Use negative angles to rotate in the opposite direction.

The axis parameter of the routine does not need to be normalized to the Euclidean length 1. However, it must not be of zero length.

If no return type is specified via the option `ReturnType = t`, the domain type of the result depends on the type of the input matrix `axis`:

- If the axis is of domain type array, then the rotation matrix is returned as an array.
- If the axis is of domain type hfarray, then the result is returned as an hfarray.
- If the axis is of domain type `Dom::DenseMatrix()`, then the rotation matrix is returned as a matrix of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- If axis is of any different matrix type, the result is a matrix of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `axis` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.
- If axis is a list with 3 elements, the rotation matrix is also returned as an `Dom::Matrix()` over the ring of MuPAD expressions.

Without the option `Symbolic`, all arguments are automatically converted to floating-point arguments (if possible). Use the option `Symbolic` if no such conversion is desired.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

The rotation around the z axis by 45 degrees is given by the following matrix:
numeric::rotationMatrix(PI/4, [0, 0, 1])matrix([[0.7071067812, -0.7071067812, 0], [0.7071067812, 0.7071067812, 0], [0, 0, 1.0]])

$$\begin{pmatrix} 0.7071067812 & -0.7071067812 & 0 \\ 0.7071067812 & 0.7071067812 & 0 \\ 0 & 0 & 1.0 \end{pmatrix}$$

Symbolic arguments are accepted:
numeric::rotationMatrix(a, [1, 2, 3])matrix([[0.9285714286*cos(a) + 0.07142857143, 0.1428571429 - 0.8017837257*sin(a) - 0.1428571429*cos(a), 0.5345224838*sin(a) - 0.2142857143*cos(a)

+ 0.2142857143], [0.8017837257*sin(a) - 0.1428571429*cos(a) + 0.1428571429, 0.7142857143*cos(a) + 0.2857142857, 0.4285714286 - 0.2672612419*sin(a) - 0.4285714286*cos(a)], [0.2142857143 - 0.5345224838*sin(a) - 0.2142857143*cos(a), 0.2672612419*sin(a) - 0.4285714286*cos(a) + 0.4285714286, 0.3571428571*cos(a) + 0.6428571429]])

With the option `Symbolic`, no automatic conversion to floating-point numbers occurs:

```
numeric::rotationMatrix(a, [1, 2, 3], Symbolic)matrix([[(13*cos(a))/14
+ 1/14, 1/7 - (3*sqrt(14)*sin(a))/14 - cos(a)/7, (sqrt(14)*sin(a))/7 -
(3*cos(a))/14 + 3/14], [(3*sqrt(14)*sin(a))/14 - cos(a)/7 + 1/7, (5*cos(a))/7
+ 2/7, 3/7 - (sqrt(14)*sin(a))/14 - (3*cos(a))/7], [3/14 - (sqrt(14)*sin(a))/7
- (3*cos(a))/14, (sqrt(14)*sin(a))/14 - (3*cos(a))/7 + 3/7, (5*cos(a))/14
+ 9/14]])
```

$$\begin{pmatrix} \frac{13\cos(a)}{14} + \frac{1}{14} & \frac{1}{7} - \frac{3\sqrt{14}\sin(a)}{14} - \frac{\cos(a)}{7} & \frac{\sqrt{14}\sin(a)}{7} - \frac{3\cos(a)}{14} + \frac{3}{14} \\ \frac{3\sqrt{14}\sin(a)}{14} - \frac{\cos(a)}{7} + \frac{1}{7} & \frac{5\cos(a)}{7} + \frac{2}{7} & \frac{3}{7} - \frac{\sqrt{14}\sin(a)}{14} - \frac{3\cos(a)}{7} \\ \frac{3}{14} - \frac{\sqrt{14}\sin(a)}{7} - \frac{3\cos(a)}{14} & \frac{\sqrt{14}\sin(a)}{14} - \frac{3\cos(a)}{7} + \frac{3}{7} & \frac{5\cos(a)}{14} + \frac{9}{14} \end{pmatrix}$$

Example 2

The return type coincides with the type of the input parameter representing the axis:

numeric::rotationMatrix(0.3, matrix([1,2,3]))matrix([[0.9585267399, -0.2305627908, 0.1675329472], [0.2433237939, 0.9680974922, -0.05983959278], [-0.1483914426, 0.0981226021, 0.9840487461]])

$$\begin{pmatrix} 0.9585267399 & -0.2305627908 & 0.1675329472 \\ 0.2433237939 & 0.9680974922 & -0.05983959278 \\ -0.1483914426 & 0.0981226021 & 0.9840487461 \end{pmatrix}$$

domtype(%)Dom::Matrix()

Dom::Matrix()

numeric::rotationMatrix(0.3, hfarray(1..3, [1,2,3]))hfarray(1..3, 1..3, [0.9585267399, -0.2305627908, 0.1675329472, 0.2433237939, 0.9680974922, -0.05983959278, -0.1483914426, 0.0981226021, 0.9840487461])

$$\begin{pmatrix} 0.9585267399 & -0.2305627908 & 0.1675329472 \\ 0.2433237939 & 0.9680974922 & -0.05983959278 \\ -0.1483914426 & 0.0981226021 & 0.9840487461 \end{pmatrix}$$

domtype(%)DOM_HFARRAY

DOM_HFARRAY

The option `ReturnType` allows to specify the type of the result: numeric::rotationMatrix(0.3, hfarray(1..3, [1,2,3]), ReturnType = matrix)matrix([[0.9585267399, -0.2305627908, 0.1675329472], [0.2433237939, 0.9680974922, -0.05983959278], [-0.1483914426, 0.0981226021, 0.9840487461]])

$$\begin{pmatrix} 0.9585267399 & -0.2305627908 & 0.1675329472 \\ 0.2433237939 & 0.9680974922 & -0.05983959278 \\ -0.1483914426 & 0.0981226021 & 0.9840487461 \end{pmatrix}$$

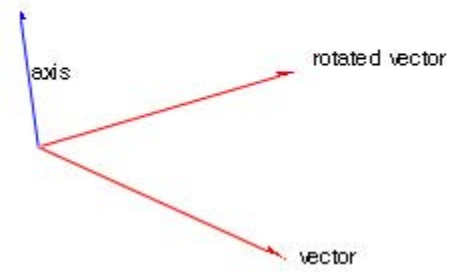
domtype(%)Dom::Matrix()

Dom::Matrix()

Example 3

The direction of the rotation is given by the “right hand rule”: Stretch the thumb of your right hand and bend the fingers. When the thumb points into the direction of the rotation axis, your finger tips indicate the direction of the rotation:

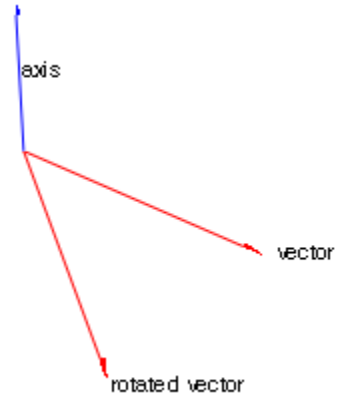
```
axis := matrix([0, 0, 1]): vector := matrix([1, 0, 0]): Q :=
numeric::rotationMatrix(PI/4, axis): plot(plot::Arrow3d(axis,
Color = RGB::Blue), plot::Arrow3d(vector, Color = RGB::Red),
plot::Arrow3d(Q*vector, Color = RGB::Red), plot::Text3d("axis", [0.01,
0.01, 0.5]), plot::Text3d("vector", [1.05, 0, 0]), plot::Text3d("rotated
vector", [0.75, 0.75, 0]), CameraDirection = [1, -2, 4], Scaling =
Constrained, Axes = None):
```



Use negative angles to rotate in the opposite direction:

```
axis := matrix([0, 0, 1]): vector := matrix([1, 0, 0]): Q :=
numeric::rotationMatrix(-PI/4, axis): plot(plot::Arrow3d(axis,
Color = RGB::Blue), plot::Arrow3d(vector, Color = RGB::Red),
plot::Arrow3d(Q*vector, Color = RGB::Red), plot::Text3d("axis", [0.01,
0.01, 0.5]), plot::Text3d("vector", [1.05, 0, 0]), plot::Text3d("rotated
```

vector", [0.75, -0.75, 0]), CameraDirection = [1, -2, 4], Scaling = Constrained, Axes = None):



delete axis, vector, Q:

Parameters

angle

An arithmetical expression

axis

A vector represented by a list with 3 entries or by a 3 1 matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

Options

Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used.

ReturnType

Option, specified as `ReturnType = t`

Return the result as a matrix of domain type `t`. The following return types are available: DOM_ARRAY, DOM_HFARRAY, matrix, or densematrix.

Return Values

Depending on the type of the input matrix `axis`, the 3 3 rotation matrix is returned as a matrix of domain type DOM_ARRAY, DOM_HFARRAY, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

numeric::singularvalues

Purpose

Numerical singular values of a matrix

Syntax

```
numeric::singularvalues(A, <Hard | HardwareFloats
| Soft | SoftwareFloats>)
```

Description

`numeric::singularvalues(A)` returns numerical singular values of the matrix `A`.

The singular values of an m n matrix A are the $p = min(m, n)$ real nonnegative square roots of the eigenvalues of $A^H A$ (for $p = n$) or of AA^H (for $p = m$). The Hermitean transpose A^H is the complex conjugate of the transpose of A.

`numeric::singularvalues` returns a list of real singular values $[d_1, \ldots, d_p]$ sorted by numeric::sort, i.e., $d_1 \geq \ldots \geq d_p \geq 0.0$.

All entries of `A` must be numerical. Numerical expressions such as exp(PI), sqrt(2)e^{π}, $\sqrt{2}$ etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

Cat::Matrix objects, i.e., matrices `A` of a matrix domain such as `Dom::Matrix( )` or `Dom::SquareMatrix( )` are internally converted to arrays over expressions via `expr(A)`.

Note Singular values are approximated with an *absolute* precision of 10^(-DIGITS)*r$\frac{1}{10^{DIGITS}}\,r$ where r is largest singular value of `A`. Consequently, large singular values should be computed correctly to DIGITS decimal places. The numerical approximations of small singular values are less accurate.

Singular values may also be computed via `map ( numeric::eigenvalues( A  A^H), sqrt )` or `map ( numeric::eigenvalues( A^H  A ), sqrt )`, respectively. The use of `numeric::singularvalues` avoids the costs of the matrix multiplication. Further, the eigenvalue routine requires about twice as

many DIGITS to compute small singular values with the same precision as `numeric::singularvalues`. Cf. “Example 2” on page 19-331.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

The singular values of A and A^H coincide:
A := array(1..3, 1..2, [[1, 2*I], [2, 3],[3, sqrt(2)]]):numeric::singularvalues(A)[4.994802008, 2.012946323]

```
[4.994802008, 2.012946323]
```

The Hermitean transpose $B = A^H$:
B := array(1..2, 1..3, [[1, 2, 3], [-2*I, 3, sqrt(2)]]):numeric::singularvalues(B)[4.994802008, 2.012946323]

```
[4.994802008, 2.012946323]
```

delete A, B:

Example 2

We use numeric::eigenvalues to compute singular values:
A := matrix([[1/15, 2/15*I], [PI, 314159265358980/50000000000000*I], [2, 4*I]]):

The Hermitean transpose $B = A^H$ can be computed by the methods `conjugate` and `transpose` of the matrix domain:
B := A::dom::conjugate(A::dom::transpose(A)):

Note that $A^H A$ is positive semi-definite and cannot have negative eigenvalues. However, computing small eigenvalues is numerically ill-conditioned, and a small negative value occurs due to roundoff:
numeric::eigenvalues(B*A)[69.37024423, -2.310493271e-15]

$$\left[69.37024423,\ -2.310493271\ 10^{-15}\right]$$

Consequently, an (incorrect) imaginary singular value is computed:
map(%, sqrt)[8.32888013, 0.00000004806759065*I]

$$[8.32888013,\ 0.00000004806759065\ i]$$

We have to increase DIGITS in order to compute this value more accurately:
DIGITS := 22: map(numeric::eigenvalues(B*A), sqrt)[8.328880130465871055353, 0.00000000000000329345372622554275419 6]

$$\left[8.32888013046587105535,\ 3.29345372622554275419\ 6\ 10^{-15}\right]$$

With `numeric::singularvalues`, the standard precision suffices:
DIGITS := 10: numeric::singularvalues(A, SoftwareFloats)[8.32888013, 3.249076763e-15]

$$\left[8.32888013,\ 3.249076763\ 10^{-15}\right]$$

numeric::singularvalues(A, HardwareFloats)[8.32888013, 3.6920369e-15]

$$\left[8.32888013,\ 3.6920369\ 10^{-15}\right]$$

delete A, B:

Example 3

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned: the computation of the small singular values is subject to severe roundoff effects. In the following results, both with `HardwareFloats` as well as with `SoftwareFloats`, the small singular values are dominated by numerical roundoff. Consequently, the results with `HardwareFloats` differ from those with with `SoftwareFloats`:
numeric::singularvalues(linalg::hilbert(13))[1.813830119, 0.396833076, dots, 8.878210699e-16, 3.222901015e-18]

3.017915362e-21]

delete A:

Parameters

A

A numerical matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

Options

Hard

HardwareFloats

Soft

SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic

is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix `A` is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill-conditioned matrices, the result is subject to roundoff errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ! See "Example 3" on page 19-332.

Return Values

Ordered list of real floating-point values.

Algorithms

The code implements standard numerical algorithms from the Handbook of Automatic Computation by Wilkinson and Reinsch.

numeric::singularvectors

Purpose

Numerical singular value decomposition of a matrix

Syntax

```
numeric::singularvectors(A, options)
```

Description

`numeric::singularvectors(A)` and the equivalent call `numeric::svd(A)` return numerical singular values and singular vectors of the matrix `A`.

All entries of `A` must be numerical. Numerical expressions such as exp(PI), sqrt(2)e^{π}, $\sqrt{2}$ etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

Cat::Matrix objects, i.e., matrices `A` of a matrix domain such as `Dom::Matrix( )` or `Dom::SquareMatrix( )` are internally converted to arrays over expressions via `expr(A)`.

The list `[U, d, V, res`$_U$`, res`$_V$`]` returned by `numeric::singularvectors` corresponds to the singular data of an m n matrix A as described below.

Let V^H denote the Hermitean transpose of the matrix V, i.e., the complex conjugate of the transpose. The singular value decomposition of an m n matrix A is a factorization $A = UDV^H$. D is an m n "diagonal" matrix with real nonnegative entries $D_{ii} = d_i$, $i = 1, \ldots, p$ where $p = min(m, n)$:

D=matrix([[d[1], ", 0], [", dots, "], [", ", d[p]], [0, ", 0]])

$$D = \begin{pmatrix} d_1 & \cdots & 0 \\ & & d_p \\ 0 & & 0 \end{pmatrix}$$

or

D= matrix([[d[1], ", ", 0], [", dots, ", "], [0, ", d[p], 0]])

$$D = \begin{pmatrix} d_1 & \cdots & & 0 \\ 0 & & d_p & 0 \end{pmatrix}$$

respectively. The list $d = [d_1, \ldots, d_p]$ returned by `numeric::singularvectors` are the "singular values" of A. They are sorted by numeric::sort, i.e., $d_1 \geq \ldots \geq d_p \geq 0.0$.

U is a unitary m m matrix. Its i-th column is an eigenvector of AA^H associated with the eigenvalue d_i^2 ($d_i = 0$ for $i > p$). These are the "left singular vectors" of A. They are returned by `numeric::singularvectors` as a matrix of floating-point numbers.

V is a unitary n n matrix. Its i-th column is an eigenvector of A^HA associated with the eigenvalue d_i^2 ($d_i = 0$ for $i > p$). These are the "right singular vectors" of A. They are returned by `numeric::singularvectors` as an array of floating-point numbers. The matrix `V` is normalized such that, in each column, the first entry of absolute size larger than 10^(-DIGITS)$_{\frac{1}{10^{DIGITS}}}$ is real and positive.

If no return type is specified via the option `ReturnType = t`, the domain type of the singular vectors U and V depends on the type of the input matrix `A`:

- The singular vectors of an array are returned as arrays.
- The singular vectors of an hfarray are returned as hfarrays.
- The singular vectors of a dense matrix of type `Dom::DenseMatrix()` are returned as dense matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category Cat::Matrix, the singular vectors are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix( )`, `Dom::SquareMatrix( )`, `Dom::MatrixGroup( )` etc.

$res_U = [resU_1, \ldots, resU_m]$ is a list of float residues associated with the left singular vectors:

resU[i] = linalg::scalarProduct(A^H*u_i, A^H*u_i)-d[i]^2, 1<=i<=m

$\text{resU}_i = \langle A^H u_i, A^H u_i \rangle - d_i^2,\ 1 \le i \le m$

Here, u_i is the (normalized) i-th column of `U`, linalg::scalarProduct(dots, dots)$\langle ..., ... \rangle$ is the usual complex Euclidean scalar product and $d_i = 0$ for $p < i \le m$.

$res_V = [resV_1, \ldots, resV_n]$ is a list of float residues associated with the right singular vectors:

resV[i] =linalg::scalarProduct(A*v_i, A*v_i) - d[i]^2, 1<=i<=n

$\text{resV}_i = \langle A\, v_i, A\, v_i \rangle - d_i^2,\ 1 \le i \le n$

Here, v_i is the (normalized) i-th column of `V`, $d_i = 0$ for $p < i \le n$.

The residues res_U, res_V vanish for exact singular data U, d, V. Their sizes indicate the quality of the numerical data `U, d, V`.

Note Singular values are approximated with an *absolute* precision of 10^(-DIGITS)*r$_{\frac{1}{10^{DIGITS}}\ r}$, where r is the largest singular value of `A`. Consequently, large singular values should be computed correctly to DIGITS decimal places. The numerical approximations of small singular values are less accurate.

The singular values computed by `numeric::singularvectors` are identical to those computed by numeric::svd.

Singular data may also be computed via `[d2, U, resU] := numeric::eigenvectors(A*A^H)` or `[d2, V, resV] := numeric::eigenvectors(A^H*A)`, respectively. The list `d2` is related to the singular values by

d2=[d[1]^2,d[2]^2,dots,d[p]^2, 0, dots, 0]

$\text{d2} = \left[d_1^2, d_2^2, \ldots, d_p^2, 0, \ldots, 0\right]$

The use of `numeric::singularvectors` avoids the costs of the matrix multiplication. Further, the eigenvector routine requires about twice as many DIGITS to compute the data associated with small singular values with the same precision as `numeric::singularvectors`. Also note that the normalization of `U` and `V` may be different.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

Numerical expressions are converted to floats:
DIGITS := 5: A := array(1..3, 1..2, [[1, PI], [2, 3], [3, exp(sqrt(2))]]): [U, d, V, resU, resV] := numeric::singularvectors(A):

The singular data are:
U, d, Varray(1..3, 1..3, [[0.45729, -0.88078, 0.12293], [0.51483, 0.14947, -0.84416], [0.72515, 0.44932, 0.5218]]), [6.9986, 0.89905], array(1..2, 1..2, [[0.5233, 0.85215], [0.85215, -0.5233]])

$$\begin{pmatrix} 0.45729 & -0.88078 & 0.12293 \\ 0.51483 & 0.14947 & -0.84416 \\ 0.72515 & 0.44932 & 0.5218 \end{pmatrix}, [6.9986, 0.89905], \begin{pmatrix} 0.5233 & 0.85215 \\ 0.85215 & -0.5233 \end{pmatrix}$$

The small residues indicate that these results are not severely affected by roundoff:
resU, resV[2.247e-14, 2.247e-14, 3.898e-32], [5.6175e-15, 5.6175e-15]

$$\left[2.247\,10^{-14}, 2.247\,10^{-14}, 3.898\,10^{-32}\right], \left[5.6175\,10^{-15}, 5.6175\,10^{-15}\right]$$

delete DIGITS, A, U, d, V, resU, resV:

Example 2

We demonstrate how to reconstruct a matrix from its singular data. With the specified `ReturnType`, the singular vectors are returned as matrices of type `Dom::Matrix()` and can be handled with the overloaded arithmetic:

```
DIGITS := 3: A := array(1..2, 1..3, [[1.0, I, PI], [2, 3, I]]): [U, d, V,
resU, resV] := numeric::singularvectors(A, NoResidues, ReturnType =
Dom::Matrix())[matrix([[0.514 + (- 0.028*I), - 0.788 + 0.336*I], [0.857 +
0.014*I, 0.487 + (- 0.168*I)]]), [3.9, 3.27], matrix([[0.571, 0.0568, 0.819],
[0.652 + (- 0.121*I), 0.55 + 0.0871*I, - 0.493 + 0.0785*I], [0.418 + (-
0.242*I), - 0.81 + 0.174*I, - 0.236 + 0.157*I]]), NIL, NIL]
```

$$\left[\begin{pmatrix} 0.514 - 0.028\,i & -0.788 + 0.336\,i \\ 0.857 + 0.014\,i & 0.487 - 0.168\,i \end{pmatrix}, [3.9, 3.27], \begin{pmatrix} 0.571 & 0.0568 & 0.819 \\ 0.652 - 0.121\,i & 0.55 + 0.0871\,i & -0.493 + 0.0 \\ 0.418 - 0.242\,i & -0.81 + 0.174\,i & -0.236 + 0. \end{pmatrix}\right.$$

A "diagonal" matrix is built from the singular values:

```
d := matrix(2, 3, d, Diagonal)matrix([[3.9, 0, 0], [0, 3.27, 0]])
```

$$\begin{pmatrix} 3.9 & 0 & 0 \\ 0 & 3.27 & 0 \end{pmatrix}$$

We use the methods `conjugate` and `transpose` of the matrix domain to compute the Hermitean transpose of `V` and reconstruct `A`. Numerical roundoff is eliminated via numeric::complexRound:

```
VH := V::dom::conjugate(V::dom::transpose(V)): map(U*d*VH,
numeric::complexRound)matrix([[1.0, 1.0*I, 3.14], [2.0, 3.0, 1.0*I]])
```

$$\begin{pmatrix} 1.0 & 1.0\,i & 3.14 \\ 2.0 & 3.0 & 1.0\,i \end{pmatrix}$$

delete DIGITS, A, U, d, V, resU, resV, VH:

Example 3

We demonstrate the use of hardware floats. The following matrix A is degenerate: it has rank 1. For the double eigenvalue 0 of the matrix $A^H A$, different base vectors of the corresponding eigenspace are returned with `HardwareFloats` and `SoftwareFloats`, respectively:

```
A := array(1..2, 1..3, [[1, 2, 3], [30, 60, 90]]): [U1, d1, V1, resU1,
resV1] := numeric::singularvectors(A, HardwareFloats): [U2, d2, V2,
resU2, resV2] := numeric::singularvectors(A, SoftwareFloats): V1,
V2array(1..3, 1..3, [[0.2672612419, 0.5345224838, 0.8017837257],
```

[0.5345224838, -0.7745419206, 0.3381871191], [0.8017837257, 0.3381871191, -0.4927193213]]), array(1..3, 1..3, [[0.2672612419, 0.9561828875, 0.1195228609], [0.5345224838, -0.04390192219, -0.8440132318], [0.8017837257, -0.289459681, 0.5228345342]])

$$\begin{pmatrix} 0.2672612419 & 0.5345224838 & 0.8017837257 \\ 0.5345224838 & -0.7745419206 & 0.3381871191 \\ 0.8017837257 & 0.3381871191 & -0.4927193213 \end{pmatrix} \begin{pmatrix} 0.2672612419 & 0.9561828875 & 0.11952 \\ 0.5345224838 & -0.04390192219 & -0.8440 \\ 0.8017837257 & -0.289459681 & 0.52283 \end{pmatrix}$$

delete A, U1, d1, V1, resU1, resV1, U2, d2, V2, resU2, resV2:

Parameters

A

A numerical matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix.

Options

Hard

HardwareFloats

Soft

SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic

is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix `A` is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill-conditioned matrices, the result is subject to roundoff errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ! See “Example 3” on page 19-341.

NoLeftVectors

Suppresses the computation of left singular vectors

If only right singular vectors are required, this option may be used to suppress the computation of `U` and the corresponding residues $\texttt{res}_U$. The return values for these data are `NIL`.

Depending on the size of `U`, this option may speed up the computation considerably.

NoRightVectors

Suppresses the computation of right singular vectors

If only left singular vectors are required, this option may be used to suppress the computation of `V` and the corresponding residues $\texttt{res}_V$. The return values for these data are `NIL`.

Depending on the size of `V`, this option may speed up the computation considerably.

NoResidues

Suppresses the computation of error estimates

If no error estimates are required, this option may be used to suppress the computation of the residues $\texttt{res}_U$ and $\texttt{res}_V$. The return values for these data are `NIL`.

The alternative option name `NoErrors` used in previous MuPAD versions is still available.

ReturnType

Option, specified as `ReturnType = t`

Return the left and right singular vectors as matrices of domain type `t`. The following return types *t* are available: DOM_ARRAY, or DOM_HFARRAY, or `Dom::Matrix()`, or `Dom::DenseMatrix()`.

This option determines the domain type of the matrices containing the singular vectors.

NoWarning

Suppresses warnings

Return Values

List `[U, d, V, res`$_U$`, res`$_V$`]`. `U` is a unitary square float matrix whose columns are left singular vectors. The list `d` contains the singular values. `V` is a unitary square float matrix whose columns are right singular vectors. The lists of float residues `res`$_U$ and `res`$_V$ provide error estimates for the numerical data.

numeric::svd

Purpose

Numerical singular value decomposition of a matrix

Syntax

```
numeric::svd(A, options)
```

Description

`numeric::svd(A)` and the equivalent call `numeric::singularvectors(A)` return numerical singular values and singular vectors of the matrix `A`.

All entries of `A` must be numerical. Numerical expressions such as exp(PI), sqrt(2)e^{π}, $\sqrt{2}$ etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

Cat::Matrix objects, i.e., matrices `A` of a matrix domain such as `Dom::Matrix( )` or `Dom::SquareMatrix( )` are internally converted to arrays over expressions via `expr(A)`.

The list `[U, d, V, res`$_U$`, res`$_V$`]` returned by `numeric::svd` corresponds to the singular data of an m n matrix A as described below.

Let V^H denote the Hermitean transpose of the matrix V, i.e., the complex conjugate of the transpose. The singular value decomposition of an m n matrix A is a factorization $A = UDV^H$. D is an m n "diagonal" matrix with real nonnegative entries $D_{ii} = d_i$, $i = 1, \ldots, p$ where $p = min(m, n)$:

D=matrix([[d[1], ", 0], [", dots, "], [", ", d[p]], [0, ", 0]])

$$D = \begin{pmatrix} d_1 & \cdots & 0 \\ & & d_p \\ 0 & & 0 \end{pmatrix}$$

or

D= matrix([[d[1], ", ", 0], [", dots, ", "], [0, ", d[p], 0]])

$$D = \begin{pmatrix} d_1 & \cdots & & 0 \\ 0 & & d_p & 0 \end{pmatrix}$$

respectively. The list $d = [d_1, \ldots, d_p]$ returned by `numeric::svd` are the "singular values" of A. They are sorted by numeric::sort, i.e., $d_1 \geq \ldots \geq d_p \geq 0.0$.

U is a unitary m m matrix. Its i-th column is an eigenvector of AA^H associated with the eigenvalue d_i^2 ($d_i = 0$ for $i > p$). These are the "left singular vectors" of A. They are returned by `numeric::svd` as a matrix of floating-point numbers.

V is a unitary n n matrix. Its i-th column is an eigenvector of A^HA associated with the eigenvalue d_i^2 ($d_i = 0$ for $i > p$). These are the "right singular vectors" of A. They are returned by `numeric::svd` as an array of floating-point numbers. The matrix `V` is normalized such that, in each column, the first entry of absolute size larger than 10^(-DIGITS)$^{\frac{1}{10^{DIGITS}}}$ is real and positive.

If no return type is specified via the option `ReturnType = t`, the domain type of the singular vectors U and V depends on the type of the input matrix `A`:

- The singular vectors of an array are returned as arrays.
- The singular vectors of an hfarray are returned as hfarrays.
- The singular vectors of a dense matrix of type `Dom::DenseMatrix()` are returned as dense matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category Cat::Matrix, the singular vectors are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix( )`, `Dom::SquareMatrix( )`, `Dom::MatrixGroup( )` etc.

$res_U = [resU_1, \ldots, resU_m]$ is a list of float residues associated with the left singular vectors:

resU[i] = linalg::scalarProduct(A^H*u_i, A^H*u_i)-d[i]^2, 1<=i<=m

$\text{resU}_i = \langle A^H u_i, A^H u_i \rangle - d_i^2,\ 1 \le i \le m$

Here, u_i is the (normalized) i-th column of `U`, linalg::scalarProduct(dots, dots)$\langle ..., ... \rangle$ is the usual complex Euclidean scalar product and $d_i = 0$ for $p < i \le m$.

$res_V = [resV_1, \ldots, resV_n]$ is a list of float residues associated with the right singular vectors:

resV[i] =linalg::scalarProduct(A*v_i, A*v_i) - d[i]^2, 1<=i<=n

$\text{resV}_i = \langle A\, v_i, A\, v_i \rangle - d_i^2,\ 1 \le i \le n$

Here, v_i is the (normalized) i-th column of `V`, $d_i = 0$ for $p < i \le n$.

The residues res_U, res_V vanish for exact singular data U, d, V. Their sizes indicate the quality of the numerical data `U, d, V`.

Note Singular values are approximated with an *absolute* precision of 10^(-DIGITS)*r$\frac{1}{10^{DIGITS}}\,r$, where r is the largest singular value of `A`. Consequently, large singular values should be computed correctly to DIGITS decimal places. The numerical approximations of small singular values are less accurate.

The singular values computed by `numeric::svd` are identical to those computed by numeric::singularvalues.

Singular data may also be computed via `[d2, U, resU] := numeric::eigenvectors(A*A^H)` or `[d2, V, resV] := numeric::eigenvectors(A^H*A)`, respectively. The list `d2` is related to the singular values by

d2=[d[1]^2,d[2]^2,dots,d[p]^2, 0, dots, 0]

$\text{d2} = \left[d_1^2, d_2^2, \ldots, d_p^2, 0, \ldots, 0\right]$

The use of `numeric::svd` avoids the costs of the matrix multiplication. Further, the eigenvector routine requires about twice as many DIGITS to compute the data associated with small singular values with the same precision as numeric::singularvectors. Also note that the normalization of `U` and `V` may be different.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

Numerical expressions are converted to floats:
DIGITS := 5: A := array(1..3, 1..2, [[1, PI], [2, 3], [3, exp(sqrt(2))]]): [U, d, V, resU, resV] := numeric::singularvectors(A):

The singular data are:
U, d, Varray(1..3, 1..3, [[0.45729, -0.88078, 0.12293], [0.51483, 0.14947, -0.84416], [0.72515, 0.44932, 0.5218]]), [6.9986, 0.89905], array(1..2, 1..2, [[0.5233, 0.85215], [0.85215, -0.5233]])

$$\begin{pmatrix} 0.45729 & -0.88078 & 0.12293 \\ 0.51483 & 0.14947 & -0.84416 \\ 0.72515 & 0.44932 & 0.5218 \end{pmatrix}, [6.9986, 0.89905], \begin{pmatrix} 0.5233 & 0.85215 \\ 0.85215 & -0.5233 \end{pmatrix}$$

The small residues indicate that these results are not severely affected by roundoff:
resU, resV[2.247e-14, 2.247e-14, 3.898e-32], [5.6175e-15, 5.6175e-15]

$$\left[2.247\,10^{-14}, 2.247\,10^{-14}, 3.898\,10^{-32}\right], \left[5.6175\,10^{-15}, 5.6175\,10^{-15}\right]$$

delete DIGITS, A, U, d, V, resU, resV:

Example 2

We demonstrate how to reconstruct a matrix from its singular data. With the specified `ReturnType`, the singular vectors are returned as matrices of type `Dom::Matrix()` and can be handled with the overloaded arithmetic:

```
DIGITS := 3: A := array(1..2, 1..3, [[1.0, I, PI], [2, 3, I]]): [U, d, V,
resU, resV] := numeric::singularvectors(A, NoResidues, ReturnType =
Dom::Matrix())[matrix([[0.514 + (- 0.028*I), - 0.788 + 0.336*I], [0.857 +
0.014*I, 0.487 + (- 0.168*I)]]), [3.9, 3.27], matrix([[0.571, 0.0568, 0.819],
[0.652 + (- 0.121*I), 0.55 + 0.0871*I, - 0.493 + 0.0785*I], [0.418 + (-
0.242*I), - 0.81 + 0.174*I, - 0.236 + 0.157*I]]), NIL, NIL]
```

$$\left[\begin{pmatrix} 0.514 - 0.028\,i & -0.788 + 0.336\,i \\ 0.857 + 0.014\,i & 0.487 - 0.168\,i \end{pmatrix}, [3.9, 3.27], \begin{pmatrix} 0.571 & 0.0568 & 0.819 \\ 0.652 - 0.121\,i & 0.55 + 0.0871\,i & -0.493 + 0.0785 \\ 0.418 & -0.242\,i & -0.81 + 0.174\,i \end{pmatrix}, \text{NIL}, \text{NIL}\right]$$

A "diagonal" matrix is built from the singular values:

```
d := matrix(2, 3, d, Diagonal)matrix([[3.9, 0, 0], [0, 3.27, 0]])
```

$$\begin{pmatrix} 3.9 & 0 & 0 \\ 0 & 3.27 & 0 \end{pmatrix}$$

We use the methods `conjugate` and `transpose` of the matrix domain to compute the Hermitean transpose of `V` and reconstruct `A`. Numerical roundoff is eliminated via numeric::complexRound:

```
VH := V::dom::conjugate(V::dom::transpose(V)): map(U*d*VH,
numeric::complexRound)matrix([[1.0, 1.0*I, 3.14], [2.0, 3.0, 1.0*I]])
```

$$\begin{pmatrix} 1.0 & 1.0\,i & 3.14 \\ 2.0 & 3.0 & 1.0\,i \end{pmatrix}$$

delete DIGITS, A, U, d, V, resU, resV, VH:

Example 3

We demonstrate the use of hardware floats. The following matrix A is degenerate: it has rank 1. For the double eigenvalue 0 of the matrix $A^H A$, different base vectors of the corresponding eigenspace are returned with `HardwareFloats` and `SoftwareFloats`, respectively:

```
A := array(1..2, 1..3, [[1, 2, 3], [30, 60, 90]]): [U1, d1, V1, resU1,
resV1] := numeric::singularvectors(A, HardwareFloats): [U2, d2, V2,
resU2, resV2] := numeric::singularvectors(A, SoftwareFloats): V1,
V2array(1..3, 1..3, [[0.2672612419, 0.5345224838, 0.8017837257],
```

[0.5345224838, -0.7745419206, 0.3381871191], [0.8017837257, 0.3381871191, -0.4927193213]]), array(1..3, 1..3, [[0.2672612419, 0.9561828875, 0.1195228609], [0.5345224838, -0.04390192219, -0.8440132318], [0.8017837257, -0.289459681, 0.5228345342]])

$$\begin{pmatrix} 0.2672612419 & 0.5345224838 & 0.8017837257 \\ 0.5345224838 & -0.7745419206 & 0.3381871191 \\ 0.8017837257 & 0.3381871191 & -0.4927193213 \end{pmatrix}, \begin{pmatrix} 0.2672612419 & 0.9561828875 & 0.1 \\ 0.5345224838 & -0.04390192219 & -0.8 \\ 0.8017837257 & -0.289459681 & 0.5 \end{pmatrix}$$

delete A, U1, d1, V1, resU1, resV1, U2, d2, V2, resU2, resV2:

Parameters

A

A numerical matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix.

Options

Hard

HardwareFloats

Soft

SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic

is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix `A` is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill-conditioned matrices, the result is subject to roundoff errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ! See "Example 3" on page 19-350.

NoLeftVectors

Suppresses the computation of left singular vectors

If only right singular vectors are required, this option may be used to suppress the computation of `U` and the corresponding residues $\texttt{res}_{\texttt{U}}$. The return values for these data are `NIL`.

Depending on the size of `U`, this option may speed up the computation considerably.

NoRightVectors

Suppresses the computation of right singular vectors

If only left singular vectors are required, this option may be used to suppress the computation of `V` and the corresponding residues $\texttt{res}_{\texttt{V}}$. The return values for these data are `NIL`.

Depending on the size of `V`, this option may speed up the computation considerably.

NoResidues

Suppresses the computation of error estimates

If no error estimates are required, this option may be used to suppress the computation of the residues $\texttt{res}_{\texttt{U}}$ and $\texttt{res}_{\texttt{V}}$. The return values for these data are `NIL`.

The alternative option name `NoErrors` used in previous MuPAD versions is still available.

ReturnType

Option, specified as `ReturnType = t`

Return the left and right singular vectors as matrices of domain type `t`. The following return types *t* are available: DOM_ARRAY, or DOM_HFARRAY, or `Dom::Matrix()`, or `Dom::DenseMatrix()`.

This option determines the domain type of the matrices containing the singular vectors.

NoWarning

Suppresses warnings

Return Values

List `[U, d, V, res`$_U$`, res`$_V$`]`. `U` is a unitary square float matrix whose columns are left singular vectors. The list `d` contains the singular values. `V` is a unitary square float matrix whose columns are right singular vectors. The lists of float residues `res`$_U$ and `res`$_V$ provide error estimates for the numerical data.

- "Compute Factorizations Numerically"

numeric::solve

Purpose

Numerical solution of equations (the float attribute of solve)

Syntax

```
numeric::solve(eqs, <vars>, options)
float(holdsolve(eqs, <vars>, options))
float(freezesolve(eqs, <vars>, options))
```

Description

`numeric::solve` computes numerical solutions of equations. For polynomial equations, *all* solutions are returned. For non-polynomial equations, only *one* solution, if any, is returned unless the option `AllRealRoots` is used.

Note Note that only for polynomial/rational equations *all* solutions are searched for. For non-polynomial/non-rational equations, only one solution, if any, is returned unless the option `AllRealRoots` is used.

If the equations contain non-polynomial expressions, it is in general not possible to isolate *all* roots numerically. Think of equations such as sin(1/x)=0$\sin(\frac{1}{x}) = 0$ that have infinitely many real solutions around the origin! If a complete set of *all* real solutions of a single non-polynomial/non-rational equation in one unknown is desired, you may try the opton `AllRealRoots`. With this option, a heuristics tries to isolate all real solutions of the equation. This, however, is purely heuristical: there is no rigor in the algorithm and it is not guaranteed that all solutions are found. Alternatively, you may also use the routine numeric::realroots to isolate the intervals in which solutions may exist.

`numeric::solve` is a simple interface function unifying the functionality of the numerical solvers numeric::fsolve, numeric::linsolve, numeric::polyroots, and numeric::polysysroots. The return format of these routines is changed to make it consistent with the return values of the symbolic solver solve.

You may call the specialized numerical solvers directly. However, note the return types specific to each of these solvers.

`numeric::solve` classifies the equations as follows:

- If `eqs` is a single univariate polynomial equation, then it is directly passed to numeric::polyroots. Cf. “Example 2” on page 19-358. The roots are returned as a set or as a Dom::Multiset if `Multiple` is used.
- If `eqs` is a multivariate polynomial equation or a list or set of such equations, then the equations and the appropriate optional arguments are passed to either numeric::linsolve or numeric::polysysroots. Cf. “Example 3” on page 19-358. The roots are returned as a set or as a Dom::Multiset if `Multiple` is used.
- A rational equation or a set or list of rational equations is replaced by its/their numerator(s). Such equations are processed like polynomial equations.
- If `eqs` is a non-polynomial/non-rational equation or a set or list containing such an equation, then the equations and the appropriate optional arguments are passed to the numerical solver numeric::fsolve.

Note For non-polynomial equations, only a single numerical root is returned, unless `AllRealRoots` is specified! Cf. “Example 4” on page 19-359.

Note For non-polynomial equations, there must not be more equations than unknowns!

Using `Multiple` for non-polynomial equations leads to an error, unless the option `AllRealRoots` is specified, too!

Note For systems of multivariate non-polynomial equations, MuPAD uses a Newton search. It must be able to evaluate the partial derivatives of the equations with respect to the variables to be solved for.

For a single univariate equation, first a bisectioning scheme with quadratic interpolation is used that does not require any differentiation of the equation. If this is not successful, a Newton search is started that requires the derivative of the functions involved.

For convenience, also polynomials of domain type DOM_POLY are accepted, wherever an equation is expected.

Note In contrast to the symbolic solver solve, the numerical solver does not react to properties of identifiers set via assume. To use these properties, call `float ( hold( solve )(arguments))` instead.

If the user does not specify indeterminates to be solved for, then the indeterminates are internally chosen by numeric::indets(`eqs`).

Starting points such as `x = a` or search ranges such as `x = a..b` specified in `vars` are ignored if `eqs` is a polynomial equation or a system of polynomial equations.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

The following three solver calls are equivalent:
eqs := {x^2 = sin(y), y^2 = cos(x)}: numeric::solve(eqs, {x, y}), float(hold(solve)(eqs, {x, y})), float(freeze(solve)(eqs, {x,y}))[[x =

-0.8517004887, y = 0.8116062151]}, {[x = -0.8517004887, y = 0.8116062151]}, {[x = -0.8517004887, y = 0.8116062151]}

$$\{[x = -0.8517004887, y = 0.8116062151]\}, \{[x = -0.8517004887, y = 0.8116062151]\}, \{[x = -0.851$$

delete eqs:

Example 2

We demonstrate the root search for univariate polynomials:
numeric::solve(x^6 - PI*x^2 = sin(3), x){-1.339589767, 1.339589767, 1.322706295*I, 0.2120113223*I, -0.2120113223*I, -1.322706295*I}

$$\{-1.339589767, 1.339589767, 1.322706295\,i, 0.2120113223\,i, -0.2120113223\,i, -1.322706295\,i\}$$

Polynomials of type DOM_POLY can be used as input:
numeric::solve(poly((x - 1/3)^3, [x]), x){0.3333333333}

$$\{0.3333333333\}$$

With `Multiple`, a Dom::Multiset is returned, indicating the multiplicity of the root:
numeric::solve(x^3 - x^2 + x/3 -1/27, x, Multiple){[0.3333333333, 3]}

$$\{[0.3333333333, 3]\}$$

Example 3

We demonstrate the root search for polynomial systems. Note that the symbolic solver solve is involved if the system is nonlinear. Symbolic parameters are accepted:
numeric::solve({x^2 + y^2 = 1, x^2 - y^2 = exp(z)}, {x, y}){[x = -0.7071067812*sqrt(exp(z) + 1.0), y = -0.7071067812*sqrt(1.0 - 1.0*exp(z))], dots, [x = 0.7071067812*sqrt(exp(z) + 1.0), y = 0.7071067812*sqrt(1.0 - 1.0*exp(z))]}

$$\left\{\left[x = -0.7071067812\sqrt{e^z + 1.0}, y = -0.7071067812\sqrt{1.0 - 1.0\,e^z}\right], \ldots, \left[x = 0.7071067812\sqrt{e^z + 1.0}\right.\right.$$

{[x = 0.7071067812*sqrt(exp(z) + 1.0), y = -0.7071067812*sqrt(1.0 - 1.0*exp(z))], [x = 0.7071067812*sqrt(exp(z) + 1.0), y = 0.7071067812*sqrt(1.0 - 1.0*exp(z))], [x = -0.7071067812*sqrt(exp(z) + 1.0), y = 0.7071067812*sqrt(1.0 - 1.0*exp(z))], [x = -0.7071067812*sqrt(exp(z) + 1.0), y = -0.7071067812*sqrt(1.0 - 1.0*exp(z))]}

$$\left\{\left[x = 0.7071067812\sqrt{e^z + 1.0},\ y = -0.7071067812\sqrt{1.0 - 1.0\,e^z}\right],\ \left[x = 0.7071067812\sqrt{e^z + 1.0},\right.\right.$$
$$\left.\left[x = -0.7071067812\sqrt{e^z + 1.0},\ y = 0.7071067812\sqrt{1.0 - 1.0\,e^z}\right],\ \left[x = -0.7071067812\sqrt{e^z + 1.\right.\right.$$

Example 4

We demonstrate the root search for non-polynomial equations. Without the option `AllRealRoots`, only one solution is searched for:
eq := exp(-x) - 10*x^2: numeric::solve(eq, x){0.2755302947}

$$\{0.2755302947\}$$

Since `numeric::solve` just calls the root finder numeric::fsolve, one may also use this routine directly. Note the different output format:
numeric::fsolve(eq, x)[x = 0.2755302947]

$$[x = 0.2755302947]$$

The input syntax of `numeric::solve` and numeric::fsolve are identical, i.e., starting points, search ranges and options may be used. E.g., another solution of the previous equation is found by a restricted search over the interval Interval([-1, 0])[-1, 0]:
numeric::solve(eq, x = -1..0, RestrictedSearch){-0.3829657727}

$$\{-0.3829657727\}$$

We use the option `AllRealRoots` to isolate all real solutions of the equation:

numeric::solve(eq, x, AllRealRoots){-5.827897796, -0.3829657727, 0.2755302947}

$$\{-5.827897796, -0.3829657727, 0.2755302947\}$$

With the following call we restrict the search to the negative semi-axis:
numeric::solve(eq, x = -infinity..0, AllRealRoots){-5.827897796, -0.3829657727}

$$\{-5.827897796, -0.3829657727\}$$

Example 5

For the following system, `numeric::solve` finds the solution with positive *y*:
eqs := [exp(x) = 2*y^2, sin(y) = y*x^3]: numeric::solve(eqs, [x, y]){[x = 0.9290711314, y = 1.125201325]}

$$\{[x = 0.9290711314, y = 1.125201325]\}$$

Another solution with negative *y* is found with an appropriate search range:
numeric::solve(eqs, [x = 1, y = -infinity..0]){[x = 0.9290711314, y = -1.125201325]}

$$\{[x = 0.9290711314, y = -1.125201325]\}$$

delete eq, eqs:

Parameters

eqs

An equation, a list, set, array, or matrix (Cat::Matrix) of equations. Also arithmetical expressions are accepted and interpreted as homogeneous equations.

vars

An unknown, a list of unknowns or a set of unknowns. Unknowns may be identifiers or indexed identifiers. Also equations of the form `x=a` or `x=a..b` are accepted wherever an unknown `x` is expected. This way, starting points and search ranges are specified for the numerical search. They must be numerical; infinite search ranges are accepted.

Options

AllRealRoots

Only to be used if `eqs` is a single equation in one unknown. With this option, a *heuristics* is used to find *all* real solutions of the equation.

Note Note that there is no guarantee that all real solutions will be found.

Note Interval arithmetic is used to isolate search intervals for the solutions. The expressions in `eqs` must be suitable for such arithmetic. Internally, the procedure numeric::realroots is called. See the help page of numeric::realroots for restrictions on the expressions in `eqs`.

Note There is no rigor in the heuristics behind this option. There is no guarantee that all real solutions will be found!

Note The equation must be suitable for evaluation with interval arithmetic. See numeric::realroots for restrictions on the expressions in the equation.

With `AllRealRoots`, only the additonal options `Multiple` and `NoWarning` have an effect. All other options such as `UnrestrictedSearch` etc. are ignored.

It is highly recommend to specify a search interval by a call such as `numeric::solve(f(x), x = a..b, AllRealRoots)`. In this case, only the real solutions between `a` and `b` are searched for.

The search for all real solutions may be very time consuming!

Multiple

Only to be used if `eqs` is a polynomial equation or a system of polynomial equations or in conjunction with the option `AllRealRoots`. With this option, information on the multiplicity of degenerate polynomial roots is returned.

It changes the return type from DOM_SET to Dom::Multiset.

FixedPrecision

Only to be used if `eqs` is a single univariate polynomial. It launches a quick numerical search with fixed internal precision.

It is passed to numeric::polyroots, which uses a numerical search with fixed internal precision. This is fast, but degenerate roots may be returned with a restricted precision. See the help page of numeric::polyroots for details.

SquareFree

Only to be used if `eqs` is a single univariate polynomial. Symbolic square free factorization is applied, before the numerical search starts.

It is passed to numeric::polyroots, which preprocesses the polynomial by a symbolic square free factorization. See the help page of numeric::polyroots for details.

Factor

Only to be used if `eqs` is a single univariate polynomial. Symbolic factorization is applied, before the numerical search starts.

It is passed to numeric::polyroots, which preprocesses the polynomial by a symbolic factorization. See the help page of numeric::polyroots for details.

RestrictedSearch

The numerical search is restricted to the search ranges specified in `vars`.

This option is passed to numeric::fsolve, which uses a corresponding search strategy when looking for roots in the search range specified in `vars`. It must be used only in conjunction with search range and only for non-polynomial equations.

See numeric::fsolve for details.

UnrestrictedSearch

The numerical search may return results outside the search ranges specified in `vars`.

This option is passed to numeric::fsolve, which uses a corresponding search strategy when looking for roots in the search range specified in `vars`. It must be use only in conjunction with search ranges and only for non-polynomial equations.

See numeric::fsolve for details.

MultiSolutions

Only to be used for non-polynomial equations in conjunction with `RestrictedSearch`. Several roots may be returned.

It is passed to numeric::fsolve, which returns a sequence of all roots found in the internal search. See the help page of numeric::fsolve for details.

Random

Only to be used for non-polynomial equations. With this option, several calls to `numeric::solve` may lead to different solutions of the equation(s).

It is passed to numeric::fsolve which switches to a random search strategy. See the help page of numeric::fsolve for details.

NoWarning

This option only has an effect when it is used for polynomial equations in conjunction with `AllRealRoots`. When you use `AllRealRoots`, warnings are issued if interval arithmetic indicates technical difficulties such as serious overestimation (for example, when encountering multiple roots). With this option, the warnings are suppressed.

Note This option has an effect if `eqs` is a multivariate polynomial system or a univariate polynomial with a symbolic parameter.

In such a case, this option is passed to numeric::polysysroots.

Return Values

Set of numerical solutions. With the option `Multiple`, a set of domain type Dom::Multiset is returned.

Concepts

- "Solve Equations Numerically"

numeric::sort

Purpose

Sort a numerical list

Syntax

```
numeric::sort(list)
```

Description

`numeric::sort(list)` sorts the elements in `list`.

The elements of the list are sorted such that their real parts are descending. Elements with the same real part are sorted from large absolute value to small absolute value. In case of a tie (i.e., two elements form a complex conjugate pair), the element with positive imaginary part comes first.

The elements of the list are converted to floating-point numbers via float. Elements that cannot be converted lead to an error.

This function is used to sort the return values of numeric::eigenvalues, numeric::eigenvectors, numeric::polyroots, numeric::singularvalues, and numeric::singularvectors.

Environment Interactions

The function is sensitive to the environment variable DIGITS.

Examples

Example 1

The elements in the sorted list have descending real parts:
numeric::sort([1, 2.0, I, -3, -I, PI, sqrt(2)])[3.141592654, 2.0, 1.414213562, 1.0, 1.0*I, -1.0*I, -3.0]

```
[3.141592654, 2.0, 1.414213562, 1.0, 1.0 i, – 1.0 i, – 3.0]
```

In the following example, the sorting criterion does not seem to be satisfied. Elements with the same real part are supposed to be ordered from large absolute values to small absolute values:
x := sin(PI/3): L := numeric::sort([x, sin(float(PI/3)) - I, x + I])[0.8660254038 + 1.0*I, 0.8660254038 + (- 1.0*I), 0.8660254038]

```
[0.8660254038 + 1.0 i, 0.8660254038 - 1.0 i, 0.8660254038]
```

This is explained by the fact that the floating-point numbers internally have a more accurate representation than shown on the screen. The real part of the last element is indeed a little bit smaller than the other real parts:
DIGITS := 20: L[0.8660254037844386469 + 1.0*I, 0.8660254037844386469 + (- 1.0*I), 0.8660254037844386469]

```
[0.8660254037844386469 + 1.0 i, 0.8660254037844386469 - 1.0 i, 0.8660254037844386469]
```

delete x, L, DIGITS:

Parameters

list

A list of numbers or numerical expressions

Return Values

Sorted list.

See Also

sort

Purpose

Spectral radius of a matrix

Syntax

```
numeric::spectralradius(A, <x0>, <n>, <mode>,
<ReturnType = t>, <NoWarning>)
```

Description

`numeric::spectralradius(A)` returns data corresponding to the eigenvalue of the matrix `A` that has the largest absolute value.

`numeric::spectralradius` and numeric::spectralRadius are equivalent.

The spectral radius of a matrix with eigenvalues λ_i is $max(|\lambda_i|)$.

The return value `lambda` is an approximation of the corresponding eigenvalue: `abs(lambda)` is the spectral radius.

The return value `x` is the corresponding normalized eigenvector: norm(x, 2) = 1 $\|x\|_2 = 1$.

The return value residue = norm(A*x-lambda*x, 2) $\text{residue} = \|A\,x - \text{lambda}\,x\|_2$ provides an error estimate for the eigenvalue. For Hermitean matrices this is a rigorous upper bound for the error $|lambda - \lambda_{exact}|$, where λ_{exact} is the exact eigenvalue.

`numeric::spectralradius` implements the power method to compute the eigenvalue and the associated eigenvector defining the spectral radius: the vector iteration x[i]=(A^i*x[0])/norm(A^i*x[0],2) $x_i = \frac{A^i x_0}{\|A^i x_0\|_2}$ "converges" towards the eigenspace associated with the spectral radius. The starting vector x_0 is provided by the second argument of `numeric::spectralradius`. If no starting vector is provided by the user, a randomly chosen vector is used.

Note The iteration does not converge (converges slowly), if the spectral radius is generated by several distinct eigenvalues with the same (similar) absolute value.

Internally, the iteration stops, when the approximation of the eigenvalue becomes stationary within the relative precision given by DIGITS. If this does not happen within *n* iterations, then a warning is issued and the present values are returned. Cf. “Example 4” on page 19-371.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We let the routine choose a random starting vector:
A := matrix(2, 2, [[10, 1], [1, 20]]):
numeric::spectralradius(A)[20.09901951, matrix([[0.0985376181], [0.9951333267]]), 0.000000001332123191]

$$\left[20.09901951, \begin{pmatrix} 0.0985376181 \\ 0.9951333267 \end{pmatrix}, 0.000000001332123191\right]$$

We define a starting vector as a 1-dimensional array and allow a maximum of 1000 internal iterations:
A := array(1..2, 1..2, [[1, 2], [5, -10]]): x0 := array(1..2, [1, 1]):
numeric::spectralradius(A, x0, 1000)[-10.84428877, array(1..2, [0.1665007247, -0.9860413321]), 7.808576008e-11]

$$\left[-10.84428877, \begin{pmatrix} 0.1665007247 & -0.9860413321 \end{pmatrix}, 7.808576008\ 10^{-11}\right]$$

Next, we use a list to specify a starting vector:
A := array(1..2, 1..2, [[I, 3], [3, I]]): numeric::spectralradius(A, [1, 1], 1000)[3.0 + 1.0*I, [0.7071067812, 0.7071067812], 0.0]

$$[3.0 + 1.0\,i, [0.7071067812, 0.7071067812], 0.0]$$

delete A, x0:

Example 2

With the default setting of DIGITS = 10, the following result is computed using `HardwareFloats`.

```
A := hfarray(1..2, 1..2, [[10^4, 10^4], [50, 60]]): x0 := array(1..2, [1, 1]):
numeric::spectralradius(A, x0)[10050.0498, array(1..2, [0.9999874753,
0.00500491737]), 0.000000004820940092]
```

```
[10050.0498, ( 0.9999874753  0.00500491737 ), 0.000000004820940092]
```

We request `SoftwareFloats` in the next call. Note the difference in the trailing digits:

```
numeric::spectralradius(A, x0, Soft)[10050.0498, array(1..2,
[0.9999874753, 0.00500491737]), 0.000000004820942201]
```

```
[10050.0498, ( 0.9999874753  0.00500491737 ), 0.000000004820942201]
```

delete DIGITS, A, x0:

Example 3

The eigenvector that is returned can have various types. If no starting vector is provided, the type of the matrix determines the type of the eigenvector:

```
A:= array(1..2, 1..2, [[1, 2], [3, 4]]):  [l, x, residue]:=
numeric::spectralradius(A);[5.372281324, array(1..2, [0.4159735579,
0.9093767091]), 0.0000000002881934691]
```

```
[5.372281324, ( 0.4159735579  0.9093767091 ), 0.0000000002881934691]
```

domtype(x)DOM_ARRAY

```
DOM_ARRAY
```

```
A:= hfarray(1..2, 1..2, [[1, 2], [3, 4]]):  [l, x, residue]:=
numeric::spectralradius(A): domtype(x)DOM_HFARRAY
```

```
DOM_HFARRAY
```

A:= matrix(2, 2, [[1, 2], [3, 4]]): [l, x, residue]:= numeric::spectralradius(A): domtype(x)Dom::Matrix()

Dom::Matrix()

If a starting vector is provided, its type determines the type of the return vector:
A:= hfarray(1..2, 1..2, [[1, 2], [3, 4]]): x0:= [1, 1]: [l, x, residue]:= numeric::spectralradius(A, x0): domtype(x)DOM_LIST

DOM_LIST

x0:= array(1..2, [1, 1]): [l, x, residue]:= numeric::spectralradius(A, x0): domtype(x)DOM_ARRAY

DOM_ARRAY

x0:= hfarray(1..2, [1, 1]): [l, x, residue]:= numeric::spectralradius(A, x0): domtype(x)DOM_HFARRAY

DOM_HFARRAY

x0:= matrix([1, 1]): [l, x, residue]:= numeric::spectralradius(A, x0): domtype(x)Dom::Matrix()

Dom::Matrix()

The return type can be requested explicitly:
[l, x, residue]:= numeric::spectralradius(A, x0, ReturnType = DOM_LIST): domtype(x)DOM_LIST

DOM_LIST

[l, x, residue]:= numeric::spectralradius(A, x0, ReturnType = DOM_HFARRAY): domtype(x)DOM_HFARRAY

DOM_HFARRAY

delete A, x0, l, x, residue:

Example 4

The following matrix has two distinct eigenvalues 1 and -1 of the same absolute value. The power method must fail.
A := array(1..2, 1..2, [[1, 0], [0, -1]]):

We allow a maximum of 1000 internal steps. The call results in a warning. The large residue also indicates that the power method did not converge:
numeric::spectralradius(A, [1, 1], 1000) Warning: There is no convergence of vector iteration. [numeric::spectralradius] [1.0, [0.7071067812, -0.7071067812], 1.414213562]

```
[1.0, [0.7071067812, -0.7071067812], 1.414213562]
```

delete A:

Parameters

A

An *m* *m* array of domain type DOM_ARRAY or DOM_HFARRAY or a matrix of category Cat::Matrix

x_0

A starting vector: a 1-dimensional array, or an hfarray, or a list of length *m*. Also 2-dimensional arrays (`array(1..m, 1..1, ...)`, `hfarray(1..m, 1..1, ...)`) and matrices representing vectors are accepted.

n

The maximal number of iterations: a positive integer. The default value is 1000.

mode

One of the flags `Hard`, `HardwareFloats`, `Soft`, or `SoftwareFloats`

Options

Hard

HardwareFloats

Soft

SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix `A` is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD

computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

ReturnType

Option, specified as `ReturnType = t`

Return the eigenvector associated with the spectral radius as a vector of domain type `t`. The following return types are available: DOM_ARRAY, or DOM_HFARRAY, or DOM_LIST, or `Dom::Matrix()`, or `Dom::DenseMatrix()`.

NoWarning

Suppresses warnings

Return Values

A list `[lambda, x, residue]` is returned. The floating-point number `lambda` is an approximation of the eigenvalue of largest absolute value. The vector `x` is a numerical eigenvector corresponding to `lambda`.

`residue` is a floating-point number indicating the numerical quality of `lambda` and `x`.

If no return type is requested via the `ReturnType` option, the type of the returned vector `x` coincides with the type of the input vector x_0 (i.e., it is a 1-dimensional array of type DOM_ARRAY or DOM_HFARRAY, respectively, or a list, or a column vector of type matrix or densematrix. If no starting vector is specified, the type of `x` is determined by the type of `A`.

numeric::spectralRadiuslinalg::eigenvalueslinalg::eigenvectorsnumeric::eigenvaluesnumeric::

Purpose

Spectral radius of a matrix

Syntax

```
numeric::spectralRadius(A, <x0>, <n>, <mode>,
<ReturnType = t>, <NoWarning>)
```

Description

`numeric::spectralRadius(A)` returns data corresponding to the eigenvalue of the matrix `A` that has the largest absolute value.

`numeric::spectralRadius` and numeric::spectralradius are equivalent.

The spectral radius of a matrix with eigenvalues λ_i is $max(|\lambda_i|)$.

The return value `lambda` is an approximation of the corresponding eigenvalue: `abs(lambda)` is the spectral radius.

The return value `x` is the corresponding normalized eigenvector: norm(x, 2) = 1 $\|x\|_2 = 1$.

The return value residue = norm(A*x-lambda*x, 2) $\text{residue} = \|A\,x - \text{lambda}\,x\|_2$ provides an error estimate for the eigenvalue. For Hermitean matrices this is a rigorous upper bound for the error $|lambda - \lambda_{exact}|$, where λ_{exact} is the exact eigenvalue.

`numeric::spectralRadius` implements the power method to compute the eigenvalue and the associated eigenvector defining the spectral radius: the vector iteration x[i]=(A^i*x[0])/norm(A^i*x[0],2) $x_i = \frac{A^i x_0}{\|A^i x_0\|_2}$ "converges" towards the eigenspace associated with the spectral radius. The starting vector x_0 is provided by the second argument of numeric::spectralradius. If no starting vector is provided by the user, a randomly chosen vector is used.

Note The iteration does not converge (converges slowly), if the spectral radius is generated by several distinct eigenvalues with the same (similar) absolute value.

Internally, the iteration stops, when the approximation of the eigenvalue becomes stationary within the relative precision given by DIGITS. If this does not happen within *n* iterations, then a warning is issued and the present values are returned. Cf. “Example 4” on page 19-379.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We let the routine choose a random starting vector:

```
A := matrix(2, 2, [[10, 1], [1, 20]]):
numeric::spectralradius(A)[20.09901951, matrix([[0.0985376181],
[0.9951333267]]), 0.000000001332123191]
```

$$\left[20.09901951,\ \begin{pmatrix} 0.0985376181 \\ 0.9951333267 \end{pmatrix},\ 0.000000001332123191\right]$$

We define a starting vector as a 1-dimensional array and allow a maximum of 1000 internal iterations:

```
A := array(1..2, 1..2, [[1, 2], [5, -10]]): x0 := array(1..2, [1, 1]):
numeric::spectralradius(A, x0, 1000)[-10.84428877, array(1..2,
[0.1665007247, -0.9860413321]), 7.808576008e-11]
```

$$\left[-10.84428877,\ \begin{pmatrix} 0.1665007247 & -0.9860413321 \end{pmatrix},\ 7.808576008\ 10^{-11}\right]$$

Next, we use a list to specify a starting vector:

```
A := array(1..2, 1..2, [[I, 3], [3, I]]): numeric::spectralradius(A, [1, 1],
1000)[3.0 + 1.0*I, [0.7071067812, 0.7071067812], 0.0]
```

$$[3.0 + 1.0\,i,\ [0.7071067812,\ 0.7071067812],\ 0.0]$$

delete A, x0:

Example 2

With the default setting of DIGITS = 10, the following result is computed using `HardwareFloats`.

```
A := hfarray(1..2, 1..2, [[10^4, 10^4], [50, 60]]): x0 := array(1..2, [1, 1]):
numeric::spectralradius(A, x0)[10050.0498, array(1..2, [0.9999874753,
0.00500491737]), 0.000000004820940092]
```

```
[10050.0498, ( 0.9999874753  0.00500491737 ), 0.000000004820940092]
```

We request `SoftwareFloats` in the next call. Note the difference in the trailing digits:

```
numeric::spectralradius(A, x0, Soft)[10050.0498, array(1..2,
[0.9999874753, 0.00500491737]), 0.000000004820942201]
```

```
[10050.0498, ( 0.9999874753  0.00500491737 ), 0.000000004820942201]
```

delete DIGITS, A, x0:

Example 3

The eigenvector that is returned can have various types. If no starting vector is provided, the type of the matrix determines the type of the eigenvector:

```
A:= array(1..2, 1..2, [[1, 2], [3, 4]]):  [l, x, residue]:=
numeric::spectralradius(A);[5.372281324, array(1..2, [0.4159735579,
0.9093767091]), 0.0000000002881934691]
```

```
[5.372281324, ( 0.4159735579  0.9093767091 ), 0.0000000002881934691]
```

domtype(x)DOM_ARRAY

```
DOM_ARRAY
```

```
A:= hfarray(1..2, 1..2, [[1, 2], [3, 4]]):  [l, x, residue]:=
numeric::spectralradius(A): domtype(x)DOM_HFARRAY
```

```
DOM_HFARRAY
```

```
A:= matrix(2, 2, [[1, 2], [3, 4]]): [l, x, residue]:=
numeric::spectralradius(A): domtype(x)Dom::Matrix()
```

```
Dom::Matrix()
```

If a starting vector is provided, its type determines the type of the return vector:

```
A:= hfarray(1..2, 1..2, [[1, 2], [3, 4]]): x0:= [1, 1]: [l, x, residue]:=
numeric::spectralradius(A, x0): domtype(x)DOM_LIST
```

```
DOM_LIST
```

```
x0:= array(1..2, [1, 1]): [l, x, residue]:= numeric::spectralradius(A, x0):
domtype(x)DOM_ARRAY
```

```
DOM_ARRAY
```

```
x0:= hfarray(1..2, [1, 1]): [l, x, residue]:= numeric::spectralradius(A,
x0): domtype(x)DOM_HFARRAY
```

```
DOM_HFARRAY
```

```
x0:= matrix([1, 1]): [l, x, residue]:= numeric::spectralradius(A, x0):
domtype(x)Dom::Matrix()
```

```
Dom::Matrix()
```

The return type can be requested explicitly:

```
[l, x, residue]:= numeric::spectralradius(A, x0, ReturnType =
DOM_LIST): domtype(x)DOM_LIST
```

```
DOM_LIST
```

```
[l, x, residue]:= numeric::spectralradius(A, x0, ReturnType =
DOM_HFARRAY): domtype(x)DOM_HFARRAY
```

```
DOM_HFARRAY
```

delete A, x0, l, x, residue:

Example 4

The following matrix has two distinct eigenvalues 1 and -1 of the same absolute value. The power method must fail.
A := array(1..2, 1..2, [[1, 0], [0, -1]]):

We allow a maximum of 1000 internal steps. The call results in a warning. The large residue also indicates that the power method did not converge:
numeric::spectralradius(A, [1, 1], 1000) Warning: There is no convergence of vector iteration. [numeric::spectralradius] [1.0, [0.7071067812, -0.7071067812], 1.414213562]

```
[1.0, [0.7071067812, -0.7071067812], 1.414213562]
```

delete A:

Parameters

A

An *m* *m* array of domain type DOM_ARRAY or DOM_HFARRAY or a matrix of category Cat::Matrix

x_0

A starting vector: a 1-dimensional array, or an hfarray, or a list of length *m*. Also 2-dimensional arrays (`array(1..m, 1..1, ...)`, `hfarray(1..m, 1..1, ...)`) and matrices representing vectors are accepted.

n

The maximal number of iterations: a positive integer. The default value is 1000.

mode

One of the flags `Hard`, `HardwareFloats`, `Soft`, or `SoftwareFloats`

Options

Hard

HardwareFloats

Soft

SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix `A` is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix `A` is not of domain type DOM_HFARRAY, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD

computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

ReturnType

Option, specified as `ReturnType = t`

Return the eigenvector associated with the spectral radius as a vector of domain type `t`. The following return types are available: DOM_ARRAY, or DOM_HFARRAY, or DOM_LIST, or `Dom::Matrix()`, or `Dom::DenseMatrix()`.

NoWarning

Suppresses warnings

Return Values

A list `[lambda, x, residue]` is returned. The floating-point number `lambda` is an approximation of the eigenvalue of largest absolute value. The vector `x` is a numerical eigenvector corresponding to `lambda`.

`residue` is a floating-point number indicating the numerical quality of `lambda` and `x`.

If no return type is requested via the `ReturnType` option, the type of the returned vector `x` coincides with the type of the input vector x_0 (i.e., it is a 1-dimensional array of type DOM_ARRAY or DOM_HFARRAY, respectively, or a list, or a column vector of type matrix or densematrix. If no starting vector is specified, the type of `x` is determined by the type of `A`.

numeric::sum

Purpose

Numerical approximation of sums (the Float attribute of Sum)

Syntax

```
numeric::sum(f(x), x = a .. b)
numeric::sum(f(x), x in {x1, x2,  })
numeric::sum(f(x), x = {x1, x2,  })
numeric::sum(f(x), x in RootOf(p(X), X))
numeric::sum(f(x), x = RootOf(p(X), X))
float(holdsum(f(x), x = a .. b))
float(holdsum(f(x), x in {x1, x2,  }))
float(holdsum(f(x), x = {x1, x2,  }))
float(holdsum(f(x), x in RootOf(p(X), X)))
float(holdsum(f(x), x = RootOf(p(X), X)))
float(freezesum(f(x), x = a .. b))
float(freezesum(f(x), x in {x1, x2,  }))
float(freezesum(f(x), x = {x1, x2,  }))
float(freezesum(f(x), x in RootOf(p(X), X)))
float(freezesum(f(x), x = RootOf(p(X), X)))
```

Description

`numeric::sum(f(i), i=a..b)` computes a numerical approximation of sum(f(i), i=a..b) $\sum_{i=a}^{b} f(i)$.

`numeric::sum(f(x), x  {x1, x2,  })` computes a numerical approximation of sum(f(x), x in {x[1], x[2], Symbol::dots}) $\sum_{x \in \{x_1, x_2, \ldots\}} f(x)$.

`numeric::sum(f(x), x in RootOf(p(X), X))` computes a numerical approximation of sum(f(x), x in RootOf(p(X), X)) $\sum_{x \in \mathrm{RootOf}(p(X), X)} f(x)$.

The call `numeric::sum( )` is equivalent to calling the `float` attribute of sum via `float ( hold( sum )( ))` or `float ( freeze( sum )( ))`.

If there are other symbolic parameters in $f(x)$, apart from the summation variable x, a symbolic sum is returned. Numerical expressions such as exp(PI) e^{π}, sqrt(2) $\sqrt{2}$ etc. are accepted and converted to floating-point numbers.

Note For infinite sums, the expression $f(i)$ with integer i must have an extension $f(x)$ to all real x in the interval Interval([a, b]) $[a, b]$. Internally, the integral int(f(x), x=a..b) $\int_a^b f(x)\,dx$ is computed numerically and used in the approximation process.

Note For finite sums, `numeric::sum` just returns `_plus ( float(f(i)$i=a..b))`. Note that numerical cancellation may occur! If `f(i)` does not contain floating-point numbers, cancellation can be avoided summing the symbolic terms by `_plus(f(i)$i=a..b)` instead. Cf. "Example 3" on page 19-386.

Convergence is fast, if $f(x)$ decays rapidly for `x -> infinity` or `| x | -> infinity`, respectively

Note Convergence may be slow for alternating sums containing expressions such as $(-1)^i$. Such sums are also often subject to cancellation problems!

The call `numeric::sum(f(x), x = {x1, x2, ...})` computes numerical approximations of x_1, x_2 etc., substitutes these values into $f(x)$ and adds up the results. This process may be subject to cancellation problems!

The calls `numeric::sum(f(x), x in {x1, x2, ...})` and `numeric::sum(f(x), x = {x1, x2, ...})` are equivalent.

The call `numeric::sum(f(x), x in RootOf(p(X), X))` computes numerical approximations of all roots of p, substitutes these values into $f(x)$ and adds up the results. Cf. "Example 4" on page 19-386. This process may be subject to cancellation problems!

The calls `numeric::sum(f(x), x in RootOf(p(X), X)))` and `numeric::sum(f(x), x = RootOf(p(X), X)))` are equivalent.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We demonstrate some equivalent calls for numerical summation:
numeric::sum(1/i!, i = 0..infinity), float(hold(sum)(1/i!, i = 0..infinity)), float(freeze(sum)(1/i!, i = 0..infinity))2.718281828, 2.718281828, 2.718281828

```
2.718281828, 2.718281828, 2.718281828
```

The MuPAD symbolic summation sum does not find a simple representation of the following sum:
sum(1/i!/(i+1)!, i = 0..infinity)sum(1/((i + 1)!*i!), i = 0..infinity)

$$\sum_{i=0}^{\infty} \frac{1}{(i+1)!\,i!}$$

The following float evaluation calls `numeric::sum`:
float(%)1.590636855

```
1.590636855
```

The exact value of the following sum is $\pi coth(\pi)$:
numeric::sum(1/(1+i^2), i = -infinity..infinity) = float(PI*coth(PI))3.153348095 = 3.153348095

```
3.153348095 = 3.153348095
```

Example 2

The following sum cannot be evaluated numerically because of the symbolic parameter `x`:
numeric::sum(1/(x+i^2), i = -infinity..infinity)numeric::sum(1/(i^2 + x), i = -infinity..infinity)

$$\text{numeric::sum}\left(\frac{1}{i^2+x},\ i=-\infty..\infty\right)$$

Example 3

We demonstrate numerical cancellation when summing the Taylor series for exp(-20)e^{-20}:
exp(-20.0) <> numeric::sum((-20)^i/i!, i = 0..100)0.000000002061153622 <> 0.000000002148938644

$$0.000000002061153622 \neq 0.000000002148938644$$

Also the infinite sum suffers from cancellation:
exp(-20.0) <> numeric::sum((-20)^i/i!, i = 0..infinity)0.000000002061153622 <> 0.000000002205327316

$$0.000000002061153622 \neq 0.000000002205327316$$

Cancellation can be avoided using a finite sum with exact terms:
exp(-20.0) = float(_plus((-20)^i/i! $ i = 0..100))0.000000002061153622 = 0.000000002061153622

$$0.000000002061153622 = 0.000000002061153622$$

Example 4

The following call computes the numerical roots of the polynomial in the RootOf expression and sums over all the roots:
numeric::sum(exp(x)/x, x in RootOf(X^10 - X - PI, X))9.681693381

$$9.681693381$$

Parameters

f(x)

An arithmetical expression in *x*

i, x

Summation variables: identifiers or indexed identifiers

a

b

Integers or ±infinity satisfying $a \le b$

x_1, x_2, ...

Numerical expressions

p(X)

A univariate polynomial expression in X

X

The indeterminate of p: an identifier or an indexed identifier

Return Values

Floating point number or a symbolic expression of type `numeric::sum`.

Algorithms

Depending on whether the series is alternating or monotone, `numeric::sum` tries a number of strategies to calculate its limit: Levin's u transformation, the Euler-MacLaurin formula or van Wijngaarden's trick.

The Euler-MacLaurin formula is

sum(f(i), i=a..b)= (f(a)+f(b))/2+int(f(x), x=a..b) + sum(B[2*m]/(2*m)! *((f^(fenced(2*m-1))) (b) - (f^(fenced(2*m-1))) (a)), m=1..M) + Symbol::cdots

$$\sum_{i=a}^{b} f(i) = \frac{f(a)+f(b)}{2} + \int_a^b f(x)\,\mathrm{d}\,x + \left(\sum_{m=1}^{M} \frac{B_{2\,m}}{(2\,m)!}\left(f(b)^{(2\,m-1)} - f(a)^{(2\,m-1)}\right)\right) + \cdots$$

involving the Bernoulli numbers B_{2m}.

numlib – Number Theory

numlib::Lambda
numlib::lambda
numlib::omega
numlib::Omega

numlib::checkPrimalityCertificate

Purpose

Test the primality certificate

Syntax

```
numlib::checkPrimalityCertificate(certificate)
```

Description

`numlib::checkPrimalityCertificate` tests the certificate of primality returned by numlib::proveprime. For large prime numbers, the numlib::proveprime function generates certificates that provide all data you need for proving primality of a number by the Atkin-Goldwasser-Kilian-Morain algorithm. See “Example 1” on page 20-2.

For small prime numbers, numlib::proveprime does not returns a certificate of primality. Instead, it returns TRUE. For nonprime numbers numlib::proveprime returns FALSE. In both cases, you do not need to use `numlib::checkPrimalityCertificate`.

To expose the comments that `numlib::checkPrimalityCertificate` produces for each step of the primalty-proving routine, use the setuserinfo function. By default, MuPAD hides these comments. See “Example 2” on page 20-3.

Examples

Example 1

Use the numlib::proveprime function to check the primality of the number 1299709. The function returns the following sequence of lists. This sequence is the certificate of primality:
certificate := numlib::proveprime(1299709)[1299709, 15, [2, 2, 2, 2, 2, 107, 379], 700619, 67686, 0, 796444, [107, 379]]

```
[1299709, 15, [2, 2, 2, 2, 2, 107, 379], 700619, 67686, 0, 796444, [107, 379]]
```

The certificate provides all data that you need for proving primality of 1299709 by the Atkin-Goldwasser-Kilian-Morain algorithm. You can substitute the numbers into the algorithm and verify the primality of the number. Alternatively, you can verify the certificate by using the `numlib::checkPrimalityCertificate` function:
numlib::checkPrimalityCertificate(certificate)TRUE

TRUE

Example 2

By default, MuPAD functions do not display information about intermediate steps and algorithms that they use. If you want to expose such details, increase the information level by using the setuserinfo function. When you test a primality certificate with the `numlib::checkPrimalityCertificate` function, the detailed information can help you understand the primality proving process: setuserinfo(Any, 2):

The first argument of setuserinfo specifies the name of a procedure or a domain for which you want increase the information level. The second argument specifies the level itself. (Typically, setting this value to 1 or 2 exposes the most important details.) Now, testing the primality certificate of the number 1299709 with the `numlib::checkPrimalityCertificate` function, you get the following step-by-step description: numlib::checkPrimalityCertificate(certificate)Info: The proof is based on the following theorem due to Gold- wasser and Kilian, see article "Almost all primes can be quickly certified", Proc. 18th STOC, ACM, 1986: Theorem GK: Let N be an integer prime to 6, E an elliptic curve over Z/NZ, together with a point P on E and m and s two integers with s dividing m. For each prime divisor q of s, we put (m/q)P = (xq:yq:zq). We assume that mP is the zero of E and gcd(zq,N)=1 for all q. Then, if s>(N^(1/4)+1)^2, N is prime. Info: N=1299709 D=15 m=1297696 Info: a=700619 b=67686 P=(0 : 796444 : 1) Info: m*P=(0 : 1 : 0) Info: 40553 > (N^(1/4)+1)^2 = 1208.576994 Info: Theorem GK applies for N=1299709 E(700619,67686) P=(0:796444:1) m=1297696 s=40553, therefore: Info: 1299709 is prime if 379 is prime TRUE

TRUE

Parameters

certificate

A list or a sequence of lists returned by numlib::proveprime

Return Values TRUE or FALSE

See Also numlib::proveprimenumlib::ecm

Concepts

- “Primes and Factorizations”

numlib::contfrac

Purpose

Domain of continued fractions

Syntax

```
numlib::contfrac(x, <n>)
```

Description

`numlib::contfrac(x)` creates a continued fraction approximation for the real number `x`.

If `x` is an integer or a rational number and `n` is not specified, a continued fraction is returned that represents `x` exactly. Cf. “Example 1” on page 20-5.

Irrational numerical values `x` such as `1 + sqrt(2)` or `PI/3` are first converted to floating-point numbers. The first `n` significant decimals of floating-point numbers are taken into account. If `n` is not specified, `n` = DIGITS is used. The value of the continued fraction (given by `numlib::contfrac ::rational`) satisfies

abs(x-numlib::contfrac::rational(x))<=abs(x)*10^(-n)

$$\left|x - \text{numlib::contfrac::rational}(x)\right| \le |x| \cdot \frac{1}{10^n}$$

Integers or rational numbers are also converted to floating point numbers, if a precision `n` is specified.

Objects of type `numlib::contfrac` can be handled by the usual arithmetical operations. They are sensitive to the environment variable DIGITS if floating-point numbers or irrational numerical values are involved.

Use contfrac to compute continued fraction approximations of expressions involving symbolic parameters.

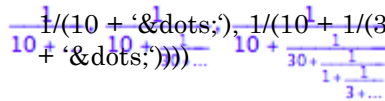
Examples

Example 1

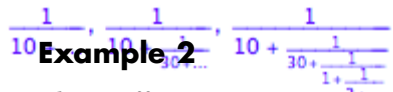
For rational numbers, exact representations are returned:
numlib::contfrac(123/1234)1/(10 + 1/(30 + 1/(1 + 1/(3 + ‘&dots;’))))

The rational representation (the second operand of the continued fraction) coincides with the original rational: numlib::contfrac::rational(%), expr(%), op(%, 2)123/1234, 123/1234, 123/1234

Restricted continued fraction approximations can be computed by passing a precision as second argument: numlib::contfrac(123/1234, 2), numlib::contfrac(123/1234, 3), numlib::contfrac(123/1234, 5)1/(10 + ‘&dots;‘), 1/(10 + 1/(30 + ‘&dots;‘)), 1/(10 + 1/(30 + 1/(1 + 1/(3 + ‘&dots;‘))))

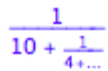


1/(10 + ‘&dots;‘), 1/(10 + 1/(30 + ‘&dots;‘)), 1/(10 + 1/(30 + 1/(1 + 1/(3 + ‘&dots;‘))))



Example 2

The coefficients are extracted by the method `nthcoeff`: cf := numlib::contfrac(12/123)1/(10 + 1/(4 + ‘&dots;‘))



nthcoeff(cf, 1), nthcoeff(cf, 2), nthcoeff(cf, 3), nthcoeff(cf, 4)0, 10, 4, FAIL

0, 10, 4, FAIL

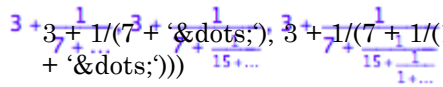
The internal list of coefficients can also be queried via op:
op(cf, 1)[0, 10, 4]

[0, 10, 4]

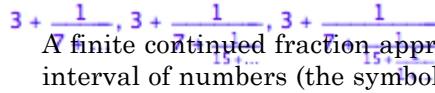
delete cf:

Example 3

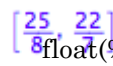
`numlib::contfrac` can also compute continued fraction approximations of irrational numbers:
numlib::contfrac(PI, 2), numlib::contfrac(PI, 4), numlib::contfrac(PI, 5)3 + 1/(7 + ‘&dots;‘), 3 + 1/(7 + 1/(15 + ‘&dots;‘)), 3 + 1/(7 + 1/(15 + 1/(1 + ‘&dots;‘)))



3 + 1/(7 + ‘&dots;‘), 3 + 1/(7 + 1/(15 + ‘&dots;‘)), 3 + 1/(7 + 1/(15 + 1/(1 + ‘&dots;‘)))



A finite continued fraction approximation may be regarded as an interval of numbers (the symbol … represents a number between 0 and 1):
numlib::contfrac::rationalInterval(numlib::contfrac(PI, 2));[25/8, 22/7]



float(%)[3.125, 3.142857143]

[3.125, 3.142857143]

Example 4

All basic arithmetical operations are available for continued fractions:
x := numlib::contfrac(PI, 3): y := numlib::contfrac(1/12): DIGITS:= 3: 3/x + sqrt(2)*y^(1/3)1 + 1/(1 + 1/(1 + 1/(2 + 1/(1 + 1/(26 + &dots;)))))

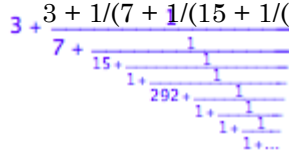
1 + 
delete x, y, DIGITS:

Example 5

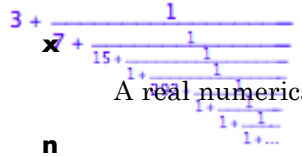
We search for a simple continued fraction in an interval:
numlib::contfrac::convert(1/2 - 1/10^8, 1/2 + 1/10^8)1/(2 + &dots;)

numlib::contfrac::convert(PI, PI + 1/10^10)3 + 1/(7 + 1/(15 + 1/(1 + 1/(292 + 1/(1 + 1/(1 + 1/(1 + &dots;)))))))

3 + 1/(7 + 1/(15 + 1/(1 + 1/(292 + 1/(1 + 1/(1 + 1/(1 + &dots;)))))))



Parameters



x

A real numerical expression

n

The number of significant digits: a positive integer greater one

Methods

Mathematical Methods

_plusSum of two continued fractions

```
_plus(x, y)
```

_multProduct of two continued fractions

```
_mult(x, y)
```

_invertReciprocal of a continued fraction

```
_invert(x)
```

Inverting a continued fraction means a shift of the coefficients by one to the left or to the right.

If `x` is an exact representation of a rational number, the continued fraction expansion of the reciprocal is also an exact representation.

_powerPower of a continued fraction

```
_power(x, m)
```

Access Methods

printPrint a continued fraction

```
print(cf)
```

See Also

contfracnumeric::rationalize

numlib::contfracPeriodic

Purpose

Periodic continued fraction expansions

Syntax

```
numlib::contfracPeriodic(p, q, n)
```

Description

`numlib::contfracPeriodic(p, q, n)` returns the continued fraction expansion of `p + q*sqrt(n)` as a sequence of two lists: the first one contains the non-periodic part, the second one contains the periodic part of the expansion.

The non-periodic part may be an empty list. No periodic part is returned for rational input, i.e., $q = 0$ or `n` square.

Examples

Example 1

The non-periodic part may start with zero. All other coefficients of a continued fraction expansion are positive:
numlib::contfracPeriodic(2/7, 1/7, 2)[0, 2, 19], [1, 8, 1, 18]

```
[0, 2, 19], [1, 8, 1, 18]
```

The result agrees with that one of contfrac:
op(contfrac(2/7 + 1/7 *sqrt(2)), 1)[0, 2, 19, 1, 8, 1, 18, 1, 8, 1]

```
[0, 2, 19, 1, 8, 1, 18, 1, 8, 1]
```

Example 2

The golden mean is famous for its simple continued fraction expansion:
numlib::contfracPeriodic(1/2, 1/2, 5)[], [1]

```
[], [1]
```

Example 3

Since 81 is a perfect square, there is no periodic part in the continued fraction expansion of its square root:
numlib::contfracPeriodic(0, 1, 81)[9]

[9]

Parameters

p

A rational number

q

A rational number

n

A positive integer

Return Values

If p + q*sqrt(n) $p + q\sqrt{n}$ is a rational number, then `numlib::contfracPeriodic` returns one list, otherwise two lists of integers.

Algorithms

A real number has a periodic continued fraction expansion if and only if it is of the form p + q*sqrt(n) $p + q\sqrt{n}$.

See Also

numlib::contfracnumlib::sqrt2cfrac

numlib::cornacchia

Purpose

Cornachia's algorithm

Syntax

```
numlib::cornacchia(a, b, m)
```

Description

`numlib::cornacchia(a, b, m)` returns all pairs of positive and relatively prime integers x, y that solve the equation $ax^2 + by^2 = m$.

The arguments `a`, `b`, `m` must be pairwise relatively prime.

Examples

Example 1

We compute the solutions to $3x^2 + 5y^2 = 74533332452454382449233$:
numlib::cornacchia(3, 5, 74533332452454382449233){[22457088474, 120847316879]}

```
{[22457088474, 120847316879]}
```

Example 2

For non-prime `m`, there may be many solutions:
numlib::cornacchia(1, 4, 5*13*17*29*73){[103, 763], [151, 761], [217, 757], [521, 719], [553, 713], [583, 707], [809, 649], [887, 623], [1081, 541], [1127, 517], [1159, 499], [1367, 343], [1369, 341], [1463, 223], [1481, 191], [1529, 19]}

```
{[103, 763], [151, 761], [217, 757], [521, 719], [553, 713], [583, 707], [809, 649], [887, 623], [1
 [1367, 343], [1369, 341], [1463, 223], [1481, 191], [1529, 19]}
```

Parameters

a

A positive integer

b

A positive integer

m

A positive integer

Return Values `numlib::cornacchia` returns a set each element of which is a list of two positive integers.

See Also numlib::msqrts

numlib::decimal

Purpose

Infinite representation of rational numbers

Syntax

```
numlib::decimal(q)
```

Description

`numlib::decimal(q)` computes the decimal expansion of a rational number `q`.

If `q` is a nonnegative rational number whose decimal expansion is finite, then `numlib::decimal(q)` returns the expression sequence starting with the integral part of `q` and followed by the digits after the decimal point.

If `q` is a nonnegative rational number whose decimal expansion is infinite, then `numlib::decimal(q)` returns the expression sequence starting with the integral part of `q`, followed by the digits of the pre-period and terminated with a list, containing the digits of a minimal period.

Examples

Example 1

Computing the decimal expansion of 1999:
numlib::decimal(1999)1999

```
1999
```

Example 2

Computing the (finite) decimal expansion of 52187/78125 $\frac{52187}{78125}$:
numlib::decimal(52187/78125)0, 6, 6, 7, 9, 9, 3, 6

```
0, 6, 6, 7, 9, 9, 3, 6
```

Example 3

Computing the (infinite) decimal expansion of 111/7 $\frac{111}{7}$:
numlib::decimal(111/7)15, [8, 5, 7, 1, 4, 2]

```
15, [8, 5, 7, 1, 4, 2]
```

Example 4

Computing the (infinite) decimal expansion of 37/28$\frac{37}{28}$:
numlib::decimal(37/28)1, 3, 2, [1, 4, 2, 8, 5, 7]

```
1, 3, 2, [1, 4, 2, 8, 5, 7]
```

Parameters

q

Nonnegative rational number

Return Values

`numlib::decimal(q)` returns an expression sequence consisting of nonnegative integers or an expression sequence consisting of nonnegative integers and terminated by a list of nonnegative integers.

numlib::divisors

Purpose

Divisors of an integer

Syntax

```
numlib::divisors(n)
```

Description

`numlib::divisors(n)` returns the list of positive divisors of `n`.

If `a` is a non-zero integer then `numlib::divisors(a)` returns the sorted list of all positive divisors of `a`.

`numlib::divisors(0)` returns `[0]`.

`numlib::divisors` returns an error if the argument evaluates to a number of wrong type.

Examples

Example 1

We compute the list of all positive divisors of 72:
numlib::divisors(72)[1, 2, 3, 4, 6, 8, 9, 12, 18, 24, 36, 72]

```
[1, 2, 3, 4, 6, 8, 9, 12, 18, 24, 36, 72]
```

Example 2

`numlib::divisors` returns the positive divisors of negative numbers, too:
numlib::divisors(-63)[1, 3, 7, 9, 21, 63]

```
[1, 3, 7, 9, 21, 63]
```

Parameters

`n`

Integer

Return Values

`numlib::divisors` returns a list of nonnegative integers.

Algorithms Internally, ifactor is used for factoring n.

See Also ifactornumlib::numdivisorsnumlib::taunumlib::primedivisorsnumlib::numprimedivisorspolylib

numlib::ecm

Purpose

Factor an integer using the elliptic curve method

Syntax

```
numlib::ecm(n)
numlib::ecm(n, BaseBound)
numlib::ecm(n, Base)
numlib::ecm(n, BaseBound, s)
numlib::ecm(n, Base, s)
numlib::ecm(n, BaseBound, s, Step2Bound)
numlib::ecm(n, Base, s, Step2Bound)
```

Description

`numlib::ecm(n)` tries to factor the positive integer `n` using the elliptic curve method. Basically, it takes an elliptic curve modulo `n` and a point on that curve and computes some multiple of that point. This multiplication may fail; in this case, a proper factor of `n` can be found. Otherwise, the point computed is likely to have small order; it is used in a post-processing step.

`numlib::ecm(n, BaseBound, s, Step2Bound)` and `numlib::ecm(n, Base, s, Step2Bound)` do the same, but lets you specify internal parameters of the algorithm. The last, or the last two, parameters can be omitted.

The starting point is computed from the parameter `s`. It is chosen at random if `s` is not given.

The starting point chosen is multiplied either by all primes in `Base`, or all primes below `BaseBound`, or — if neither of both is given — by all primes below 1000.

The post-processing step consists of a certain number of iterations, determined by the parameter `Step2Bound`. By default, 100 times `BaseBound` (or the maximum of `Base`, respectively) is chosen.

Examples

Example 1

We factor an integer using the default parameters.
numlib::ecm(10000019070000133)10000019

```
10000019
```

Example 2

If too few multiplications on the elliptic curve are carried out, the algorithm is likely to fail.
numlib::ecm(10000019070000133, 50)1

```
1
```

Parameters

n

Positive integer

BaseBound

Positive integer

Base

List of primes

s

Integer

Step2Bound

Positive integer

Return Values

`numlib::ecm` returns an integer that divides `n`; the return value may equal 1 or `n`.

References

A description of the algorithm can be found in “Speeding the Pollard and Elliptic Curve Methods of Factorization”, by Peter Montgomery, Math. of Comp. 48 (177), pages 243-264, January 1987.

See Also

ifactor

numlib::factorGaussInt

Purpose

Factorization of Gaussian integers

Syntax

```
numlib::factorGaussInt(n)
```

Description

`numlib::factorGaussInt(n)` returns the factorization of the Gaussian integer `n` into Gaussian primes. Among associate primes, that one with smallest polar angle is chosen.

Examples

Example 1

In the Gaussian integers, 3 remains prime while 5 does not:
numlib::factorGaussInt(3), numlib::factorGaussInt(5)[1, 3, 1], [-I, 1 + 2*I, 1, 2 + I, 1]

$$[1, 3, 1], [-i, 1 + 2\,i, 1, 2 + i, 1]$$

Example 2

The argument to `numlib::factorGaussInt` may be any Gaussian integer, that is, every complex number of the form $a + bi$ where a and b are integers:
numlib::factorGaussInt(2+2*I)[-I, 1 + I, 3]

$$[-i, 1 + i, 3]$$

Parameters

n

An integer, or a complex number whose real and imaginary part are integers

Return Values

`numlib::factorGaussInt` returns a list `[u, p1, a1, ..., pk, ak]` where u is a unit in the Gaussian integers, the p_i are Gaussian primes and the a_i are positive integers, such that n=u * product(p[i]^(a[i]), i=1..k) $n = u\left(\prod_{i=1}^{k} p_i^{a_i}\right)$.

Algorithms

The function ifactor is used to factor the norm; this step takes most of the running time. Hence, the running time of the algorithm mainly depends on the size of the prime factors of the norm of n.

See Also

factor

numlib::fibonacci

Purpose

Fibonacci numbers

Syntax

```
numlib::fibonacci(n)
```

Description

`numlib::fibonacci(n)` returns the `n`-th Fibonacci number.

If `n` is a nonnegative integer then `numlib::fibonacci(n)` returns the `n`-th Fibonacci number.

`numlib::fibonacci` returns an error if the argument evaluates to a number of wrong type. `numlib::fibonacci` returns the unevaluated function call if `n` does not evaluate to a number.

Examples

Example 1

We compute the 201st Fibonnacci number:
numlib::fibonacci(201)453973694165307953197296969697410619233826

```
453973694165307953197296969697410619233826
```

Parameters

`n`

A nonnegative integer

Return Values

Nonnegative integer, or the function call with its arguments evaluated.

Algorithms

The n-th Fibonacci number F_n is defined by the recursion formula $F_0 = 0$, $F_1 = 1$, and $F_{n+2} = F_n + F_{n+1}$.

`numlib::fibonacci` uses quadratic recursion formulas.

numlib::fromAscii

Purpose

Decoding of ASCII codes

Syntax

```
numlib::fromAscii(listOfCodes)
```

Description

If `L` is a list of ASCII codes then `numlib::fromAscii(L)` returns the string coded by `L`.

ASCII codes of non-printable characters, i. e., codes between `0` and `8` and between `11` and `31`, are ignored.

`numlib::fromAscii` returns an error if its argument is not a list of integers between `0` and `127`, i. e., not a list of legal ASCII codes.

Examples

Example 1

Non-printable characters are ignored, but tabulator and newline characters are decoded.

```
L := [0,1,2,3,9,10,31,10,9,32,45,32,101,105,110,32,
84,101,115,116,32,61,32,97,32,116,101,115,116]:numlib::fromAscii(L)"\t\n\n\t
- ein Test = a test"
```

Parameters

listOfCodes

A list of ASCII codes

Return Values

String

See Also

numlib::toAscii

numlib::g_adic

Purpose

G-adic representation of a nonnegative integer

Syntax

```
numlib::g_adic(number, base)
```

Description

`numlib::g_adic(0, g)` returns `[0]`.

`numlib::g_adic` returns an error if the arguments evaluate to numbers which are not both of the correct type.

If `a` is a natural number and `g` is an integer such that $|g| > 1$, `numlib::g_adic(a, g)` returns the `g`-adic representation of `a` as a list $[a_0, \ldots, a_r]$ such that

a=a_0 + a_1*g+a_2*g^2 + dots + a_r*g^r

$$a = a_0 + a_1\, g + a_2\, g^2 + \ldots + a_r\, g^r$$

and $0 \le a_i < |g|$ für $i = 0, \ldots, r - 1$ and $0 < a_r < |g|$.

Examples

Example 1

Computing the dyadic representation of 1994:
numlib::g_adic(1994, 2)[0, 1, 0, 1, 0, 0, 1, 1, 1, 1, 1]

```
[0, 1, 0, 1, 0, 0, 1, 1, 1, 1, 1]
```

Example 2

Computing the hexadecimal representation of 2001:
numlib::g_adic(2001, 16)[1, 13, 7]

```
[1, 13, 7]
```

Parameters

number

An nonnegative integer

base

An integer with absolute value is greater than 1

Return Values

List of nonnegative integers, or the function call with evaluated arguments if one of the arguments is not a number.

See Also

genpolyint2texttext2int

numlib::ichrem

Purpose

Chinese remainder theorem for integers

Syntax

```
numlib::ichrem(a, m)
```

Description

`numlib::ichrem(a,m)` returns the least nonnegative integer x such that equivMod(x, a[i], m[i]) $x \equiv a_i \pmod{m_i}$ for $i = 1, \ldots, nops(m)$ if such a number exists; otherwise `numlib::ichrem(a,m)` returns `FAIL`.

The entries in `m` need not be pairwise coprime.

`numlib::ichrem(a,m)` returns an error if `a` is not a list of integers or `m` is not a list of natural numbers or `a` and `m` are not lists of the same length.

Examples

Example 1

Here the moduli are pairwise coprime. In this case, a solution always exists:
numlib::ichrem([2,3,2],[3,5,7])23

```
23
```

Example 2

Here the moduli are not pairwise coprime, and a solution does not exist:
numlib::ichrem([5,6,8],[20,21,22])FAIL

```
FAIL
```

Example 3

Also here the moduli are not pairwise coprime, but a solution nevertheless exists:
numlib::ichrem([5,6,7],[20,21,22])4605

```
4605
```

Parameters

a

A list of integers

m

A list of natural numbers of the same length as a

Return Values

Either a nonnegative integer or FAIL.

See Also

numlib::lincongruence

numlib::igcdmult

Purpose

Extended Euclidean algorithm for integers

Syntax

```
numlib::igcdmult(par1, par2,  )
```

Description

`numlib::igcdmult` is an extension of the kernel function `igcdex`.

`numlib::igcdmult` returns an error if the arguments evaluate to numbers which are not all of the correct type.

For integers `a_1,a_2,...,a_n`, `numlib::igcdmult(a_1,a_2,...,a_n)` returns a list $[d, v_1, ..., v_n]$ of integers such that `d` is the nonnegative greatest common divisor of `a_1,a_2,...,a_n` and `d = a_1*v_1 + a_2*v_2 + ...+ a_n*v_n`.

For integers `a_1,a_2,...,a_n`, `numlib::igcdmult(a_1,a_2,...,a_n)` returns a list $[d, v_1, ..., v_n]$ of integers such that `d` is the nonnegative greatest common divisor of `a_1,a_2,...,a_n` and `d = a_1*v_1 + a_2*v_2 + ...+ a_n*v_n`.

Examples

Example 1

Computing the greatest non-negative common divisor d of 455, 385, 165, 273 and integers v_1, v_2, v_3, v_4 such that $d = 455v_1 + 385v_2 + 165v_3 + 273v_4$: numlib::igcdmult(455,385,165,273)[1, -7630, 9156, -327, 2]

```
[1, -7630, 9156, -327, 2]
```

Parameters

par1

Integer

par2, ...

Integers

Return Values

List of integers, or the function call with evaluated arguments if some argument is not a number.

See Also igcdigcdex

numlib::invphi

Purpose

Inverse of the Euler phi function

Syntax

```
numlib::invphi(n)
```

Description

`numlib::invphi(n)` computes all positive integers `i` with $\varphi(i) = n$.

Examples

Example 1

We compute all numbers `i` with $\varphi(i) = 500$:
s := numlib::invphi(500)[625, 753, 1004, 1250, 1506]

```
[625, 753, 1004, 1250, 1506]
```

Test for correctness:
map(s, numlib::phi)[500, 500, 500, 500, 500]

```
[500, 500, 500, 500, 500]
```

Parameters

n

A positive integer

Return Values

List of positive integer numbers.

See Also

numlib::phi

numlib::ispower

Purpose

Test for perfect powers

Syntax

```
numlib::ispower(n)
```

Description

`numlib::ispower(n)` tests whether `n` is of the form a^k for some integers a, k with a, $k \geq 2$.

`numlib::ispower` returns FALSE if `n` is not a perfect power.

Among several pairs (a, k) for which $n = a^k$, that one with minimal a is returned.

Examples

Example 1

This number is a perfect power:
numlib::ispower(1977326743)7, 11

```
7, 11
```

This number is not a perfect power:
numlib::ispower(1977326744)FALSE

```
FALSE
```

Parameters

n

An integer

Return Values

`numlib::ispower` returns a sequence of two positive integers greater than 1, or FALSE if `n` is not a perfect power.

See Also

_powerifactorisqrt

numlib::isquadres

Purpose

Test for quadratic residues

Syntax

```
numlib::isquadres(a, m)
```

Description

If the integer number `a` is a quadratic residue modulo the natural number `mnumlib::isquadres(a,m)` returns `TRUE`, and if `a` is a quadratic non-residue modulo `mnumlib::isquadres(a,m)` returns `FALSE`.

If `a` and `m` are not coprime `numlib::isquadres(a,m)` returns an error.

`numlib::isquadres` returns an error if the arguments evaluate to numbers which are not both of the correct type.

`numlib::isquadres` returns the function call with its arguments evaluated if the arguments do not evaluate to numbers.

Examples

Example 1

132132 is a quadratic residue modulo 3231227:
numlib::isquadres(132132, 3231227)TRUE

```
TRUE
```

Example 2

222222 is a quadratic non-residue modulo 324899:
numlib::isquadres(222222,324899)FALSE

```
FALSE
```

Example 3

37 is a quadratic residue modulo 48884:
numlib::isquadres(37,48884)TRUE

```
TRUE
```

Parameters

a

An integer

m

A natural number coprime to `a`

Return Values

`numlib::isquadres` returns TRUE, FALSE, or the function call with its arguments evaluated.

See Also

numlib::legendrenumlib::jacobinumlib::msqrts

numlib::issqr

Purpose

Test for perfect squares

Syntax

```
numlib::issqr(a)
```

Description

`numlib::issqr(a)` returns `TRUE` if `a` is the square of an integer, and FALSE otherwise.

Examples

Example 1

361 is the square of 19:
numlib::issqr(361)TRUE

```
TRUE
```

Example 2

362 is not a square:
numlib::issqr(362)FALSE

```
FALSE
```

Example 3

Negative integers are not squares:
numlib::issqr(-361)FALSE

```
FALSE
```

Parameters

a

An integer

Return Values

`numlib::issqr` returns TRUE, FALSE, or the unevaluated call.

See Also isqrtnumlib::ispowersqrt

numlib::jacobi

Purpose

Jacobi symbol

Syntax

```
numlib::jacobi(a, m)
```

Description

`numlib::jacobi(a,m)` returns the Jacobi symbol `(a | m)`.

`numlib::jacobi` returns an error if one of its arguments evaluates to a number of wrong type.

Examples

Example 1

Computing the Jacobi symbol `(222222 | 304679)`:
numlib::jacobi(222222, 304679)-1

```
-1
```

Example 2

Computing the Jacobi-Symbol `(222222 | 324889)`:
numlib::jacobi(222222, 324899)1

```
1
```

Example 3

Computing the Jacobi symbol `(222222 | 333333)`:
numlib::jacobi(222222, 333333)0

```
0
```

Parameters

a

An integer

m

An odd positive integer

Return Values

`numlib::jacobi(a,m)` returns 0, 1, or -1, or the function call with evaluated arguments if one of the arguments is not a number.

Algorithms

`numlib::jacobi` doesn't use `ifactor`.

If a is an integer and m is an odd integer not coprime to a then by definition the Jacobi Symbol `(a | m)` is zero.

See Also numlib::legendrenumlib::isquadres

Purpose

Von Mangoldt's function

Syntax

```
numlib::Lambda(m)
```

Description

`numlib::Lambda(m)` returns the value of von Mangoldt's function at `m`.

It is an error if `m` is a number but not a natural number.

If `m` is not a number, `numlib::Lambda` returns the unevaluated function call.

Examples

Example 1

`numlib::Lambda` takes on non-zero values only for prime powers:
numlib::Lambda(49)ln(7)

$$\ln(7)$$

numlib::Lambda(48)0

$$0$$

Example 2

`numlib::Lambda` returns the function call if its argument is not a number:
numlib::Lambda(3+n^4)numlib::Lambda(n^4 + 3)

$$\text{numlib::Lambda}(n^4 + 3)$$

Parameters

m

Arithmetical expression

Return Values

`numlib::Lambda` returns an arithmetical expression

Algorithms

The function value of `Lambda` at `m` is defined to be *logp* if $m = p^n$ for some prime number p and some positive integer n, and to be zero for positive integers that are not prime powers.

See Also

numlib::ispower

Purpose

Carmichael function

Syntax

```
numlib::lambda(n)
```

Description

`numlib::lambda(n)` returns the value of the Carmichael function at `n`.

If `m` is a natural number then `numlib::lambda(m)` returns the value of the Carmichael function in `m`, i. e., the maximal order of an element in the group of units modulo `m`.

`numlib::lambda` returns an error if the argument evaluates to a number of wrong type. `numlib::lambda` returns the function call with its argument evaluated if `m` is not a number.

Examples

Example 1

We compute the value of the Carmichael function λ in 97:
numlib::lambda(97)96

```
96
```

Example 2

We compute the value of the Carmichael function λ in 96:
numlib::lambda(96)8

```
8
```

Parameters

`n`

A natural number

Return Values

`numlib::lambda(n)` returns a natural number, or the function call with its argument evaluated.

Algorithms

Internally, ifactor is used for factoring `n`.

See Also numlib::ordernumlib::phi

numlib::legendre

Purpose

Legendre symbol

Syntax

```
numlib::legendre(a, p)
```

Description

`numlib::legendre(a, p)` returns the Legendre symbol `(a | p)`.

`numlib::legendre` returns an error if one of its arguments evaluates to a number of wrong type.

`numlib::legendre` returns the function call with evaluated arguments if at least one of its arguments does not evaluate to a number.

Examples

Example 1

Computing the Legendre symbol `(132132 | 3231277)`:
numlib::legendre(132132,3231227)1

```
1
```

Example 2

Computing the Legendre symbol `fenced(132131 | 3231277)`:
numlib::legendre(132131,3231227)-1

```
-1
```

Example 3

Computing the Legendre symbol `(-303 | 101)`:
numlib::legendre(-303,101)0

```
0
```

Parameters

a

An integer

p

An odd prime

Return Values

`numlib::legendre(a,p)` returns `-1`, `0`, `1`, or the function call with evaluated arguments.

Algorithms

If *p* is an odd prime and if *a* is an integer divisible by *p* then by definition the Legendre symbol `(a | p)` is zero.

See Also

numlib::jacobinumlib::isquadres

numlib::lincongruence

Purpose

Linear congruence

Syntax

```
numlib::lincongruence(a, b, m)
```

Description

`numlib::lincongruence(a,b,m)` returns an error if one of the arguments evaluates to a number of wrong type.

For integers `a` and `b` and a non-zero integer `m` `numlib::lincongruence(a,b,m)` returns the sorted list of all solutions $x \in \{0, 1, \ldots, m - 1\}$ of the linear congruence equivMod(a * x, b, m) $a\,x \equiv b \pmod{m}$ if this congruence is solvable. Otherwise `FAIL` is returned.

For integers `a` and `b` and a non-zero integer `m` `numlib::lincongruence(a,b,m)` returns the sorted list of all solutions $x \in \{0, 1, \ldots, m - 1\}$ of the linear congruence equivMod(a * x, b, m) $a\,x \equiv b \pmod{m}$ if this congruence is solvable. Otherwise `FAIL` is returned.

Examples

Example 1

A linear congruence possessing one solution:
numlib::lincongruence(7,19,23)[6]

```
[6]
```

Example 2

A linear congruence possessing several solutions:
numlib::lincongruence(77,209,253)[6, 29, 52, 75, 98, 121, 144, 167, 190, 213, 236]

```
[6, 29, 52, 75, 98, 121, 144, 167, 190, 213, 236]
```

Example 3

A linear congruence possessing no solutions:

numlib::lincongruence(77,208,253)FAIL

FAIL

Parameters

a

An integer

b

An integer

m

A non-zero integer

Return Values

`numlib::lincongruence(a,b,m)` returns a list of nonnegative integers if the linear congruence is solvable.

`numlib::lincongruence(a,b,m)` returns `FAIL` if the linear congruence is not solvable.

`numlib::lincongruence(a,b,m)` returns the function call with its arguments evaluated if one of the arguments is a symbolic expression.

See Also

numlib::ichremnumlib::mrootsnumlib::msqrts

numlib::mersenne

Purpose

Mersenne primes

Syntax

```
numlib::mersenne(n)
numlib::mersenne()
```

Description

`numlib::mersenne()` returns the list of known Mersenne primes `p`. For these numbers, the Mersenne number 2^p - 1 is prime.

`numlib::mersenne(n)` returns the `n`th currently known Mersenne prime. The numbers of the Mersenne primes after the 40th prime can change in the future. More Mersenne primes might be found.

Examples

Example 1

The following primes p are known to have the property that the Mersenne number 2^p - 1 is prime:
numlib::mersenne()[2, 3, 5, 7, 13, 17, 19, 31, 61, 89, 107, 127, 521, 607, 1279, 2203, 2281, 3217, 4253, 4423, 9689, 9941, 11213, 19937, 21701, 23209, 44497, 86243, 110503, 132049, 216091, 756839, 859433, 1257787, 1398269, 2976221, 3021377, 6972593, 13466917, 20996011, 24036583, 25964951, 30402457, 32582657, 37156667, 42643801, 43112609]

[2, 3, 5, 7, 13, 17, 19, 31, 61, 89, 107, 127, 521, 607, 1279, 2203, 2281, 3217, 4253, 4423, 968
44497, 86243, 110503, 132049, 216091, 756839, 859433, 1257787, 1398269, 2976221, 302
2402[illegible]2457, 32582657, 37156667, 42643801, 43112609]

Example 2

Display the 10th Mersenne prime:
numlib::mersenne(10)89

89

Return Values Natural number or a list of natural numbers.

References See `http://www.mersenne.org/`

numlib::moebius

Purpose

Möbius function

Syntax

```
numlib::moebius(n)
```

Description

`numlib::moebius(n)` returns the value of the Möbius function at `n`.

`numlib::moebius` returns an error if the argument evaluates to a number of wrong type.

If `n` is a natural number `numlib::moebius(n)` returns the value of the Möbius function in `n`.

If `n` is not a number, `numlib::moebius(n)` returns the function call with its argument evaluated.

Examples

Example 1

Computing the value of the Möbius function μ at 99937:
numlib::moebius(99937)0

```
0
```

Example 2

`numlib::moebius` works for arbitrarily large integers:
numlib::moebius(45397369416530795319729696969741061923382 6)-1

```
-1
```

Parameters

`n`

A natural number

Return Values

`numlib::moebius(n)` returns a nonnegative integer.

Algorithms

Internally, ifactor is used for factoring `n`.

See Also numlib::lambdanumlib::phi

numlib::mpqs

Purpose

Multi-polynomial Quadratic Sieve

Syntax

```
numlib::mpqs(n, options)
```

Description

`numlib::mpqs(n)` returns a proper factor of `n`, using some version of the quadratic sieve. `n` is returned if it is prime.

The multi-polynomial quadratic sieve is an algorithm to factor large integers without small prime factors. For small integers that can be factored within a reasonable amount of time by ifactor, using this algorithm does not pay off. However, `numlib::mpqs` may give you some insight how the algorithm works if you set the information level to a high value (see setuserinfo).

Examples

Example 1

If `n` is prime, it is returned.
numlib::mpqs(10000000019)10000000019

```
10000000019
```

Example 2

Using the default parameters, no factor is found:
n:=300000000580000000019: numlib::mpqs(n)FAIL

```
FAIL
```

However, using more polynomials and a larger factor base, the input can be factored:
numlib::mpqs(n,MaxInFactorbase=200,NumberOfPolynomials=30)30000000001

```
30000000001
```

Parameters

n

Integer

Options

InteractiveInput

Prompt the user for all parameters given below

SieveArrayLimit

Option, specified as `SieveArrayLimit = M`

For any polynomial `f`, $f(x)$ is tested for - $M \le x \le M$. `M` must be a positive integer.

Tolerance

Option, specified as `Tolerance = t`

Sets an exponent `t` that is used to define "smoothness" of values investigated by the sieve: if the maximum of the factorbase is b, let a value pass the first part of the sieve step if it has presumably no prime divisor greater than b^t. `t` must be a positive real number.

Factorbase

Option, specified as `Factorbase = l`

Define `l` to be the factor base. `l` must be a list of primes; they are investigated whether they divide a certain set of values of each polynomial.

MaxInFactorbase

Option, specified as `MaxInFactorbase = b`

The factorbase consists of all suitable primes that are smaller than `b`. `b` must be a positive integer. This option cannot be used together with `Factorbase`.

NumberOfPolynomials

Option, specified as `NumberOfPolynomials = N`

The number of polynomials the values of which are tested for smoothness. `N` must be a positive integer.

LargeFactorBound

Option, specified as `LargeFactorBound = K`

Define `K` to be the bound below which every factor of a given value must be to make that value pass the trial-division part of the sieve step and become a sieve report. All prime numbers outside the factor base, but below that bound, are added to the factor base if they divide at least two sieve reports. `K` must be a positive integer.

CollectInformation

Do not return a divisor of `n`, but some information on the course of the algorithm.

Return Values

`numlib::mpqs` returns a positive integer dividing `n`, or `FAIL` if `n` is not prime, but a proper factor could not be found. If the option `CollectInformation` has been given, a list of equations is returned; each of the equations contains some piece of information on an intermediate result in some step of the algorithm.

ifactor

numlib::mroots

Purpose

Modular roots of polynomials

Syntax

```
numlib::mroots(P, m)
```

Description

`numlib::mroots(P,m)` returns an error if `P` is not a polynomial over the integers or `m` is not a natural number.

For a univariate polynomial `P` over the integers and for a natural number `m` the function call `numlib::mroots(P,m)` returns the sorted list of all integers x $\{0, 1, \ldots, m - 1\}$ such that equivMod(P(x), 0, m)$P(x) = 0 \pmod m$.

For a multivariate polynomial `P`, `numlib::mroots(P, m)` returns a lexicographically sorted list of all lists $[x_1, \ldots, x_n]$ of integers between 0 and m - 1 such that equivMod(P(x[1], Symbol::hellip, x[n]), 0, m)$P(x_1, \ldots, x_n) = 0 \pmod m$.

For a univariate polynomial `P` over the integers and for a natural number `m` the function call `numlib::mroots(P,m)` returns the sorted list of all integers x $\{0, 1, \ldots, m - 1\}$ such that equivMod(P(x), 0, m)$P(x) = 0 \pmod m$.

For a multivariate polynomial `P`, `numlib::mroots(P, m)` returns a lexicographically sorted list of all lists $[x_1, \ldots, x_n]$ of integers between 0 and m - 1 such that equivMod(P(x[1], Symbol::hellip, x[n]), 0, m)$P(x_1, \ldots, x_n) = 0 \pmod m$.

Examples

Example 1

Defining a polynomial
P := poly(3*T^7 + 2*T^2 + T - 17, [T])poly(3*T^7 + 2*T^2 + T - 17, [T])

$$\text{poly}(3T^7 + 2T^2 + T - 17, [T])$$

and computing its roots modulo 1751:
numlib::mroots(P, 1751)[221, 260, 612, 736, 1127, 1496]

```
[221, 260, 612, 736, 1127, 1496]
```

The polynomial `P` doesn't have roots modulo 1994:
numlib::mroots(P, 1994)[]

```
[]
```

Example 2

We use `numlib::mroots` to find all points on a particular elliptic curve modulo 13:
numlib::mroots(poly(y^2 - x^3 - x - 2, [x, y]), 13)[[1, 2], [1, 11], [2, 5], [2, 8], [6, 4], [6, 9], [7, 1], [7, 12], [9, 5], [9, 8], [12, 0]]

```
[[1, 2], [1, 11], [2, 5], [2, 8], [6, 4], [6, 9], [7, 1], [7, 12], [9, 5], [9, 8], [12, 0]]
```

Parameters

`P`

A polynomial over the integers

`m`

A natural number

Return Values

If `P` is univariate, `numlib::mroots` returns a list of nonnegative integers. If `P` has more than one variable, `numlib::mroots` returns a list of lists of nonnegative integers.

Algorithms

`numlib::mroots` uses `factor`.

See Also

numlib::lincongruencenumlib::msqrts

numlib::msqrts

Purpose

Modular square roots

Syntax

```
numlib::msqrts(a, m)
```

Description

`numlib::msqrts(a,m)` returns the list of all integers x {0, 1, …, m - 1} such that equivMod(x^2, a, m)$x^2 = a \pmod{m}$.

Examples

Example 1

Computing the square roots of 132132 modulo 3231227:
numlib::msqrts(132132,3231227)[219207, 3012020]

```
[219207, 3012020]
```

Example 2

There are no square roots of 222222 modulo 324899:
numlib::msqrts(222222,324899)[]

```
[]
```

Example 3

48884 is a composite number, so a number can have more than two square roots modulo 48884:
numlib::msqrts(37,48884)[383, 585, 23857, 24059, 24825, 25027, 48299, 48501]

```
[383, 585, 23857, 24059, 24825, 25027, 48299, 48501]
```

Parameters

a

An integer

m

A natural number relatively prime to `a`

Return Values

`numlib::msqrts(a,m)` returns a list of nonnegative integers

Algorithms

`numlib::msqrts` uses D. Shanks' algorithm RESSOL.

See Also

numlib::lincongruencenumlib::mroots

numlib::numdivisors

Purpose

Number of divisors of an integer

Syntax

```
numlib::numdivisors(n)
```

Description

`numlib::numdivisors(n)` returns the number of positive divisors of `n`.

`numlib::numdivisors(0)` returns `0`.

`numlib::numdivisors` returns the function call with evaluated argument if the argument is not a number.

`numlib::numdivisors` returns an error if the argument evaluates to a number of wrong type.

`numlib::numdivisors` is the same function as `numlib::tau`.

Examples

Example 1

We compute the number of positive divisors of the number 6746328388800 (one of the highly composite numbers studied by S. Ramanujan in 1915):

```
numlib::numdivisors(6746328388800)10080
```

```
10080
```

Parameters

`n`

An integer

Return Values

`numlib::numdivisors(n)` returns a nonnegative integer.

Algorithms

Internally, ifactor is used for factoring `n`.

See Also

numlib::divisorsnumlib::numprimedivisorsnumlib::primedivisors

numlib::numprimedivisors

Purpose

Number of prime factors of an integer

Syntax

```
numlib::numprimedivisors(n)
```

Description

`numlib::numprimedivisors(n)` returns the number of prime factors of the integer `n`, counted without multiplicity.

`numlib::numprimedivisors` and `numlib::omega` are synonyms.

`numlib::numprimedivisors(0)` returns `0`.

`numlib::numprimedivisors` returns the function call with evaluated argument if the argument is not a number.

`numlib::numprimedivisors` returns an error if the argument evaluates to a number of wrong type.

Examples

Example 1

We compute the number of primes dividing 6746328388800:
numlib::numprimedivisors(6746328388800)9

```
9
```

Parameters

`n`

An integer

Return Values

`numlib::numprimedivisors(n)` returns a nonnegative integer.

Algorithms

Internally, ifactor is used for factoring `n`.

See Also

numlib::omeganumlib::primedivisorsnumlib::numdivisors

numlib::omega

Purpose

Number of prime factors of an integer

Syntax

```
numlib::omega(n)
```

Description

`numlib::omega(n)` returns the number of prime factors of the integer `n`, counted without multiplicity.

numlib::numprimedivisors and `numlib::omega` are synonyms.

`numlib::omega(0)` returns `0`.

`numlib::omega` returns the function call with evaluated argument if the argument is not a number.

`numlib::omega` returns an error if the argument evaluates to a number of wrong type.

Examples

Example 1

We compute the number of primes dividing 6746328388800:
numlib::numprimedivisors(6746328388800)9

```
9
```

Parameters

`n`

An integer

Return Values

`numlib::numprimedivisors(n)` returns a nonnegative integer.

Algorithms

Internally, ifactor is used for factoring `n`.

See Also

numlib::numprimedivisorsnumlib::primedivisorsnumlib::numdivisors

Purpose

Number of prime divisors (with multiplicity)

Syntax

```
numlib::Omega(a)
```

Description

`numlib::Omega(a)` returns, for a given positive integer `a`, the finite sum sum(Symbol::alpha(p, a), p)$\sum_p \alpha(p, a)$, where p runs through all primes, and $\alpha(p, a)$ denotes the highest exponent for which p^a divides `a`.

Examples

Example 1

In contrast to numlib::numprimedivisors, the prime factor 2 of 120 is counted thrice:
numlib::Omega(120)5

```
5
```

The same happens here:
numlib::Omega(8)3

```
3
```

Parameters

a

Positive integer

Return Values

`numlib::Omega` returns a positive integer.

See Also

numlib::numprimedivisors

numlib::order

Purpose

Order of a residue class

Syntax

```
numlib::order(a, m)
```

Description

`numlib::order(a,m)` returns the order of the residue class modulo `m` of `a` in the group of units modulo `m` if `a` and `m` are coprime.

`numlib::order(a,m)` returns the function call with its arguments evaluated if `a` or `m` is not a number.

`numlib::order` returns an error if one of the arguments evaluates to a number of wrong type.

Examples

Example 1

We compute the order of the residue class of 23 in the unit group modulo 2161:
numlib::order(23, 2161)2160

```
2160
```

Example 2

We compute the order of all elements in the unit group modulo 13:
map([$ 1..12],numlib::order,13)[1, 12, 3, 6, 4, 12, 12, 4, 3, 6, 12, 2]

```
[1, 12, 3, 6, 4, 12, 12, 4, 3, 6, 12, 2]
```

Example 3

The residue class of 7 is not a unit in the ring modulo 21:
numlib::order(7,21)FAIL

```
FAIL
```

Parameters

a

An integer

m

A natural number

Return Values

`numlib::order(a,m)` returns a natural number if `a` is coprime to `m`, and FAIL if `a` is not coprime to `m`.

Algorithms

`numlib::order` uses ifactor and numlib::phi.

See Also

numlib::lambdanumlib::phi

numlib::phi

Purpose

Euler phi function

Syntax

```
numlib::phi(n)
```

Description

`numlib::phi(n)` calculates the Euler φ function of the argument `n`, i.e. the number of numbers smaller than $|n|$ which are relatively prime to `n`. Cf. “Example 1” on page 20-64.

`numlib::phi` returns an error if the argument is a number but not an integer unequal to zero.
